TECHNICAL AND RELIABILITY DATA FOR RASPBERRY PI PRODUCTS (INCLUDING DATASHEETS) AS MODIFIED FROM TIME TO TIME ("RESOURCES") ARE PROVIDED BY RASPBERRY PI LTD ("RPL") "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW IN NO EVENT SHALL RPL BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THE RESOURCES, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

RPL reserves the right to make any enhancements, improvements, corrections or any other modifications to the RESOURCES or any products described in them at any time and without further notice.

The RESOURCES are intended for skilled users with suitable levels of design knowledge. Users are solely responsible for their selection and use of the RESOURCES and any application of the products described in them. User agrees to indemnify and hold RPL harmless against all liabilities, costs, damages or other losses arising out of their use of the RESOURCES.

RPL grants users permission to use the RESOURCES solely in conjunction with the Raspberry Pi products. All other use of the RESOURCES is prohibited. No licence is granted to any other RPL or other third party intellectual property right.

HIGH RISK ACTIVITIES. Raspberry Pi products are not designed, manufactured or intended for use in hazardous environments requiring fail safe performance, such as in the operation of nuclear facilities, aircraft navigation or communication systems, air traffic control, weapons systems or safety-critical applications (including life support systems and other medical devices), in which the failure of the products could lead directly to death, personal injury or severe physical or environmental damage ("High Risk Activities"). RPL specifically disclaims any express or implied warranty of fitness for High Risk Activities and accepts no liability for use or inclusions of Raspberry Pi products in High Risk Activities.

Raspberry Pi products are provided subject to RPL's [Standard Terms](#). RPL's provision of the RESOURCES does not expand or otherwise modify RPL's [Standard Terms](#) including but not limited to the disclaimers and warranties expressed in them.

法律免责声明

Raspberry Pi 产品的技术及可靠性数据（包括数据表），其文本内容可能不定期更新（以下简称“资源”），由 Raspberry Pi Ltd（以下简称“RPL”）按“现状”提供，明确否认任何明示或默示保证，包括但不限于对适销性和特定用途适用性的默示保证。在适用法律允许的最大范围内，RPL 不对使用该资源所导致的任何直接、间接、附带、特殊、示范性或后果性损害承担责任（包括但不限于采购替代品或服务、使用损失、数据或利润损失，或业务中断），无论基于何种责任理论（合同、严格责任或侵权，包括疏忽与否），即使已被告知可能发生此类损害。

RPL 保留在任何时候对资源或其中描述的产品进行任何增强、改进、修正或其他修改的权利，且无需另行通知。

这些资源专为具备相应设计知识水平的熟练用户而设计。用户对其选择和使用这些资源及其中描述的任何产品应用承担全部责任。用户同意赔偿并使 RPL 免于因其使用资源而产生的所有责任、费用、损害或其他损失。

RPL 授权用户仅可将资源与 Raspberry Pi 产品配合使用。严禁对资源进行任何其他用途。未授予任何 RPL 或第三方知识产权的任何许可。

高风险活动。Raspberry Pi 产品非为在需具备故障安全性能的危险环境中使用而设计、制造或意图使用，例如核设施运营、飞机导航或通信系统、空中交通管制、武器系统或安全关键应用（含生命支持系统及其他医疗设备）。在此类环境中，产品故障可能直接导致死亡、人身伤害或严重的物理或环境损害（“高风险活动”）。RPL 明确否认对高风险活动适用性的任何明示或暗示保证，且不对 Raspberry Pi 产品在高风险活动中的使用或纳入承担任何责任。

树莓派产品依照 RPL 标准条款提供。RPL 对资源的提供不扩展或以其他方式修改 RPL 的标准条款，包括但不限于其中所列的免责声明及保证条款。

3.1.1. 安全与非安全 SIO	37
3.1.2. CPUID	38
3.1.3. GPIO 控制	39
3.1.4. 硬件自旋锁	41
3.1.5. 处理器间 FIFO（邮箱）	42
3.1.6. 门铃	42
3.1.7. 整数除法器	43
3.1.8. RISC-V 平台定时器	43
3.1.9. TMDS 编码器	44
3.1.10. 插值器	44
3.1.11. 寄存器列表	54
3.2. 中断	82
3.2.1. 不可屏蔽中断（NMI）	83
3.2.2. 中断的进一步阅读	83
3.3. 事件信号（Arm）	84
3.4. 事件信号（RISC-V）	84
3.5. 调试	84
3.5.1. 连接至 SW-DP	85
3.5.2. Arm 调试	86
3.5.3. RISC-V 调试	86
3.5.4. 调试电源域	87
3.5.5. SWD 引脚的软件控制	87
3.5.6. 自托管调试	87
3.5.7. 跟踪	88
3.5.8. 救援重置	90

3.5.9. Security	91
3.5.10. RP-AP	93
3.6. Cortex-M33 coprocessors	100
3.6.1. GPIO coprocessor (GPIOC)	101
3.6.2. Double-precision coprocessor (DCP)	104
3.6.3. Redundancy coprocessor (RCP)	112
3.6.4. Floating point unit	123
3.7. Cortex-M33 processor	123
3.7.1. Features	124
3.7.2. Configuration	124
3.7.3. Compliance	128
3.7.4. Programmer's model	131
3.7.5. List of registers	148
3.8. Hazard3 processor	233
3.8.1. Instruction set reference	233
3.8.2. Memory access	278
3.8.3. Memory protection	279
3.8.4. Interrupts and exceptions	282
3.8.5. Debug	285
3.8.6. Custom extensions	286
3.8.7. Instruction cycle counts	296
3.8.8. Configuration	302
3.8.9. Control and status registers	304
3.9. Arm/RISC-V architecture switching	335
3.9.1. Automatic switching	335
3.9.2. Mixed architecture combinations	336
4. Memory	337
4.1. ROM	337
4.2. SRAM	337
4.2.1. Other on-chip memory	338
4.3. Boot RAM	339
4.3.1. List of registers	339
4.4. External flash and PSRAM (XIP)	340
4.4.1. XIP cache	341
4.4.2. QSPI Memory Interface (QMI)	345
4.4.3. Streaming DMA interface	345
4.4.4. Performance counters	346
4.4.5. List of XIP_CTRL registers	346
4.4.6. List of XIP_AUX registers	350
4.5. OTP	352
5. Bootrom	353
5.1. Bootrom concepts	354
5.1.1. Secure and Non-secure	354
5.1.2. Partition tables	354
5.1.3. Flash permissions	355
5.1.4. Image definitions	355
5.1.5. Blocks and block loops	356
5.1.6. Block versioning	357
5.1.7. A/B versions	357
5.1.8. Hashing and signing	357
5.1.9. Load maps	358
5.1.10. Packaged binaries	358
5.1.11. Anti-rollback protection	359
5.1.12. Flash image boot	359
5.1.13. Flash partition boot	360
5.1.14. Partition-Table-in-Image boot	360
5.1.15. Flash boot slots	360
5.1.16. Flash update boot and version downgrade	361
5.1.17. Try before you buy	362
5.1.18. UF2 targeting	362

3.5.9. 安全	91
3.5.10. RP-AP	93
3.6. Cortex-M33 协处理器	100
3.6.1. GPIO 协处理器 (GPIOC)	101
3.6.2. 双精度协处理器 (DCP)	104
3.6.3. 冗余协处理器 (RCP)	112
3.6.4. 浮点运算单元	123
3.7. Cortex-M33 处理器	123
3.7.1. 特性	124
3.7.2. 配置	124
3.7.3. 合规性	128
3.7.4. 程序员模型	131
3.7.5. 寄存器列表	148
3.8. Hazard3 处理器	233
3.8.1. 指令集参考	233
3.8.2. 内存访问	278
3.8.3. 内存保护	279
3.8.4. 中断与异常	282
3.8.5. 调试	285
3.8.6. 自定义扩展	286
3.8.7. 指令周期计数	296
3.8.8. 配置	302
3.8.9. 控制与状态寄存器	304
3.9. Arm/RISC-V 架构切换	335
3.9.1. 自动切换	335
3.9.2. 混合架构组合	336
4. 内存	337
4.1. 只读存储器	337
4.2. 静态随机存取存储器	337
4.2.1. 其他片上存储器	338
4.3. 启动RAM	339
4.3.1. 寄存器列表	339
4.4. 外部闪存和PSRAM (XIP)	340
4.4.1. XIP缓存	341
4.4.2. QSPI存储器接口 (QMI)	345
4.4.3. 流式DMA接口	345
4.4.4. 性能计数器	346
4.4.5. XIP_CTRL 寄存器列表	346
4.4.6. XIP_AUX 寄存器列表	350
4.5. OTP	352
5. 启动只读存储器	353
5.1. 启动只读存储器概念	354
5.1.1. 安全与非安全	354
5.1.2. 分区表	354
5.1.3. 闪存权限	355
5.1.4. 镜像定义	355
5.1.5. 块及块循环	356
5.1.6. 块版本控制	357
5.1.7. A/B 版本	357
5.1.8. 哈希与签名	357
5.1.9. 加载映射	358
5.1.10. 打包二进制文件	358
5.1.11. 防回滚保护	359
5.1.12. 闪存镜像启动	359
5.1.13. 闪存分区启动	360
5.1.14. 镜像内分区表启动	360
5.1.15. 闪存启动槽	360
5.1.16. 闪存更新启动及版本降级	361
5.1.17. 试用功能	362
5.1.18. UF2 目标支持	362

5.1.19. Address translation	363
5.1.20. Automatic architecture switching	364
5.2. Processor-controlled boot sequence	365
5.2.1. Boot outcomes	365
5.2.2. Sequence	366
5.2.3. POWMAN boot vector	371
5.2.4. Watchdog boot vector	371
5.2.5. RAM image boot	372
5.2.6. OTP boot	373
5.2.7. Flash boot	373
5.2.8. BOOTSEL (USB/UART) boot	374
5.2.9. Boot configuration (OTP)	375
5.3. Launching code on Processor Core 1	375
5.4. Bootrom APIs	376
5.4.1. Locating the API functions	376
5.4.2. API function availability	378
5.4.3. API function return codes	378
5.4.4. API functions and exclusive access	379
5.4.5. SDK access to the API	380
5.4.6. Categorised list of API functions and ROM data	380
5.4.7. Alphabetical list of API functions and ROM data	382
5.4.8. API function listings	383
5.5. USB mass storage interface	399
5.5.1. The RP2350 drive	399
5.5.2. UF2 format details	400
5.5.3. UF2 targeting rules	401
5.6. USB PICOBLOCK interface	403
5.6.1. Identifying the device	403
5.6.2. Identifying the interface	404
5.6.3. Identifying the endpoints	404
5.6.4. PICOBLOCK Commands	405
5.6.5. Control requests	410
5.7. USB white-labelling	412
5.7.1. USB device descriptor	413
5.7.2. USB device strings	413
5.7.3. USB configuration descriptor	413
5.7.4. MSD drive	413
5.7.5. UF2 INDEX.HTM file	413
5.7.6. UF2 INFO_UF2.TXT file	414
5.7.7. SCSI Inquiry	414
5.7.8. Volume label simple example	414
5.7.9. Volume label in-depth example	415
5.8. UART boot	416
5.8.1. Baud rate and clock requirements	416
5.8.2. UART boot shell protocol	416
5.8.3. UART boot programming flow	417
5.8.4. Recovering from a stuck interface	417
5.8.5. Requirements for UART boot binaries	418
5.9. Metadata block details	418
5.9.1. Blocks and block loops	418
5.9.2. Common block items	419
5.9.3. Image definition items	421
5.9.4. Partition table items	425
5.9.5. Minimum viable image metadata	428
5.10. Example boot scenarios	429
5.10.1. Secure boot	429
5.10.2. Signed images	430
5.10.3. Packaged binaries	433
5.10.4. A/B booting	433
5.10.5. A/B booting with owned partitions	435

5.1.19. 地址转换	363
5.1.20. 自动架构切换	364
5.2. 处理器控制的启动序列	365
5.2.1. 启动结果	365
5.2.2. 启动序列	366
5.2.3. POWMAN 启动向量	371
5.2.4. 看门狗启动向量	371
5.2.5. RAM 镜像启动	372
5.2.6. OTP 启动	373
5.2.7. 闪存启动	373
5.2.8. BOOTSEL (USB/UART) 启动	374
5.2.9. 启动配置 (OTP)	375
5.3. 在处理器核 1 上启动代码	375
5.4. Bootrom API	376
5.4.1. 定位 API 函数	376
5.4.2. API 函数可用性	378
5.4.3. API 函数返回码	378
5.4.4. API 函数与独占访问权限	379
5.4.5. SDK 对 API 的访问	380
5.4.6. API 函数及只读存储器数据的分类列表	380
5.4.7. API 函数及只读存储器数据的字母顺序列表	382
5.4.8. API 函数清单	383
5.5. USB 大容量存储接口	399
5.5.1. RP2350 驱动	399
5.5.2. UF2 格式详情	400
5.5.3. UF2 目标规则	401
5.6. USB PICOBLOCK 接口	403
5.6.1. 设备识别	403
5.6.2. 接口识别	404
5.6.3. 端点识别	404
5.6.4. PICOBLOCK 命令	405
5.6.5. 控制请求	410
5.7. USB 白标化	412
5.7.1. USB 设备描述符	413
5.7.2. USB 设备字符串	413
5.7.3. USB 配置描述符	413
5.7.4. MSD 驱动	413
5.7.5. UF2 INDEX.HTM 文件	413
5.7.6. UF2 INFO_UF2.TXT 文件	414
5.7.7. SCSI 查询命令	414
5.7.8. 卷标简单示例	414
5.7.9. 卷标深入示例	415
5.8. UART 启动	416
5.8.1. 波特率及时钟要求	416
5.8.2. UART 启动 Shell 协议	416
5.8.3. UART 启动编程流程	417
5.8.4. 恢复卡死的接口	417
5.8.5. UART 启动二进制文件要求	418
5.9. 元数据块详细信息	418
5.9.1. 块及块循环	418
5.9.2. 通用块项	419
5.9.3. 镜像定义项	421
5.9.4. 分区表项	425
5.9.5. 最小可用镜像元数据	428
5.10. 启动示例场景	429
5.10.1. 安全启动	429
5.10.2. 签名映像	430
5.10.3. 打包二进制文件	433
5.10.4. A/B 启动	433
5.10.5. 具所有权分区的 A/B 启动	435

5.10.6. Custom bootloader	437
5.10.7. OTP bootloader	439
5.10.8. Rollback versions and bootloaders	440
6. Power	441
6.1. Power supplies	441
6.1.1. Digital IO supply (IOVDD)	441
6.1.2. QSPI IO supply (QSPI_IOVDD)	441
6.1.3. Digital core supply (DVDD)	441
6.1.4. USB PHY and OTP supply (USB OTP_VDD)	442
6.1.5. ADC supply (ADC_AVDD)	442
6.1.6. Core voltage regulator input supply (VREG_VIN)	442
6.1.7. On-chip voltage regulator analogue supply (VREG_AVDD)	442
6.1.8. Power supply sequencing	443
6.2. Power management	443
6.2.1. Core power domains	443
6.2.2. Power states	444
6.2.3. Power state transitions	445
6.3. Core voltage regulator	448
6.3.1. Operating modes	448
6.3.2. Software control	449
6.3.3. Power Manager control	449
6.3.4. Status	450
6.3.5. Current limit	450
6.3.6. Over temperature protection	450
6.3.7. Application circuit	450
6.3.8. External components and PCB layout requirements	452
6.3.9. List of registers	457
6.4. Power management (POWMAN) registers	457
6.5. Power reduction strategies	488
6.5.1. Top-level clock gates	489
6.5.2. SLEEP state	489
6.5.3. DORMANT state	489
6.5.4. Memory periphery power down	490
6.5.5. Full memory power down	490
6.5.6. Programmer's model	491
7. Resets	494
7.1. Overview	494
7.2. Changes from RP2040	494
7.3. Chip-level resets	495
7.3.1. Chip-level reset table	495
7.3.2. Chip-level reset destinations	496
7.3.3. Chip-level reset sources	496
7.4. System resets (Power-on State Machine)	497
7.4.1. Reset sequence	498
7.4.2. Register control	499
7.4.3. Interaction with watchdog	499
7.4.4. List of registers	499
7.5. Subsystem resets	503
7.5.1. Overview	503
7.5.2. Programmer's model	503
7.5.3. List of Registers	505
7.6. Power-on resets and brownout detection	508
7.6.1. Power-on reset (POR)	509
7.6.2. Brownout detection (BOD)	509
7.6.3. Supply monitor	512
7.6.4. List of registers	512
8. Clocks	513
8.1. Overview	513
8.1.1. Changes between RP2350 revisions	514
8.1.2. Clock sources	514

5.10.6. 自定义引导加载程序	437
5.10.7. OTP 引导加载程序	439
5.10.8. 回滚版本及引导加载程序	440
6. 电源	441
6.1. 电源供应	441
6.1.1. 数字 IO 电源 (<code>IOVDD</code>)	441
6.1.2. QSPI IO 电源 (<code>QSPI_IOVDD</code>)	441
6.1.3. 数字核心电源 (<code>DVDD</code>)	441
6.1.4. USB PHY 与 OTP 电源 (<code>USB OTP_VDD</code>)	442
6.1.5. ADC 电源 (<code>ADC_AVDD</code>)	442
6.1.6. 核心电压稳压器输入电源 (<code>VREG_VIN</code>)	442
6.1.7. 芯片内电压稳压器模拟电源 (<code>VREG_AVDD</code>)	442
6.1.8. 电源供应顺序	443
6.2. 电源管理	443
6.2.1. 核心电源域	443
6.2.2. 电源状态	444
6.2.3. 电源状态转换	445
6.3. 核心电压调节器	448
6.3.1. 运行模式	448
6.3.2. 软件控制	449
6.3.3. 电源管理器控制	449
6.3.4. 状态	450
6.3.5. 电流限制	450
6.3.6. 过温保护	450
6.3.7. 应用电路	450
6.3.8. 外部元件及 PCB 布局要求	452
6.3.9. 寄存器列表	457
6.4. 电源管理 (POWMAN) 寄存器	457
6.5. 电源降低策略	488
6.5.1. 顶层时钟门控	489
6.5.2. 睡眠状态	489
6.5.3. 休眠状态	489
6.5.4. 内存外围断电	490
6.5.5. 全内存断电	490
6.5.6. 程序员模型	491
7. 复位	494
7.1. 概述	494
7.2. 与 RP2040 的变更	494
7.3. 芯片级复位	495
7.3.1. 芯片级复位表	495
7.3.2. 芯片级复位目标	496
7.3.3. 芯片级复位源	496
7.4. 系统复位 (上电状态机)	497
7.4.1. 复位序列	498
7.4.2. 寄存器控制	499
7.4.3. 与看门狗的交互	499
7.4.4. 寄存器列表	499
7.5. 子系统复位	503
7.5.1. 概述	503
7.5.2. 程序员模型	503
7.5.3. 寄存器列表	505
7.6. 上电复位与欠压检测	508
7.6.1. 上电复位 (POR)	509
7.6.2. 欠压检测 (BOD)	509
7.6.3. 电源监控器	512
7.6.4. 寄存器列表	512
8. 时钟	513
8.1. 概述	513
8.1.1. RP2350 版本间的变更	514
8.1.2. 时钟源	514

8.1.3. Clock generators	518
8.1.4. Frequency counter	522
8.1.5. Resus	522
8.1.6. Programmer's model	523
8.1.7. List of registers	529
8.2. Crystal oscillator (XOSC)	554
8.2.1. Overview	554
8.2.2. Changes from RP2040	556
8.2.3. Usage	556
8.2.4. Startup delay	556
8.2.5. XOSC counter	557
8.2.6. DORMANT mode	557
8.2.7. Programmer's model	558
8.2.8. List of registers	559
8.3. Ring oscillator (ROSC)	561
8.3.1. Overview	561
8.3.2. Changes from RP2040	562
8.3.3. Changes between RP2350 revisions	562
8.3.4. ROSC/XOSC trade-offs	562
8.3.5. Modifying the frequency	563
8.3.6. Randomising the frequency	563
8.3.7. ROSC divider	563
8.3.8. Random number generator	564
8.3.9. ROSC counter	564
8.3.10. DORMANT mode	564
8.3.11. List of registers	565
8.4. Low Power oscillator (LPOSC)	569
8.4.1. Frequency accuracy and calibration	569
8.4.2. Using an external low-power clock	570
8.4.3. List of registers	570
8.5. Tick generators	570
8.5.1. Overview	570
8.5.2. List of registers	571
8.6. PLL	575
8.6.1. Overview	575
8.6.2. Changes from RP2040	575
8.6.3. Calculating PLL parameters	576
8.6.4. Configuration	580
8.6.5. List of Registers	583
9. GPIO	587
9.1. Overview	587
9.2. Changes from RP2040	588
9.3. Reset state	588
9.4. Function select	589
9.5. Interrupts	594
9.6. Pads	595
9.6.1. Bus keeper mode	596
9.7. Pad isolation latches	596
9.8. Processor GPIO controls (SIO)	597
9.9. GPIO coprocessor port	597
9.10. Software examples	598
9.10.1. Select an IO function	598
9.10.2. Enable a GPIO interrupt	603
9.11. List of registers	604
9.11.1. IO - User Bank	604
9.11.2. IO - QSPI Bank	760
9.11.3. Pad Control - User Bank	785
9.11.4. Pad Control - QSPI Bank	812
10. Security	816
10.1. Overview (Arm)	816

8.1.3. 时钟发生器	518
8.1.4. 频率计数器	522
8.1.5. 复苏 (Resus)	522
8.1.6. 程序员模型	523
8.1.7. 寄存器列表	529
8.2. 晶体振荡器 (XOSC)	554
8.2.1. 概述	554
8.2.2. 相较于 RP2040 的变更	556
8.2.3. 使用方法	556
8.2.4. 启动延迟	556
8.2.5. XOSC 计数器	557
8.2.6. DORMANT 模式	557
8.2.7. 程序员模型	558
8.2.8. 寄存器列表	559
8.3. 环形振荡器 (ROSC)	561
8.3.1. 概述	561
8.3.2. 相较于 RP2040 的变更	562
8.3.3. RP2350 修订版本之间的变更	562
8.3.4. ROSC 与 XOSC 的权衡	562
8.3.5. 频率调整	563
8.3.6. 频率随机化	563
8.3.7. ROSC 分频器	563
8.3.8. 随机数发生器	564
8.3.9. ROSC 计数器	564
8.3.10. DORMANT 模式	564
8.3.11. 寄存器列表	565
8.4. 低功耗振荡器 (LPOSC)	569
8.4.1. 频率精度与校准	569
8.4.2. 使用外部低功率时钟	570
8.4.3. 寄存器列表	570
8.5. 计时发生器	570
8.5.1. 概述	570
8.5.2. 寄存器列表	571
8.6. PLL	575
8.6.1. 概述	575
8.6.2. 相较于 RP2040 的变化	575
8.6.3. PLL 参数计算	576
8.6.4. 配置	580
8.6.5. 寄存器列表	583
9. GPIO.	587
9.1. 概述	587
9.2. 相较于 RP2040 的变化	588
9.3. 复位状态	588
9.4. 功能选择	589
9.5. 中断	594
9.6. 引脚	595
9.6.1. 总线保持器模式	596
9.7. 引脚隔离锁存器	596
9.8. 处理器 GPIO 控制 (SIO)	597
9.9. GPIO 协处理器端口	597
9.10. 软件示例	598
9.10.1. 选择 IO 功能	598
9.10.2. 启用 GPIO 中断	603
9.11. 寄存器列表	604
9.11.1. IO - 用户银行	604
9.11.2. IO - QSPI 银行	760
9.11.3. 引脚控制 - 用户银行	785
9.11.4. 引脚控制 - QSPI 银行	812
10. 安全	816
10.1. 概述 (Arm)	816

10.1.1. Secure boot	816
10.1.2. Encrypted boot	817
10.1.3. Isolating trusted and untrusted software	818
10.2. Processor security features (Arm)	819
10.2.1. Background	819
10.2.2. IDAU address map	820
10.3. Overview (RISC-V)	821
10.4. Processor security features (RISC-V)	821
10.5. Secure boot enable procedure	822
10.6. Access control	822
10.6.1. GPIO access control	823
10.6.2. Bus access control	824
10.6.3. List of registers	826
10.7. DMA	867
10.7.1. Channel security attributes	868
10.7.2. Memory protection unit	868
10.7.3. DREQ attributes	868
10.7.4. IRQ attributes	868
10.8. OTP	869
10.9. Glitch detector	869
10.9.1. Theory of operation	870
10.9.2. Trigger response	870
10.9.3. List of registers	871
10.10. Factory test JTAG	874
10.11. Decommissioning	874
11. PIO	876
11.1. Overview	876
11.1.1. Changes from RP2040	877
11.2. Programmer's model	878
11.2.1. PIO programs	879
11.2.2. Control flow	879
11.2.3. Registers	881
11.2.4. Autopull	881
11.2.5. Stalling	884
11.2.6. Pin mapping	884
11.2.7. IRQ flags	884
11.2.8. Interactions between state machines	885
11.3. PIO assembler (pioasm)	885
11.3.1. Directives	885
11.3.2. Values	887
11.3.3. Expressions	887
11.3.4. Comments	888
11.3.5. Labels	888
11.3.6. Instructions	888
11.3.7. Pseudo-instructions	889
11.4. Instruction Set	889
11.4.1. Summary	889
11.4.2. JMP	890
11.4.3. WAIT	891
11.4.4. IN	892
11.4.5. OUT	893
11.4.6. PUSH	894
11.4.7. PULL	895
11.4.8. MOV (to RX)	896
11.4.9. MOV (from RX)	897
11.4.10. MOV	898
11.4.11. IRQ	900
11.4.12. SET	901
11.5. Functional details	902
11.5.1. Side-set	902

10.1.1. 安全启动	816
10.1.2. 加密启动	817
10.1.3. 隔离可信与不可信软件	818
10.2. 处理器安全特性 (Arm)	819
10.2.1. 背景	819
10.2.2. IDAU地址映射.	820
10.3. 概述 (RISC-V)	821
10.4. 处理器安全特性 (RISC-V)	821
10.5. 安全启动启用流程	822
10.6. 访问控制	822
10.6.1. GPIO 访问控制.	823
10.6.2. 总线访问控制	824
10.6.3. 寄存器列表	826
10.7. DMA	867
10.7.1. 通道安全属性	868
10.7.2. 内存保护单元	868
10.7.3. DREQ属性	868
10.7.4. IRQ属性	868
10.8. OTP.	869
10.9. 故障检测器.	869
10.9.1. 工作原理	870
10.9.2. 触发响应	870
10.9.3. 寄存器列表	871
10.10. 工厂测试 JTAG.	874
10.11. 退役	874
11. PIO	876
11.1. 概述	876
11.1.1. 与 RP2040 的变化	877
11.1.2. 程序员模型	878
11.2.1. PIO 程序	879
11.2.2. 控制流	879
11.2.3. 寄存器	881
11.2.4. 自动拉取.	881
11.2.5. 停滞	884
11.2.6. 引脚映射	884
11.2.7. IRQ 标志	884
11.2.8. 状态机之间的交互	885
11.3. PIO汇编器 (pioasm)	885
11.3.1. 指令	885
11.3.2. 值	887
11.3.3. 表达式	887
11.3.4. 注释	888
11.3.5. 标签	888
11.3.6. 指令	888
11.3.7. 伪指令	889
11.4. 指令集	889
11.4.1. 概要	889
11.4.2. JMP	890
11.4.3. WAIT	891
11.4.4. IN	892
11.4.5. OUT	893
11.4.6. PUSH.	894
11.4.7. PULL	895
11.4.8. MOV (至RX)	896
11.4.9. MOV (来自 RX)	897
11.4.10. MOV	898
11.4.11. IRQ.	900
11.4.12. SET	901
11.5. 功能细节	902
11.5.1. Side-set	902

11.5.2. Program wrapping	903
11.5.3. FIFO joining	905
11.5.4. Autopush and Autopull	906
11.5.5. Clock Dividers	911
11.5.6. GPIO mapping	911
11.5.7. Forced and EXEC'd instructions	913
11.6. Examples	915
11.6.1. Duplex SPI	915
11.6.2. WS2812 LEDs	919
11.6.3. UART TX	921
11.6.4. UART RX	923
11.6.5. Manchester serial TX and RX	926
11.6.6. Differential Manchester (BMC) TX and RX	929
11.6.7. I2C	932
11.6.8. PWM	936
11.6.9. Addition	938
11.6.10. Further examples	939
11.7. List of registers	939
12. Peripherals	961
12.1. UART	961
12.1.1. Overview	961
12.1.2. Functional description	962
12.1.3. Operation	964
12.1.4. UART hardware flow control	966
12.1.5. UART DMA interface	967
12.1.6. Interrupts	969
12.1.7. Programmer's model	970
12.1.8. List of registers	972
12.2. I2C	983
12.2.1. Features	984
12.2.2. IP configuration	984
12.2.3. I2C overview	985
12.2.4. I2C terminology	987
12.2.5. I2C behaviour	988
12.2.6. I2C protocols	989
12.2.7. TX FIFO Management and START, STOP and RESTART Generation	993
12.2.8. Multiple master arbitration	995
12.2.9. Clock synchronisation	995
12.2.10. Operation modes	996
12.2.11. Spike suppression	1001
12.2.12. Fast mode plus operation	1002
12.2.13. Bus clear feature	1002
12.2.14. IC_CLK frequency configuration	1003
12.2.15. DMA controller interface	1007
12.2.16. Operation of interrupt registers	1008
12.2.17. List of registers	1008
12.3. SPI	1046
12.3.1. Changes from RP2040	1047
12.3.2. Overview	1047
12.3.3. Functional description	1047
12.3.4. Operation	1050
12.3.5. List of registers	1060
12.4. ADC and Temperature Sensor	1066
12.4.1. Changes from RP2040	1068
12.4.2. ADC controller	1069
12.4.3. SAR ADC	1069
12.4.4. ADC ENOB	1073
12.4.5. INL and DNL	1073
12.4.6. Temperature sensor	1073
12.4.7. List of registers	1073

11.5.2. 程序包装	903
11.5.3. FIFO 连接	905
11.5.4. 自动推送与自动拉取	906
11.5.5. 时钟分频器	911
11.5.6. GPIO 映射	911
11.5.7. 强制执行及 EXEC 指令	913
11.6. 示例	915
11.6.1. 双工 SPI	915
11.6.2. WS2812 LED	919
11.6.3. UART 发送	921
11.6.4. UART 接收	923
11.6.5. 曼彻斯特码串行发送与接收	926
11.6.6. 差分曼彻斯特编码 (BMC) 发送与接收	929
11.6.7. I2C	932
11.6.8. PWM	936
11.6.9. 加法运算	938
11.6.10. 进一步示例	939
11.7. 寄存器列表	939
12. 外设	961
12.1. UART	961
12.1.1. 概述	961
12.1.2. 功能描述	962
12.1.3. 操作	964
12.1.4. UART 硬件流控	966
12.1.5. UART DMA 接口	967
12.1.6. 中断	969
12.1.7. 程程序员模型	970
12.1.8. 寄存器列表	972
12.2. I2C	983
12.2.1. 功能特性	984
12.2.2. IP 配置	984
12.2.3. I2C 概述	985
12.2.4. I2C 术语	987
12.2.5. I2C 行为	988
12.2.6. I2C 协议	989
12.2.7. 发送 FIFO 管理及 START、STOP 和 RESTART 生成	993
12.2.8. 多主仲裁	995
12.2.9. 时钟同步	995
12.2.10. 操作模式	996
12.2.11. 突波抑制	1001
12.2.12. 快速模式加速操作	1002
12.2.13. 总线清除功能	1002
12.2.14. IC_CLK 频率配置	1003
12.2.15. DMA 控制器接口	1007
12.2.16. 中断寄存器操作	1008
12.2.17. 寄存器列表	1008
12.3. SPI	1046
12.3.1. 与 RP2040 的变更	1047
12.3.2. 概述	1047
12.3.3. 功能描述	1047
12.3.4. 操作	1050
12.3.5. 寄存器列表	1060
12.4. ADC 与温度传感器	1066
12.4.1. 与 RP2040 的变化	1068
12.4.2. ADC 控制器	1069
12.4.3. SAR ADC	1069
12.4.4. ADC ENOB	1073
12.4.5. INL 与 DNL	1073
12.4.6. 温度传感器	1073
12.4.7. 寄存器列表	1073

12.5. PWM	1076
12.5.1. Overview	1077
12.5.2. Programmer's model	1077
12.5.3. List of registers	1086
12.6. DMA	1094
12.6.1. Changes from RP2040	1095
12.6.2. Configuring channels	1096
12.6.3. Triggering channels	1098
12.6.4. Data request (DREQ)	1100
12.6.5. Interrupts	1102
12.6.6. Security	1102
12.6.7. Bus error handling	1105
12.6.8. Additional features	1107
12.6.9. Example use cases	1108
12.6.10. List of Registers	1112
12.7. USB	1141
12.7.1. Overview	1141
12.7.2. Changes from RP2040	1142
12.7.3. Architecture	1144
12.7.4. Programmer's model	1155
12.7.5. List of registers	1159
12.8. System timers	1182
12.8.1. Overview	1182
12.8.2. Counter	1183
12.8.3. Alarms	1183
12.8.4. Programmer's model	1184
12.8.5. List of registers	1188
12.9. Watchdog	1193
12.9.1. Overview	1193
12.9.2. Changes from RP2040	1193
12.9.3. Watchdog counter	1193
12.9.4. Control watchdog reset levels	1194
12.9.5. Scratch registers	1194
12.9.6. Programmer's model	1194
12.9.7. List of registers	1196
12.10. Always-on timer	1197
12.10.1. Overview	1197
12.10.2. Changes from RP2040	1198
12.10.3. Accessing the AON Timer	1198
12.10.4. Using the alarm	1198
12.10.5. Selecting the AON Timer tick source	1199
12.10.6. Synchronising the AON timer to an external 1Hz clock	1201
12.10.7. Using an external clock or tick from GPIO	1201
12.10.8. Using a tick faster than 1ms	1201
12.10.9. List of registers	1202
12.11. HSTX	1202
12.11.1. Data FIFO	1203
12.11.2. Output shift register	1203
12.11.3. Bit crossbar	1204

Chapter 1. Introduction

RP2350 is a new family of microcontrollers from Raspberry Pi that offers major enhancements over RP2040. Key features include:

- Dual Cortex-M33 or Hazard3 processors at 150 MHz
- 520 kB on-chip SRAM, in 10 independent banks
- 8 kB of one-time-programmable storage (OTP)
- Up to 16 MB of external QSPI flash or PSRAM through dedicated QSPI bus
- Additional 16 MB flash or PSRAM through optional second chip-select
- On-chip switched-mode power supply to generate core voltage
- Optional low-quiescent-current LDO mode for sleep states
- 2 × on-chip PLLs for internal or external clock generation
- GPIOs are 5 V-tolerant (powered) and 3.3 V-failsafe (unpowered)
- Security features:
 - Optional boot signing, enforced by on-chip mask ROM, with key fingerprint in OTP
 - Protected OTP storage for optional boot decryption key
 - Global bus filtering based on Arm or RISC-V security/privilege levels
 - Peripherals, GPIOs, and DMA channels individually assignable to security domains
 - Hardware mitigations for fault injection attacks
 - Hardware SHA-256 accelerator
- Peripherals:
 - 2 × UARTs
 - 2 × SPI controllers
 - 2 × I2C controllers
 - 24 × PWM channels
 - USB 1.1 controller and PHY, with host and device support
 - 12 × PIO state machines
 - 1 × HSTX peripheral

Table 1 shows the RP2350 family of devices, including options for QFN-80 (10 × 10 mm) and QFN-60 (7 × 7 mm) packages, with and without flash-in-package.

Table 1. RP2350 device family

Product	Package	Internal Flash	GPIO	Analogue Inputs
RP2350A	QFN-60	None	30	4
RP2350B	QFN-80	None	48	8
RP2354A	QFN-60	2 MB	30	4
RP2354B	QFN-80	2 MB	48	8

第1章 引言

RP2350 是 Raspberry Pi 推出的新一代微控制器系列，较 RP2040 实现了重大提升。主要特性包括：

- 双核 Cortex-M33 或 Hazard3 处理器，主频150 MHz
- 520 kB片上SRAM，分为10个独立存储区
- 8 kB一次性可编程存储（OTP）
- 通过专用QSPI总线支持最多16 MB外部QSPI闪存或PSRAM
- 通过可选第二芯片选择支持额外16 MB闪存或PSRAM
- 片上开关模式电源，生成核心电压
- 睡眠状态下可选低静态电流LDO模式
- 2个片上锁相环（PLL），用于内部或外部时钟生成
- GPIO支持5 V耐受（加电）及3.3 V故障安全（断电）
- 安全特性：
 - 可选启动签名，由片上掩膜ROM强制执行，密钥指纹存于OTP
 - 用于可选启动解密密钥的保护性OTP存储
 - 基于Arm或RISC-V安全/特权级的全局总线过滤
 - 外设、GPIO与DMA通道可单独分配至安全域
 - 针对故障注入攻击的硬件防护机制
 - 硬件SHA-256加速器
- 外设：
 - 2 × UARTs
 - 2 × SPI 控制器
 - 2 × I2C 控制器
 - 24×PWM 通道
 - USB 1.1 控制器及 PHY，支持主机和设备功能
 - 12×PIO 状态机
 - 1 × HSTX 外设

表1显示了RP2350系列设备，包括带有或不带有封装内闪存的QFN-80（10 × 10 毫米）和QFN-60（7 × 7 毫米）封装选项。

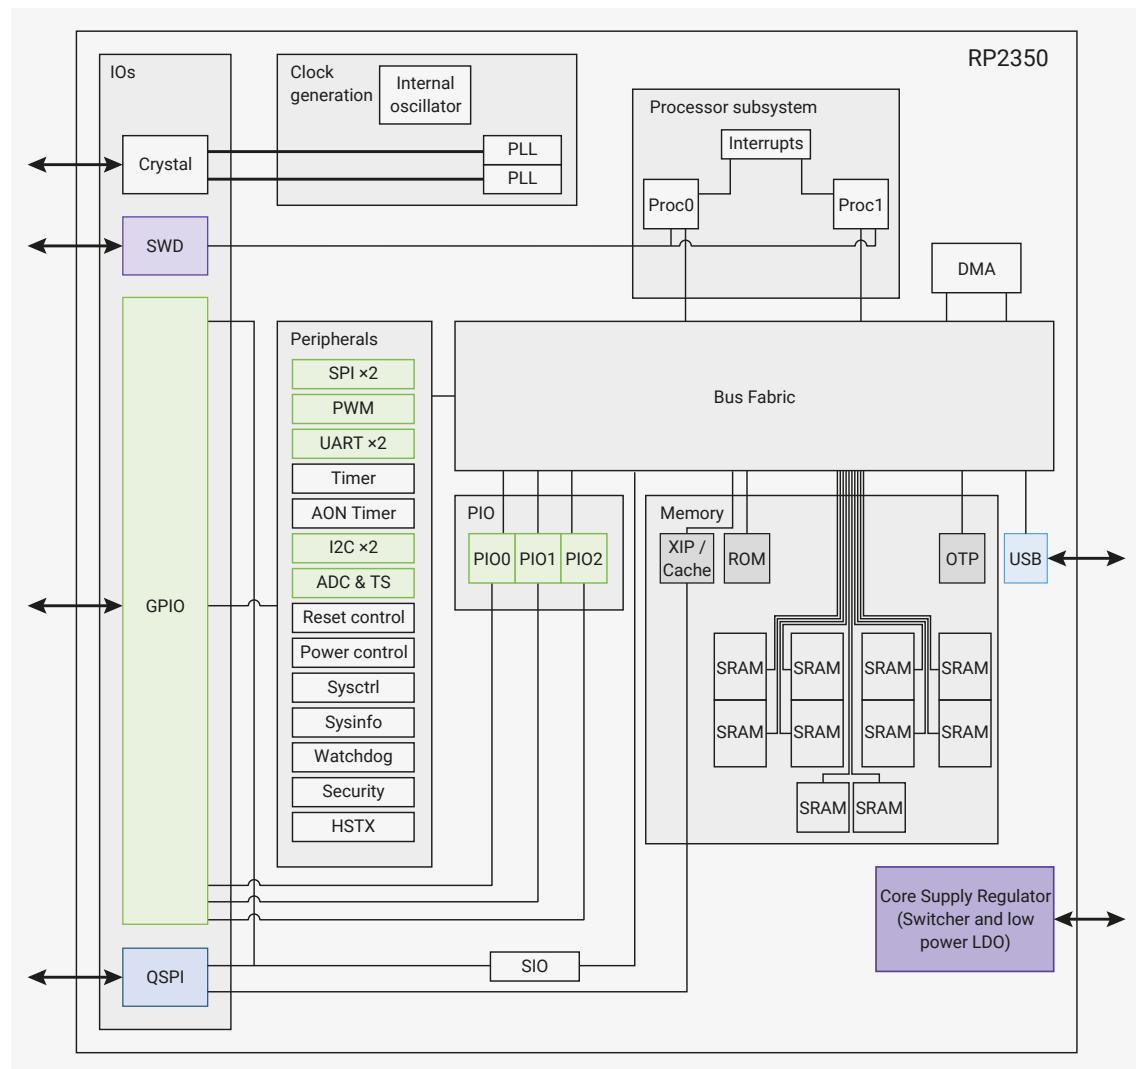

表1. RP2350
设备系列

产品	封装	内部闪存	GPIO	模拟输入
RP2350A	QFN-60	无	30	4
RP2350B	QFN-80	无	48	8
RP2354A	QFN-60	2 MB	30	4
RP2354B	QFN-80	2 MB	48	8

1.1. The chip

Dual Cortex-M33 or Hazard3 processors access RP2350's memory and peripherals via AHB and APB bus fabric.

Figure 1. A system overview of the RP2350 chip

Code may execute directly from external memory through a dedicated QSPI memory interface in the execute-in-place subsystem (XIP). The cache improves XIP performance significantly. Both flash and RAM can attach via this interface.

Debug is available via the SWD interface. This allows an external host to load, run, halt and inspect software running on the system, or configure the execution trace output.

Internal SRAM can contain code or data. It is addressed as a single 520 kB region, but physically partitioned into 10 banks to allow simultaneous parallel access from different managers. All SRAM supports single-cycle access.

A high-bandwidth system DMA offloads repetitive data transfer tasks from the processors.

GPIO pins can be driven directly via single-cycle IO (SIO), or from a variety of dedicated logic functions such as the hardware SPI, I2C, UART and PWM. Programmable IO controllers (PIO) can provide a wider variety of IO functions, or supplement the number of fixed-function peripherals.

A USB controller with embedded PHY provides FS/LS Host or Device connectivity under software control.

Four or eight ADC inputs (depending on package size) are shared with GPIO pins.

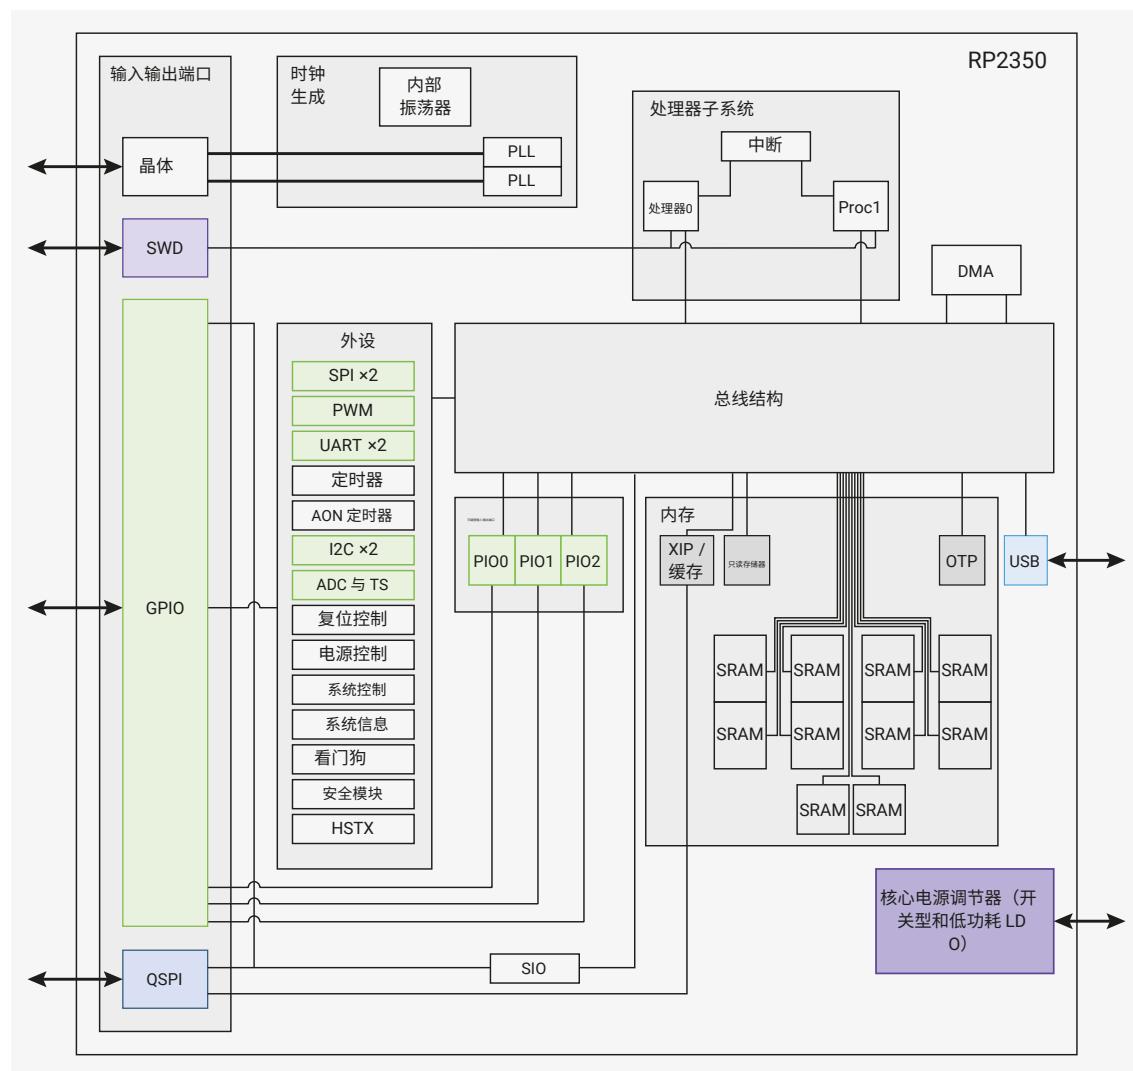

Two PLLs provide a fixed 48 MHz clock for USB or ADC, and a flexible system clock up to 150 MHz. A crystal oscillator provides a precise reference for the PLLs.

An internal voltage regulator supplies the core voltage, so you need generally only supply the IO voltage. It operates as a

1.1. 芯片

双核 Cortex-M33 或 Hazard3 处理器通过 AHB 和 APB 总线结构访问 RP2350 的内存及外设。

图 1. RP2350 芯片系统概述

代码可通过执行就地子系统（XIP）中的专用QSPI存储接口直接从外部存储器执行。缓存显著提升了XIP的性能。闪存和RAM均可通过该接口连接。

调试功能通过SWD接口提供。此功能允许外部主机加载、运行、暂停及检查系统运行的软件，或配置执行跟踪输出。

内部SRAM可包含代码或数据。地址空间为单一的520 kB区域，物理上分为10个银行，以支持来自不同管理器的并行访问。所有SRAM均支持单周期访问。

高带宽系统DMA减轻了处理器的重复数据传输负担。

GPIO引脚可通过单周期IO（SIO）直接驱动，或由多种专用逻辑功能如硬件SPI、I2C、UART及PWM驱动。可编程IO控制器（PIO）提供更多样的IO功能，或扩展固定功能外设的数量。

带有嵌入式PHY的USB控制器在软件控制下提供FS/LS主机或设备连接功能。

四个或八个ADC输入（视封装尺寸而定）与GPIO引脚共享。

两个PLL为USB或ADC提供固定的48 MHz时钟，并为系统提供最高150 MHz的灵活时钟。晶体振荡器为PLL提供精确的参考时钟。

内部电压调节器为核心电压供电，因此通常只需提供IO电压。它作为一个

switched mode buck converter when the system is awake, providing up to 200 mA at a variable output voltage, and can switch to a low-quiescent-current LDO mode when the system is asleep, providing up to 1 mA for state retention.

The system features low-power states where unused logic is powered off, supporting wakeup from timer or IO events. The amount of SRAM retained during power-down is configurable.

The internal 8 kB one-time-programmable storage (OTP) contains chip information such as unique identifiers, can be used to configure hardware and bootrom security features, and can be programmed with user-supplied code and data.

The built-in bootrom implements direct boot from flash or OTP, and serial boot from USB or UART. Code signature enforcement is supported for all boot media, using a key fingerprint registered in internal OTP storage. OTP can also store decryption keys for encrypted boot, preventing flash contents from being read externally.

RISC-V architecture support is implemented by dynamically swapping the Cortex-M33 (Armv8-M) processors with Hazard3 (RV32IMAC+) processors. Both architectures are available on all RP2350-family devices. The RISC-V cores support debug over SWD, and can be programmed with the same SDK as the Arm cores.

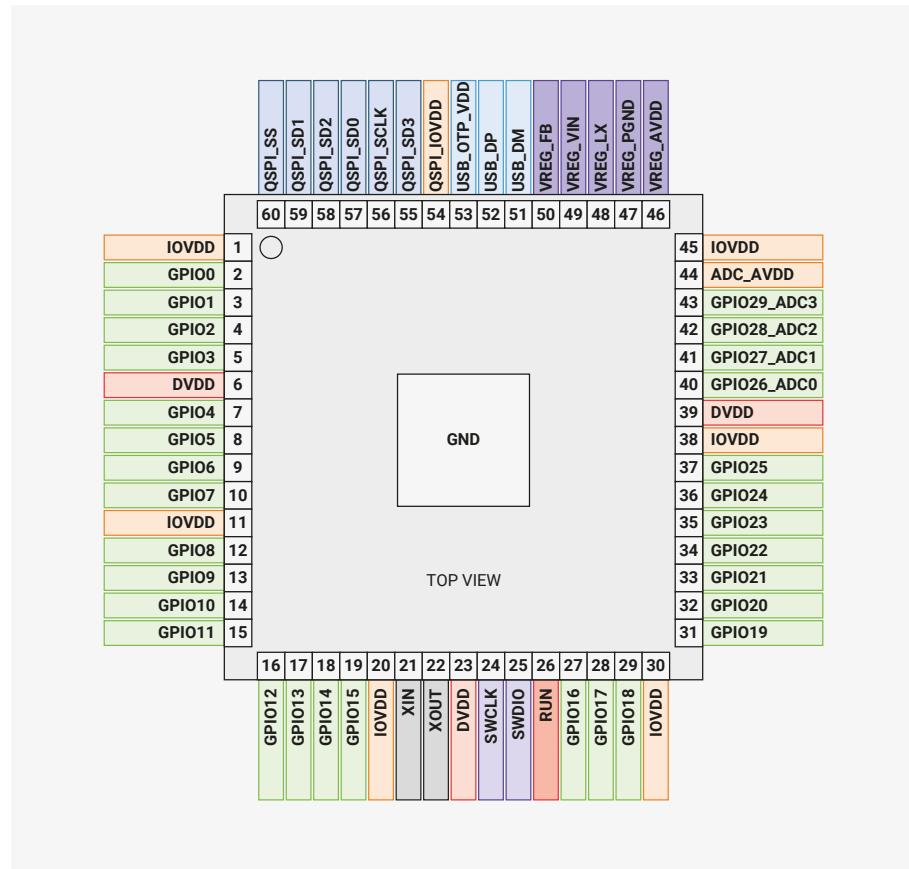

1.2. Pinout reference

This section provides a quick reference for pinout and pin functions. Full details, including electrical specifications and package drawings, can be found in [Chapter 14](#).

1.2.1. Pin locations

1.2.1.1. QFN-60 (RP2350A)

**Figure 2. RP2350
Pinout for QFN-60
7x7mm (reduced ePad
size)**

开关模式降压转换器在系统唤醒时工作，提供最高200 mA的可变输出电压；系统睡眠时可切换至低静态电流的LDO模式，提供最高1 mA的状态保持电流。

系统设有低功耗状态，未使用的逻辑电路会被断电，支持通过定时器或IO事件唤醒。
掉电期间SRAM保持的容量可配置。

内部8 kB一次性可编程存储器（OTP）存储芯片信息，如唯一标识符，可用于配置硬件及BootROM安全功能，也可编程用户提供的代码和数据。

内置启动只读存储器实现了从闪存或OTP的直接启动，以及通过USB或UART的串行启动。所有启动介质均支持代码签名强制执行，使用注册于内部OTP存储的密钥指纹。OTP还可存储加密启动的解密密钥，防止闪存内容被外部读取。

RISC-V架构支持通过动态替换Cortex-M33（Armv8-M）处理器为Hazard3（RV32IMAC+）处理器实现。所有RP2350系列设备均支持这两种架构。RISC-V内核支持通过SWD调试，且可使用与Arm内核相同的SDK进行编程。

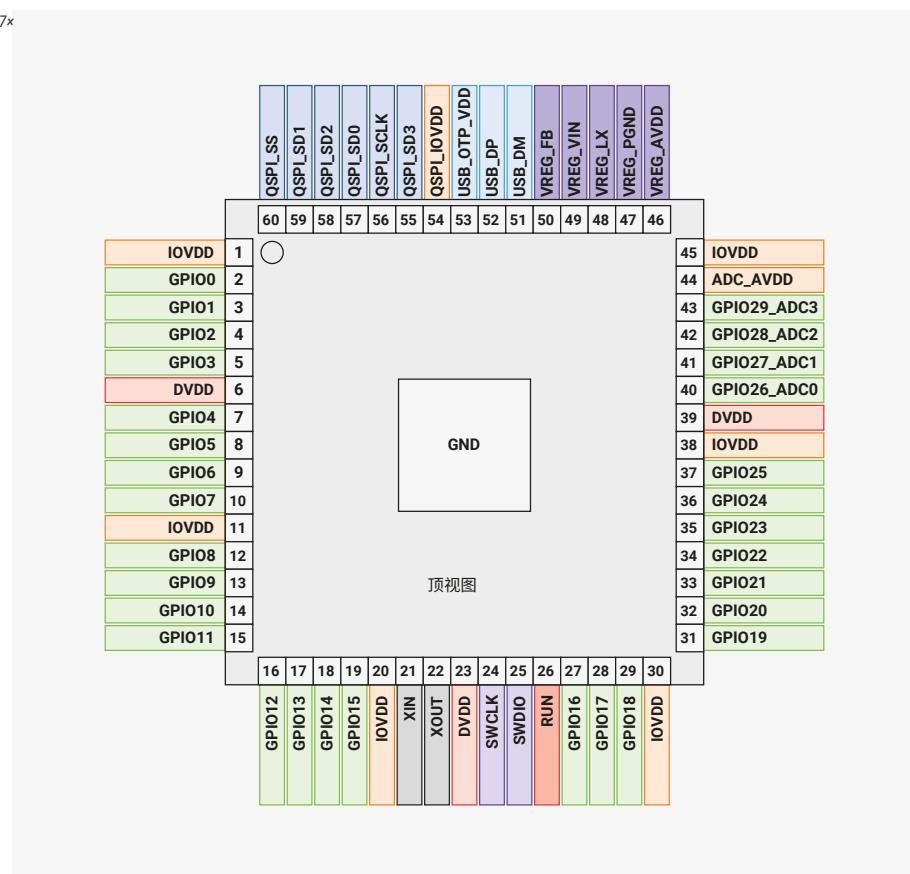

1.2. 引脚参考

本节提供引脚布局及引脚功能的快速参考。详尽信息，包括电气规格与封装图纸，详见第14章。

1.2.1. 引脚位置

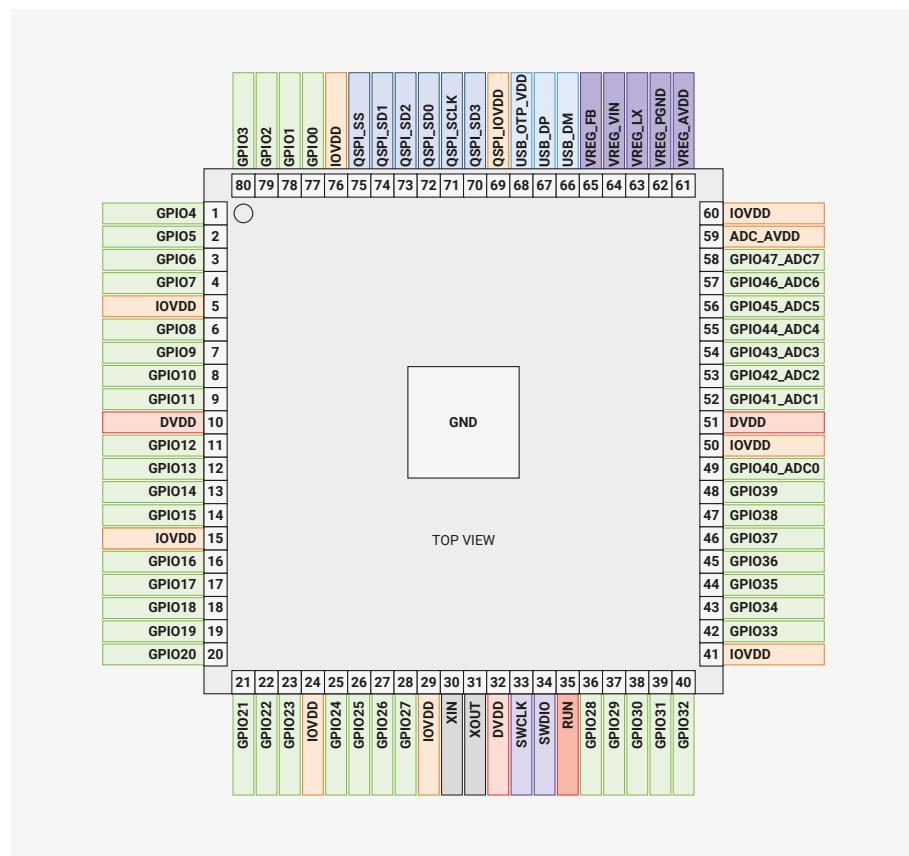

1.2.1.1. QFN-60 (RP2350A)

图2。RP2350 QFN-60 7x
7毫米引脚分布

1.2.2. Pin descriptions

Table 2. The function of each pin is briefly described here. Full electrical specifications can be found in Chapter 14.

Name	Description
GPIOx	General-purpose digital input and output. RP2350 can connect one of a number of internal peripherals to each GPIO, or control GPIOs directly from software.
GPIOx/ADCy	General-purpose digital input and output, with analogue-to-digital converter function. The RP2350 ADC has an analogue multiplexer which can select any one of these pins, and sample the voltage.
QSPIx	Interface to a SPI, Dual-SPI or Quad-SPI flash or PSRAM device, with execute-in-place support. These pins can also be used as software-controlled GPIOs, if they are not required for flash access.
USB_DM and USB_DP	USB controller, supporting Full Speed device and Full/Low Speed host. A 27Ω series termination resistor is required on each pin, but bus pullups and pulldowns are provided internally. These pins can be used as software-controlled GPIOs, if USB is not required.
XIN and XOUT	Connect a crystal to RP2350's crystal oscillator. XIN can also be used as a single-ended CMOS clock input, with XOUT disconnected. The USB bootloader defaults to a 12MHz crystal or 12MHz clock input, but this can be configured via OTP.
RUN	Global asynchronous reset pin. Reset when driven low, run when driven high. If no external reset is required, this pin can be tied directly to IOVDD.
SWCLK and SWDIO	Access to the internal Serial Wire Debug multi-drop bus. Provides debug access to both processors, and can be used to download code.
GND	Single external ground connection, bonded to a number of internal ground pads on the RP2350 die.

ePad尺寸）

1.2.2. 引脚说明

表2。各引脚功能
简述如下。完整
电气规格详见第1
4章。

名称	描述
GPIOx	通用数字输入和输出。RP2350能够将多个内部外设之一连接至每个GPIO，或通过软件直接控制GPIO。
GPIOx/ADCy	通用数字输入和输出，具备模拟到数字转换功能。RP2350的ADC内置模拟多路复用器，可选择上述引脚中的任意一个采样电压。
QSPIx	用于连接SPI、双SPI或四SPI闪存或PSRAM设备的接口，支持原地执行（execute-in-place）。若不用于闪存访问，这些引脚亦可作为软件控制的GPIO使用。
USB_DM 和 USB_DP	USB控制器，支持全速设备及全速/低速主机模式。每个引脚需串联一个27Ω终端电阻，但总线上的上拉和下拉由内部提供。若不使用USB，这些引脚可作为软件控制的GPIO。
XIN 和 XOUT	将晶体连接至RP2350的晶体振荡器引脚。XIN 亦可用作单端 CMOS 时钟输入，XOUT 应断开连接。USB 引导加载程序默认使用 12MHz 晶振或 12MHz 时钟输入，但可通过 OTP 进行配置。
RUN	全局异步复位引脚。置低复位，置高运行。如无外部复位需求，该引脚可直接连接至 IOVDD。
SWCLK 和 SWDIO	访问内部串行线调试多点总线。提供对双处理器的调试访问，并支持代码下载。
GND	单个外部地线连接，焊接至 RP2350 芯片内部多个接地焊盘。

Name	Description
IOVDD	Power supply for digital GPIOs, nominal voltage 1.8V to 3.3V
USB OTP_VDD	Power supply for internal USB Full Speed PHY and OTP storage, nominal voltage 3.3V
ADC_AVDD	Power supply for analogue-to-digital converter, nominal voltage 3.3V
QSPI_IOVDD	Power supply for QSPI IOs, nominal voltage 1.8V to 3.3V
VREG_AVDD	Analogue power supply for internal core voltage regulator, nominal voltage 3.3V
VREG_PGND	Power-ground connection for internal core voltage regulator, tie to ground externally
VREG_LX	Switched-mode output for internal core voltage regulator, connected to external inductor. Max current 200 mA, nominal voltage 1.1V after filtering.
VREG_VIN	Power input for internal core voltage regulator, nominal voltage 2.7V to 5.5V
VREG_FB	Voltage feedback for internal core voltage regulator, connect to filtered VREG output (e.g. to DVDD, if the regulator is used to supply DVDD)
DVDD	Digital core power supply, nominal voltage 1.1V. Must be connected externally, either to the voltage regulator output, or an external board-level power supply.

1.2.3. GPIO functions (Bank 0)

Each individual GPIO pin can be connected to an internal peripheral via the GPIO functions defined below. Some internal peripheral connections appear in multiple places to allow some system level flexibility. SIO, PIO0, PIO1 and PIO2 can connect to all GPIO pins and are controlled by software (or software controlled state machines) so can be used to implement many functions.

名称	描述
IOVDD	数字 GPIO 电源，标称电压范围为 1.8V 至 3.3V。
USB OTP VDD	内部 USB 全速 PHY 及 OTP 存储电源，标称电压为 3.3V。
ADC_AVDD	模数转换器电源，标称电压为 3.3V。
QSPI_IOVDD	QSPI IO 电源，标称电压范围为 1.8V 至 3.3V。
VREG_AVDD	内部核心电压调节器的模拟电源，标称电压为 3.3V
VREG_PGND	内部核心电压调节器的电源地连接，需外部接地
VREG_LX	内部核心电压调节器的开关模式输出，连接至外部电感最大电流 200 mA，滤波后标称电压为 1.1V
VREG_VIN	内部核心电压调节器的电源输入，标称电压范围为 2.7V 至 5.5V
VREG_FB	内部核心电压调节器的电压反馈，连接至滤波后的 VREG 输出（例如，若调节器用于供电 DVDD，则连接至 DVDD）
DVDD	数字核心电源，标称电压为 1.1V。必须外部连接，连接方式可为电压调节器输出或外部板级电源

1.2.3. GPIO功能（银行0）

每个独立GPIO引脚均可通过以下定义的GPIO功能连接至内部外设部分内部外设连接分布于多个位置，以提供系统级灵活性SIO、PIO0、PIO1和PIO2可连接所有GPIO引脚，由软件（或软件控制的状态机）控制，能实现多种功能

Table 3. General Purpose Input/Output (GPIO) Bank 0 Functions

Table 4. GPIO bank 0 function descriptions

Function Name	Description
SPIx	Connect one of the internal PL022 SPI peripherals to GPIO
UARTx	Connect one of the internal PL011 UART peripherals to GPIO
I2Cx	Connect one of the internal DW I2C peripherals to GPIO
PWMx A/B	Connect a PWM slice to GPIO. There are twelve PWM slices, each with two output channels (A/B). The B pin can also be used as an input, for frequency and duty cycle measurement.
SIO	Software control of GPIO, from the single-cycle IO (SIO) block. The SIO function (F5) must be selected for the processors to drive a GPIO, but the input is always connected, so software can check the state of GPIOs at any time.
PIOx	Connect one of the programmable IO blocks (PIO) to GPIO. PIO can implement a wide variety of interfaces, and has its own internal pin mapping hardware, allowing flexible placement of digital interfaces on bank 0 GPIOs. The PIO function (F6, F7, F8) must be selected for PIO to drive a GPIO, but the input is always connected, so the PIOs can always see the state of all pins.
HSTX	Connect the high-speed transmit peripheral (HSTX) to GPIO
CLOCK GPINx	General purpose clock inputs. Can be routed to a number of internal clock domains on RP2350, e.g. to provide a 1Hz clock for the AON Timer, or can be connected to an internal frequency counter.
CLOCK GPOUTx	General purpose clock outputs. Can drive a number of internal clocks (including PLL outputs) onto GPIOs, with optional integer divide.
TRACECLK, TRACEDATAx	CoreSight TPIU execution trace output from Cortex-M33 processors (Arm-only)
USB OVCUR DET/VBUS DET/VBUS EN	USB power control signals to/from the internal USB controller
QMI CS1n	Auxiliary chip select for QSPI bus, to allow execute-in-place from an additional flash or PSRAM device

i NOTE

GPIOs 0 through 29 are available in all package variants. GPIOs 30 through 47 are available only in QFN-80 (RP2350B) package.

i NOTE

Analogue input is available on GPIOs 26 through 29 in the QFN-60 package (RP2350A), for a total of four inputs, and on GPIOs 40 through 47 in the QFN-80 package (RP2350B), for a total of eight inputs.

1.2.4. GPIO functions (Bank 1)

GPIO functions are also available on the six dedicated QSPI pins, which are usually used for flash execute-in-place, and on the USB DP/DM pins. These may become available for general-purpose use depending on the use case, for example, QSPI pins may not be needed for code execution if RP2350 is booting from internal OTP storage, or being controlled externally via SWD.

Table 5. GPIO Bank 1 Functions

Pin	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
USB DP			UART1 TX	I2C0 SDA		SIO						

表 4. GPIO 组 0
功能说明

功能名称	描述
SPIx	将内部 PL022 SPI 外设之一连接至 GPIO
UARTx	将内部 PL011 UART 外设之一连接至 GPIO
I2Cx	将内部 DW I2C 外设之一连接至 GPIO
PWMx A/B	将 PWM 片段连接至 GPIO。共有十二个 PWM 片段，每个包含两个输出通道（A/B）。B 引脚亦可用作输入，用于频率及占空比测量。
SIO	通过单周期 IO (SIO) 模块进行 GPIO 的软件控制。处理器驱动 GPIO 时必须选择 SIO 功能 (F5)，但输入端始终连接，因而软件可随时检测 GPIO 状态。
PIOx	将可编程IO模块 (PIO) 之一连接到GPIO。PIO能够实现多种接口，并配备自身的内部引脚映射硬件，允许在bank 0 GPIO上灵活配置数字接口。要使PIO驱动GPIO，必须选择PIO功能 (F6、F7、F8)，但输入端始终连接，因此PIO可持续监测所有引脚的状态。
HSTX	将高速传输外设 (HSTX) 连接到GPIO。
时钟 GPINx	通用时钟输入。可路由至RP2350的多个内部时钟域，例如为AON定时器提供1Hz时钟，或连接至内部频率计数器。
时钟 GPOUTx	通用时钟输出。可将多个内部时钟（包括PLL输出）驱动至GPIO，支持可选的整数分频。
TRACECLK, TRACEDATAx	CoreSight TPIU 执行追踪输出，来自 Cortex-M33 处理器（仅限 Arm）
USB 过流检测 / VBUS 电源线 检测 / VBUS 电源线使能	内部 USB 控制器的 USB 电源控制信号
QMI CS1n	QSPI 总线辅助芯片选择信号，支持从额外的闪存或 PSRAM 设备执行就地运行

i 注意

GPIO 0 至 29 在所有封装型号中均可用。GPIO 30 至 47 仅在 QFN-80 (RP2350B) 封装中可用。

i 注意

模拟输入在 QFN-60 封装 (RP2350A) 的 GPIO 26 至 29 上可用，共计四个输入；在 QFN-80 封装 (RP2350B) 的 GPIO 40 至 47 上可用，共计八个输入。

1.2.4. GPIO功能（银行1）

GPIO 功能还适用于一般用于闪存就地执行的六个专用 QSPI 引脚及 USB DP/DM 引脚。根据具体使用情况，这些接口可能可用作通用用途，例如，如果 RP2350 从内部只读存储器启动，或通过 SWD 进行外部控制，则 QSPI 引脚可能不需要用于代码执行。

表 5. GPIO 库 1
功能

引脚	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
USB DP			UART1 TX	I2C0 SDA		SIO						

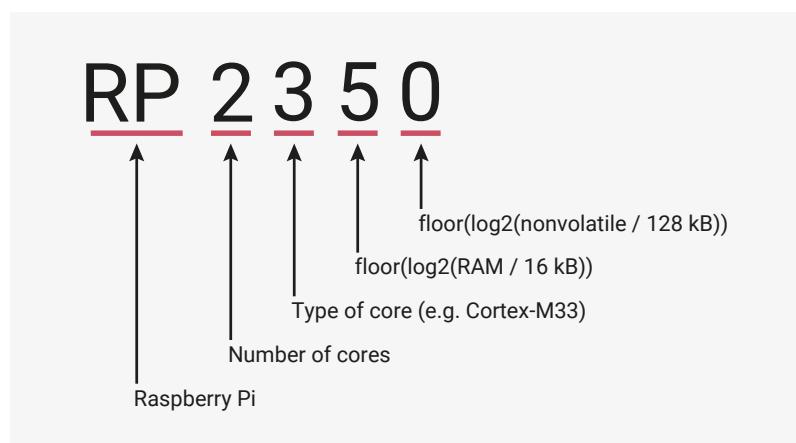

Pin	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
USB DM			UART1 RX	I2C0 SCL		SIO						
QSPI SCK	QMI SCK		UART1 CTS	I2C1 SDA		SIO						UART1 TX
QSPI CSn	QMI CS0n		UART1 RTS	I2C1 SCL		SIO						UART1 RX
QSPI SD0	QMI SD0		UART0 TX	I2C0 SDA		SIO						
QSPI SD1	QMI SD1		UART0 RX	I2C0 SCL		SIO						
QSPI SD2	QMI SD2		UART0 CTS	I2C1 SDA		SIO						UART0 TX
QSPI SD3	QMI SD3		UART0 RTS	I2C1 SCL		SIO						UART0 RX

Table 6. GPIO bank 1 function descriptions

Function Name	Description
UARTx	Connect one of the internal PL011 UART peripherals to GPIO
I2Cx	Connect one of the internal DW I2C peripherals to GPIO
SIO	Software control of GPIO, from the single-cycle IO (SIO) block. The SIO function (F5) must be selected for the processors to drive a GPIO, but the input is always connected, so software can check the state of GPIOs at any time.
QMI	QSPI memory interface peripheral, used for execute-in-place from external QSPI flash or PSRAM memory devices.

1.3. Why is the chip called RP2350?

Figure 4. An explanation for the name of the RP2350 chip.

The post-fix numeral on RP2350 comes from the following,

1. Number of processor cores
 - 2 indicates a dual-core system
2. Loosely which type of processor
 - 3 indicates Cortex-M33 or Hazard3
3. Internal memory capacity: $\lfloor \frac{\text{RAM}}{16 \text{ kB}} \rfloor$
 - 5 indicates at least $2^5 \times 16 \text{ kB} = 512 \text{ kB}$
 - RP2350 has 520 kB of main system SRAM
4. Internal storage capacity: $\lfloor \frac{\text{nonvolatile}}{128 \text{ kB}} \rfloor$ (or 0 if no onboard nonvolatile storage)

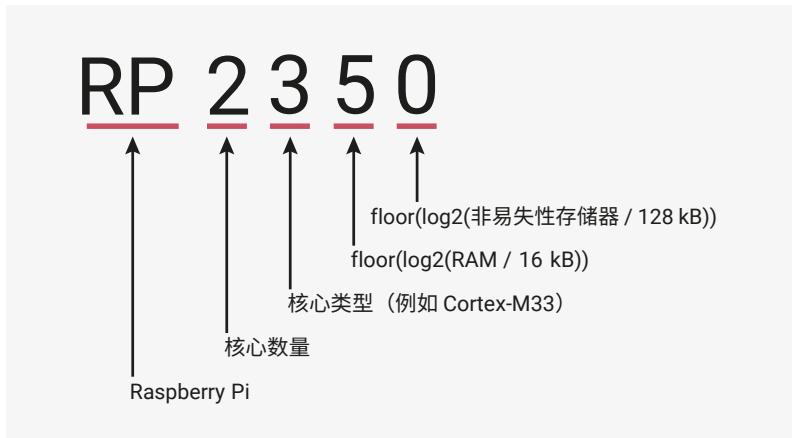

引脚	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
USB DM			UART1 RX	I2C0 时钟线 (SCL)		SIO						
QSPI SCK	QMI SCK		UART1 CTS	I2C1 数据线 (SDA)		SIO						UART1 TX
QSPI CSn	QMI CS0n		UART1 RTS	I2C0 时钟线 (SCL)		SIO						UART1 RX
QSPI SD0	QMI SD0		UART0 TX	I2C0 SDA		SIO						
QSPI SD1	QMI SD1		UART0 接收 (RX)	I2C0 时钟线 (SCL)		SIO						
QSPI SD2	QMI SD2		UART0 清除发送 (CTS)	I2C1 数据线 (SDA)		SIO						UART0 TX
QSPI SD3	QMI SD3		UART0 请求发送 (RTS)	I2C1 时钟线 (SCL)		SIO						UART0 接收 (RX)

表6. GPIO 组 1
功能描述

功能名称	描述
UARTx	将内部 PL011 UART 外设之一连接至 GPIO
I2Cx	将内部 DW I2C 外设之一连接至 GPIO
SIO	通过单周期 IO (SIO) 模块进行 GPIO 的软件控制。处理器驱动 GPIO 时必须选择 SIO 功能 (F5)，但输入端始终连接，因而软件可随时检测 GPIO 状态。
QMI	QSPI 存储器接口外设，用于从外部 QSPI 闪存或 PSRAM 存储器设备执行就地操作。

1.3. 芯片为何命名为RP2350?

图 4。RP2350 芯片名称说明。

RP2350 后缀数字含义如下：

1. 处理器核心数量
 - 2 表示双核系统 2。大致处理器

类型

- 3 表示 Cortex-M33 或 Hazard3

3. 内部存储容量： $\log_2 \frac{RAM}{16kB}$

- 5 表示至少 $2^5 \times 16 kB = 512 kB$

◦ RP2350 具有 520 kB 主系统 SRAM

4. 内部存储容量： $\log_2 \frac{nonvolatile}{128kB}$ (若无板载非易失性存储，则为 0)

- RP2350 uses external flash
- RP2354 has $2^4 \times 128 \text{ kB} = 2 \text{ MB}$ of internal flash

1.4. Version History

[Table 7](#) lists versions of RP2350. Later versions fix bugs in earlier versions. For more information about the changes made between versions, see [Appendix C](#). Also refer to Product Change Notification (PCN) 28.

*Table 7. RP2350
version history*

Version	Use
A0	Internal development
A1	Internal development
A2	Initial release
A3	Internal development, samples, and limited production
A4	Production version

- RP2350 采用外部闪存
- RP2354 具备 $2^4 \times 128 \text{ kB} = 2 \text{ MB}$ 内部闪存

1.4. 版本历史

表 7 列出了 RP2350 版本。后续版本修正了早期版本中的缺陷。有关版本间变更的详细信息，请参见附录 C。亦请参阅产品变更通知 (PCN) 28。

表 7. RP2350
版本历史

版本	用途
A0	内部开发
A1	内部开发
A2	初始发布
A3	内部开发、样品及有限量生产
A4	生产版本

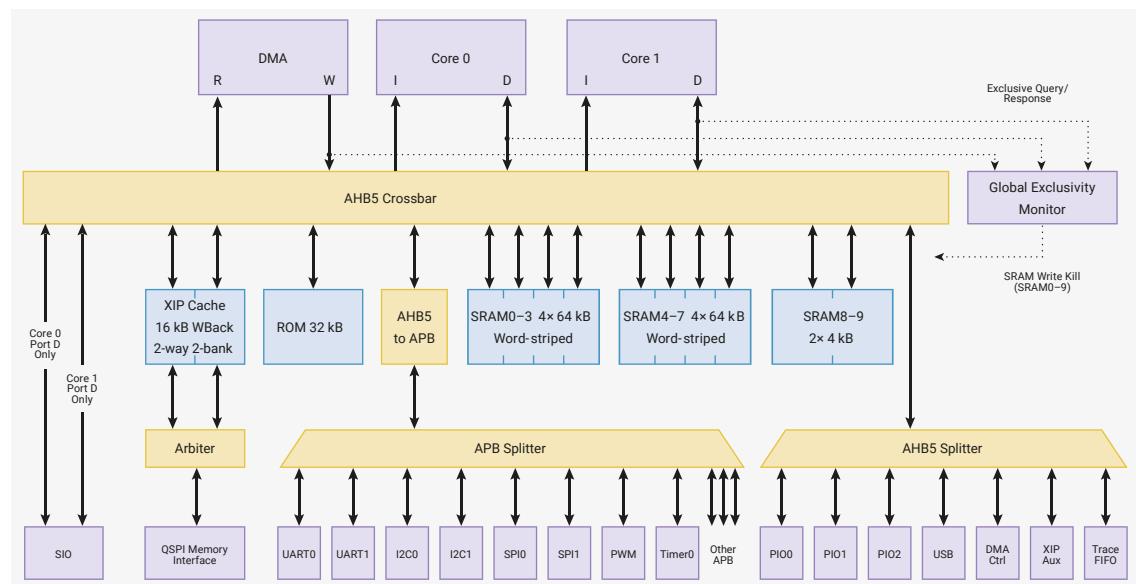

Chapter 2. System bus

2.1. Bus fabric

The RP2350 bus fabric routes addresses and data across the chip.

Figure 5 shows the high-level structure of the bus fabric. The main AHB5 crossbar routes addresses and data between its 6 upstream ports and 17 downstream ports, with up to six bus transfers taking place each cycle. All data paths are 32 bits wide. Memories connect to multiple dedicated ports on the main crossbar, for the best possible memory bandwidth. High-bandwidth AHB peripherals share a port on the crossbar. An APB bridge provides access to system control registers and lower-bandwidth peripherals. The SIO peripherals are accessed via a dedicated path from each processor.

Figure 5. RP2350 bus fabric overview.

The bus fabric connects 6 AHB5 managers, i.e. bus ports which generate addresses:

- Core 0: Instruction port (instruction fetch), and Data port (load/store access)
- Core 1: Instruction port (instruction fetch), and Data port (load/store access)
- DMA controller: Read port, Write port

The following 13 downstream ports are symmetrically accessible from all 6 upstream ports:

- Boot ROM (1 port)
- XIP (2 ports, striped)
- SRAM (10 ports, striped)

Additionally, the following 2 ports are accessible for processor load/store and DMA read/write only:

- 1 shared port for fast AHB5 peripherals: PIO0, PIO1, PIO2, USB, DMA control registers, XIP DMA FIFOs, HSTX FIFO, CoreSight trace DMA FIFO
- 1 port for the APB bridge, to all APB peripherals and control registers

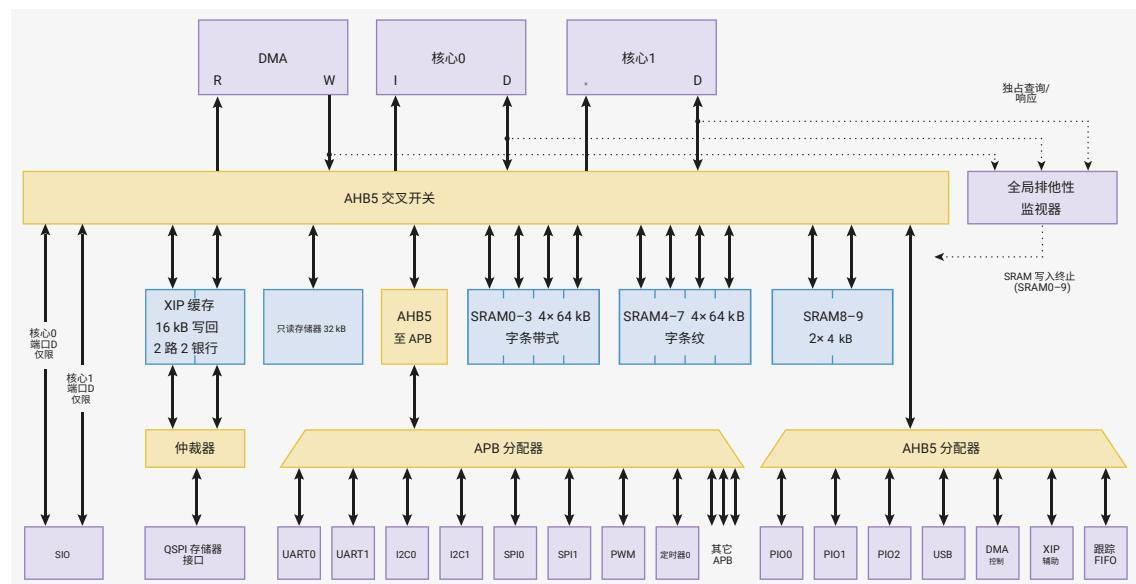

第2章 系统总线

2.1. 总线结构

RP2350总线结构在芯片内进行地址和数据的路由。

图5展示了总线结构的高层次架构。主AHB5交叉开关在其6个上游端口与17个下游端口之间路由地址和数据，每个周期最多可执行六次总线传输。所有数据通路宽度均为32位。存储器连接至主交叉开关的多个专用端口，以实现最佳存储带宽。高带宽AHB外设共享交叉开关上的一个端口。APB桥接器提供对系统控制寄存器及低带宽外设的访问。SIO外设通过每个处理器的专用路径进行访问。

图5. RP2350总线
结构概览。

总线结构连接6个AHB5管理器，即生成地址的总线端口：

- 核心0：指令端口（取指）和数据端口（加载/存储访问）
- 核心1：指令端口（取指）和数据端口（加载/存储访问）
- DMA控制器：读端口，写端口

以下13个下游端口可被所有6个上游端口对称访问：

- 启动只读存储器（1个端口）
- XIP（2个端口，条纹化）
- SRAM（10个端口，分条）

此外，以下两个端口仅供处理器负载/存储及DMA读写使用：

- 1个用于快速AHB5外设的共享端口：PIO0、PIO1、PIO2、USB、DMA控制寄存器、XIP DMA FIFO、HSTX FIFO，CoreSight追踪DMA FIFO
- 1个用于APB桥接的端口，连接所有APB外设及控制寄存器

NOTE

Instruction fetch from peripherals is *physically disconnected*, to avoid this IDAU-Exempt region ever becoming both Non-secure-writable and Secure-executable. This includes USB RAM, OTP and boot RAM. See [Section 10.2.2](#).

The SIO block, which was connected to the Cortex-M0+ IOPORT on RP2040, provides two AHB ports, each dedicated to load/store access from one core.

The six managers can access any six *different* crossbar ports simultaneously. So, at a system clock of 150 MHz, the maximum sustained bus bandwidth is 3.6 GB/s.

2.1.1. Bus priority

The main AHB5 crossbar implements a two-level bus priority scheme. Priority levels are configured separately for core 0, core 1, DMA read and DMA write, using the [BUS_PRIORITY](#) register in the BUSCTRL register block.

When a downstream subordinate receives multiple simultaneous access requests, the port serves high-priority (priority level 1) managers before serving any requests from low-priority (priority 0) managers. If all requests come from managers with the same priority level, the port applies a round-robin tie break, granting access to each manager in turn.

NOTE

Priority arbitration only applies when multiple managers attempt to access the **same** subordinate on the same cycle. When multiple managers access different subordinates, e.g. different SRAM banks, the requests proceed simultaneously.

A subordinate with zero wait states can be accessed once per system clock cycle. When accessing a subordinate with zero wait states (e.g. SRAM), high-priority managers never experience delays caused by accesses from low-priority managers. This *guarantees* latency and throughput for real-time use cases. However, it also means that low-priority managers may stall until there is a free cycle.

2.1.2. Bus security filtering

Every point where the fabric connects to a downstream AHB or APB peripheral is interposed by a bus security filter, which enforces the following access control lists as defined by the ACCESSCTRL registers ([Section 10.6](#)):

- A list of who can access the port: core 0, core 1, DMA, debugger
- A list of the security states from which the port can be accessed: the four combinations of Secure/Non-secure and Privileged/Unprivileged.

Accesses that fail either check are prevented from accessing the downstream port, and return a bus error upstream.

There are three exceptions, which do not implement bus security filters because they implement their own security filtering internally:

- The ACCESSCTRL block itself, which is always world-readable, but filters writes on security and privilege
- Boot RAM, which is hardwired to Secure access only
- The single-cycle IO subsystem (SIO), which is internally banked over Secure and Non-secure

The Cortex-M Private Peripheral Bus (PPB) registers also lack ACCESSCTRL permissions because they are internal to the processors, not accessed through the system bus. The PPB registers are internally banked over Secure and Non-secure.

● 注意

外设指令取指物理断开，以避免此 IDAU-Exempt 区域同时成为非安全可写及安全可执行区域。包括 USB RAM、OTP 和启动 RAM。详见第 10.2.2 节。

SIO 模块，原连接至 RP2040 上的 Cortex-M0+ IOPORT，提供两个 AHB 端口，每个端口专门支持单核的负载/存储访问。

六个管理器可同时访问任意六个不同的交叉开关端口。因此，在 150 MHz 系统时钟下，最大持续总线带宽为 3.6 GB/s。

2.1.1. 总线优先级

主AHB5交叉开关实现了两级总线优先级方案。优先级等级分别针对核心0、核心1、DMA读和DMA写进行配置，使用BUS CTRL寄存器块中的BUS_PRIORITY寄存器。

当下游从属设备同时接收多个访问请求时，端口会优先服务高优先级（优先级等级1）管理器，再处理低优先级（优先级等级0）管理器的请求。如果所有请求均来自相同优先级等级的管理器，端口将采用轮询方式依次授予各管理器访问权限。

● 注意

优先级仲裁仅适用于多个管理器在同一周期试图访问同一从属设备的情况。

当多个管理器访问不同的从属设备时，例如不同的SRAM银行，请求将同时被处理。

具有零等待状态的从属设备可以在每个系统时钟周期内被访问一次。访问具有零等待状态的从属设备（例如SRAM）时，高优先级管理器不会因低优先级管理器的访问而产生延迟。该设计保证实时应用中的延迟和吞吐量。然而，这也意味着低优先级管理器可能会阻塞，直到有空闲周期为止。

2.1.2. 总线安全过滤

所有连接至下游AHB或APB外设的总线交汇点均设有总线安全过滤器，该过滤器依据ACCESSCTRL寄存器（第10.6节）定义的访问控制列表执行如下权限控制：

- 允许访问该端口的实体列表：核0，核1，DMA，调试器
- 允许访问该端口的安全状态列表：安全/非安全与特权/非特权四种组合。

任何未通过上述任一检查的访问请求均被阻止访问下游端口，并在上游返回总线错误。

存在三处例外未启用总线安全过滤器，因其内部实现了自身的安全过滤机制：

- ACCESSCTRL模块本身，始终对所有主体可读，但在安全与特权写入操作上设有限制。
- 启动只读存储器，仅支持硬连线的安全访问。
- 单周期IO子系统（SIO），内部按安全和非安全区域分组

Cortex-M专用外设总线（PPB）寄存器同样不具备ACCESSCTRL权限，因为它们是处理器内部资源，非通过系统总线访问。PPB寄存器内部按安全和非安全区域分组。

2.1.3. Atomic register access

Each peripheral register block is allocated 4 kB of address space, with registers accessed using one of 4 methods, selected by address decode.

- `Addr + 0x0000` : normal read write access
- `Addr + 0x1000` : atomic XOR on write
- `Addr + 0x2000` : atomic bitmask set on write
- `Addr + 0x3000` : atomic bitmask clear on write

This allows software to modify individual fields of a control register without performing a read-modify-write sequence. Instead, the peripheral itself modifies its contents in-place. Without this capability, it is difficult to safely access IO registers when an interrupt service routine is concurrent with code running in the foreground, or when the two processors run code in parallel.

The four atomic access aliases occupy a total of 16 kB. Native atomic writes take the same number of clock cycles as normal writes. Most peripherals on RP2350 provide this functionality natively, but some peripherals (I2C, UART, SPI and SSI) add this functionality using a bus interposer. The bus interposer translates upstream atomic writes into downstream read-modify-write sequences at the boundary of the peripheral, at the cost of additional clock cycles. Atomic writes that use a bus interposer take two additional clock cycles compared to normal writes.

The following registers do not support atomic register access:

- SIO ([Section 3.1](#)), though some individual registers (for example, GPIO) have set, clear, and XOR aliases.
- Any register accessed through the self-hosted CoreSight window, including Arm Mem-APs and the RISC-V Debug Module.
- Standard Arm control registers on the Cortex-M33 private peripheral bus (PPB), except for Raspberry Pi-specific registers on the EPPB.
- OTP programming registers accessed through the SBPI bridge.

2.1.4. APB bridge

The APB bridge provides an interface between the high-speed main AHB5 interconnect and the lower-bandwidth peripherals. Unlike the AHB5 fabric, which offers zero-wait-state accesses everywhere, APB accesses take a minimum of three cycles for a read, and four cycles for a write.

As a result, the throughput of the APB portion of the bus fabric is lower than the AHB5 portion. However, there is more than sufficient bandwidth to saturate the APB serial peripherals.

The following APB ports contain asynchronous bus crossings, which insert additional stall cycles on top of the typical cost of a read or write in the APB bridge:

- ADC
- HSTX_CTRL
- OTP
- POWMAN

The APB bridge implements a fixed timeout for stalled downstream transfers. The downstream bus may stall indefinitely, such as when accessing an asynchronous bus crossing when the destination clock is stopped, or deadlock conditions when accessing system APB registers through Mem-APs in the self-hosted debug window ([Section 3.5.6](#)). When an APB transfer exceeds 65,535 cycles the APB bridge abandons the transfer and returns a bus fault. This keeps the system bus available so that software or the debugger can diagnose the reason for the overly long transfer.

2.1.3. 原子寄存器访问

每个外设寄存器块分配有4 KB的地址空间，寄存器通过以下四种方法之一访问，由地址译码选择。

- `Addr + 0x0000` : 正常读写访问
- `Addr + 0x1000` : 写操作时的原子异或 (XOR)
- `Addr + 0x2000` : 写操作时的原子位掩码置位
- `Addr + 0x3000` : 写操作时的原子位掩码清除

此机制使软件能够修改控制寄存器的单个字段，无需执行读-改-写操作。

外设自身则会在原位 (in-place) 修改其内容。若无此项功能，在中断服务例程与前台代码并发执行，或双处理器并行运行代码时，安全访问IO寄存器将极其困难。

四个原子访问别名共占用16 kB。原子写操作所需的时钟周期与普通写操作相同。RP2350上的大多数外设原生支持此功能，但某些外设 (I2C、UART、SPI和SSI) 通过总线中介器实现该功能。总线中介器将上游的原子写操作转换为外设边界处的下游读-改-写序列，代价是增加额外的时钟周期。

使用总线中介器的原子写操作相比普通写操作多消耗两个时钟周期。

以下寄存器不支持原子寄存器访问：

- SIO (第3.1节)，但某些单独寄存器 (例如GPIO) 具有置位、清除和异或别名。
- 通过自托管CoreSight窗口访问的任何寄存器，包括Arm Mem-AP和RISC-V调试模块。
- Cortex-M33专用外设总线 (PPB) 上的标准Arm控制寄存器，Raspberry Pi特定的EPPB寄存器除外。
- 通过SBPI桥访问的一次性编程寄存器。

2.1.4. APB桥接

APB桥提供了高速主AHB5互连与低带宽外设之间的接口。与在所有区域提供零等待状态访问的AHB5结构不同，APB访问读取操作至少需三个周期，写入操作至少需四个周期。

因此，APB部分总线结构的吞吐量低于AHB5部分。然而，其带宽足以饱和APB串行外设。

以下APB端口包含异步总线交叉，该交叉在APB桥的典型读写延迟基础上插入额外的停顿周期：

- ADC
- HSTX_CTRL
- OTP
- POWMAN

APB桥对下游传输的停滞实现固定超时机制。下游总线可能会无限期停滞，例如目标时钟停止时访问异步总线交叉，或通过自托管调试窗口中的Mem-AP访问系统APB寄存器时发生死锁 (详见第3.5.6节)。

当APB传输超过65,535个周期时，APB桥会放弃该传输并返回总线故障。此举保持系统总线可用，以便软件或调试器能够诊断传输时间过长的原因。

2.1.5. Narrow IO register writes

The majority of memory-mapped IO registers on RP2350 ignore the width of bus read/write accesses. They treat all writes as though they were 32 bits in size. This means software cannot use byte or halfword writes to modify part of an IO register: any write to an address where the 30 address MSBs match the register address affects the contents of the entire register.

To update part of an IO register without a read-modify-write sequence, the best solution on RP2350 is atomic set/clear/XOR (see [Section 2.1.3](#)). This is more flexible than byte or halfword writes, as any combination of fields can be updated in one operation.

Upon a 8-bit or 16-bit write (such as a `strb` instruction on the Cortex-M33), the narrow value is replicated multiple times across the 32-bit data bus, so that it is broadcast to all 8-bit or 16-bit segments of the destination register:

Pico Examples: https://github.com/raspberrypi/pico-examples/blob/master/system/narrow_io_write/narrow_io_write.c Lines 19 - 62

```

19 int main() {
20     stdio_init_all();
21
22     // We'll use WATCHDOG_SCRATCH0 as a convenient 32 bit read/write register
23     // that we can assign arbitrary values to
24     io_rw_32 *scratch32 = &watchdog_hw->scratch[0];
25     // Alias the scratch register as two halfwords at offsets +0x0 and +0x2
26     volatile uint16_t *scratch16 = (volatile uint16_t *) scratch32;
27     // Alias the scratch register as four bytes at offsets +0x0, +0x1, +0x2, +0x3:
28     volatile uint8_t *scratch8 = (volatile uint8_t *) scratch32;
29
30     // Show that we can read/write the scratch register as normal:
31     printf("Writing 32 bit value\n");
32     *scratch32 = 0xdeadbeef;
33     printf("Should be 0xdeadbeef: 0x%08x\n", *scratch32);
34
35     // We can do narrow reads just fine -- IO registers treat this as a 32 bit
36     // read, and the processor/DMA will pick out the correct byte lanes based
37     // on transfer size and address LSBs
38     printf("\nReading back 1 byte at a time\n");
39     // Little-endian!
40     printf("Should be ef be ad de: %02x ", scratch8[0]);
41     printf("%02x ", scratch8[1]);
42     printf("%02x ", scratch8[2]);
43     printf("%02x\n", scratch8[3]);
44
45     // Byte writes are replicated four times across the 32-bit bus, and IO
46     // registers usually sample the entire write bus.
47     printf("\nWriting 8 bit value 0xa5 at offset 0\n");
48     scratch8[0] = 0xa5;
49     // Read back the whole scratch register in one go
50     printf("Should be 0xa5a5a5a5: 0x%08x\n", *scratch32);
51
52     // The IO register ignores the address LSBs [1:0] as well as the transfer
53     // size, so it doesn't matter what byte offset we use
54     printf("\nWriting 8 bit value at offset 1\n");
55     scratch8[1] = 0x3c;
56     printf("Should be 0x3c3c3c3c: 0x%08x\n", *scratch32);
57
58     // Halfword writes are also replicated across the write data bus
59     printf("\nWriting 16 bit value at offset 0\n");
60     scratch16[0] = 0xf00d;
61     printf("Should be 0xf00df00d: 0x%08x\n", *scratch32);
62 }
```

To disable this behaviour on RP2350, set bit 14 of the address by accessing the peripheral at an offset of `+0x4000`. This

2.1.5. 窄带IO寄存器写入

RP2350上大多数内存映射I/O寄存器忽略总线读写访问的宽度。它们将所有写操作视为32位大小处理。这意味着软件无法使用字节或半字写操作来修改I/O寄存器的部分内容：任何写入地址，其30位最高有效位与寄存器地址匹配，都会影响整个寄存器的内容。

在不进行读-改-写序列的情况下，更新I/O寄存器部分内容的最佳方案是RP2350上的原子设定/清除/XOR操作（参见第2.1.3节）。此方法比字节或半字写操作更为灵活，因其可在单次操作中更新任意组合的字段。

进行8位或16位写操作（如Cortex-M33上的 `strb` 指令）时，窄值会在32位数据总线上被多次复制，广播到目标寄存器的所有8位或16位字段：

Pico示例：https://github.com/raspberrypi/pico-examples/blob/master/system/narrow_io_write/narrow_io_write.c 第19至62行

```

19 int main() {
20     stdio_init_all();
21
22     // 我们将使用 WATCHDOG_SCRATCH0 作为一个便于操作的32位读写寄存器
23     // 可向其分配任意值
24     io_rw_32 *scratch32 = &watchdog_hw->scratch[0];
25     // 将 scratch 寄存器在偏移 +0x0 和 +0x2 处别名为两个半字
26     volatile uint16_t *scratch16 = (volatile uint16_t *) scratch32;
27     // 将 scratch 寄存器在偏移 +0x0、+0x1、+0x2 和 +0x3 处别名为四个字节：
28     volatile uint8_t *scratch8 = (volatile uint8_t *) scratch32;
29
30     // 演示我们可以像正常一样读写 scratch 寄存器：
31     printf("Writing 32 bit value\n");
32     *scratch32 = 0xdeadbeef;
33     printf("Should be 0xdeadbeef: 0x%08x\n", *scratch32);
34
35     // 我们可以正常进行窄宽度读取——IO寄存器将此视为一次32位
36     // 读取，处理器/DMA将根据传输大小和地址最低有效位
37     // 选择正确的字节线
38     printf("\n逐字节读取\n");
39     // 小端序！
40     printf("应该是 ef be ad de : %02x ", scratch8[0]);
41     printf("%02x ", scratch8[1]);
42     printf("%02x ", scratch8[2]);
43     printf("%02x\n", scratch8[3]);
44
45     // 字节写入会在32位总线上复制四次，IO
46     // 寄存器通常会采样整个写入总线。
47     printf("\n在偏移量0写入8位值0xa5\n");
48     scratch8[0] = 0xa5;
49     // 一次性读取整个scratch寄存器的全部内容
50     printf("应为0xa5a5a5a5: 0x%08x\n", *scratch32);
51
52     // IO寄存器忽略地址最低有效位[1:0]及传输
53     // 大小，因此使用任何字节偏移量均无影响
54     printf("\n在偏移量1写入8位值\n");
55     scratch8[1] = 0x3c;
56     printf("应为0x3c3c3c3c: 0x%08x\n", *scratch32);
57
58     // 半字写入同样会在写数据总线上被复制
59     printf("\n在偏移量0写入16位值\n");
60     scratch16[0] = 0xf00d;
61     printf("应为0xf00df00d: 0x%08x\n", *scratch32);
62 }
```

要在RP2350上禁用此行为，请通过访问偏移量为 `+0x4000` 的外设，将地址的第 14位设置为1。此操作

causes invalid byte lanes to be driven to zero, rather than being driven with replicated data. In some situations, such as DMA of 8-bit values to the PWM peripheral, the default replication behaviour is not desirable.

2.1.6. Global Exclusive Monitor

The Global Exclusive Monitor enables standard Arm and RISC-V atomic instructions to safely access shared variables in SRAM from both cores. This underpins software libraries for manipulating shared variables, such as `stdatomic.h` in C11. For detailed rules governing the monitor's operation, see the [Armv8-M Architecture Reference Manual](#).

Arm describes exclusive monitor interactions in terms of a *processing element*, PE, which performs a sequence of bus accesses. For RP2350 purposes, this is one AHB5 manager out of the following three: core 0 load/store, core 1 load/store, and DMA write. The DMA does not itself perform exclusive accesses, but its writes are monitored with respect to exclusive sequences on either processor. No distinction is made between debugger and non-debugger accesses from a processor.

The monitor observes all transfers on SRAM initiated by the DMA write and processor load/store ports, and pays particular attention to two types of transfer:

- AHB5 *exclusive reads*: Arm `ldrex*` instructions, RISC-V `lr.w` instructions, and the read phase of RISC-V AMOs (The Hazard3 cores on RP2350 implement AMOs as an exclusive read/write pair that retries until the write succeeds).
- AHB5 *exclusive writes*: Arm `strex*` instructions, RISC-V `sc.w` instructions, and the writeback phase of RISC-V AMOs

Based on these observations, the monitor enforces that an atomic read-modify-write sequence (formed of an exclusive read followed by a successful exclusive write by the same PE) is not interleaved with another PE's successful write (exclusive or not) to the same reservation granule. A reservation granule is any 16-byte, naturally aligned area of SRAM. An exclusive write succeeds when all of the following are true:

- It is preceded by an exclusive read by the same PE
- No other exclusive writes were performed by this PE since that exclusive read
- The exclusive read was to the same reservation granule
- The exclusive read was of the same size (byte/halfword/word)
- The exclusive read was from the same security and privilege state
- No other PEs successfully wrote to the same granule since that exclusive read

If the above conditions are *not* met, the Global Exclusive Monitor shoots down the exclusive write before SRAM can commit the write data. The failure is reported to the originating PE, for example by a non-zero return value from an Arm `strex` instruction.

This implementation of the Armv8-M Global Exclusive Monitor also meets the requirements for RISC-V `lr/sc` and `amo*` instructions, with the caveat that the *RsrvEventual* PMA is not supported. (In practice, whilst it is quite easy to come up with contrived examples of starvation such as the DMA writing to a shared variable on every single cycle, bounded LR/SC and AMO sequences will generally complete quickly.)

CAUTION

Secure software should avoid shared variables in Non-secure-accessible memory. Such variables are vulnerable to deliberate starvation from exclusive accesses by repeatedly performing non-exclusive writes.

Exclusive accesses are only supported on SRAM. The system treats exclusive accesses to other memory regions as normal reads and writes, reporting exclusivity failure to the originating PE, for example by a non-zero return value from an Arm `strex` instruction.

会导致无效字节通道输出为零，而非输出复制的数据。在某些情况下，例如向PWM外设传输8位值的DMA，默认的复制行为并不理想。

2.1.6. 全局独占监控器

全局排他监视器使标准Arm和RISC-V原子指令能够安全地从两个核访问SRAM中的共享变量。这为操作共享变量的软件库提供支持，例如C11中的`stdatomic.h`头文件。

有关该监视器操作的详细规则，请参阅Armv8-M架构参考手册。

Arm将排他监视器的交互描述为一个处理单元（PE），该单元执行一系列总线访问。就RP2350而言，这是以下三者中的一个AHB5管理器：核心0负载/存储、核心1负载/存储以及DMA写入。DMA本身不执行排他访问，但其写操作会针对任一处理器上的排他序列受到监控。处理器的调试器访问与非调试器访问之间不作区分。

监视器监控由DMA写入及处理器负载/存储端口发起的所有SRAM传输，特别关注以下两种传输类型：

- AHB5排他读取：Arm `ldrex*`指令，RISC-V `lr.w`指令，以及RISC-V AMO的读取阶段（RP2350上的Hazard3内核将AMO实现为一对排他读/写操作，直到写入成功为止进行重试）。
- AHB5 排他写入：Arm `strex*`指令，RISC-V `sc.w`指令，以及RISC-V AMO的写回阶段。

基于上述观察，监视器保证同一处理执行单元的原子读-改-写序列（由排他读取随后成功的排他写入组成）不得与另一处理执行单元对相同预留粒度的成功写入（无论是否排他）交错进行。保留粒度是任何16字节的自然对齐SRAM区域。

当且仅当以下所有条件均满足时，排他写入才会成功：

- 该写入之前由相同PE执行了排他读取
- 自该排他读取以来，该PE未执行任何其他排他写入
- 该排他读取针对相同的保留粒度
- 该排他读取的大小相同（字节／半字／字）
- 该排他读取来自相同的安全和特权状态
- 自该排他读取以来，其他PE未对该粒度成功写入

如果上述条件未满足，全球排他监视器将在SRAM提交写入数据之前阻止该排他写入。该失败会报告给发起PE，例如通过Arm `strex`指令的非零返回值。

此实现的Armv8-M全局排他监视器也满足RISC-V `lr/sc`和 `amo*`指令的要求，但需注意不支持`RsrvEventual/PMA`。（实际上，尽管很容易构造诸如DMA在每个周期写入共享变量的刻意饥饿例子，但有界的LR/SC和AMO序列通常能够快速完成。）

⚠ 警告

安全软件应避免在非安全可访问内存中使用共享变量。此类变量容易受到通过反复执行非独占写入而导致的独占访问故意饿死攻击。

独占访问仅支持SRAM。系统将其他内存区域的独占访问视为普通读写操作，并通过例如Arm `strex`指令的非零返回值向发起处理单元报告独占失败。

2.1.6.1. Implementation-defined monitor behaviour

The [Armv8-M Architecture Reference Manual](#) leaves several aspects of the Global Exclusive Monitor up to the implementation. For completeness, the RP2350 implementation defines them as follows:

- The reservation granule size is fixed at 16 bytes
- A single reservation is tracked per PE
- The Arm `clrex` instruction does not affect global monitor state
- Any exclusive write by a PE clears that PE's global reservation
- A non-exclusive write by a PE does *not* clear that PE's global reservation, no matter the address

Only the following updates a PE's reservation tag, setting its reservation state to **Exclusive**:

- An exclusive read on SRAM

Only the following changes a PE's reservation state from **Exclusive** to **Open**:

- A *successful* exclusive write from another PE to this PE's reservation
- A non-exclusive write from another PE to this PE's reservation
- Any exclusive write by this PE
- An exclusive read by this PE, *not* on SRAM

A reservation granule can span multiple SRAM banks, so multiple operations on the same reservation granule may complete on the same cycle. This can result in the following problematic situations:

- Multiple exclusive writes to the same reservation granule, reserved on each PE: in this case the lowest-numbered PE succeeds (in the order DMA < core 0 < core 1), and all others fail.
- A mixture of non-exclusive and exclusive writes to the same reservation granule on the same cycle: in this case, the exclusive writes fail.
- One PE x can write to a reservation granule on the same cycle that another PE y attempts to reserve the *same* reservation granule via exclusive load: in this case, y's reservation is granted (i.e. the write takes place logically before the load).
- One PE x can write to a reservation granule reserved by another PE y, on the same cycle that PE y makes a new reservation on a *different* reservation granule: in this case, again, y's reservation is granted.

These rules can be summarised by a *logical* ordering of all possible events on a reservation granule that can occur on the same cycle: first all normal writes in arbitrary order, then all exclusive writes in ascending PE order (DMA, core 0, core 1), then all loads in arbitrary order.

2.1.6.2. Regions without exclusives support

The Global Exclusive monitor only supports exclusive transactions on certain address ranges. The main system SRAM supports exclusive transactions throughout its entire range: `0x20000000` through `0x20082000`. Within ranges that support exclusive transactions, the Global Exclusive monitor:

- Tracks exclusive sequences across all participating PEs.
- Drives the exclusive success/failure response correctly based on the observed ordering.
- Shoots down failing exclusive writes so that they have no effect.

Exclusive transactions aren't supported outside of this range; all exclusive accesses report exclusive failure (both exclusive reads and exclusive writes), and exclusive writes aren't suppressed.

Outside of regions with exclusive transaction support, load/store exclusive loops run forever while still affecting SRAM contents. This applies to both Arm processors performing exclusive reads/writes and RISC-V processors performing `lr.w/sc.w` instructions. However, an `amo*.w` instruction on Hazard3 will result in a Store/AMO Fault, as the hardware

2.1.6.1. 实现定义的监视器行为

Armv8-M架构参考手册对全局独占监视器的若干方面留待具体实现确定。为完整性起见，RP2350实现定义如下：

- 保留粒度大小固定为16字节
- 每个处理单元仅跟踪单个保留
- Arm `clrex`指令不影响全局监视器状态
- 任何处理单元（PE）执行的独占写操作都会清除该处理单元的全局保留
- 处理单元（PE）执行的非独占写操作，无论地址为何，均不会清除该处理单元的全局保留

仅以下情况会更新处理单元的保留标签，将其保留状态设置为 **Exclusive**：

- 对SRAM的独占读取

仅以下情况会将处理单元的保留状态从 **Exclusive** 变更为 **Open**：

- 另一处理单元对该处理单元保留执行的成功独占写操作
- 另一处理单元对该处理单元保留执行的非独占写操作
- 该处理单元执行的任何独占写操作
- 该处理单元的独占读取操作，非针对SRAM

保留粒度可能跨越多个SRAM银行，因此针对同一保留粒度的多个操作可能在同一周期完成。这可能导致以下问题情况：

- 对同一保留粒度进行多重独占写操作，且该粒度在各处理单元均已保留：此时编号最低的处理单元成功（顺序为 DMA < 核心0 < 核心1），其余处理单元操作失败。
- 在同一时钟周期内对同一保留单元进行非排他性与排他性写入的混合操作：在此情况下，排他性写入失败。
- 一个处理单元 *x*可以在另一处理单元 *y*尝试通过排他性加载保留相同保留单元的同一时钟周期内，向该保留单元写入数据：在此情况下，*y*的保留请求被授予（即该写入在逻辑上早于加载操作）。
- 一个处理单元 *x*可以在另一处理单元 *y*于同一时钟周期对不同保留单元进行新保留的同时，写入 *y*已保留的保留单元：在此情况下，同样授予*y*的保留请求。

这些规则可归纳为对同一时钟周期内可能发生在同一保留单元上的所有事件的逻辑排序：先以任意顺序处理所有普通写入，然后按处理单元编号递增顺序（DMA、核心0、核心1）处理所有排他性写入，最后以任意顺序处理所有加载操作。

2.1.6.2. 不支持排他性的区域

全局排他监视器仅支持特定地址范围内的排他事务。主系统SRAM在其整个地址范围内支持排他事务：`0x20000000`直到`0x20082000`。在支持排他事务的地址范围内，全局排他监视器：

- 跟踪所有参与处理单元（PE）之间的排他序列。
- 根据观察到的顺序准确驱动排他成功或失败响应。
- 取消失败的排他写操作，确保其不产生任何影响。

排他事务不支持该范围之外；所有排他访问（包括排他读和排他写）均报告排他失败，且排他写操作不被抑制。

在无排他事务支持的区域外，负载/存储排他循环将无限执行，同时仍会影响SRAM内容。该规则适用于执行排他读/写的Arm处理器以及执行`lr.w`/`sc.w`指令的RISC-V处理器。然而，在Hazard3处理器上执行`amo*.w`指令将触发存储/原子内存操作故障，因为硬件

detects the failed exclusive read and bails out to avoid an infinite loop.

It is recommended not to perform exclusive accesses on regions outside of main SRAM. Shared variables outside of main SRAM can be protected using either lock variables in main SRAM, the SIO spinlocks, or a locking protocol that does not require exclusive accesses, such as a lock-free queue.

2.1.7. Bus performance counters

Bus performance counters automatically count accesses to the main AHB5 crossbar arbiters. These counters can help diagnose high-traffic performance issues.

There are four performance counters, starting at [PERFCTR0](#). Each is a 24-bit saturating counter. Counter values can be read from [BUSCTRL_PERFCTR_x](#) and cleared by writing any value to [BUSCTRL_PERFCTR_x](#). Each counter can count one of the 20 available events at a time, as selected by [BUSCTRL_PERFSEL_x](#). For more information, see [Section 12.15.4](#).

2.2. Address map

The address map for the device is split into sections as shown in [Table 8](#). Details are shown in the following sections. Unmapped address ranges raise a bus error when accessed.

Each link in the left-hand column of [Table 8](#) goes to a detailed address map for that address range. The detailed address maps have a link for each address to the relevant documentation for that address.

Rough address decode is first performed on bits 31:28 of the address:

Table 8. Address Map Summary

Bus Segment	Base Address
ROM	0x00000000
XIP	0x10000000
SRAM	0x20000000
APB Peripherals	0x40000000
AHB Peripherals	0x50000000
Core-local Peripherals (SIO)	0xd0000000
Cortex-M33 private registers	0xe0000000

2.2.1. ROM

ROM is accessible to DMA, processor load/store, and processor instruction fetch. It is located at address zero, which is the starting point for both Arm processors when the device is reset.

Table 9. Address map for ROM bus segment

Bus Endpoint	Base Address
ROM_BASE	0x00000000

2.2.2. XIP

XIP is accessible to DMA, processor load/store, and processor instruction fetch. This address range contains various mirrors of a 64 MB space which is mapped to external memory devices. On RP2350 the lower 32 MB is occupied by the QSPI Memory Interface (QMI), and the remainder is reserved. QMI controls are in the APB register section.

检测到排他读失败并终止操作，以避免无限循环。

建议不要对主SRAM以外的区域进行独占访问。主SRAM以外的共享变量可通过主SRAM中的锁变量、SIO自旋锁，或无需独占访问的锁定协议（例如无锁队列）加以保护。

2.1.7. 总线性能计数器

总线性能计数器自动统计对主AHB5交叉开关仲裁器的访问次数。这些计数器有助于诊断高流量下的性能问题。

共有四个性能计数器，编号从PERFCTR0开始。每个计数器为24位饱和计数器。计数器数值可从BUSCTRL_PERFCTR x 读取，向BUSCTRL_PERFCTR x 写入任意值可将其清零。每个计数器每次可计数20个可用事件中的一个，通过BUSCTRL_PERFSEL x 进行选择。更多信息详见第12.15.4节。

2.2. 地址映射

设备的地址映射如表8所示被划分为若干部分。详细信息请参见下述章节。

访问未映射的地址范围时将引发总线错误。

表8左侧列中的每个链接均指向对应地址范围的详细地址映射。详细地址映射内的每个地址均提供指向相关文档的链接。

先对地址的第31至28位进行粗略地址解码：

表8. 地址映射概要

总线分段	基地址
只读存储器	0x00000000
XIP	0x10000000
SRAM	0x20000000
APB 外设	0x40000000
AHB 外设	0x50000000
核心本地外设 (SIO)	0xd0000000
Cortex-M33 私有寄存器	0xe0000000

2.2.1. 只读存储器 (ROM)

只读存储器可被DMA、处理器加载/存储及指令抓取访问。其位于地址0，这是设备复位时Arm处理器的起始点。

表9。只读存储器总线段地址映射

总线端点	基地址
ROM_BASE	0x00000000

2.2.2. 执行代码于闪存 (XIP)

XIP可被DMA、处理器加载/存储及指令抓取访问。此地址范围包含映射至外部存储设备的64MB空间的多个镜像。在RP2350上，低32MB由QSPI存储接口 (QMI) 占用，剩余部分为保留。QMI控制寄存器位于APB寄存器区。

Table 10. Address map for XIP bus segment

Bus Endpoint	Base Address
XIP_BASE	0x1000000
XIP_NOCACHE_NOALLOC_BASE	0x14000000
XIP_MAINTENANCE_BASE	0x18000000
XIP_NOCACHE_NOALLOC_NOTRANSlate_BASE	0x1c000000

NOTE

XIP_SRAM_BASE no longer exists as a separate address range. Cache-as-SRAM is now achieved by pinning cache lines within the cached XIP address space.

2.2.3. SRAM

SRAM is accessible to DMA, processor load/store, and processor instruction fetch.

SRAM0-3 and SRAM4-7 are always striped on bits 3:2 of the address:

Table 11. Address map for SRAM bus segment, SRAM0-7 (striped)

Bus Endpoint	Base Address
SRAM_BASE	0x2000000
SRAM_STRIPEd_BASE	0x20000000
SRAM0_BASE	0x20000000
SRAM4_BASE	0x20040000
SRAM_STRIPEd_END	0x20080000

There are two striped regions, each 256 kB in size, and each striped over 4 SRAM banks. SRAM0-3 are in the SRAM0 power domain, and SRAM4-7 are in the SRAM1 power domain.

SRAM 8-9 are always non-striped:

Table 12. Address map for SRAM bus segment, SRAM8-9 (non-striped)

Bus Endpoint	Base Address
SRAM8_BASE	0x20080000
SRAM9_BASE	0x20081000
SRAM_END	0x20082000

These smaller blocks of SRAM are useful for hoisting high-bandwidth data structures like the processor stacks. They are in the SRAM1 power domain.

2.2.4. APB registers

APB peripheral registers are accessible to processor load/store and DMA only. Instruction fetch will always fail.

The APB peripheral segment provides access to control and configuration registers, as well as data access for lower-bandwidth peripherals. APB writes cost a minimum of four cycles, and APB reads a minimum of three.

Table 13. Address map for APB bus segment

Bus Endpoint	Base Address
SYSINFO_BASE	0x40000000
SYSCFG_BASE	0x40008000

表10。XIP总线段地址映射

总线端点	基地址
XIP_BASE	0x1000000
XIP_NOCACHE_NOALLOC_BASE	0x1400000
XIP_MAINTENANCE_BASE	0x1800000
XIP_NOCACHE_NOALLOC_NOTRANSFER_BASE	0x1c00000

i 注意

XIP_SRAM_BASE不再作为独立地址范围存在。缓存即SRAM的功能现通过在缓存的XIP地址空间内固定缓存行来实现。

2.2.3. 静态随机存取存储器 (SRAM)

SRAM可供DMA、处理器加载/存储操作及处理器指令获取访问。

SRAM0-3与SRAM4-7始终按地址的3:2位进行条带分布：

表11。SRAM总线段映射，SRA M0-7(条带式)

总线端点	基地址
SRAM_BASE	0x2000000
SRAM_STRIPE_BASE	0x2000000
SRAM0_BASE	0x2000000
SRAM4_BASE	0x2004000
SRAM_STRIPE_END	0x2008000

共有两个条带区域，每个大小为256 kB，且均跨越4个SRAM银行。SRAM0-3属于SRAM0电源域，SRAM4-7属于SRA M1电源域。

SRAM8-9始终为非条带式：

表12。SRAM总线段映射，SRA M8-9(非条带式)

总线端点	基地址
SRAM8_BASE	0x2008000
SRAM9_BASE	0x2008100
SRAM_END	0x2008200

这些较小的SRAM块适用于承载高带宽数据结构，如处理器堆栈。它们属于SRAM1电源域。

2.2.4. APB 寄存器

APB外设寄存器仅允许处理器负载/存储操作及DMA访问。指令取指操作将始终失败。

APB外设段提供对控制寄存器和配置寄存器的访问，以及对低带宽外设的数据访问。APB写入操作至少需四个周期，AP B读取操作至少需三个周期。

表13。APB总线段地址映射

总线端点	基地址

2.2.5. AHB registers

AHB peripheral registers are accessible to processor load/store and DMA only. Instruction fetch will always fail.

The AHB peripheral segment provides access to higher-bandwidth peripherals. The minimum read/write cost is one cycle, and peripherals may insert up to one wait state.

Table 14. Address map for AHB peripheral bus segment

Bus Endpoint	Base Address
DMA_BASE	0x50000000
USBCTRL_BASE	0x50100000
USBCTRL_DPRAM_BASE	0x50100000
USBCTRL_REGS_BASE	0x50110000
PIO0_BASE	0x50200000
PIO1_BASE	0x50300000
PIO2_BASE	0x50400000
XIP_AUX_BASE	0x50500000
HSTX_FIFO_BASE	0x50600000
CORESIGHT_TRACE_BASE	0x50700000

2.2.6. Core-local peripherals (SIO)

SIO is accessible to processor load/store only. It contains registers which need single-cycle access from both cores concurrently, such as the GPIO registers. Access is always zero-wait-state.

总线端点	基地址
OTP_DATA_RAW_GUARDED_BASE	0x4013c000
CORESIGHT_PERIPH_BASE	0x40140000
CORESIGHT_ROMTABLE_BASE	0x40140000

GLITCH_DETECTOR_BASE	0x40158000
TBMAN_BASE	0x40160000

2.2.5. AHB 寄存器

AHB 外设寄存器仅允许处理器加载/存储和 DMA 访问。指令取指操作将始终失败。

AHB 外设段提供对高带宽外设的访问。最小读写代价为一个周期，外设可能插入最多一个等待状态。

表 14。 AHB 外设总线段地址映射

总线端点	基地址
DMA_BASE	0x50000000
USBCTRL_BASE	0x50100000
USBCTRL_DPRAM_BASE	0x50100000
USBCTRL_REGS_BASE	0x50110000
PIO0_BASE	0x50200000
PIO1_BASE	0x50300000
PIO2_BASE	0x50400000
XIP_AUX_BASE	0x50500000
HSTX_FIFO_BASE	0x50600000
CORESIGHT_TRACE_BASE	0x50700000

2.2.6. 核心本地外设 (SIO)

SIO 仅允许处理器加载/存储访问。包含需要两个核心同时单周期访问的寄存器，如 GPIO 寄存器。访问始终为零等待状态。

Table 15. Address map for SIO bus segment

Bus Endpoint	Base Address
SIO_BASE	0xd0000000
SIO_NONSEC_BASE	0xd0020000

2.2.7. Cortex-M33 private peripherals

The PPB is accessible to processor load/store only.

The PPB region contains standard control registers defined by Arm, Non-secure aliases of some of those registers, and a handful of other core-local registers defined by Raspberry Pi (the EPPB).

These addresses are only accessible to Arm processors: RISC-V processors will return a bus fault.

Table 16. Address map for PPB bus segment

Bus Endpoint	Base Address
PPB_BASE	0xe0000000
PPB_NONSEC_BASE	0xe0020000
EPPB_BASE	0xe0080000

表 15。SIO总线
段地址映射

总线端点	基地址
SIO_BASE	0xd0000000
SIO_NONSEC_BASE	0xd0020000

2.2.7. Cortex-M33 私有外设

PPB 仅对处理器的加载/存储操作开放访问。

PPB 区域包含 Arm 定义的标准控制寄存器、部分这些寄存器的非安全别名及 Raspberry Pi 定义的少量其他核心本地寄存器（EPPB）。

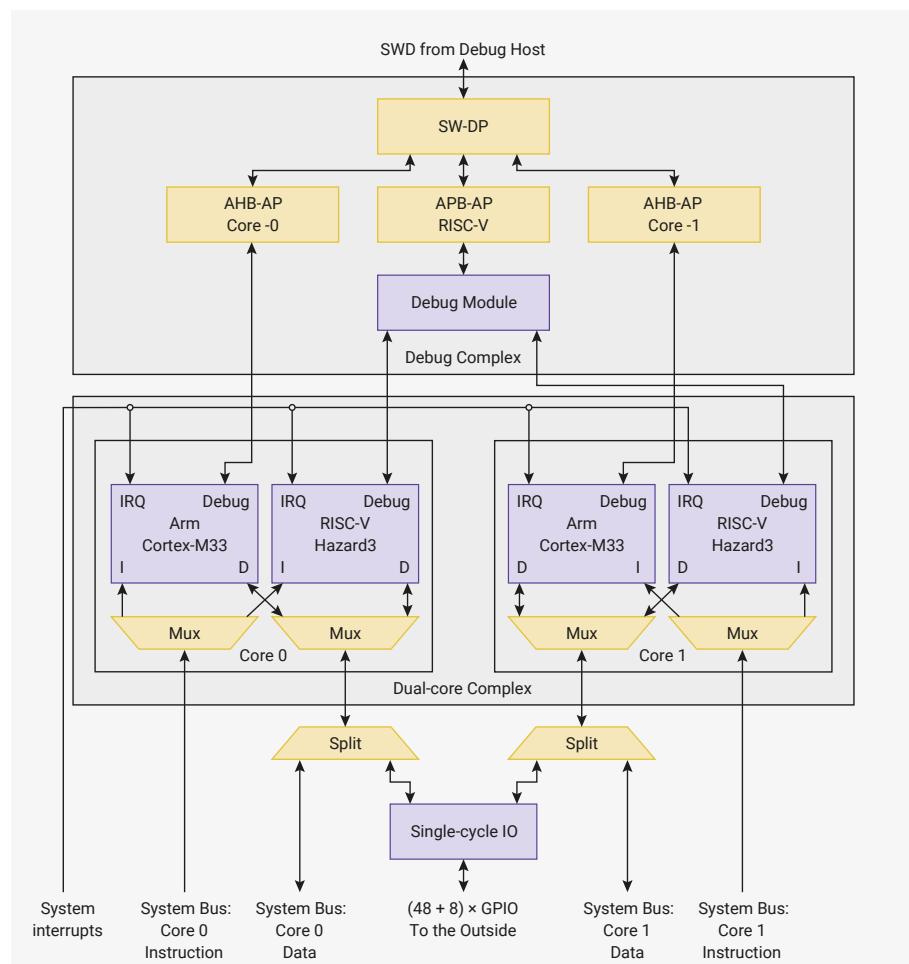

这些地址仅限 Arm 处理器访问：RISC-V 处理器访问将导致总线错误。

表 16。PPB总
线段地址映射

总线端点	基地址
PPB_BASE	0xe0000000
PPB_NONSEC_BASE	0xe0020000
EPPB_BASE	0xe0080000

Chapter 3. Processor subsystem

Figure 6. The RP2350 processor subsystem connects two processors to the system bus, peripheral interrupts, GPIOs, and a Serial Wire Debug (SWD) connection from an external debug host. It also contains closely-coupled peripherals, and peripherals used for synchronisation and communication, which are collectively referred to as the single-cycle I/O subsystem (SIO).

RP2350 is a symmetric dual-core system. Two cores operate simultaneously and independently, offering high processing throughput and the ability to route interrupts to different cores to improve throughput and latency of interrupt handling. The two cores have a symmetric view of the system bus; all memory resources on RP2350 are accessible equally on both cores, with the same performance.

Each core has a pair of 32-bit AHB5 links to the system bus. One is used exclusively for instruction fetch, the other exclusively for load or store instructions and debugger access. Each core can perform one instruction fetch and one load or store access per cycle, provided there are no conflicts on the downstream bus ports.

There are two sockets for cores to attach to the system bus, referred to as **core 0** and **core 1** throughout this datasheet. (They may synonymously be referred to as core0, core1, proc0 and proc1 in register documentation.) The processor plugged into each socket is selectable at boot time:

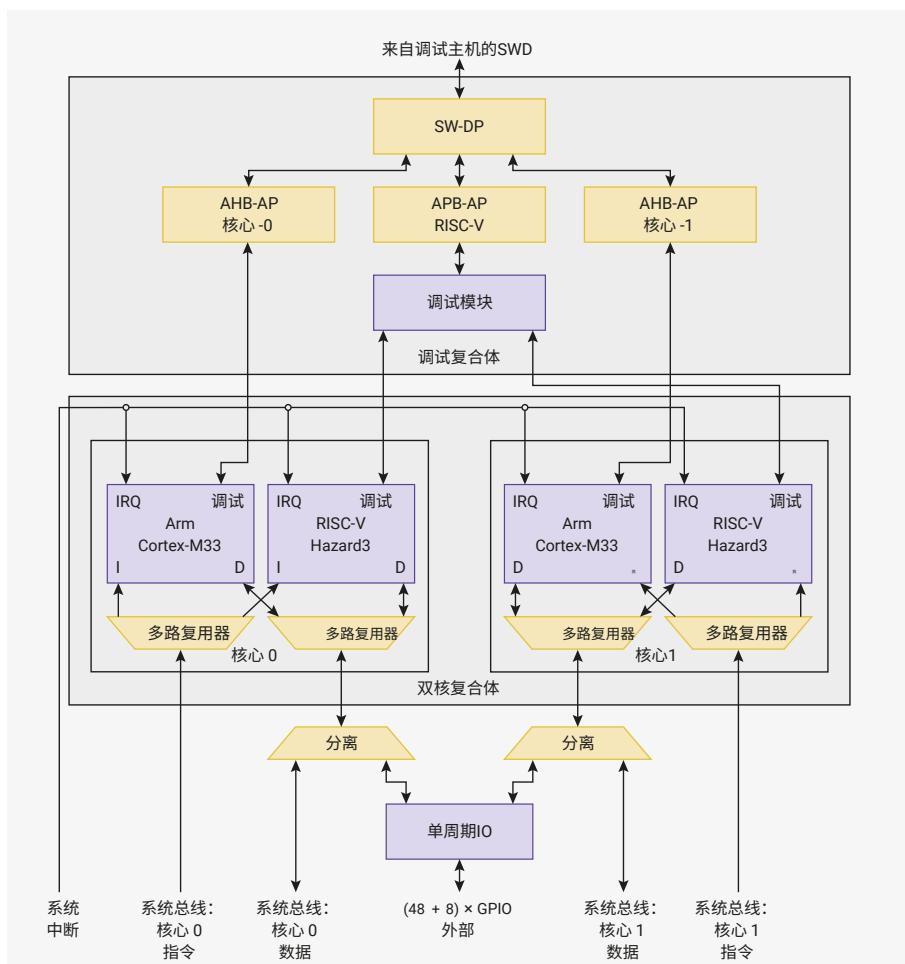

- A Cortex-M33 processor, implementing the Armv8-M Main instruction set, plus extensions
- A Hazard3 processor, implementing the RV32IMAC instruction set, plus extensions

Cortex-M33 is the default option. Whichever processor is unused is held in reset with its clock gated at the top level. Unused processors use zero dynamic power. See [Section 3.9](#) for information about the architecture selection hardware.

The two Cortex-M33 instances are identical. They are configured with the Security, DSP and FPU extensions, as well as 8x SAU regions, 8x Secure MPU regions and 8x Non-secure MPU regions. [Section 3.7](#) documents the Cortex-M33 processor as well as the specific configuration used on RP2350. The two Hazard3 instances are also identical to one another; see [Section 3.8](#) for the features and operation of the Hazard3 processors.

第3章 处理器子系统

图6. RP2350 处理器子系统将两个处理器连接至系统总线、外设中断、GPIO 以及来自外部调试主机的串行线调试 (SWD) 连接。它还包含紧密耦合的外设及用于同步和通信的外设，统称为单周期 I/O 子系统 (SIO)。

RP2350 是对称双核系统。两个核心同时且独立运行，提供高处理吞吐量，并能将中断路由至不同核心，以提升中断处理的吞吐量和延迟。两个核心对系统总线具有对称视图；RP2350 上所有内存资源在两个核心上均可平等访问，性能一致。

每个核心配备一对 32 位 AHB5 链接至系统总线。一个链路专用于指令获取，另一个专用于加载或存储指令及调试器访问。每个核心每周期可执行一次指令获取及一次加载或存储访问，前提是下游总线端口无冲突。

系统总线上有两个核心插槽，分别称为**core 0** 和 **core 1**，在本数据手册中采用此命名。

(在寄存器文档中，它们亦可同义称为 core0、core1、proc0 和 proc1。) 各插槽所插入的处理器可在启动时选择：

- 一颗实现 Armv8-M Main 指令集及其扩展的 Cortex-M33 处理器
- 一颗实现 RV32IMAC 指令集及其扩展的 Hazard3 处理器

默认选用 Cortex-M33。未使用的处理器将被复位，并在顶层对其时钟进行门控。

未使用的处理器不消耗动态功率。有关架构选择硬件的详细信息，请参见第 3.9 节。

两个 Cortex-M33 实例完全相同。它们配置了安全、DSP 及 FPU 扩展，以及

8x SAU 区域、8 个安全 MPU 区域和 8 个非安全 MPU 区域。第 3.7 节对 Cortex-M33 处理器及其在 RP2350 上的具体配置进行了说明。两个 Hazard3 实例也彼此完全相同；有关 Hazard3 处理器功能和操作的内容，请参见第 3.8 节。

The Cortex-M33 implementation of the Armv8-M Security extension (also known as TrustZone-M) isolates trusted and untrusted software running on-device. RP2350 extends the strict partitioning of the Arm Secure and Non-secure states throughout the system, including the ability to assign peripherals, GPIOs and DMA channels to each security domain. See [Section 10.2](#) for a high-level overview of Armv8-M Security extension features in the context of the RP2350 security architecture.

Not shown on [Figure 6](#) are the coprocessors for the Cortex-M33. These are closely coupled to the core, offering a transfer rate of 64 bits per cycle in and out of the Arm register file. You may consider them to be inside the Cortex-M33 block on the diagram. RP2350 equips each Cortex-M33 with the following coprocessors:

- Coprocessor **0**: GPIO coprocessor (GPIOC), described in [Section 3.6.1](#)
- Coprocessors **4** and **5**: Secure and Non-secure instances of the double-precision coprocessor (DCP), described in [Section 3.6.2](#)
- Coprocessor **7**: redundancy coprocessor (RCP), described in [Section 3.6.3](#)

An external debug host can access both cores over a Serial Wire Debug (SWD) bus. The host can:

- run, halt and reset the cores
- inspect internal core state such as registers
- access memory from the core's point of view
- load code onto the device and run it

[Section 3.5](#) describes the debug hardware in addition to the instruction trace hardware available on the Arm processors.

Peripherals throughout the system assert **interrupt requests** (IRQs) to demand attention from the processors. For example, a UART peripheral asserts its interrupt when it has received a character, so the processor can collect it from the receive FIFO. All interrupts route to both cores, and the core's internal interrupt controller selects the interrupt signals it wishes to subscribe to. [Section 3.2](#) defines the system-level IRQ numbering as well as details of the Arm non-maskable interrupt (NMI).

The event signals described in [Section 3.3](#) are a mechanism for processors to sleep when waiting for other processors in the system to complete a task or free up some resource. Each processor sees events emitted by the other processor. They also see exclusivity events generated by the Global Exclusive Monitor described in [Section 2.1.6](#), which is the piece of hardware that allows the processors to safely manipulate shared variables using atomic read-modify-write sequences.

3.1. SIO

The Single-cycle IO subsystem (SIO) contains peripherals that require low-latency, deterministic access from the processors. It is accessed via the AHB Fabric. The SIO has a dedicated bus interface for each processor, as shown in [Figure 7](#).

Cortex-M33对Armv8-M安全扩展（亦称TrustZone-M）的实现，将设备上运行的受信任软件与非受信任软件隔离。RP2350在整个系统中扩展了Arm安全态与非安全态的严格分区功能，包括为每个安全域分配外设、GPIO和DMA通道的能力。

有关RP2350安全架构中Armv8-M安全扩展特性的概览，请参见第10.2节。

图6未显示Cortex-M33的协处理器。该协处理器与核心紧密耦合，提供每个时钟周期64位的数据向Arm寄存器文件的传输速率。您可将其视为位于示意图中Cortex-M33模块内部。RP2350为每个Cortex-M33配备了以下协处理器：

- 协处理器 0：GPIO 协处理器（GPIOC），详见第3.6.1节
- 协处理器 4和 5：双精度协处理器（DCP）的安全与非安全实例，详见第3.6.2节
- 协处理器 7：冗余协处理器（RCP），详见第3.6.3节

外部调试主机可通过串行线调试（SWD）总线访问两个核心。主机能够：

- 运行、停止及重置核心
- 检查内部核心状态，如寄存器
- 从核心视角访问内存
- 将代码加载至设备并执行

[第3.5节介绍了调试硬件，及Arm处理器上可用的指令追踪硬件。](#)

系统中的外设会断言**中断请求**（IRQ），以请求处理器响应。例如，当UART外设接收到字符时，会断言其中断请求，以使处理器能够从接收FIFO中读取字符。所有中断信号均路由至两个核心，核心内部的中断控制器选择其所需订阅的中断信号。第3.2节定义了系统级IRQ编号及Arm不可屏蔽中断（NMI）的详细信息。

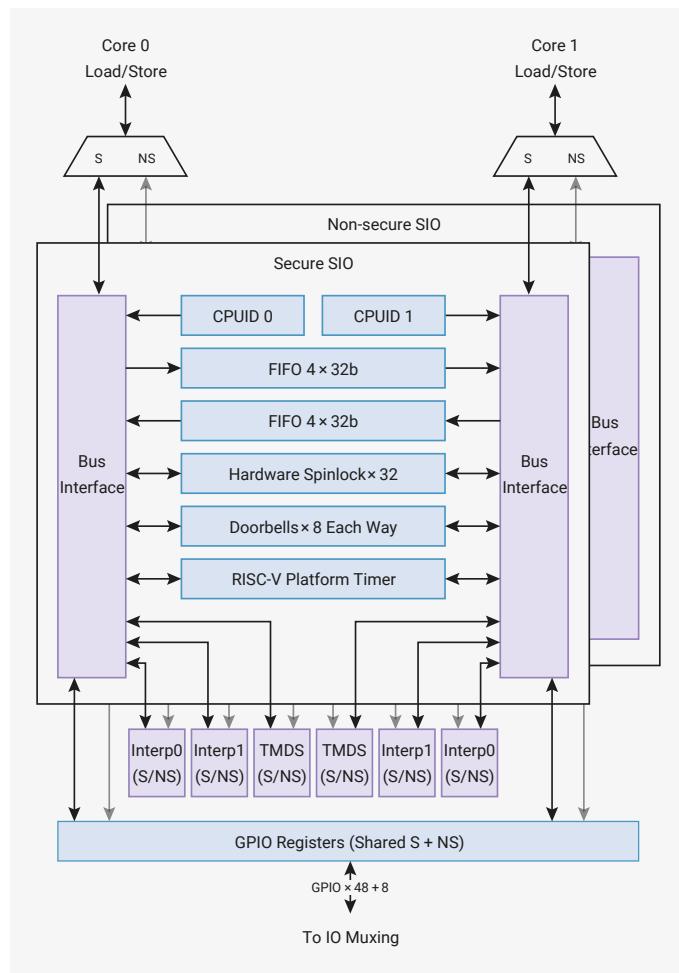

第3.3节中描述的事件信号机制使处理器在等待系统中其他处理器完成任务或释放资源时进入休眠状态。每个处理器均能检测到由另一处理器发出的事件。

处理器还会检测到由第2.1.6节所述的全局排他监控器生成的排他事件，该硬件模块允许处理器通过原子读-改-写序列安全操作共享变量。

3.1. SIO

单周期IO子系统（SIO）包含需要处理器低延迟且确定性访问的外设。该子系统通过AHB结构进行访问。SIO为每个处理器配备了专用总线接口，如图7所示。

Figure 7. The single-cycle I/O block contains registers which processors must access quickly. FIFOs, doorbells and spinlocks support message passing and synchronisation between the two cores. The shared GPIO registers provide fast, direct access to GPIO-capable pins. Interpolators can accelerate common software tasks. Most SIO hardware is banked (duplicated) for Secure and Non-secure access. Grey arrows show bus connections for Non-secure access.

The SIO contains:

- CPUID registers which read as 0/1 on core 0/1 ([Section 3.1.2](#))
- Mailbox FIFOs for passing ordered messages between cores ([Section 3.1.5](#))
- Doorbells for interrupting the opposite core on cumulative and unordered events ([Section 3.1.6](#))
- Hardware spinlocks for implementing critical sections without using exclusive bus accesses ([Section 3.1.4](#))
- Interpolators ([Section 3.1.10](#)) and TMDS encoders ([Section 3.1.9](#))
- Standard RISC-V 64-bit platform timer ([Section 3.1.8](#)) which is usable by both Arm and RISC-V software
- GPIO registers for fast software bitbanging ([Section 3.1.3](#)), with shared access from both cores

Most SIO hardware is duplicated for Secure/Non-secure access. Non-secure access to the FIFO registers will see a physically different FIFO than Secure access to the same address, so that messages belonging to Secure and Non-secure software are not mixed: [Section 3.1.1](#) describes this Secure/Non-secure banking in more detail.

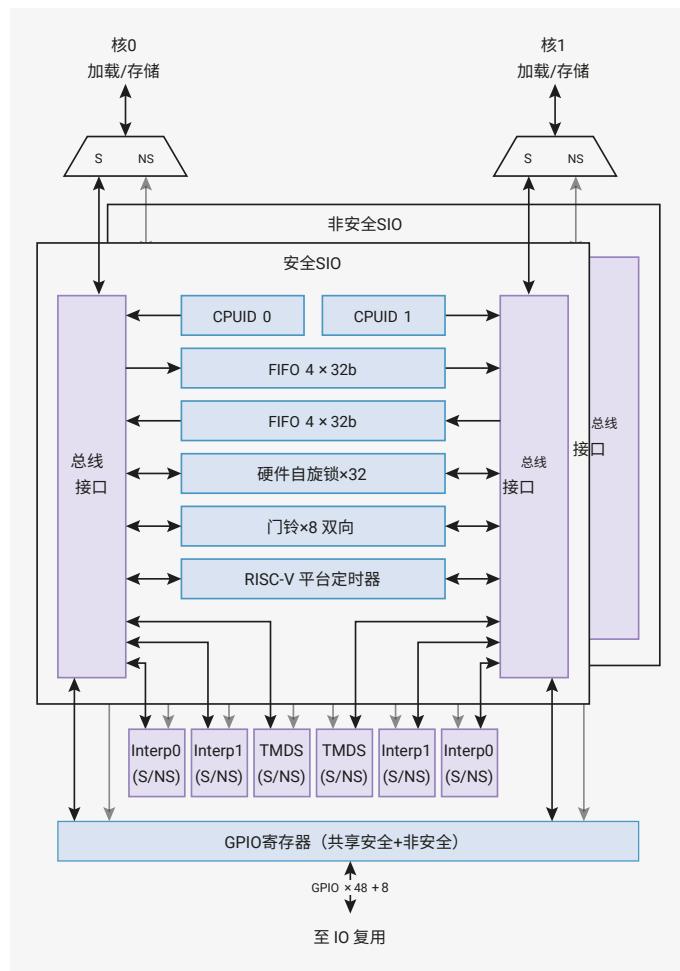

3.1.1. Secure and Non-secure SIO

To allow isolation of Secure and Non-secure software, whilst keeping a consistent programming model for software written to run in either domain, the SIO is duplicated into a Secure and a Non-secure bank. Most hardware is duplicated between the two banks, including:

- Mailbox FIFOs
- Doorbell registers

图7. 单周期 I/O
模块包含处理器必须快速访问的寄存器。
FIFO、门铃和自旋锁支持两个核心之间的消息传递与同步。共享 GPIO 寄存器提供对具备 GPIO 功能引脚的快速直接访问。

插值器能够加速常见的软件任务。大多数 SIO 硬件针对安全与非安全访问进行了分组（复制）。灰色箭头表示非安全访问的总线连接。

SIO 包含：

- CPUID 寄存器，核心 0/1 上读取值分别为 0/1（见第3.1.2节）
- 用于在核心之间传递有序消息的邮箱FIFO（第3.1.5节）
- 用于在累计和无序事件上中断对方核心的门铃（第3.1.6节）
- 用于实现临界区的硬件自旋锁，无需使用独占总线访问（第3.1.4节）
- 插值器（第3.1.10节）和TMDS编码器（第3.1.9节）
- 标准RISC-V 64位平台定时器（第3.1.8节），可被Arm与RISC-V软件共用
- 用于快速软件位段操作的GPIO寄存器（第3.1.3节），由两个核心共享访问

大多数SIO硬件均为安全和非安全访问提供了重复设计。非安全访问FIFO寄存器时，观察到的FIFO在物理上与安全访问相同地址的FIFO不同，确保安全与非安全软件的消息不混合：第3.1.1节对此安全/非安全分区做了详细说明。

3.1.1. 安全与非安全 SIO

为了实现安全与非安全软件的隔离，同时保持在任一域中运行的软件编程模型的一致性，SIO被复制为安全与非安全两套。大多数硬件均在这两套之间复制，包括：

- 邮箱FIFO
- 门铃寄存器

- Interrupt outputs to processors
- Spinlocks

For example, Non-secure code on core 0 can pass messages to Non-secure code on core 1 through the Non-secure instance of the mailbox FIFO. In turn, this message will generate a Non-secure interrupt, which is separate from the Secure FIFO interrupt line. This does not interfere with any Secure message passing that might be going on at the same time, and Non-secure code can not snoop Secure messages because it does not have access to the Secure mailboxes. The software running in the Secure and Non-secure domain can be identical, and the processors' bus accesses to the SIO will automatically be routed to the Secure or Non-secure version of the mailbox registers.

The following hardware is *not* duplicated:

- The GPIO registers are shared, and Non-secure accesses are filtered on a per-GPIO basis by the Non-secure GPIO mask defined in the ACCESSCTRL [GPIO_NSmask0](#) and [GPIO_NSmask1](#) registers
- The RISC-V standard platform timer ([MTIME](#), [MTIMEH](#)), which is also usable by Arm processors, is present only in the Secure SIO, as it is a Machine-mode peripheral on RISC-V
- The interpolator and TMDS encoder peripherals are assignable to either the Secure or Non-secure SIO using the [PERI_NONSEC](#) register

Accesses to the SIO register address range, starting at [0xd0000000](#) ([SIO_BASE](#)), are mapped to the SIO bank which matches the security attribute of the bus access. This means accesses from the Arm Secure state, or RISC-V Machine mode, will access the Secure SIO bank, and accesses from the Arm Non-secure state, or RISC-V User mode, will access the Non-secure SIO bank.

Additionally, Secure accesses can use the mirrored address range starting at [0xd0020000](#) ([SIO_NONSEC_BASE](#)) to access the Non-secure view of SIO, for example, using the Non-secure doorbells to interrupt Non-secure code running on the other core. Attempting to access this address range from Non-secure code will generate a bus fault.

ⓘ NOTE

The [0x20000](#) offset of the Secure-to-Non-secure mirror matches the PPB mirrors at [0xe0000000](#) ([PPB_BASE](#)) and [0xe0020000](#) ([PPB_NONSEC_BASE](#)), which function similarly.

ⓘ NOTE

Debug access is mapped to the Secure/Non-secure SIO using the security attribute of the debugger's bus access, which may differ from the security state that the core was halted in.

3.1.2. CPUID

The [CPUID](#) SIO register returns a value of 0 when read by core 0, and 1 when read by core 1. This helps software identify the core running the current application. The initial boot sequence also relies on this check: both cores start running simultaneously, core 1 goes into a deep sleep state, and core 0 continues the main boot sequence.

❗ IMPORTANT

Don't confuse the SIO [CPUID](#) register with the Cortex-M33 [CPUID](#) register on each processor's internal Private Peripheral Bus, which lists the processor's part number and version.

- 向处理器输出的中断信号
- 自旋锁

例如，核心0上的非安全代码可以通过非安全实例的邮箱FIFO向核心1上的非安全代码传递消息。此消息将触发一个非安全中断，该中断信号独立于安全FIFO的中断线。这不会干扰可能同时进行的任何安全消息传递，且非安全代码无法监听安全消息，因为其无权访问安全邮箱。

在安全域与非安全域中运行的软件可以相同，处理器对SIO的总线访问将自动路由至安全版或非安全版的邮箱寄存器。

以下硬件未被重复：

- GPIO寄存器为共享资源，非安全访问依据ACCESSCTRL寄存器中的GPIO_NSmask0和GPIO_NSmask1中定义的非安全GPIO掩码在每个GPIO级别进行过滤
- RISC-V标准平台计时器（MTIME, MTIMEH），亦可被Arm处理器使用，仅存在于安全SIO中，因其为RISC-V的机器模式外设
- 内插器和TMDS编码器外设可通过PERI_NONSEC寄存器分配至安全或非安全SIO

对起始于 `0xd0000000` (SIO_BASE) 地址范围内SIO寄存器的访问，将映射至与总线访问安全属性匹配的SIO存储器块此即表示，来自Arm安全态或RISC-V机器模式的访问将访问安全SIO存储器块，来自Arm非安全态或RISC-V用户模式的访问将访问非安全SIO存储器块

此外，安全访问可使用从 `0xd0020000` (SIO_NONSEC_BASE) 起的镜像地址范围，以访问SIO的非安全视图，例如，利用非安全门铃中断在另一核上运行的非安全代码。非安全代码尝试访问该地址范围将引发总线错误。

ⓘ 注意

Secure-to-Non-secure镜像的 `0x20000` 偏移与PPB镜像在 `0xe0000000` (PPB_BASE) 及 `0xe0020000` (PPB_NONSEC_BASE) 处相匹配，功能类似。

ⓘ 注意

调试访问依据调试器总线访问的安全属性映射到安全/非安全SIO，该安全属性可能与核心停下时的安全状态不同。

3.1.2. CPUID

当核心0读取CPUID SIO寄存器时返回值为0，核心1读取时返回值为1。此功能有助于软件识别正在运行当前应用程序的核心。初始启动序列同样依赖此检查：两个内核同时运行，内核1进入深度休眠状态，内核0继续执行主启动序列。

! 重要

请勿将SIO CPUID寄存器与每个处理器内部私有外围总线上的Cortex-M33 CPUID寄存器混淆，后者列明处理器的部件编号及版本。

NOTE

Reading the [MHARTID](#) CSR on each Hazard3 core returns the same values as [CPUID](#): 0 on core 0, and 1 on core 1.

3.1.3. GPIO control

The SIO GPIO registers control GPIOs which have the SIO function selected (function 5). This function is supported on the following pins:

- All user GPIOs (GPIOs 0 through 29, or 0 through 47, depending on package option)
- QSPI pins
- USB DP/DM pins

All SIO GPIO control registers come in pairs. The lower-addressed register in each pair (for example, [GPIO_IN](#)) is connected to GPIOs 0 through 31, and the higher-addressed register in each pair (for example, [GPIO_HI_IN](#)) is connected to GPIOs 32 through 47, the QSPI pins, and the USB DP/DM pins.

NOTE

To drive a pin with the SIO's GPIO registers, the GPIO multiplexer for this pin must first be configured to select the SIO GPIO function. See [Table 646](#).

These GPIO registers are *shared* between the two cores: both cores can access them simultaneously. There are three groups of registers:

- Output registers, [GPIO_OUT](#) and [GPIO_HI_OUT](#) set the output level of the GPIO. 0 for low output, 1 for high output.
- Output enable registers, [GPIO_OE](#) and [GPIO_HI_OE](#), are used to enable the output driver. 0 for high-impedance, 1 for drive high or low based on [GPIO_OUT](#) and [GPIO_HI_OUT](#).
- Input registers, [GPIO_IN](#) and [GPIO_HI_IN](#), allow the processor to sample the current state of the GPIOs.

Reading [GPIO_IN](#) returns up to 32 input values in a single read, and software then masks out individual pins it is interested in.

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 869 - 879

```

869 static inline bool gpio_get(uint gpio) {
870 #ifdef NUM_BANK0_GPIOS <= 32
871     return sio_hw->gpio_in & (1u << gpio);
872 #else
873     if (gpio < 32) {
874         return sio_hw->gpio_in & (1u << gpio);
875     } else {
876         return sio_hw->gpio_hi_in & (1u << (gpio - 32));
877     }
878 #endif
879 }
```

The [OUT](#) and [OE](#) registers also have atomic [SET](#), [CLR](#), and [XOR](#) aliases. This allows software to update a subset of the pins in one operation. This ensures safety for concurrent GPIO access, both between the two cores and between a single core's interrupt handler and foreground code.

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 918 - 924

```

918 static inline void gpio_set_mask(uint32_t mask) {
919 #ifdef PICO_USE_GPIO_COPROCESSOR
920     gpioc_lo_out_set(mask);
```

注意

读取每个Hazard3内核的MHARTID CSR返回与CPUID相同的值：内核0为0，内核1为1。

3.1.3. GPIO 控制

SIO GPIO寄存器控制已选择SIO功能（功能 5）的GPIO。该功能支持以下引脚：

- 所有用户GPIO（GPIO 0至29，或根据封装选项为0至47）
- QSPI引脚
- USB DP/DM引脚

所有SIO GPIO控制寄存器均成对出现。每对寄存器中地址较低者（例如GPIO_IN）连接GPIO 0至31，地址较高者（例如GPIO_HI_IN）连接GPIO 32至47、QSPI引脚及USB DP/DM引脚。

注意

要通过SIO的GPIO寄存器驱动引脚，必须首先将该引脚的GPIO多路复用器配置为选择SIO GPIO功能。详见表646。

这些GPIO寄存器由两个核心共享，两者可同时访问。寄存器分为三组：

- 输出寄存器GPIO_OUT和GPIO_HI_OUT用于设置GPIO输出电平，0表示低电平，1表示高电平。
- 输出使能寄存器GPIO_OE和GPIO_HI_OE用于启用输出驱动，0表示高阻，1根据GPIO_OUT和GPIO_HI_OUT驱动高电平或低电平。
- 输入寄存器GPIO_IN和GPIO_HI_IN使处理器能够采样GPIO的当前状态。

读取GPIO_IN可一次返回最多32个输入值，软件随后对感兴趣的单个引脚进行掩码处理。

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h 第869至879行

```

869 static inline bool gpio_get(uint gpio) {
870 #ifdef NUM_BANK0_GPIOS <= 32
871     return sio_hw->gpio_in & (1u << gpio);
872 #else
873     if (gpio < 32) {
874         return sio_hw->gpio_in & (1u << gpio);
875     } else {
876         return sio_hw->gpio_hi_in & (1u << (gpio - 32));
877     }
878 #endif
879 }
```

OUT 和 OE 寄存器还具有原子操作的 SET、CLR 和 XOR 别名。这使软件能够在一次操作中更新部分引脚。这保证了 GPIO 访问的并发安全，无论是在双核之间，还是单核的中断处理程序与前台代码之间。

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h 第 918 - 924 行

```

918 static inline void gpio_set_mask(uint32_t mask) {
919 #ifdef PICO_USE_GPIO_COPROCESSOR
920     gpioc_lo_out_set(mask);
```

```

921 #else
922     sio_hw->gpio_set = mask;
923 #endif
924 }

```

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 965 - 971

```

965 static inline void gpio_clr_mask(uint32_t mask) {
966 #ifdef PICO_USE_GPIO_COPROCESSOR
967     gpioc_lo_out_clr(mask);
968 #else
969     sio_hw->gpio_clr = mask;
970 #endif
971 }

```

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h Lines 1155 - 1180

```

1155 static inline void gpio_put(uint gpio, bool value) {
1156 #ifdef PICO_USE_GPIO_COPROCESSOR
1157     gpioc_bit_out_put(gpio, value);
1158 #elif NUM_BANK0_GPIOS <= 32
1159     uint32_t mask = 1ul << gpio;
1160     if (value)
1161         gpio_set_mask(mask);
1162     else
1163         gpio_clr_mask(mask);
1164 #else
1165     uint32_t mask = 1ul << (gpio & 0x1fu);
1166     if (gpio < 32) {
1167         if (value) {
1168             sio_hw->gpio_set = mask;
1169         } else {
1170             sio_hw->gpio_clr = mask;
1171         }
1172     } else {
1173         if (value) {
1174             sio_hw->gpio_hi_set = mask;
1175         } else {
1176             sio_hw->gpio_hi_clr = mask;
1177         }
1178     }
1179 #endif
1180 }

```

If both processors write to an **OUT** or **OE** register (or any of its **SET/CLR/XOR** aliases) on the same clock cycle, the result is as though core 0 wrote first, then core 1 wrote immediately afterward. For example, if core 0 SETs a bit and core 1 XORs it on the same clock cycle, the bit ends up with a value of **0**.

```

921 #else
922     sio_hw->gpio_set = mask;
923 #endif
924 }

```

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h 行 965 - 971

```

965 static inline void gpio_clr_mask(uint32_t mask) {
966 #ifdef PICO_USE_GPIO_COPROCESSOR
967     gpioc_lo_out_clr(mask);
968 #else
969     sio_hw->gpio_clr = mask;
970 #endif
971 }

```

SDK: https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/include/hardware/gpio.h 行 1155 - 1180

```

1155 static inline void gpio_put(uint gpio, bool value) {
1156 #ifdef PICO_USE_GPIO_COPROCESSOR
1157     gpioc_bit_out_put(gpio, value);
1158 #elif NUM_BANK0_GPIOS <= 32
1159     uint32_t mask = 1ul << gpio;
1160     if (value)
1161         gpio_set_mask(mask);
1162     else
1163         gpio_clr_mask(mask);
1164 #else
1165     uint32_t mask = 1ul << (gpio & 0x1fu);
1166     if (gpio < 32) {
1167         if (value) {
1168             sio_hw->gpio_set = mask;
1169         } else {
1170             sio_hw->gpio_clr = mask;
1171         }
1172     } else {
1173         if (value) {
1174             sio_hw->gpio_hi_set = mask;
1175         } else {
1176             sio_hw->gpio_hi_clr = mask;
1177         }
1178     }
1179 #endif
1180 }

```

如果两个处理器在同一时钟周期内同时写入同一个 OUT或 OE寄存器（或其任何 SET/CLR/XOR别名），其结果相当于先由核心0写入，然后核心1紧接着写入。例如，如果核心0在同一时钟周期内对某个位执行 SET 操作，而核心1对其执行 XOR 操作，则该位最终值为 0。

NOTE

This is a conceptual model for the result produced when two cores write to a GPIO register simultaneously. The register never contains the intermediate values at any point. In the previous example, if the pin is initially **0**, and core 0 performs a **SET** while core 1 performs a **XOR**, the GPIO output remains low throughout the clock cycle.

As well as being shared between cores, the GPIO registers are also shared between security domains. The Secure and Non-secure SIO offer alternative views of the same GPIO registers, which are always mapped as GPIO function **5**. However, the Non-secure SIO can only access pins which are enabled in the GPIO Non-secure mask configured by the ACCESSCTRL registers **GPIO_NSMASK0** and **GPIO_NSMASK1**. The layout of the NSMASK registers matches the layout of the SIO registers – for example, **QSPI_SCK** is bit **26** in both **GPIO_HI_IN** and **GPIO_NSMASK1**.

When a pin is not enabled in Non-secure code:

- Writes to the corresponding GPIO registers from a Non-secure context have no effect.
- Reads from a Non-secure context return zeroes.
- Reads and writes from a Secure context function as usual using the Secure bank.

The GPIO coprocessor port ([Section 3.6.1](#)) provides dedicated instructions for accessing the SIO GPIO registers from the Cortex-M33 processors. This includes the ability to read and write 64 bits in a single operation.

3.1.4. Hardware spinlocks

The SIO provides 32 hardware spinlocks, which can be used to manage mutually-exclusive access to shared software resources. Each spinlock is a one-bit flag, mapped to a different address (from **SPINLOCK0** to **SPINLOCK31**). Software interacts with each spinlock with one of the following operations:

- Read: Attempt to claim the lock. Read value is non-zero if the lock was successfully claimed, or zero if the lock had already been claimed by a previous read.
- Write (any value): Release the lock. The next attempt to claim the lock will succeed.

If both cores try to claim the same lock on the same clock cycle, core 0 succeeds.

Generally software will acquire a lock by repeatedly polling the lock bit ("spinning" on the lock) until it is successfully claimed. This is inefficient if the lock is held for long periods, so generally the spinlocks should be used to protect short critical sections of higher-level primitives such as mutexes, semaphores and queues.

For debugging purposes, the current state of all 32 spinlocks can be observed via **SPINLOCK_ST**.

NOTE

RP2350 has separate spinlocks for Secure and Non-secure SIO banks because sharing these registers would allow Non-secure code to deliberately starve Secure code that attempts to acquire a lock. See [Section 3.1.1](#).

NOTE

The processors on RP2350 support standard atomic/exclusive access instructions which, in concert with the global exclusive monitor ([Section 2.1.6](#)), allow both cores to safely share variables in SRAM. The SIO spinlocks are still included for compatibility with RP2040.

i 注意

这是一个概念性模型，用以说明两个核心同时写入 GPIO 寄存器时产生的结果。该寄存器在任何时刻均不会包含中间值。在前例中，若引脚初始值为 0，且核心 0 执行 SET 操作而核心 1 执行 XOR 操作，则整个时钟周期内 GPIO 输出保持低电平。

GPIO 寄存器不仅在核心间共享，也在安全域间共享。安全与非安全 SIO 提供了同一 GPIO 寄存器的不同视图，该寄存器始终映射为 GPIO 功能 5。

然而，非安全 SIO 仅能访问由 ACCESSCTRL 寄存器 GPIO_NSMASK0 和 GPIO_NSMASK1 配置的 GPIO 非安全掩码中启用的引脚。NSMASK 寄存器的布局与 SIO 寄存器一致——例如，**QSPI_SCK** 在 GPIO_HI_IN 和 GPIO_NSMASK1 中均位于第 26 位。

当引脚未在非安全代码中启用时：

- 从非安全上下文对相应 GPIO 寄存器的写入操作无效。
- 从非安全上下文读取的值均为零。
- 从安全上下文的读写操作正常执行，使用安全区域。

SIO 协处理器端口（第3.6.1节）为 Cortex-M33 处理器访问 SIO GPIO 寄存器提供了专用指令。其中包括在单次操作中读取和写入 64 位数据的能力。

3.1.4. 硬件自旋锁

SIO 提供 32 个硬件自旋锁，可用于管理对共享软件资源的互斥访问。每个自旋锁为一位标志，映射到不同地址（从 SPINLOCK0 至 SPINLOCK31）。软件通过以下操作之一与自旋锁交互：

- 读取：尝试获取锁。若成功获取锁，则读取值非零；若锁已被先前读取获取，则读取值为零。
- 写入（任意值）：释放锁。下一次尝试获取该锁将成功。

若两个内核在同一时钟周期尝试获取相同锁，内核 0 将成功。

通常，软件通过反复轮询锁位（“自旋”锁）来获取锁，直至成功。若锁长时间被持有，此方式效率低，故自旋锁通常用于保护更高级原语（如互斥锁、信号量及队列）中的短关键区段。

出于调试目的，可通过 SPINLOCK_ST 观察所有 32 个自旋锁的当前状态。

i 注意

RP2350 对安全与非安全 SIO 寄存器组设有独立自旋锁，因共享寄存器将允许非安全代码故意阻塞获取锁的安全代码。详见第3.1.1节。

i 注意

RP2350 处理器支持标准原子/独占访问指令，结合全局独占监视器（第2.1.6节），使两个内核安全共享 SRAM 变量。SIO 自旋锁仍保留以兼容 RP2040。

NOTE

Due to [RP2350-E2](#), writes to new SIO registers above an offset of `+0x180` alias the spinlocks, causing spurious lock releases. The SDK by default uses atomic memory accesses to implement the `hardware_sync_spin_lock` API, as a workaround on RP2350 A2.

3.1.5. Inter-processor FIFOs (Mailboxes)

The SIO contains two FIFOs for passing data, messages or ordered events between the two cores. Each FIFO is 32 bits wide and four entries deep. One of the FIFOs can only be written by core 0 and read by core 1. The other can only be written by core 1 and read by core 0.

Each core writes to its outgoing FIFO by writing to `FIFO_WR` and reads from its incoming FIFO by reading from `FIFO_RD`. A status register, `FIFO_ST`, provides the following status signals:

- Incoming FIFO contains data (`VLD`).
- Outgoing FIFO has room for more data (`RDY`).
- The incoming FIFO was read from while empty at some point in the past (`ROE`).
- The outgoing FIFO was written to while full at some point in the past (`WOF`).

Writing to the outgoing FIFO while full, or reading from the incoming FIFO while empty, does not affect the FIFO state. The current contents and level of the FIFO is preserved. However, this does represent some loss of data or reception of invalid data by the software accessing the FIFO, so a sticky error flag is raised (`ROE` or `WOF`).

The SIO has a FIFO IRQ output for each core to notify the core that it has received FIFO data. This is a *core-local interrupt*, mapped to the same IRQ number on each core (`SIO_IRQ_FIFO`, interrupt number [25](#)). Non-secure FIFO interrupts use a separate interrupt line, (`SIO_IRQ_FIFO_NS`, interrupt number [27](#)). It is not possible to interrupt on the opposite core's FIFO.

Each IRQ output is the logical OR of the `VLD`, `ROE` and `WOF` bits in that core's `FIFO_ST` register: that is, the IRQ is asserted if any of these three bits is high, and clears again when they are all low. To clear the `ROE` and `WOF` flags, write any value to `FIFO_ST`. To clear the `VLD` flag, read data from the FIFO until it is empty.

If the corresponding interrupt line is enabled in the processor's interrupt controller, the processor takes an interrupt each time data appears in its FIFO, or if it has performed some invalid FIFO operation (read on empty, write on full).

NOTE

`ROE` and `WOF` only become set if software misbehaves in some way. Generally, the interrupt handler triggers when data appears in the FIFO, raising the `VLD` flag. Then, the interrupt handler clears the IRQ by reading data from the FIFO until `VLD` goes low once more.

The inter-processor FIFOs and the Event signals are used by the bootrom ([Chapter 5](#)) `wait_for_vector` routine, where core 1 remains in a sleep state until it is woken, and provided with its initial stack pointer, entry point and vector table through the FIFO.

NOTE

RP2350 has separate FIFOs and interrupts for Secure and Non-secure SIO banks. See [Section 3.1.1](#)

3.1.6. Doorbells

The doorbell registers raise an interrupt on the opposite core. There are 8 doorbell flags in each direction, combined into a single doorbell interrupt per core. This is a core-local interrupt: the same interrupt number on each core (`SIO_IRQ_BELL`, interrupt number [26](#)) notifies that core of incoming doorbell interrupts.

i 注意

由于RP2350-E2，对偏移量 `+0x180`以上的新SIO寄存器的写入操作会产生别名，影响自旋锁，导致伪锁释放。SDK默认使用原子内存访问来实现`hardware_sync_spin_lock`API，此为RP2350 A2上的一种权宜之计。

3.1.5. 处理器间 FIFO（邮箱）

SIO包含两个FIFO队列，用以在两个核心之间传递数据、消息或有序事件。每个FIFO宽度为32位，深度为四个条目。其中一个FIFO仅允许核心0写入，核心1读取。另一个FIFO仅允许核心1写入，核心0读取。

每个核心通过写入FIFO_WR来向其输出FIFO写入数据，通过读取FIFO_RD来从其输入FIFO读取数据。
状态寄存器FIFO_ST提供下列状态信号：

- 输入FIFO中含有数据（`VLD`）。
- 输出FIFO还有空间可供写入（`RDY`）。
- 输入FIFO曾在空时被读取过（`ROE`）。
- 过去某个时刻曾向已满的输出FIFO写入数据（`WOF`）。

向已满的输出FIFO写入数据或从空的输入FIFO读取数据均不影响FIFO状态。

FIFO当前的内容和容量水位保持不变。然而，这意味着访问FIFO的软件出现了数据丢失或接收无效数据，因此会触发一个粘滞错误标志（`ROE`或 `WOF`）。

SIO为每个核心提供了FIFO中断输出，用以通知核心已收到FIFO数据。这是一种核心本地中断，在每个核心上映射为相同的IRQ号（`SIO_IRQ_FIFO`，中断号 25）。非安全FIFO中断使用独立的中断线（`SIO_IRQ_FIFO_NS`，中断号 27）。无法对另一个核心的FIFO触发中断。

每个IRQ输出是该核心FIFO_ST寄存器中 `VLD`、`ROE`和 `WOF`位的逻辑或：只要这三个位中有任一位为高，IRQ即被置位；当这三个位全为低时，IRQ清除。清除 `ROE`和 `WOF`标志，需向`FIFO_ST`写入任意值；清除 `VLD`标志，需从FIFO读取数据直至其为空。

如果处理器中断控制器中对应的中断线被使能，则每当数据出现在其FIFO中，或者发生无效的FIFO操作（如空时读取、满时写入），处理器都会响应中断。

i 注意

`ROE`和 `WOF`仅在软件出现异常行为时才会被置位。通常，中断处理程序在FIFO出现数据时触发，并置位 `VLD`标志。随后，中断处理程序通过读取FIFO中的数据直到`VLD`再次清零，从而清除IRQ。

多处理器间FIFO和事件信号被引导只读存储器（第5章）中的`wait_for_vector`例程使用，核心1保持睡眠状态，直到被唤醒，并通过FIFO接收其初始栈指针、入口地址和向量表。

i 注意

RP2350为安全和非安全SIO银行分别设有独立的FIFO和中断。详见第3.1.1节。

3.1.6. 门铃

门铃寄存器会在对向核心引发中断。每个方向有8个门铃标志，汇总为每个核心的单一门铃中断。这是一个核心本地中断：每个核心上的相同中断号（`SIO_IRQ_BELL`，中断号 26）通知该核心收到门铃中断。

Whereas the mailbox FIFOs are used for cross-core events whose count and order is important, doorbells are used for events which are accumulative (i.e. may post multiple times, but only answered once) and which can be responded to in any order.

Writing a non-zero value to the [DOORBELL_OUT_SET](#) register raises the opposite core's doorbell interrupt. The interrupt remains raised until all bits are cleared. Generally, the opposite core enters its doorbell interrupt handler, reads its [DOORBELL_IN_CLR](#) register to get the mask of active doorbell flags, and then writes back to acknowledge and clear the interrupt.

The [DOORBELL_IN_SET](#) register allows a processor to ring its own doorbell. This is useful when the routine which rings a doorbell can be scheduled on either core. Likewise, for symmetry, a processor can clear the opposite core's doorbell flags using the [DOORBELL_OUT_CLR](#) register: this is useful for setup code, but should be avoided in general because of the potential for race conditions when acknowledging interrupts meant for the opposite core.

At any time, a core can read back its [DOORBELL_OUT_SET](#) or [DOORBELL_OUT_CLR](#) register (they return the same result) to see the status of doorbell interrupts posted to the opposite core. Likewise, reading either [DOORBELL_IN_SET](#) or [DOORBELL_IN_CLR](#) returns the status of doorbell interrupts posted to this core.

NOTE

RP2350 has separate per-core doorbell interrupt signals and doorbell registers for Secure and Non-secure SIO banks. Non-secure doorbells are posted on [SIO_IRQ_BELL_NS](#), interrupt number 28. See [Section 3.1.1](#).

3.1.7. Integer divider

RP2040's memory-mapped integer divider peripheral is not present on RP2350, since the processors support divide instructions. The address space previously allocated for the divider registers is now reserved.

3.1.8. RISC-V platform timer

This 64-bit timer is a standard peripheral described in the RISC-V privileged specification, usable equally by the Arm and RISC-V processors on RP2350. It drives the per-core [SIO_IRQ_MTIMECMP](#) system-level interrupt ([Section 3.2](#)), as well as the [mip.mtip](#) timer interrupt on the RISC-V processors.

There is a single 64-bit counter, shared between both cores. The low and high half can be accessed through the [MTIME](#) and [MTIMEH](#) SIO registers. Use the following procedure to safely read the 64-bit time using 32-bit register accesses:

1. Read the upper half, [MTIMEH](#).
2. Read the lower half, [MTIME](#).
3. Read the upper half again.
4. Loop if the two upper-half reads returned different values.

This is similar to the procedure for reading RP2350 system timers ([Section 12.8](#)). The loop should only happen once, when the timer is read at exactly the instant of a 32-bit rollover, and even this is only occasional. If you require constant-time operation, you can instead zero the lower half when the two upper-half reads differ.

Timer interrupts are generated based on a per-core 64-bit time comparison value, accessed through the [MTIMECMP](#) and [MTIMECMPPH](#) SIO registers. Each core gets its own copy of these registers, accessed at the same address. The per-core interrupt is asserted whenever the current time indicated in the [MTIME](#) registers is greater than or equal to that core's [MTIMECMP](#). Use the following sequence to write a new 64-bit timer comparison value without causing spurious interrupts:

1. Write all-ones to [MTIMECMP](#) (guaranteed greater than or equal to the old value, *and* the lower half of the target value).
2. Write the upper half of the target value to [MTIMECMPPH](#) (combined 64-bit value is still greater than or equal to the target value).

信箱FIFO用于跨核心事件，计数和顺序非常重要；而门铃用于累积性事件（即可能多次触发，但仅需响应一次），且可按任意顺序处理。

向DOORBELL_OUT_SET寄存器写入非零值将触发对端核心的门铃中断。中断将持续激活，直到所有相关位被清除。通常，对端核心进入门铃中断处理程序，读取其DOORBELL_IN_CLR寄存器以获取活动门铃标志的掩码，然后写回以确认并清除中断。

DOORBELL_IN_SET寄存器允许处理器触发自身的门铃中断。当响铃例程可安排在任一核心执行时，此方法非常有用。同理，为了对称，处理器可使用DOORBELL_OUT_CLR寄存器清除对方核心的门铃标志：这对初始化代码有用，但一般应避免使用，以防在确认针对对方核心的中断时发生竞态条件。

核心可随时读取其DOORBELL_OUT_SET或DOORBELL_OUT_CLR寄存器（两者返回相同结果），以查询发送至对方核心的门铃中断状态。同样，读取DOORBELL_IN_SET或DOORBELL_IN_CLR任一寄存器均可返回发送至本核心的门铃中断状态。

i 注意

RP2350 为安全与非安全 SIO 银行分别设置了独立的每核心门铃中断信号及门铃寄存器。非安全门铃通过[SIO_IRQ_BELL_NS](#)发送，中断编号为 28。详见第 3.1.1 节。

3.1.7. 整数除法器

RP2040 的内存映射整数除法外设在 RP2350 上不存在，原因是处理器支持除法指令。之前分配给除法寄存器的地址空间现已保留。

3.1.8. RISC-V 平台定时器

该64位定时器为RISC-V特权规范中描述的标准外设，RP2350上的Arm和RISC-V处理器均可使用。它触发每核[SIO_IRQ_MTIMECMP](#)系统级中断（见第3.2节），以及RISC-V处理器上的mip.mtip定时器中断。

存在一个64位计数器，两个核心共享使用。低半部和高半部可通过MTIME和MTIMEH SIO寄存器访问。请使用以下步骤，通过32位寄存器访问安全读取64位时间：

1. 读取高半部MTIMEH。
2. 读取低半部MTIME。
3. 再次读取高半部。
4. 若两次读取的高半部值不同，则循环重读。

该过程类似于读取RP2350系统定时器（见第12.8节）。循环重读仅在定时器恰好于32位溢出瞬间被读取时发生，且概率极低。如需恒定时间操作，当两次高半部读取值不同时，可选择将低半部清零。

定时器中断基于每核64位时间比较值产生，该值通过MTIMECMP和MTIMECMPPH SIO寄存器访问。每个核心均拥有这组寄存器的独立副本，且访问地址相同。当MTIME寄存器指示的当前时间大于或等于该核心的MTIMECMP时，便断言该核的中断。请按以下步骤写入新的64位定时器比较值，以避免产生虚假中断：

1. 向MTIMECMP写入全1（二进制，确保该值大于或等于旧值及目标值的低半部分）。
2. 向MTIMECMPPH写入目标值的高半部分（合并的64位值仍大于或等于目标值）。

3. Write the lower half of the target value to [MTIMECMP](#).

The RISC-V timer can count either ticks from the system-level tick generator ([Section 8.5](#)), or system clock cycles, selected by the [MTIME_CTRL](#) register. Use a 1 microsecond time base for compatibility with most RISC-V software.

3.1.9. TMDS encoder

Each core is equipped with an implementation of the TMDS encode algorithm described in chapter 3 of the DVI 1.0 specification. In general, the HSTX peripheral ([Section 12.11](#)) supports lower processor overhead for DVI-D output as well as a wider range of pixel formats, but the SIO TMDS encoders are included for use with non-HSTX-capable GPIOs.

The [TMDS_CTRL](#) register allows configuration of a number of input pixel formats, from 16-bit RGB down to 1-bit monochrome. Once the encoder has been set up, the processor writes 32 bits of colour data at a time to [TMDS_WDATA](#), and then reads TMDS data symbols from the output registers. Depending on the pixel format, there may be multiple TMDS symbols read for each write to [TMDS_WDATA](#). There are no stalls: encoding is limited entirely by the processor's load/store bandwidth, up to one 32-bit read or write per cycle per core.

To allow for framebuffer/scanbuffer resolution lower than the display resolution, the output registers have both peek and pop aliases (e.g. [TMDS_PEEK_SINGLE](#) and [TMDS_POP_SINGLE](#)). Reading either register advances the encoder's DC balance counter, but only the pop alias shifts the colour data in [TMDS_WDATA](#) so that multiple correctly-DC-balanced TMDS symbols can be generated from the same input pixel.

The TMDS encoder peripherals are not duplicated over security domains. They are assigned to the Secure SIO at reset, and can be reassigned to the Non-secure SIO using the [PERI_NONSEC](#) register.

3.1.10. Interpolator

Each core is equipped with two *interpolators* ([INTERP0](#) and [INTERP1](#)) that can accelerate tasks by combining certain pre-configured operations into a single processor cycle. Intended for cases where the pre-configured operation repeats many times, interpolators result in code which uses both fewer CPU cycles and fewer CPU registers in time-critical sections.

The interpolators already accelerate audio operations within the SDK. Their flexible configuration makes it possible to optimise many other tasks, including:

- quantization
- dithering
- table lookup address generation
- affine texture mapping
- decompression
- linear feedback

3. 向MTIMECMP写入目标值的低半部分。

RISC-V定时器可以计数系统级节拍生成器产生的节拍（详见第8.5节）或系统时钟周期，该选择由MTIME_CTRL寄存器控制。采用1微秒时间基准，以保证与大多数RISC-V软件的兼容性。

3.1.9. TMDS 编码器

每个内核均实现了TMDS编码算法，该算法详述于DVI 1.0规范第3章。通常，HSTX外设（第12.11节）支持较低的处理器负载以实现DVI-D输出，并兼容更广泛的像素格式，但SIO TMDS编码器则用于不支持HSTX功能的GPIO。

TMDS_CTRL寄存器支持多种输入像素格式配置，范围涵盖16位RGB至1位单色。编码器配置完成后，处理器每次向TMDS_WDATA写入32位颜色数据，随后从输出寄存器读取TMDS数据符号。根据像素格式不同，每次写入TMDS_WDATA后可能需读取多个TMDS符号。无任何停顿：编码速率完全受限于处理器的加载/存储带宽，最高可达每核每时钟周期一次32位读写操作。

为了支持帧缓冲区/扫描缓冲区分分辨率低于显示分辨率，输出寄存器设有peek和pop别名（例如TMDS_PEEK_SINGLE和TMDS_POP_SINGLE）。读取任一寄存器将推进编码器的DC平衡计数器，但只有pop别名会移位TMDS_WDATA中的颜色数据，从而使得能通过同一输入像素生成多个DC平衡正确的TMDS符号。

TMDS编码器外设未在安全域间重复分配。其在复位时被分配至安全SIO，并可通过PERI_NONSEC寄存器重新分配至非安全SIO。

3.1.10. 插值器

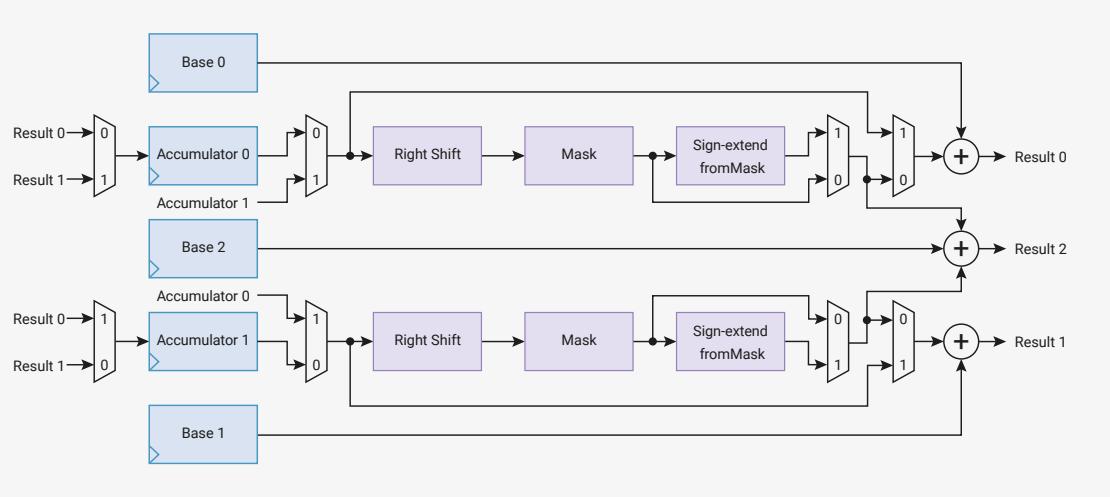

每个核心配备两个插值器（**INTERP0**和**INTERP1**），能够通过将特定预配置操作合并为单个处理器周期来加速任务处理。插值器适用于预配置操作多次重复的场景，有助于在时间关键段落中减少CPU周期数及CPU寄存器使用量。

插值器已在SDK中加速音频操作。其灵活的配置使得优化许多其他任务成为可能，包括：

- 量化
- 抖动
- 表查地址生成
- 仿射纹理映射
- 解压缩
- 线性反馈

Figure 8. An interpolator. The two accumulator registers and three base registers have single-cycle read/write access from the processor. The interpolator is organised into two lanes, which perform masking, shifting and sign-extension operations on the two accumulators. This produces three possible results, by adding the intermediate shift/mask values to the three base registers. From left to right, the multiplexers on each lane are controlled by the following flags in the **CTRL** registers:

CROSS_RESULT,
CROSS_INPUT, **SIGNED**,
and ADD_RAW.

The processor can write or read any interpolator register in one cycle, and the results are ready on the next cycle. The processor can also perform an addition on one of the two accumulators **ACCUM0** or **ACCUM1** by writing to the corresponding **ACCUMx_ADD** register.

The three results are available in the read-only locations **PEEK0**, **PEEK1**, **PEEK2**. Reading from these locations does not change the state of the interpolator. The results are also aliased at the locations **POP0**, **POP1**, **POP2**; reading from a **POPx** alias returns the same result as the corresponding **PEEKx**, and simultaneously writes back the lane results to the accumulators. Use the **POPx** aliases to advance the state of interpolator each time a result is read.

You can adjust interpolator behaviour with the following operational modes:

- fractional blending between two values
- clamping values to restrict them within a given range.

The following example shows a trivial example of *popping* a lane result to produce simple iterative feedback.

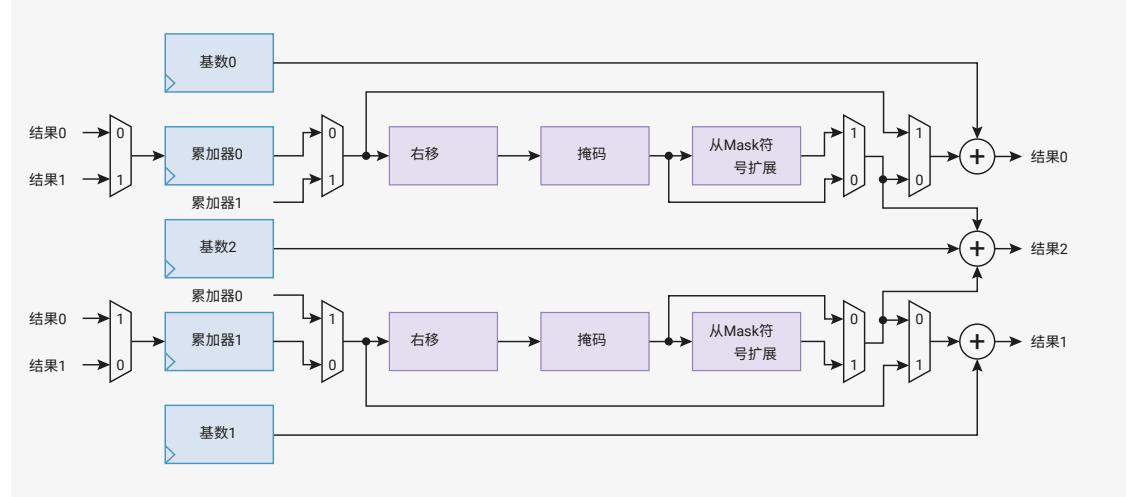

Pico Examples: https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c Lines 11 - 23

```

11 void times_table() {
12     puts("9 times table:");
13
14     // Initialise lane 0 on interp0 on this core
15     interp_config cfg = interp_default_config();
16     interp_set_config(interp0, 0, &cfg);
17
18     interp0->accum[0] = 0;
19     interp0->base[0] = 9;
20
21     for (int i = 0; i < 10; ++i)
22         printf("%d\n", interp0->pop[0]);
23 }
```

3.1.10.1. Lane operations

图8. 一个插值器。两个累加器寄存器和三个基寄存器允许处理器进行单周期的读写访问。插值器被组织为两个通道，分别对两个累加器执行屏蔽、移位和符号扩展操作。通过将中间的移位/屏蔽加到三个基寄存器上，从而产生三种可能的结果。从左至右，每个通道上的多路复用器由CTR L寄存器中的以下标志控制：

处理器可在一周期内读写任何插值器寄存器，结果将在下一周期准备就绪。处理器还可通过写入对应的ACCUMx_ADD寄存器，对两个累加器ACCUM0或ACCUM1之一执行加法操作。

这三种结果在只读寄存器PEEK0、PEEK1和PEEK2中可用。从这些位置读取不会改变插值器的状态。结果也别名于位置POP0、POP1、POP2；从POPx别名读取返回与对应的PEEKx相同的结果，同时将该通道结果写回累加器。每次读取结果时，使用POPx别名以推进插值器状态。

您可以通过以下操作模式调整插值器的行为：

- 两个数值之间的分数混合
- 将数值限定在指定范围内。

以下示例显示了一个简单的弹出通道结果以实现简单迭代反馈的例子。

Pico 示例：https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c 第11至23行

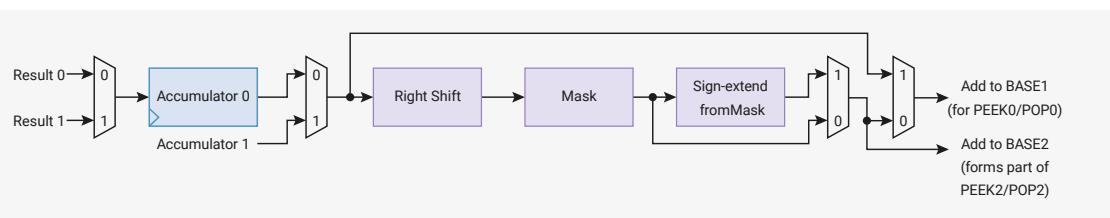

```

11 void times_table() {
12     puts("9 的乘法表: ");
13
14     // 在此核心上初始化 interp0 的通道 0
15     interp_config cfg = interp_default_config();
16     interp_set_config(interp0, 0, &cfg);
17
18     interp0->accum[0] = 0;
19     interp0->base[0] = 9;
20
21     for (int i = 0; i < 10; ++i)
22         printf("%d\n", interp0->pop[0]);
23 }
```

3.1.10.1 通道操作

Figure 9. Each lane of each interpolator can be configured to perform mask, shift and sign-extension on one of the accumulators. This is fed into adders which produce final results, which may optionally be fed back into the accumulators with each read. The datapath can be configured using a handful of 32-bit multiplexers. From left to right, these are controlled by the following CTRL flags:

- CROSS_RESULT,
- CROSS_INPUT, SIGNED,
- and ADD_RAW.

Each lane performs these three operations, in sequence:

- A right shift by `CTRL_LANEx_SHIFT` (0 to 31 bits)
- A mask of bits from `CTRL_LANEx_MASK_LSB` to `CTRL_LANEx_MASK_MSB` inclusive (each ranging from bit 0 to bit 31)
- A sign extension from the top of the mask, i.e. take bit `CTRL_LANEx_MASK_MSB` and OR it into all more-significant bits, if `CTRL_LANEx_SIGNED` is set

For example, if:

- `ACCUM0 = 0xdeadbeef`
- `CTRL_LANE0_SHIFT = 8`
- `CTRL_LANE0_MASK_LSB = 4`
- `CTRL_LANE0_MASK_MSB = 7`
- `CTRL_SIGNED = 1`

Then lane 0 would produce the following results at each stage:

- Right shift by 8 to produce `0x00deadbe`
- Mask bits 7 to 4 to produce `0x00deadbe & 0x000000f0 = 0x000000b0`
- Sign-extend up from bit 7 to produce `0xffffffffb0`

In software:

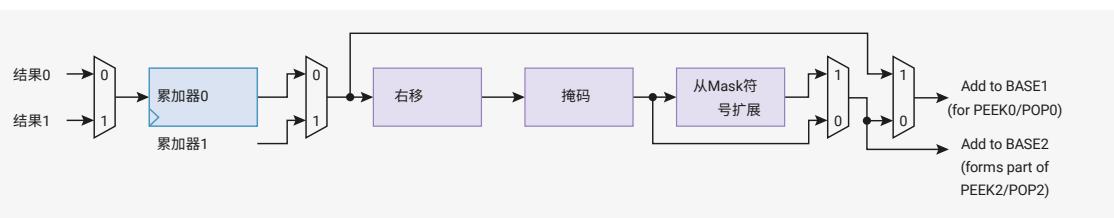

Pico Examples: https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c Lines 25 - 46

```

25 void moving_mask() {
26     interp_config cfg = interp_default_config();
27     interp0->accum[0] = 0x1234abcd;
28
29     puts("Masking:");
30     printf("ACCUM0 = %08x\n", interp0->accum[0]);
31     for (int i = 0; i < 8; ++i) {
32         // LSB, then MSB. These are inclusive, so 0,31 means "the entire 32 bit register"
33         interp_config_set_mask(&cfg, i * 4, i * 4 + 3);
34         interp_set_config(interp0, 0, &cfg);
35         // Reading from ACCUMx_ADD returns the raw lane shift and mask value, without BASEx
36         // added
37         printf("Nibble %d: %08x\n", i, interp0->add_raw[0]);
38     }
39
39     puts("Masking with sign extension:");
40     interp_config_set_signed(&cfg, true);
41     for (int i = 0; i < 8; ++i) {
42         interp_config_set_mask(&cfg, i * 4, i * 4 + 3);
43         interp_set_config(interp0, 0, &cfg);
44         printf("Nibble %d: %08x\n", i, interp0->add_raw[0]);
45     }
46 }
```

The above example should print the following:

图 9. 每个插值器的每个通道均可配置为对某个累加器执行掩码、移位及符号扩展操作。该结果输入加法器生成最终输出，且可选择性地在每次读取时反馈至累加器。数据路径可通过若干32位多路复用器进行配置。从左到右，这些均由以下 CTRL 标志控制：
：

每个通道依次执行以下三项操作：

- 向右移位`CTRL_LANEx_SHIFT`位（范围0至31位）
- 掩码位于`CTRL_LANEx_MASK_LSB`至`CTRL_LANEx_MASK_MSB`（含）之间，均在第0至31位范围内
- 从掩码最高位进行符号扩展，即当设置`CTRL_LANEx_SIGNED`时，将`CTRL_LANEx_MASK_MSB`位扩展至所有更高有效位

例如，当：

- ```
CROSS_RESULT,
CROSS_INPUT, SIGNED,
以及 ADD_RAW。
```
- `ACCUM0 = 0xdeadbeef`
  - `CTRL_LANE0_SHIFT = 8`
  - `CTRL_LANE0_MASK_LSB = 4`
  - `CTRL_LANE0_MASK_MSB = 7`
  - `CTRL_SIGNED = 1`

则通道0在每阶段将产生如下结果：

- 右移8位，结果为 `0x00deadbe`
- 对第7至4位进行掩码处理，结果为 `0x00deadbe & 0x000000f0 = 0x000000b0`
- 对第7位进行符号扩展，结果为 `0xffffffffb0`

在软件中：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 第25至46行

```

25 void moving_mask() {
26 interp_config cfg = interp_default_config();
27 interp0->accum[0] = 0x1234abcd;
28
29 puts("掩码：");
30 printf("ACCUM0 = %08x\n", interp0->accum[0]);
31 for (int i = 0; i < 8; ++i) {
32 // 从最低有效位 (LSB) 到最高有效位 (MSB)。这些范围包含端点，因此0到31表示“整个32位寄存器”
33 interp_config_set_mask(&cfg, i * 4, i * 4 + 3);
34 interp_set_config(interp0, 0, &cfg);
35 // 从 ACCUMx_ADD 读取的是原始的通道偏移和掩码值，未加 BASEx
36
37 printf("Nibble %d: %08x\n", i, interp0->add_raw[0]);
38 }
39
39 puts("带符号扩展的掩码处理：");
40 interp_config_set_signed(&cfg, true);
41 for (int i = 0; i < 8; ++i) {
42 interp_config_set_mask(&cfg, i * 4, i * 4 + 3);
43 interp_set_config(interp0, 0, &cfg);
44 printf("Nibble %d: %08x\n", i, interp0->add_raw[0]);
45 }
46 }
```

上述示例应打印以下内容：

```

ACCUM0 = 1234abcd
Nibble 0: 0000000d
Nibble 1: 000000c0
Nibble 2: 0000b000
Nibble 3: 000a0000
Nibble 4: 00040000
Nibble 5: 00300000
Nibble 6: 02000000
Nibble 7: 10000000
Masking with sign extension:
Nibble 0: ffffffd
Nibble 1: ffffffc0
Nibble 2: fffffb00
Nibble 3: fffffa000
Nibble 4: 00040000
Nibble 5: 00300000
Nibble 6: 02000000
Nibble 7: 10000000

```

Changing the result and input multiplexers can create feedback between the accumulators. This is useful for audio dithering.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 48 - 66

```

48 void cross_lanes() {
49 interp_config cfg = interp_default_config();
50 interp_config_set_cross_result(&cfg, true);
51 // ACCUM0 gets lane 1 result:
52 interp_set_config(interp0, 0, &cfg);
53 // ACCUM1 gets lane 0 result:
54 interp_set_config(interp0, 1, &cfg);
55
56 interp0->accum[0] = 123;
57 interp0->accum[1] = 456;
58 interp0->base[0] = 1;
59 interp0->base[1] = 0;
60 puts("Lane result crossover:");
61 for (int i = 0; i < 10; ++i) {
62 uint32_t peek0 = interp0->peek[0];
63 uint32_t pop1 = interp0->pop[1];
64 printf("PEEK0, POP1: %d, %d\n", peek0, pop1);
65 }
66 }

```

This should print the following :

```

PEEK0, POP1: 124, 456
PEEK0, POP1: 457, 124
PEEK0, POP1: 125, 457
PEEK0, POP1: 458, 125
PEEK0, POP1: 126, 458
PEEK0, POP1: 459, 126
PEEK0, POP1: 127, 459
PEEK0, POP1: 460, 127
PEEK0, POP1: 128, 460
PEEK0, POP1: 461, 128

```

```

ACCUM0 = 1234abcd
Nibble 0: 0000000d
Nibble 1: 000000c0
Nibble 2: 00000b00
Nibble 3: 0000a000
Nibble 4: 00040000
Nibble 5: 00300000
Nibble 6: 02000000
Nibble 7: 10000000
带符号扩展的掩码:
Nibble 0: ffffffff 第 N 个
四位组 1: ffffffc0 第 2
个四位组: ffffffb00 第 3 个
四位组: fffffa000 第 4 个四
位组: 00040000 第 5 个四位
组: 00300000 第 6 个四位组
: 02000000 第 7 个四位组:
10000000

```

更改结果和输入多路复用器可以在累加器之间形成反馈。这一功能对于音频抖动处理非常有用。

Pico 示例: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp.c) 第 48 至 66 行

```

48 void cross_lanes() {
49 interp_config cfg = interp_default_config();
50 interp_config_set_cross_result(&cfg, true);
51 // ACCUM0 获取通道 1 的结果:
52 interp_set_config(interp0, 0, &cfg);
53 // ACCUM1 获取通道 0 的结果:
54 interp_set_config(interp0, 1, &cfg);
55
56 interp0->accum[0] = 123;
57 interp0->accum[1] = 456;
58 interp0->base[0] = 1;
59 interp0->base[1] = 0;
60 puts("车道结果交叉点: ");
61 for (int i = 0; i < 10; ++i) {
62 uint32_t peek0 = interp0->peek[0];
63 uint32_t pop1 = interp0->pop[1];
64 printf("PEEK0, POP1: %d, %d\n", peek0, pop1);
65 }
66 }

```

应打印以下内容:

```

PEEK0, POP1: 124, 456
PEEK0, POP1: 457, 124
PEEK0, POP1: 125, 457
PEEK0, POP1: 458, 125
PEEK0, POP1: 126, 458
PEEK0, POP1: 459, 126
PEEK0, POP1: 127, 459
PEEK0, POP1: 460, 127
PEEK0, POP1: 128, 460
PEEK0, POP1: 461, 128

```

### 3.1.10.2. Blend mode

Blend mode is available on `INTERP0` on each core, and is enabled by the `CTRL_LANE0_BLEND` control flag. It performs linear interpolation, which we define as follows:

$$x = x_0 + \alpha(x_1 - x_0), \text{ for } 0 \leq \alpha < 1$$

Where  $x_0$  is the register `BASE0`,  $x_1$  is the register `BASE1`, and  $\alpha$  is a fractional value formed from the least significant 8 bits of the lane 1 shift and mask value.

Blend mode differs from normal mode in the following ways:

- `PEEK0, POP0` return the 8-bit alpha value (the 8 LSBs of the lane 1 shift and mask value), with zeroes in result bits 31 down to 24.
- `PEEK1, POP1` return the linear interpolation between `BASE0` and `BASE1`
- `PEEK2, POP2` do not include lane 1 result in the addition (i.e. it is `BASE2 + lane 0 shift and mask value`)

The result of the linear interpolation is equal to `BASE0` when the alpha value is 0, and equal to `BASE0 + 255/256 * (BASE1 - BASE0)` when the alpha value is all-ones.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 68 - 87

```

68 void simple_blend1() {
69 puts("Simple blend 1:");
70
71 interp_config cfg = interp_default_config();
72 interp_config_set_blend(&cfg, true);
73 interp_set_config(interp0, 0, &cfg);
74
75 cfg = interp_default_config();
76 interp_set_config(interp0, 1, &cfg);
77
78 interp0->base[0] = 500;
79 interp0->base[1] = 1000;
80
81 for (int i = 0; i <= 6; i++) {
82 // set fraction to value between 0 and 255
83 interp0->accum[1] = 255 * i / 6;
84 // ≈ 500 + (1000 - 500) * i / 6;
85 printf("%d\n", (int) interp0->peek[1]);
86 }
87 }
```

This should print the following (note the 255/256 resulting in 998 not 1000):

```

500
582
666
748
832
914
998
```

`CTRL_LANE1_SIGNED` controls whether `BASE0` and `BASE1` are sign-extended for this interpolation (this sign extension is required because the interpolation produces an intermediate product value 40 bits in size). `CTRL_LANE0_SIGNED` continues to control the sign extension of the lane 0 intermediate result in `PEEK2, POP2` as normal.

### 3.1.10.2. 混合模式

混合模式可在每个核心的 `INTERP0` 上使用，并由 `CTRL_LANE0_BLEND` 控制标志启用。其执行线性插值，定义如下：

$$x = x_0 + \alpha(x_1 - x_0), \text{ for } 0 \leq \alpha < 1$$

其中为寄存器 `BASE0`，为寄存器 `BASE1`，且为由第1通道移位与掩码值的最低8位组成的分数值。

混合模式与普通模式的区别如下：

- `PEEK0, POP0` 返回8位alpha值（第1通道移位与掩码值的最低8位），结果的第31至24位为零。

- `PEEK1, POP1` 返回 `BASE0` 与 `BASE1` 之间的线性插值值。
- `PEEK2, POP2` 在相加时不包括第1通道的结果（即为 `BASE2 + 第0通道的移位和掩码值`）

当alpha值为0时，线性插值的结果等于 `BASE0`；当alpha值全为1时，结果等于 `BASE0 + 255/256 * (BASE1 - BASE0)`

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 68-87 行

```

68 void simple_blend1() {
69 puts("简单混合1:");
70
71 interp_config cfg = interp_default_config();
72 interp_config_set_blend(&cfg, true);
73 interp_set_config(interp0, 0, &cfg);
74
75 cfg = interp_default_config();
76 interp_set_config(interp0, 1, &cfg);
77
78 interp0->base[0] = 500;
79 interp0->base[1] = 1000;
80
81 for (int i = 0; i <= 6; i++) {
82 // 将 fraction 设置为介于 0 到 255 之间的值
83 interp0->accum[1] = 255 * i / 6;
84 // ≈ 500 + (1000 - 500) * i / 6;
85 printf("%d\n", (int) interp0->peek[1]);
86 }
87 }
```

应打印以下内容（注意 `255/256` 导致结果为 `998` 而非 `1000`）：

```

500
582
666
748
832
914
998
```

`CTRL_LANE1_SIGNED` 控制 `BASE0` 和 `BASE1` 是否对该插值结果进行符号扩展（此符号扩展是必需的，因为插值产生的中间乘积值为 40 位大小）。`CTRL_LANE0_SIGNED` 继续控制 `PEEK2` 和 `POP2` 中第 0 通道中间结果的符号扩展，功能正常。

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 90 - 121

```

90 void print_simple_blend2_results(bool is_signed) {
91 // lane 1 signed flag controls whether base 0/1 are treated as signed or unsigned
92 interp_config cfg = interp_default_config();
93 interp_config_set_signed(&cfg, is_signed);
94 interp_set_config(interp0, 1, &cfg);
95
96 for (int i = 0; i <= 6; i++) {
97 interp0->accum[1] = 255 * i / 6;
98 if (is_signed) {
99 printf("%d\n", (int) interp0->peek[1]);
100 } else {
101 printf("0x%08x\n", (uint) interp0->peek[1]);
102 }
103 }
104 }
105
106 void simple_blend2() {
107 puts("Simple blend 2:");
108
109 interp_config cfg = interp_default_config();
110 interp_config_set_blend(&cfg, true);
111 interp_set_config(interp0, 0, &cfg);
112
113 interp0->base[0] = (uint32_t) -1000;
114 interp0->base[1] = 1000;
115
116 puts("signed:");
117 print_simple_blend2_results(true);
118
119 puts("unsigned:");
120 print_simple_blend2_results(false);
121 }
```

This should print the following:

```

signed:
-1000
-672
-336
-8
328
656
992
unsigned:
0xfffffc18
0xd5ffffd60
0xaafffeb0
0x80fffff8
0x56000148
0x2c000290
0x010003e0
```

Finally, in blend mode when using the **BASE\_1AND0** register to send a 16-bit value to each of **BASE0** and **BASE1** with a single 32-bit write, the sign-extension of these 16-bit values to full 32-bit values during the write is controlled by **CTRL\_LANE1\_SIGNED** for both bases, as opposed to non-blend-mode operation, where **CTRL\_LANE0\_SIGNED** affects extension into **BASE0** and **CTRL\_LANE1\_SIGNED** affects extension into **BASE1**.

Pico 示例: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 第 90 至 121 行

```

90 void print_simple_blend2_results(bool is_signed) {
91 //通道 1 的有符号标志控制基准 0/1 是否作为有符号或无符号处理
92 interp_config cfg = interp_default_config();
93 interp_config_set_signed(&cfg, is_signed);
94 interp_set_config(interp0, 1, &cfg);
95
96 for (int i = 0; i <= 6; i++) {
97 interp0->accum[1] = 255 * i / 6;
98 if (is_signed) {
99 printf("%d\n", (int) interp0->peek[1]);
100 } else {
101 printf("0x%08x\n", (uint) interp0->peek[1]);
102 }
103 }
104 }
105
106 void simple_blend2() {
107 puts("简单混合 2: ");
108
109 interp_config cfg = interp_default_config();
110 interp_config_set_blend(&cfg, true);
111 interp_set_config(interp0, 0, &cfg);
112
113 interp0->base[0] = (uint32_t) -1000;
114 interp0->base[1] = 1000;
115
116 puts("有符号: ");
117 print_simple_blend2_results(true);
118
119 puts("unsigned:");
120 print_simple_blend2_results(false);
121 }
```

应打印如下内容：

```

signed:
-1000
-672
-336
-8
328
656
992
unsigned:
0xfffffc18
0xd5ffffd60
0xaafffeb0
0x80fffff8
0x56000148
0x2c000290
0x010003e0
```

最后，在混合模式下，使用 **BASE\_1AND0** 寄存器通过单次32位写入向 **BASE0** 和 **BASE1** 分别发送16位值时，这些16位值在写入期间扩展为完整32位的符号扩展由**CTRL\_LANE1\_SIGNED**统一控制，区别于非混合模式操作中**CTRL\_LANE0\_SIGNED**控制对**BASE0**的扩展，及**CTRL\_LANE1\_SIGNED**控制对**BASE1**的扩展。

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 124 - 145

```

124 void simple_blend3() {
125 puts("Simple blend 3:");
126
127 interp_config cfg = interp_default_config();
128 interp_config_set_blend(&cfg, true);
129 interp_set_config(interp0, 0, &cfg);
130
131 cfg = interp_default_config();
132 interp_set_config(interp0, 1, &cfg);
133
134 interp0->accum[1] = 128;
135 interp0->base01 = 0x30005000;
136 printf("0x%08x\n", (int) interp0->peek[1]);
137 interp0->base01 = 0xe000f000;
138 printf("0x%08x\n", (int) interp0->peek[1]);
139
140 interp_config_set_signed(&cfg, true);
141 interp_set_config(interp0, 1, &cfg);
142
143 interp0->base01 = 0xe000f000;
144 printf("0x%08x\n", (int) interp0->peek[1]);
145 }
```

This should print the following:

```

0x00004000
0x0000e800
0xffffe800
```

### 3.1.10.3. Clamp Mode

Clamp mode is available on **INTERP1** on each core. To enable clamp mode, set the **CTRL\_LANE0\_CLAMP** control flag to high. In clamp mode, the **PEEK0/POP0** result is the lane value (shifted, masked, sign-extended **ACCUM0**) clamped between **BASE0** and **BASE1**. In other words, if the lane value is less than **BASE0**, a value of **BASE0** is produced; if greater than **BASE1**, a value of **BASE1** is produced; otherwise, the value passes through. No addition is performed. The signedness of these comparisons is controlled by the **CTRL\_LANE0\_SIGNED** flag.

Other than this, the interpolator behaves the same as in normal mode.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 193 - 211

```

193 void clamp() {
194 puts("Clamp:");
195 interp_config cfg = interp_default_config();
196 interp_config_set_clamp(&cfg, true);
197 interp_config_set_shift(&cfg, 2);
198 // set mask according to new position of sign bit..
199 interp_config_set_mask(&cfg, 0, 29);
200 // ...so that the shifted value is correctly sign extended
201 interp_config_set_signed(&cfg, true);
202 interp_set_config(interp1, 0, &cfg);
203
204 interp1->base[0] = 0;
205 interp1->base[1] = 255;
206
207 for (int i = -1024; i <= 1024; i += 256) {
```

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 行124-145

```

124 void simple_blend3() {
125 puts("简单混合3:");
126
127 interp_config cfg = interp_default_config();
128 interp_config_set_blend(&cfg, true);
129 interp_set_config(interp0, 0, &cfg);
130
131 cfg = interp_default_config();
132 interp_set_config(interp0, 1, &cfg);
133
134 interp0->accum[1] = 128;
135 interp0->base01 = 0x30005000;
136 printf("0x%08x\n", (int) interp0->peek[1]);
137 interp0->base01 = 0xe000f000;
138 printf("0x%08x\n", (int) interp0->peek[1]);
139
140 interp_config_set_signed(&cfg, true);
141 interp_set_config(interp0, 1, &cfg);
142
143 interp0->base01 = 0xe000f000;
144 printf("0x%08x\n", (int) interp0->peek[1]);
145 }

```

应打印如下内容：

```

0x00004000
0x0000e800
0xffffe800

```

### 3.1.10.3. 夹紧模式

夹紧模式适用于每个核上的 **INTERP1**。要启用夹紧模式，请将**CTRL\_LANE0\_CLAMP**控制标志设置为高电平。在钳位模式下，**PEEK0/POP0**的结果为通道值（经位移、掩码及符号扩展的**ACCUM0**），该值被限制在**BASE0**和**BASE1**之间。换言之，若通道值小于**BASE0**，则输出值为**BASE0**；若大于**BASE1**，则输出值为**BASE1**；否则，该值原样通过。不执行任何加法操作。这些比较的符号属性由**CTRL\_LANE0\_SIGNED**标志控制。

除此之外，插值器的行为与正常模式下保持一致。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 第193至211行

```

193 void clamp() {
194 puts("Clamp:");
195 interp_config cfg = interp_default_config();
196 interp_config_set_clamp(&cfg, true);
197 interp_config_set_shift(&cfg, 2);
198 // 根据符号位的新位置设置掩码。
199 interp_config_set_mask(&cfg, 0, 29);
200 // ...以确保移位后的值正确进行符号扩展。
201 interp_config_set_signed(&cfg, true);
202 interp_set_config(interp1, 0, &cfg);
203
204 interp1->base[0] = 0;
205 interp1->base[1] = 255;
206
207 for (int i = -1024; i <= 1024; i += 256) {

```

```

208 interp1->accum[0] = i;
209 printf("%d\t%d\n", i, (int) interp1->peek[0]);
210 }
211 }
```

This should print the following:

```

-1024 0
-768 0
-512 0
-256 0
0 0
256 64
512 128
768 192
1024 255
```

### 3.1.10.4. Sample use case: linear interpolation

Linear interpolation combines blend mode with other interpolator functionality. In this example, `ACCUM0` tracks a fixed-point (integer/fraction) position within a list of values to be interpolated. Lane 0 is used to produce an address into the value array for the integer part of the position. The fractional part of the position is shifted to produce a value from 0-255 for the blend. The blend is performed between two consecutive values in the array.

Finally the fractional position is updated via a single write to `ACCUM0_ADD_RAW`.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 147 - 191

```

147 void linear_interpolation() {
148 puts("Linear interpolation:");
149 const int uv_fractional_bits = 12;
150
151 // for lane 0
152 // shift and mask XXXX XXXX XXXX XXXX XXXX FFFF FFFF FFFF (accum 0)
153 // to 0000 0000 000X XXXX XXXX XXXX XXXX XXXX XXX0
154 // i.e. non fractional part times 2 (for uint16_t)
155 interp_config cfg = interp_default_config();
156 interp_config_set_shift(&cfg, uv_fractional_bits - 1);
157 interp_config_set_mask(&cfg, 1, 32 - uv_fractional_bits);
158 interp_config_set_blend(&cfg, true);
159 interp_set_config(interp0, 0, &cfg);
160
161 // for lane 1
162 // shift XXXX XXXX XXXX XXXX XXXX FFFF FFFF FFFF (accum 0 via cross input)
163 // to 0000 XXXX XXXX XXXX XXXX FFFF FFFF FFFF
164
165 cfg = interp_default_config();
166 interp_config_set_shift(&cfg, uv_fractional_bits - 8);
167 interp_config_set_signed(&cfg, true);
168 interp_config_set_cross_input(&cfg, true); // signed blending
169 interp_set_config(interp0, 1, &cfg);
170
171 int16_t samples[] = {0, 10, -20, -1000, 500};
172
173 // step is 1/4 in our fractional representation
174 uint step = (1 << uv_fractional_bits) / 4;
175
176 interp0->accum[0] = 0; // initial sample_offset;
```

```

208 interp1->accum[0] = i;
209 printf("%d\t%d\n", i, (int) interp1->peek[0]);
210 }
211 }
```

应打印如下内容：

```

-1024 0
-768 0
-512 0
-256 0
0 0
256 64
512 128
768 192
1024 255
```

### 3.1.10.4. 示例用例：线性插值

线性插值结合了混合模式与其他插值器功能。在此示例中，`ACCUM0`跟踪要插值的值列表中的定点（整数/小数）位置。通道0用于生成位置整数部分的值数组地址。位置的小数部分被移位以产生用于混合的0至255之间的值。混合操作在数组中相邻的两个值之间进行。

最后，通过对`ACCUM0_ADD_RAW`的单次写操作更新小数位位置。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 第147至191行

```

147 void linear_interpolation() {
148 puts("线性插值: ");
149 const int uv_fractional_bits = 12;
150
151 // 用于通道0
152 // 移位并掩码 XXXX XXXX XXXX XXXX XXXX FFFF FFFF FFFF (累加0)
153 // 至 0000 0000 000X XXXX XXXX XXXX XXXX XXXX XXX0 154
// 即整数部分乘以2 (针对uint16_t) 155 interp_config cfg=inter
p_default_config();
156 interp_config_set_shift(&cfg, uv_fractional_bits - 1);
157 interp_config_set_mask(&cfg, 1, 32 - uv_fractional_bits);
158 interp_config_set_blend(&cfg, true);
159 interp_set_config(interp0, 0, &cfg);
160
161 // 针对通道1
162 // 将 XXXX XXXX XXXX XXXX XXXX FFFF FFFF FFFF (通过交叉输入累加为0) 左移
163 // 至 0000 XXXX XXXX XXXX XXXX FFFF FFFF FFFF
164
165 cfg = interp_default_config();
166 interp_config_set_shift(&cfg, uv_fractional_bits - 8);
167 interp_config_set_signed(&cfg, true);
168 interp_config_set_cross_input(&cfg, true); // 有符号混合
169 interp_set_config(interp0, 1, &cfg);
170
171 int16_t samples[] = {0, 10, -20, -1000, 500};
172
173 // step 是我们分数表示中的四分之一
174 uint step = (1 << uv_fractional_bits) / 4;
175
176 interp0->accum[0] = 0; // 初始 sample_offset;
```

```

177 interp0->base[2] = (uintptr_t) samples;
178 for (int i = 0; i < 16; i++) {
179 // result2 = samples + (lane0 raw result)
180 // i.e. ptr to the first of two samples to blend between
181 int16_t *sample_pair = (int16_t *) interp0->peek[2];
182 interp0->base[0] = sample_pair[0];
183 interp0->base[1] = sample_pair[1];
184 uint32_t peek1 = interp0->peek[1];
185 uint32_t add_raw1 = interp0->add_raw[1];
186 printf("%d\t(%d% between %d and %d)\n", (int) peek1,
187 100 * (add_raw1 & 0xff) / 0xff,
188 sample_pair[0], sample_pair[1]);
189 interp0->add_raw[0] = step;
190 }
191 }
```

This should print the following:

```

0 (0% between 0 and 10)
2 (25% between 0 and 10)
5 (50% between 0 and 10)
7 (75% between 0 and 10)
10 (0% between 10 and -20)
2 (25% between 10 and -20)
-5 (50% between 10 and -20)
-13 (75% between 10 and -20)
-20 (0% between -20 and -1000)
-265 (25% between -20 and -1000)
-510 (50% between -20 and -1000)
-755 (75% between -20 and -1000)
-1000 (0% between -1000 and 500)
-625 (25% between -1000 and 500)
-250 (50% between -1000 and 500)
125 (75% between -1000 and 500)
```

This method is used for fast approximate audio upscaling in the SDK.

### 3.1.10.5. Sample use case: simple affine texture mapping

Simple affine texture mapping can be implemented by using fixed-point arithmetic for texture coordinates, and stepping a fixed amount in each coordinate for every pixel in a scanline. The integer parts of the texture coordinates form an address into the texture. Reading from `POP2` adds the offset to the texture base pointer. The processor loads the resulting address to sample a pixel colour from the texture.

By using two lanes, all three base values, and the `CTRL_LANEX_ADD_RAW` flag, you can use the interpolator to reduce an expensive CPU operation to a single cycle iteration.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) Lines 214 - 272

```

214 void texture_mapping_setup(uint8_t *texture, uint texture_width_bits, uint
215 texture_height_bits,
216 uint uv_fractional_bits) {
217 interp_config cfg = interp_default_config();
218 // set add_raw flag to use raw (un-shifted and un-masked) lane accumulator value when
219 // adding
220 // it to the lane base to make the lane result
221 interp_config_set_add_raw(&cfg, true);
222 interp_config_set_shift(&cfg, uv_fractional_bits);
```

```

177 interp0->base[2] = (uintptr_t) samples;
178 for (int i = 0; i < 16; i++) {
179 // result2 = samples + (lane0 原始结果)
180 // 即指向两个样本中第一个用于混合的指针
181 int16_t *sample_pair = (int16_t *) interp0->peek[2];
182 interp0->base[0] = sample_pair[0];
183 interp0->base[1] = sample_pair[1];
184 uint32_t peek1 = interp0->peek[1];
185 uint32_t add_raw1 = interp0->add_raw[1];
186 printf("%d\t(%d% 介于 %d 和 %d 之间)\n", (int) peek1,
187 100 * (add_raw1 & 0xff) / 0xff,
188 sample_pair[0], sample_pair[1]);
189 interp0->add_raw[0] = step;
190 }
191 }
```

应打印如下内容：

```

0 (0% 介于 0 和 10 之间)
2 (25% 介于 0 和 10 之间)
5 (50% 介于 0 和 10 之间)
7 (75% 介于 0 和 10 之间)
10 (0% 介于 10 和 -20 之间)
2 (25% 介于 10 和 -20 之间)
-5 (50% 介于 10 和 -20 之间)
-13 (75% 介于 10 和 -20 之间)
-20 (0% 介于 -20 和 -1000 之间)
-265 (25% 介于 -20 和 -1000 之间)
-510 (50% 介于 -20 和 -1000 之间)
-755 (在-20和-1000之间的75%)
-1000 (在-1000和500之间的0%)
-625 (在-1000和500之间的25%)
-250 (在-1000和500之间的50%)
125 (在-1000和500之间的75%)
```

此方法用于SDK中快速近似的音频上采样。

### 3.1.10.5. 示例用例：简单仿射纹理映射

简单仿射纹理映射可通过对纹理坐标进行定点运算，并在扫描线的每个像素上按固定量递增坐标来实现。纹理坐标的整数部分构成纹理地址。从 `POP2` 读取时，会将偏移量加至纹理基指针。处理器加载所得地址以从纹理中采样像素颜色。

通过使用两个通道、所有三个基值以及 `CTRL_LANEx_ADD_RAW` 标志，可利用插值器将高耗时的CPU操作简化为单周期迭代。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/interp/hello\\_interp/hello\\_interp.c](https://github.com/raspberrypi/pico-examples/blob/master/interp/hello_interp/hello_interp.c) 第214至272行

```

214 void texture_mapping_setup(uint8_t *texture, uint texture_width_bits, uint
215 texture_height_bits,
216 uint uv_fractional_bits) {
217 interp_config cfg = interp_default_config();
218 // 设置 add_raw 标志，以使用原始（未移位且未掩码）通道累加器值进行加法
219 interp_config_set_add_raw(&cfg, true);
220 interp_config_set_shift(&cfg, uv_fractional_bits);
```

```

221 interp_config_set_mask(&cfg, 0, texture_width_bits - 1);
222 interp_set_config(interp0, 0, &cfg);
223
224 interp_config_set_shift(&cfg, uv_fractional_bits - texture_width_bits);
225 interp_config_set_mask(&cfg, texture_width_bits, texture_width_bits +
226 texture_height_bits - 1);
227 interp_set_config(interp0, 1, &cfg);
228
229 interp0->base[2] = (uintptr_t) texture;
230 }
231
232 void texture_mapped_span(uint8_t *output, uint32_t u, uint32_t v, uint32_t du, uint32_t dv,
233 uint count) {
234 // u, v are texture coordinates in fixed point with uv_fractional_bits fractional bits
235 // du, dv are texture coordinate steps across the span in same fixed point.
236 interp0->accum[0] = u;
237 interp0->base[0] = du;
238 interp0->accum[1] = v;
239 interp0->base[1] = dv;
240 for (uint i = 0; i < count; i++) {
241 // equivalent to
242 // uint32_t sm_result0 = (accum0 >> uv_fractional_bits) & (1 << (texture_width_bits -
243 1));
244 // uint32_t sm_result1 = (accum1 >> uv_fractional_bits) & (1 << (texture_height_bits -
245 1));
246 // uint8_t *address = texture + sm_result0 + (sm_result1 << texture_width_bits);
247 // output[i] = *address;
248 // accum0 = du + accum0;
249 // accum1 = dv + accum1;
250
251 // result2 is the texture address for the current pixel;
252 // popping the result advances to the next iteration
253 output[i] = *(uint8_t *) interp0->pop[2];
254 }
255 }
256
257 void texture_mapping() {
258 puts("Affine Texture mapping (with texture wrap):");
259
260 uint8_t texture[] = {
261 0x00, 0x01, 0x02, 0x03,
262 0x10, 0x11, 0x12, 0x13,
263 0x20, 0x21, 0x22, 0x23,
264 0x30, 0x31, 0x32, 0x33,
265 };
266 // 4x4 texture
267 texture_mapping_setup(texture, 2, 2, 16);
268 uint8_t output[12];
269 uint32_t du = 65536 / 2; // step of 1/2
270 uint32_t dv = 65536 / 3; // step of 1/3
271 texture_mapped_span(output, 0, 0, du, dv, 12);
272
273 for (uint i = 0; i < 12; i++) {
274 printf("0x%02x\n", output[i]);
275 }
276 }
```

This should print the following:

```

221 interp_config_set_mask(&cfg, 0, texture_width_bits - 1);
222 interp_set_config(interp0, 0, &cfg);
223
224 interp_config_set_shift(&cfg, uv_fractional_bits - texture_width_bits);
225 interp_config_set_mask(&cfg, texture_width_bits, texture_width_bits +
226 texture_height_bits - 1);
227 interp_set_config(interp0, 1, &cfg);
228
229 interp0->base[2] = (uintptr_t) texture;
230 }
231

| 0x014  | <a href="#">GPIO_HI_OUT</a>     | <p>Output value for GPIO32...47, QSPI IOs and USB pins.</p> <p>Write to set output level (1/0 → high/low). Reading back gives the last value written, NOT the input value from the pins. If core 0 and core 1 both write to GPIO_HI_OUT simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result.</p> <p>In the Non-secure SIO, Secure-only GPIOs (as per ACCESSCTRL) ignore writes, and their output status reads back as zero. This is also true for SET/CLR/XOR aliases of this register.</p> |

| 偏移量   | 名称                 | 说明                                |
|-------|--------------------|-----------------------------------|
| 0x0a8 | INTERP0_PEEK_FULL  | 读取FULL结果，不改变任何内部状态（PEEK操作）。       |
| 0x0ac | INTERP0_CTRL_LANE0 | 通道0控制寄存器                          |
| 0x0b0 | INTERP0_CTRL_LANE1 | 通道1控制寄存器                          |
| 0x0b4 | INTERP0_ACCUM0_ADD | 写入的值将以原子方式累加至ACCUM0               |
| 0x0b8 | INTERP0_ACCUM1_ADD | 写入的值将以原子方式累加至ACCUM1               |
| 0x0bc | INTERP0_BASE_1AND0 | 写入时，低16位同时写入BASE0，高位写入BASE1。      |
| 0x0c0 | INTERP1_ACCUM0     | 累加器0的读写访问                         |
| 0x0c4 | INTERP1_ACCUM1     | 累加器1的读写访问                         |
| 0x0c8 | INTERP1_BASE0      | 对BASE0寄存器的读写访问。                   |
| 0x0cc | INTERP1_BASE1      | 对BASE1寄存器的读写访问。                   |
| 0x0d0 | INTERP1_BASE2      | 对BASE2寄存器的读写访问。                   |
| 0x0d4 | INTERP1_POP_LANE0  | 读取LANE0结果，同时将该通道结果写入两个累加器（POP操作）。 |
| 0x0d8 | INTERP1_POP_LANE1  | 读取LANE1结果，同时将该通道结果写入两个累加器（POP操作）。 |
| 0x0dc | INTERP1_POP_FULL   | 读取FULL结果，同时将该通道结果写入两个累加器（POP操作）。  |
| 0x0e0 | INTERP1_PEEK_LANE0 | 读取LANE0结果，不改变任何内部状态（PEEK操作）。      |
| 0x0e4 | INTERP1_PEEK_LANE1 | 读取LANE1结果，不改变任何内部状态（PEEK操作）。      |
| 0x0e8 | INTERP1_PEEK_FULL  | 读取FULL结果，不改变任何内部状态（PEEK操作）。       |
| 0x0ec | INTERP1_CTRL_LANE0 | 通道0控制寄存器                          |

| 0x184  | <a href="#">DOORBELL_OUT_CLR</a> | <p>Clear doorbells which have been posted to the opposite core. This register is intended for debugging and initialisation purposes.</p> <p>Writing 1 to a bit in DOORBELL_OUT_CLR clears the corresponding bit in DOORBELL_IN on the opposite core. Clearing all bits will cause that core's doorbell interrupt to deassert. Since the usual order of events is for software to send events using DOORBELL_OUT_SET, and acknowledge incoming events by writing to DOORBELL_IN_CLR, this register should be used with caution to avoid race conditions.</p> <p>Reading returns the status of the doorbells currently asserted on the other core, i.e. is equivalent to that core reading its own DOORBELL_IN status.</p> |
| 0x188  | <a href="#">DOORBELL_IN_SET</a>  | Write 1s to trigger doorbell interrupts on this core. Read to get status of doorbells currently asserted on this core.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 0x18c  | <a href="#">DOORBELL_IN_CLR</a>  | <p>Check and acknowledge doorbells posted to this core. This core's doorbell interrupt is asserted when any bit in this register is 1.</p> <p>Write 1 to each bit to clear that bit. The doorbell interrupt deasserts once all bits are cleared. Read to get status of doorbells currently asserted on this core.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0x190  | <a href="#">PERI_NONSEC</a>      | <p>Detach certain core-local peripherals from Secure SIO, and attach them to Non-secure SIO, so that Non-secure software can use them. Attempting to access one of these peripherals from the Secure SIO when it is attached to the Non-secure SIO, or vice versa, will generate a bus error.</p> <p>This register is per-core, and is only present on the Secure SIO.</p> <p>Most SIO hardware is duplicated across the Secure and Non-secure SIO, so is not listed in this register.</p>                                                                                                                                                                                                                               |

This is also true for SET/CLR/XOR aliases of this register.</p> | RW   | 0x00000000 |

## SIO: GPIO\_HI\_OUT Register

Offset: 0x014

### Description

Output value for GPIO32...47, QSPI IOs and USB pins.

Write to set output level (1/0 → high/low). Reading back gives the last value written, NOT the input value from the pins. If core 0 and core 1 both write to GPIO\_HI\_OUT simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result.

In the Non-secure SIO, Secure-only GPIOs (as per ACCESSCTRL) ignore writes, and their output status reads back as zero. This is also true for SET/CLR/XOR aliases of this register.

Table 22. GPIO\_HI\_OUT Register

| Bits  | Description                                                                     | Type | Reset  |

|------|----------------------------------------------------------------------------|------|------------|
| 31:0 | Perform an atomic bit-set on GPIO_OUT, i.e. <code>GPIO_OUT  = wdata</code> | WO   | 0x00000000 |

## SIO: GPIO\_HI\_OUT\_SET Register

Offset: 0x01c

### Description

Output value set for GPIO32..47, QSPI IOs and USB pins.

Perform an atomic bit-set on GPIO\_HI\_OUT, i.e. `GPIO_HI_OUT |= wdata`

表21. GPIO\_OUT 寄存器

| 位    | 描述                                                                                                                                                                                                                                        | 类型 | 复位         |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|------------|
| 31:0 | <p>设置GPIO0至31的输出电平（1/0 → 高/低）。读取时返回最后写入的值，而非引脚的输入值。</p> <p>若核心0与核心1同时写入GPIO_OUT寄存器（或对应的SET/CLR/XO R别名寄存器），结果等同于核心0的写入先执行，随后核心1的写入应用于该中间结果。</p> <p>在非安全 SIO 中，依据 ACCESSCTRL 的安全专用 GPIO 会忽略写操作，其输出状态读取返回零。此条款同样适用于该寄存器的 SET/CLR/XOR 别名。</p> | 读写 | 0x00000000 |

## SIO: GPIO\_HI\_OUT 寄存器

偏移量：0x014

### 描述

GPIO32...47、QSPI IO 及 USB 引脚的输出值。

写入以设置输出电平（1/0 → 高/低）。读取时返回最后写入的值，而非引脚的输入值。

如果内核 0 和内核 1 同时写入 GPIO\_HI\_OUT（或 SET/CLR/XOR 别名），结果相当于先执行内核 0 的写入，随后再将内核 1 的写入应用于该中间结果。

在非安全 SIO 中，依据 ACCESSCTRL 的安全专用 GPIO 会忽略写操作，其输出状态读取返回零。此条款同样适用于该寄存器的 SET/CLR/XOR 别名。

表22. GPIO\_HI\_OUT 寄存器

| 31:0 | <p>Set output enable (1/0 → output/input) for GPIO0...31. Reading back gives the last value written.</p> <p>If core 0 and core 1 both write to GPIO_OE simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result.</p> <p>In the Non-secure SIO, Secure-only GPIOs (as per ACCESSCTRL) ignore writes, and their output status reads back as zero. This is also true for SET/CLR/XOR aliases of this register.</p> | RW   | 0x00000000 |

**SIO: GPIO\_HI\_OE Register**

**Offset:** 0x034

**Description**

Output enable value for GPIO32...47, QSPI IOs and USB pins.

Write output enable (1/0 → output/input). Reading back gives the last value written. If core 0 and core 1 both write to GPIO\_HI\_OE simultaneously (or to a SET/CLR/XOR alias), the result is as though the write from core 0 took place first, and the write from core 1 was then applied to that intermediate result.

In the Non-secure SIO, Secure-only GPIOs (as per ACCESSCTRL) ignore writes, and their output status reads back as zero. This is also true for SET/CLR/XOR aliases of this register.

*Table 30. GPIO\_HI\_OE Register*

| Bits  | Description                                                                            | Type | Reset |
|-------|----------------------------------------------------------------------------------------|------|-------|

偏移量：0x030

**描述**

GPIO0...31 输出使能

表 29。*GPIO\_OE*  
寄存器

| 位    | 描述                                                                                                                                                                                                                                     | 类型 | 复位         |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|------------|
| 31:0 | <p>设置 GPIO0...31 的输出使能（1/0 → 输出/输入）；读取时返回最后写入的值。</p> <p>若核 0 和核 1 同时写入 GPIO_OE（或写入其 SET/CLR/XOR 别名），结果相当于先执行核 0 的写入，然后将核 1 的写入应用于该中间结果。</p> <p>在非安全 SIO 中，依据 ACCESSCTRL 的安全专用 GPIO 会忽略写操作，其输出状态读取返回零。此条款同样适用于该寄存器的 SET/CLR/XOR 别名。</p> | 读写 | 0x00000000 |

**SIO: GPIO\_HI\_OE 寄存器**

偏移：0x034

**说明**

GPIO32...47、QSPI IO 和 USB 引脚的输出使能值。

写入输出使能（1/0 → 输出/输入）。读回值为最后写入的数值。若核心0与核心1同时写入GPIO\_HI\_OE（或对应的SET/CLR/XOR别名寄存器），结果相当于先执行核心0的写入，随后在该中间结果基础上执行核心1的写入。

在非安全 SIO 中，依据 ACCESSCTRL 的安全专用 GPIO 会忽略写操作，其输出状态读取返回零。此条款同样适用于该寄存器的SET/CLR/XOR别名。

## SIO: FIFO\_ST Register

Offset: 0x050

### Description

Status register for inter-core FIFOs (mailboxes).

There is one FIFO in the core 0 → core 1 direction, and one core 1 → core 0. Both are 32 bits wide and 8 words deep.

Core 0 can see the read side of the 1→0 FIFO (RX), and the write side of 0→1 FIFO (TX).

Core 1 can see the read side of the 0→1 FIFO (RX), and the write side of 1→0 FIFO (TX).

The SIO IRQ for each core is the logical OR of the VLD, WOF and ROE fields of its FIFO\_ST register.

## SIO: FIFO\_ST 寄存器

偏移: 0x050

### 描述

核间 FIFO（邮箱）的状态寄存器

核心0 →核心1方向有一个FIFO，核心1 →核心0方向也有一个FIFO。两个FIFO均为32位宽，深度为8字。

核心0可见1→0 FIFO (RX) 的读取端和0→1 FIFO (TX) 的写入端。

核心1可见0→1 FIFO (RX) 的读取端和1→0 FIFO (TX) 的写入端。

每个核心的SIO IRQ为其FIFO\_ST寄存器中VLD、WOF和ROE字段的逻辑或。

Table 37. FIFO\_ST Register

| Bits | Description                                                                                                | Type | Reset |
|------|------------------------------------------------------------------------------------------------------------|------|-------|
| 31:4 | Reserved.                                                                                                  | -    | -     |
| 3    | <b>ROE</b> : Sticky flag indicating the RX FIFO was read when empty. This read was ignored by the FIFO.    | WC   | 0x0   |
| 2    | <b>WOF</b> : Sticky flag indicating the TX FIFO was written when full. This write was ignored by the FIFO. | WC   | 0x0   |
| 1    | <b>RDY</b> : Value is 1 if this core's TX FIFO is not full (i.e. if FIFO_WR is ready for more data)        | RO   | 0x1   |
| 0    | <b>VLD</b> : Value is 1 if this core's RX FIFO is not empty (i.e. if FIFO_RD is valid)                     | RO   | 0x0   |

| 24    | <b>OVERF1:</b> 指示 ACCUM1 中任何掩码屏蔽的最高有效位是否被置位。                                                                                                                                                                                                                                                | 只读 | 0x0 |
| 23    | <b>OVERF0:</b> 指示 ACCUM0 中任何掩码屏蔽的最高有效位是否被置位。                                                                                                                                                                                                                                                | 只读 | 0x0 |
| 22    | 保留。                                                                                                                                                                                                                                                                                         | -  | -   |
| 21    | <b>BLEND:</b> 仅存在于每个核心的 INTERP0 上。如果启用了 BLEND 模式：<br>- LANE1 结果为 BASE0 与 BASE1 之间的线性插值，由第 1 通道移位和掩码值的 8 个最低有效位控制（该值为 0 至 255/256 之间的分数）<br><br>- LANE0 结果不加 BASE0（仅输出第 1 通道移位加掩码值的 8 个最低有效位）<br><br>- FULL 结果不加第 1 通道的移位加掩码值（即 BASE2 + 第 0 通道的移位加掩码）<br><br>LANE1 的 SIGNED 标志控制插值结果是否为有符号数。 | 读写 | 0x0 |
| 20:19 | <b>FORCE_MSB:</b> 按位或至总线上传递给处理器的通道结果第 29:28 位<br>。<br>对内部 32 位数据路径无任何影响。便于用该通道生成<br><br>指向 Flash 或 SRAM 的指针序列。                                                                                                                                                                              | 读写 | 0x0 |
| 18    | <b>ADD_RAW:</b> 若值为 1，则绕过 LANE0 结果的掩码与移位操作。此操作不影响 FULL 结果。                                                                                                                                                                                                                                  | 读写 | 0x0 |
| 17    | <b>CROSS_RESULT:</b> 若为 1，则在数据弹出时将相反通道的结果馈入该通道的累加器。                                                                                                                                                                                                                                         | 读写 | 0x0 |
| 16    | <b>CROSS_INPUT:</b> 若设置为1，则将对向车道的累加器输入至本车道的移位与掩码硬件。<br>即使设置了ADD_RAW，该功能仍然生效（CROSS_INPUT多路复用器位于移位与掩码绕过之前）。                                                                                                                                                                                   | 读写 | 0x0 |
| 15    | <b>SIGNED:</b> 若设置SIGNED，移位并掩码后的累加器值将进行带符号扩展至32位。<br>在加至BASE0之前，且LANE0的PEEK/POP操作将视为扩展至32位。<br>由处理器读取时生效。                                                                                                                                                                                   | 读写 | 0x0 |

| Bits  | Description                                                                                                                                          | Type | Reset |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 14:10 | <b>MASK_MSB</b> : The most-significant bit allowed to pass by the mask (inclusive)<br>Setting MSB < LSB may cause chip to turn inside-out            | RW   | 0x00  |
| 9:5   | <b>MASK_LSB</b> : The least-significant bit allowed to pass by the mask (inclusive)                                                                  | RW   | 0x00  |
| 4:0   | <b>SHIFT</b> : Right-rotate applied to accumulator before masking. By appropriately configuring the masks, left and right shifts can be synthesised. | RW   | 0x00  |

## SIO: INTERP0\_CTRL\_LANE1 Register

Offset: 0x0b0

### Description

Control register for lane 1

Table 53.  
INTERP0\_CTRL\_LANE  
1 Register

| Bits  | Description                                                                                                                                                                                                                 | Type | Reset |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:21 | Reserved.                                                                                                                                                                                                                   | -    | -     |
| 20:19 | <b>FORCE_MSB</b> : ORed into bits 29:28 of the lane result presented to the processor on the bus.<br>No effect on the internal 32-bit datapath. Handy for using a lane to generate sequence of pointers into flash or SRAM. | RW   | 0x0   |
| 18    | <b>ADD_RAW</b> : If 1, mask + shift is bypassed for LANE1 result. This does not affect FULL result.                                                                                                                         | RW   | 0x0   |
| 17    | <b>CROSS_RESULT</b> : If 1, feed the opposite lane's result into this lane's accumulator on POP.                                                                                                                            | RW   | 0x0   |
| 16    | <b>CROSS_INPUT</b> : If 1, feed the opposite lane's accumulator into this lane's shift + mask hardware.<br>Takes effect even if ADD_RAW is set (the CROSS_INPUT mux is before the shift+mask bypass)                        | RW   | 0x0   |
| 15    | <b>SIGNED</b> : If SIGNED is set, the shifted and masked accumulator value is sign-extended to 32 bits before adding to BASE1, and LANE1 PEEK/POP appear extended to 32 bits when read by processor.                        | RW   | 0x0   |
| 14:10 | <b>MASK_MSB</b> : The most-significant bit allowed to pass by the mask (inclusive)<br>Setting MSB < LSB may cause chip to turn inside-out                                                                                   | RW   | 0x00  |
| 9:5   | <b>MASK_LSB</b> : The least-significant bit allowed to pass by the mask (inclusive)                                                                                                                                         | RW   | 0x00  |
| 4:0   | <b>SHIFT</b> : Right-rotate applied to accumulator before masking. By appropriately configuring the masks, left and right shifts can be synthesised.                                                                        | RW   | 0x00  |

## SIO: INTERP0\_ACCUM0\_ADD Register

Offset: 0x0b4

| 位     | 描述                                                          | 类型 | 复位   |
|-------|-------------------------------------------------------------|----|------|
| 14:10 | <b>MASK_MSB</b> : 掩码允许通过的最高有效位（包含该位）。将MSB设置小于LSB可能导致芯片功能反常。 | 读写 | 0x00 |
| 9:5   | <b>MASK_LSB</b> : 掩码允许通过的最低有效位（包含该位）。                       | 读写 | 0x00 |
| 4:0   | <b>SHIFT</b> : 对累加器执行的掩码前右旋操作。通过适当配置掩码，可合成左移与右移操作。          | 读写 | 0x00 |

## SIO: INTERP0\_CTRL\_LANE1 寄存器

偏移: 0x0b0

### 说明

通道1控制寄存器

表53。  
INTERP0\_CTRL\_LANE  
1 寄存器

| 位     | 描述                                                                                                           | 类型 | 复位   |
|-------|--------------------------------------------------------------------------------------------------------------|----|------|
| 31:21 | 保留。                                                                                                          | -  | -    |
| 20:19 | <b>FORCE_MSB</b> : 按位或至总线上传递给处理器的通道结果第 29:28 位。<br>对内部 32 位数据路径无任何影响。便于用该通道生成指向 Flash 或 SRAM 的指针序列。          | 读写 | 0x0  |
| 18    | <b>ADD_RAW</b> : 若值为 1，则跳过对 LANE1 结果的掩码与移位操作。此操作不影响 FULL 结果。                                                 | 读写 | 0x0  |
| 17    | <b>CROSS_RESULT</b> : 若为 1，则在数据弹出时将相反通道的结果馈入该通道的累加器。                                                         | 读写 | 0x0  |
| 16    | <b>CROSS_INPUT</b> : 若设置为1，则将对向车道的累加器输入至本车道的移位与掩码硬件。<br>即使设置了ADD_RAW，该功能仍然生效（CROSS_INPUT多路复用器位于移位与掩码绕过之前）。   | 读写 | 0x0  |
| 15    | <b>SIGNED</b> : 若设置SIGNED，移位并掩码后的累加器值将进行带符号扩展至32位。<br>在加至 BASE1 之前，且 LANE1 的 PEEK/POP 操作显示扩展至 32 位由处理器读取时生效。 | 读写 | 0x0  |
| 14:10 | <b>MASK_MSB</b> : 掩码允许通过的最高有效位（包含该位）。将MSB设置小于LSB可能导致芯片功能反常。                                                  | 读写 | 0x00 |
| 9:5   | <b>MASK_LSB</b> : 掩码允许通过的最低有效位（包含该位）。                                                                        | 读写 | 0x00 |
| 4:0   | <b>SHIFT</b> : 对累加器执行的掩码前右旋操作。通过适当配置掩码，可合成左移与右移操作。                                                           | 读写 | 0x00 |

### Description

Control register for lane 0

Table 68.  
INTERP1\_CTRL\_LANE  
0 Register

| Bits  | Description                                                                                                                                                                                                                                                           | Type | Reset |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:26 | Reserved.                                                                                                                                                                                                                                                             | -    | -     |
| 25    | <b>OVERF</b> : Set if either OVERF0 or OVERF1 is set.                                                                                                                                                                                                                 | RO   | 0x0   |
| 24    | <b>OVERF1</b> : Indicates if any masked-off MSBs in ACCUM1 are set.                                                                                                                                                                                                   | RO   | 0x0   |
| 23    | <b>OVERF0</b> : Indicates if any masked-off MSBs in ACCUM0 are set.                                                                                                                                                                                                   | RO   | 0x0   |
| 22    | <b>CLAMP</b> : Only present on INTERP1 on each core. If CLAMP mode is enabled:<br>- LANE0 result is shifted and masked ACCUM0, clamped by a lower bound of BASE0 and an upper bound of BASE1.<br>- Signedness of these comparisons is determined by LANE0_CTRL_SIGNED | RW   | 0x0   |
| 21    | Reserved.                                                                                                                                                                                                                                                             | -    | -     |
| 20:19 | <b>FORCE_MSB</b> : ORed into bits 29:28 of the lane result presented to the processor on the bus.<br>No effect on the internal 32-bit datapath. Handy for using a lane to generate sequence of pointers into flash or SRAM.                                           | RW   | 0x0   |
| 18    | <b>ADD_RAW</b> : If 1, mask + shift is bypassed for LANE0 result. This does not affect FULL result.                                                                                                                                                                   | RW   | 0x0   |
| 17    | <b>CROSS_RESULT</b> : If 1, feed the opposite lane's result into this lane's accumulator on POP.                                                                                                                                                                      | RW   | 0x0   |
| 16    | <b>CROSS_INPUT</b> : If 1, feed the opposite lane's accumulator into this lane's shift + mask hardware.<br>Takes effect even if ADD_RAW is set (the CROSS_INPUT mux is before the shift+mask bypass)                                                                  | RW   | 0x0   |
| 15    | <b>SIGNED</b> : If SIGNED is set, the shifted and masked accumulator value is sign-extended to 32 bits before adding to BASE0, and LANE0 PEEK/POP appear extended to 32 bits when read by processor.                                                                  | RW   | 0x0   |
| 14:10 | <b>MASK_MSB</b> : The most-significant bit allowed to pass by the mask (inclusive)<br>Setting MSB < LSB may cause chip to turn inside-out                                                                                                                             | RW   | 0x00  |
| 9:5   | <b>MASK_LSB</b> : The least-significant bit allowed to pass by the mask (inclusive)                                                                                                                                                                                   | RW   | 0x00  |
| 4:0   | <b>SHIFT</b> : Right-rotate applied to accumulator before masking. By appropriately configuring the masks, left and right shifts can be synthesised.                                                                                                                  | RW   | 0x00  |

## SIO: INTERP1\_CTRL\_LANE1 Register

Offset: 0x0f0

### Description

Control register for lane 1

表 67.  
INTERP1\_PEEK\_FULL  
寄存器

| 位    | 描述                          | 类型 | 复位         |
|------|-----------------------------|----|------------|
| 31:0 | 读取FULL结果，不改变任何内部状态（PEEK操作）。 | 只读 | 0x00000000 |

## SIO: INTERP1\_CTRL\_LANE0 寄存器

偏移: 0x0ec

### 描述

通道0控制寄存器

表 68.  
INTERP1\_CTRL\_LANE  
0 寄存器

| 位     | 描述                                                                                                                                                 | 类型 | 复位   |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|----|------|
| 31:26 | 保留。                                                                                                                                                | -  | -    |
| 25    | <b>OVERF</b> : 如果 OVERF0 或 OVERF1 被置位，则该位被设置。                                                                                                      | 只读 | 0x0  |
| 24    | <b>OVERF1</b> : 指示 ACCUM1 中任何掩码屏蔽的最高有效位是否被置位。                                                                                                      | 只读 | 0x0  |
| 23    | <b>OVERF0</b> : 指示 ACCUM0 中任何掩码屏蔽的最高有效位是否被置位。                                                                                                      | 只读 | 0x0  |
| 22    | <b>CLAMP</b> : 仅存在于每个核心的 INTERP1 上。若启用 CLAMP 模式：<br>- LANE0 结果为位移并掩码的 ACCUM0，由下限 BASE0 与上限 BASE1 限幅。<br>- 这些比较的符号属性由 LANE0_CTRL_SIGNED 决定。<br>- 符号 | 读写 | 0x0  |
| 21    | 保留。                                                                                                                                                | -  | -    |
| 20:19 | <b>FORCE_MSB</b> : 按位或至总线上传递给处理器的通道结果第 29:28 位。<br>对内部 32 位数据路径无任何影响。便于用该通道生成<br>指向 Flash 或 SRAM 的指针序列。                                            | 读写 | 0x0  |
| 18    | <b>ADD_RAW</b> : 若值为 1，则绕过 LANE0 结果的掩码与移位操作。此操作不影响 FULL 结果。                                                                                        | 读写 | 0x0  |
| 17    | <b>CROSS_RESULT</b> : 若为 1，则在数据弹出时将相反通道的结果馈入该通道的累加器。                                                                                               | 读写 | 0x0  |
| 16    | <b>CROSS_INPUT</b> : 若设置为1，则将对向车道的累加器输入至本车道的移位与掩码硬件。<br>即使设置了ADD_RAW，该功能仍然生效（CROSS_INPUT多路复用器位于移位与掩码绕过之前）。                                         | 读写 | 0x0  |
| 15    | <b>SIGNED</b> : 若设置SIGNED，移位并掩码后的累加器值将进行带符号扩展至32位。<br>在加至BASE0之前，且LANE0的PEEK/POP操作将视为扩展至32位。<br>由处理器读取时生效。                                         | 读写 | 0x0  |
| 14:10 | <b>MASK_MSB</b> : 掩码允许通过的最高有效位（包含该位）。<br>将MSB设置小于LSB可能导致芯片功能反常。                                                                                    | 读写 | 0x00 |
| 9:5   | <b>MASK_LSB</b> : 掩码允许通过的最低有效位（包含该位）。                                                                                                              | 读写 | 0x00 |
| 4:0   | <b>SHIFT</b> : 对累加器执行的掩码前右旋操作。通过适当配置掩码，可合成左移与右移操作。                                                                                                 | 读写 | 0x00 |

|-------|---------------------------------------------------------------------------------------------------------------------------|------|----------|
| 31:24 | Reserved.                                                                                                                 | -    | -        |
| 23:0  | Values written here are atomically added to ACCUM1<br>Reading yields lane 1's raw shift and mask value (BASE1 not added). | RW   | 0x000000 |

## SIO: INTERP1\_BASE\_1AND0 Register

Offset: 0x0fc

表 69  
INTERP1\_CTRL\_LANE  
1 寄存器

| 位     | 描述                                                                                                           | 类型 | 复位   |
|-------|--------------------------------------------------------------------------------------------------------------|----|------|
| 31:21 | 保留。                                                                                                          | -  | -    |
| 20:19 | <b>FORCE_MSB</b> : 按位或至总线上传递给处理器的通道结果第 29:28 位。<br>对内部 32 位数据路径无任何影响。便于用该通道生成指向 Flash 或 SRAM 的指针序列。          | 读写 | 0x0  |
| 18    | <b>ADD_RAW</b> : 若值为 1，则跳过对 LANE1 结果的掩码与移位操作。此操作不影响 FULL 结果。                                                 | 读写 | 0x0  |
| 17    | <b>CROSS_RESULT</b> : 若为 1，则在数据弹出时将相反通道的结果馈入该通道的累加器。                                                         | 读写 | 0x0  |
| 16    | <b>CROSS_INPUT</b> : 若设置为1，则将对向车道的累加器输入至本车道的移位与掩码硬件。<br>即使设置了ADD_RAW，该功能仍然生效（CROSS_INPUT多路复用器位于移位与掩码绕过之前）。   | 读写 | 0x0  |
| 15    | <b>SIGNED</b> : 若设置SIGNED，移位并掩码后的累加器值将进行带符号扩展至32位。<br>在加至 BASE1 之前，且 LANE1 的 PEEK/POP 操作显示扩展至 32 位由处理器读取时生效。 | 读写 | 0x0  |
| 14:10 | <b>MASK_MSB</b> : 掩码允许通过的最高有效位（包含该位）。<br>将MSB设置小于LSB可能导致芯片功能反常。                                              | 读写 | 0x00 |
| 9:5   | <b>MASK_LSB</b> : 掩码允许通过的最低有效位（包含该位）。                                                                        | 读写 | 0x00 |
| 4:0   | <b>SHIFT</b> : 对累加器执行的掩码前右旋操作。通过适当配置掩码，可合成左移与右移操作。                                                           | 读写 | 0x00 |

The doorbell interrupt deasserts once all bits are cleared. Read to get status of doorbells currently asserted on this core.</p> | WC   | 0x00  |

## SIO: PERI\_NONSEC Register

Offset: 0x190

### Description

Detach certain core-local peripherals from Secure SIO, and attach them to Non-secure SIO, so that Non-secure software can use them. Attempting to access one of these peripherals from the Secure SIO when it is attached to the Non-secure SIO, or vice versa, will generate a bus error.

This register is per-core, and is only present on the Secure SIO.

Most SIO hardware is duplicated across the Secure and Non-secure SIO, so is not listed in this register.

Table 78.

## SIO: PERI\_NONSEC 寄存器

偏移: 0x190

### 描述

将某些核心本地外设从安全SIO断开，并连接至非安全SIO，以使非安全软件得以使用。当外设连接到非安全SIO时，若从安全SIO访问该外设，反之亦然，均会导致总线错误。

此寄存器为每核心专属，且仅存在于安全SIO内。

大多数 SIO 硬件在安全与非安全 SIO 之间是复制的，因此未在此寄存器中列出。

## SIO: RISCV\_SOFTIRQ Register

Offset: 0x1a0

### Description

Control the assertion of the standard software interrupt (MIP.MSIP) on the RISC-V cores.

Unlike the RISC-V timer, this interrupt is not routed to a normal system-level interrupt line, so can not be used by the Arm cores.

It is safe for both cores to write to this register on the same cycle. The set/clear effect is accumulated across both cores, and then applied. If a flag is both set and cleared on the same cycle, only the set takes effect.

Table 79.  
RISCV\_SOFTIRQ  
Register

| Bits  | Description                                                                                                             | Type | Reset |

## SIO: MTIME\_CTRL Register

Offset: 0x1a4

### Description

Control register for the RISC-V 64-bit Machine-mode timer. This timer is only present in the Secure SIO, so is only accessible to an Arm core in Secure mode or a RISC-V core in Machine mode.

Note whilst this timer follows the RISC-V privileged specification, it is equally usable by the Arm cores. The interrupts are routed to normal system-level interrupt lines as well as to the MIP.MTIP inputs on the RISC-V cores.

Table 80.  
MTIME\_CTRL Register

| Bits | Description                                                                                                                                                        | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:4 | Reserved.                                                                                                                                                          | -    | -     |

| 0   | <b>INTERP0</b> : 如果为1，则将该核心的插值器0从安全SIO中分离，且连接至非安全 SIO。       | 读写 | 0x0 |

## SIO: RISCV\_SOFTIRQ寄存器

偏移量: 0x1a0

### 描述

控制RISC-V核心上标准软件中断（MIP.MSIP）的触发与否。

与RISC-V定时器不同，此中断未被路由至标准系统级中断线，因此Arm核心无法使用。

两个核心在同一周期内写入该寄存器是安全的。置位/清除效果在两个核心之间累积后应用。若某标志在同一周期既被置位又被清除，则仅置位生效。

## SIO: MTIME\_CTRL寄存器

偏移量: 0x1a4

### 描述

RISC-V 64位机器模式计时器控制寄存器。该计时器仅存在于安全SIO中，因此仅可由处于安全模式的Arm核心或处于机器模式的RISC-V核心访问。

注意，尽管该计时器遵循RISC-V特权规范，但同样适用于Arm核心。中断被路由至普通系统级中断线及RISC-V核心的MIP.MTIP输入。

表80。  
MTIME\_CTRL寄存器

| 位    | 描述                                                                    | 类型 | 复位  |

## 3.2. Interrupts

Each core is equipped with an internal interrupt controller, with 52 interrupt inputs. For the most part each core has exactly the same interrupts routed to it, though there are some exceptions, referred to as *core-local interrupts*, where there is an individual per-core interrupt source mapped to the same interrupt number on each core:

- Cross-core FIFO interrupts: [SIO\\_IRQ\\_FIFO](#) and [SIO\\_IRQ\\_FIFO\\_NS](#) ([Section 3.1.5](#))
- Cross-core doorbell interrupts: [SIO\\_IRQ\\_BELL](#) and [SIO\\_IRQ\\_BELL\\_NS](#) ([Section 3.1.6](#))
- RISC-V platform timer (also usable by Arm cores): [SIO\\_IRQ\\_MTIMECMP](#) ([Section 3.1.8](#))
- GPIO interrupts: [IO\\_IRQ\\_BANK0](#), [IRQ\\_IO\\_BANK0\\_NS](#), [IO\\_IRQ\\_QSPI](#), [IO\\_IRQ\\_QSPI\\_NS](#) ([Section 9.5](#))

The remaining interrupt inputs have the same interrupt source mirrored identically on both cores. Non-core-local interrupts should only be enabled in the interrupt controller of a single core at a time, and will be serviced by the core whose interrupt controller they are enabled in.

Table 95. System-level interrupt numbering.  
All interrupts are routed to both processors.

| IRQ | Interrupt Source             | IRQ | Interrupt Source          | IRQ | Interrupt Source                | IRQ | Interrupt Source             | IRQ | Interrupt Source                 |

## 3.2. 中断

每个内核配备了一个内部中断控制器，具有52个中断输入。大多数情况下，每个内核的中断路由完全相同，但存在一些例外，称为内核本地中断，即每个内核拥有单独的中断源，映射到各内核相同的中断编号：

- 跨内核FIFO中断：[SIO\\_IRQ\\_FIFO](#)和[SIO\\_IRQ\\_FIFO\\_NS](#)（第3.1.5节）
- 跨内核门铃中断：[SIO\\_IRQ\\_BELL](#)和[SIO\\_IRQ\\_BELL\\_NS](#)（第3.1.6节）
- RISC-V平台定时器（Arm内核亦可使用）：[SIO\\_IRQ\\_MTIMECMP](#)（第3.1.8节）
- GPIO中断：[IO\\_IRQ\\_BANK0](#)、[IRQ\\_IO\\_BANK0\\_NS](#)、[IO\\_IRQ\\_QSPI](#)、[IO\\_IRQ\\_QSPI\\_NS](#)（第9.5节）

剩余的中断输入在两个核心上具有完全相同的中断源镜像。非核心本地的中断应仅在单个核心的中断控制器中启用，且由启用该中断控制器的核心进行服务。

表 95。系统级  
中断编号。  
所有中断均被  
路由至两个  
处理器。

| 6   | TIMER1_IRQ_2     | 17  | PIO1_IRQ_0       | 28  | SIO_IRQ_BELL_NS  | 39  | TRNG_IRQ         | 50  | SPAREIRQ_IRQ_4   |
| 7   | TIMER1_IRQ_3     | 18  | PIO1_IRQ_1       | 29  | SIO_IRQ_MTIMECMP | 40  | PROC0_IRQ_CTI    | 51  | SPAREIRQ_IRQ_5   |
| 8   | PWM_IRQ_WRAP_0   | 19  | PIO2_IRQ_0       | 30  | CLOCKS_IRQ       | 41  | PROC1_IRQ_CTI    |     |                  |
| 9   | PWM_IRQ_WRAP_1   | 20  | PIO2_IRQ_1       | 31  | SPI0_IRQ         | 42  | PLL_SYS_IRQ      |     |                  |
| 10  | DMA_IRQ_0        | 21  | IO_IRQ_BANK0     | 32  | SPI1_IRQ         | 43  | PLL_USB_IRQ      |     |                  |

On RP2350, only the lower 46 IRQ signals are connected to system-level interrupt sources, and IRQs 46 to 51 are hardwired to zero (never firing). These six spare interrupts, referred to as `SPAREIRQ_IRQ_0` through `SPAREIRQ_IRQ_5` in the table, are deliberately reserved for the cores to interrupt themselves (via the Arm `NVIC_ISPRO` registers or the Hazard3 `MEIFA` CSR), for example, when an interrupt handler wants to schedule a "bottom half" handler for work that must be done after exiting the interrupt handler, but before returning to the code running in the foreground.

Nested interrupts are supported in hardware: a lower-priority interrupt can be pre-empted by a higher-priority interrupt or fault, and will resume once the higher-priority handler returns. The pre-emption priority order is determined by the interrupt priority registers starting from `NVIC_IPR0` (Cortex-M33) or the `MEIPRA` interrupt priority array CSR (Hazard3).

When there is a choice of multiple interrupts to be entered at the same dynamic priority, the interrupt with the lowest IRQ number is chosen as a tie-breaker. The system-level IRQ numbering has been chosen to generally put higher-priority interrupts at lower IRQ numbers for this reason, though the true priority is often dependent on the specific application.

### 3.2.1. Non-maskable interrupt (NMI)

The system IRQ signals can be routed to the Cortex-M33 non-maskable interrupt (NMI) input, by setting the bit for that IRQ number in `NMI_MASK0` or `NMI_MASK1`. The non-maskable interrupt ignores the processor's interrupt enable/disable state (PRIMASK), and can pre-empt any other active interrupt. NMIs are generally used for emergent circumstances that require the processor's unconditional attention, such as loss of PLL lock or power supply integrity.

The NMI mask registers are core-local, so each core can have a different combination of interrupts routed to its NMI input. The NMI mask, along with all other EPPB registers, is reset by a warm reset of that core. This avoids an issue on RP2040 where the NMI mask could be left set following a processor reset.

In addition to system-level interrupts, the non-maskable interrupt is asserted when an integrity check is failed in the redundancy coprocessor (RCP, [Section 3.6.3](#)). This behaviour cannot be disabled, but a correctly-programmed RCP does not trigger under normal voltage, frequency, and temperature conditions. Likewise, if user code does not execute any RCP instructions, the RCP will never trigger. The RCP NMI output is asserted on both cores when an integrity check fails, and is de-asserted by a warm processor reset.

### 3.2.2. Further reading on interrupts

This section describes the routing of system-level interrupt requests to the processor subsystem. It omits important details such as the processor's response to receiving an interrupt, and how processors choose which system-level interrupt requests to subscribe to. The following is a selection of relevant information for these topics:

- [Section 3.7.2.5](#) describes the Cortex-M33's internal interrupt controller, the NVIC
- Register listings starting from `NVIC_ISER0` describe controls for NVIC operation
- [Section 3.7.4.6](#) is an overview of Cortex-M33 exception handling

| IRQ | 中断源            | IRQ | 中断源          | IRQ | 中断源              | IRQ | 中断源           | IRQ | 中断源            |
|-----|----------------|-----|--------------|-----|------------------|-----|---------------|-----|----------------|
| 3   | TIMER0_IRQ_3   | 14  | USBCTRL_IRQ  | 25  | SIO_IRQ_FIFO     | 36  | I2C0_IRQ      | 47  | SPAREIRQ_IRQ_1 |
| 4   | TIMER1_IRQ_0   | 15  | PIO0_IRQ_0   | 26  | SIO_IRQ_BELL     | 37  | I2C1_IRQ      | 48  | SPAREIRQ_IRQ_2 |
| 5   | TIMER1_IRQ_1   | 16  | PIO0_IRQ_1   | 27  | SIO_IRQ_FIFO_NS  | 38  | OTP_IRQ       | 49  | SPAREIRQ_IRQ_3 |
| 6   | TIMER1_IRQ_2   | 17  | PIO1_IRQ_0   | 28  | SIO_IRQ_BELL_NS  | 39  | TRNG_IRQ      | 50  | SPAREIRQ_IRQ_4 |
| 7   | TIMER1_IRQ_3   | 18  | PIO1_IRQ_1   | 29  | SIO_IRQ_MTIMECMP | 40  | PROC0_IRQ_CTI | 51  | SPAREIRQ_IRQ_5 |
| 8   | PWM_IRQ_WRAP_0 | 19  | PIO2_IRQ_0   | 30  | CLOCKS_IRQ       | 41  | PROC1_IRQ_CTI |     |                |
| 9   | PWM_IRQ_WRAP_1 | 20  | PIO2_IRQ_1   | 31  | SPI0_IRQ         | 42  | PLL_SYS_IRQ   |     |                |
| 10  | DMA_IRQ_0      | 21  | IO_IRQ_BANK0 | 32  | SPI1_IRQ         | 43  | PLL_USB_IRQ   |     |                |

在RP2350上，仅较低46个IRQ信号连接到系统级中断源，IRQ 46至51则硬连线为零（永不触发）。这六个备用中断，在表中标注为SPAREIRQ\_IRQ\_0至SPAREIRQ\_IRQ\_5，专门预留给核心通过Arm NVIC\_ISPR0寄存器或Hazard3 MEIIFA CSR自中断使用，例如当中断处理程序希望调度“底半部”处理程序，以在退出中断处理程序但返回前台代码前完成必须执行的工作时。

**硬件支持嵌套中断：**较低优先级的中断可被较高优先级的中断或故障抢占，并在较高优先级处理程序返回后恢复执行。抢占优先级顺序由中断优先级寄存器确定，起始于 NVIC\_IPR0 (Cortex-M33) 或 MEIPRA 中断优先级数组 CSR (Hazard3)。

当存在多个具有相同动态优先级的中断可被触发时，将以 IRQ 号最低的中断作为决胜者。系统级 IRQ 编号设计原则通常是将高优先级中断放置于较低的 IRQ 号，尽管实际优先级通常依赖具体应用。

### 3.2.1. 不可屏蔽中断 (NMI)

系统 IRQ 信号可通过在 NMI\_MASK0 或 NMI\_MASK1 中设置相应 IRQ 号的位，路由至 Cortex-M33 的不可屏蔽中断 (NMI) 输入。不可屏蔽中断忽略处理器的中断使能/禁用状态 (PRIMASK)，可抢占任何其他正在执行的中断。非屏蔽中断 (NMI) 通常用于需要处理器无条件关注的紧急情况，例如 PLL 锁失或电源完整性异常。

NMI 掩码寄存器为核心本地寄存器，因此每个核心可以路由不同组合的中断至其 NMI 输入端。NMI 掩码及所有其他 EPP B 寄存器会在该核心执行热复位时重置。此措施避免了 RP2040 在处理器复位后可能遗留 NMI 掩码设置的问题。

除系统级中断外，当冗余协处理器 (RCP，第 3.6.3 节) 完整性检查失败时，非屏蔽中断将被断言。此行为不可禁用，但在正常电压、频率及温度条件下，正确编程的 RCP 不会触发此中断。同理，若用户代码未执行任何 RCP 指令，RCP 将永不触发中断。当完整性检查失败时，RCP 的 NMI 输出将在两个核心上断言，并通过热复位取消断言。

### 3.2.2. 中断的进一步阅读

本节描述系统级中断请求在处理器子系统中的路由。本节省略了诸如处理器接收中断时的响应机制及处理器如何选择订阅系统级中断请求等重要细节。以下摘录了与这些主题相关的部分信息：

- 第3.7.2.5节介绍了Cortex-M33内部中断控制器NVIC。
- 从NVIC\_ISER0开始的寄存器列表描述了NVIC操作的控制寄存器。
- 第3.7.4.6节为Cortex-M33异常处理提供了概述。

- The [Armv8-M Architecture Reference Manual](#) describes detailed architecture rules for exception handling
- [Section 3.8.4](#) describes standard RISC-V trap handling
- [Section 3.8.4.2](#) describes the standard RISC-V external, timer and software interrupt requests, and how they are connected on RP2350
- [Section 3.8.6.1](#) describes the Xh3irq interrupt controller, which provides priority-controlled interrupt support for the system-level interrupts on Hazard3
- Each peripheral has its own interrupt registers which control the assertion of its system-level interrupts listed in [Table 95](#) – see peripheral documentation for more information

### 3.3. Event signals (Arm)

Using the `WFE` instruction, the Cortex-M33 can enter a sleep state until an "event" (or interrupt) takes place. It can also generate events using the `SEV` instruction. RP2350 cross-wires event signals between the two processors: an event sent by one processor will be received on the other.

**NOTE**

The event flag is "sticky": if both processors send an event (`SEV`) simultaneously, then enter the sleep state (`WFE`), they will both wake immediately. This prevents the processors from getting stuck in a sleep state in this scenario.

Processors also receive an event signal from the global monitor if their reservation is lost due to a write by a different master, in accordance with Armv8-M architecture requirements.

While in a `WFE` (or `WFI`) sleep state, the processor shuts off its internal clock gates to reduce power consumption. When **both** processors are in a sleep state and the DMA is inactive, all of RP2350 can enter a sleep state, disabling clocks on unused infrastructure such as the bus fabric. The rest of RP2350 wakes automatically when either of the processors wakes. See [Section 6.5.2](#).

### 3.4. Event signals (RISC-V)

The Hazard3 `h3.block` instruction halts processor execution until an unblock signal is received. The `h3.unblock` instruction sends an unblock signal to other processors. These NOP-compatible hint instructions are documented in [Section 3.8.6.3](#).

On RP2350 the Hazard3 unblock in/out signals are cross-connected between the two processors, and each processor's unblock output is also fed back into its input. The global monitor also posts an unblock signal to each core when that core loses a reservation due to an access by another core or the system DMA.

The Hazard3 `MSLEEP` CSR defines how deep a sleep the processor will enter when executing a `h3.block` instruction. By default this is a simple pipeline stall, but the processor can also gate its own clock and negotiate the system-level clock wake/sleep state with the clocks block ([Section 6.5.2](#)).

The `h3.unblock` instruction is "sticky": an `h3.block` will fall through immediately if any unblock signal has been received since the last time the processor executed an `h3.block` instruction.

### 3.5. Debug

The Serial Wire Debug (SWD) bus provides access to hardware and software debug features including:

- Loading firmware into SRAM or external flash memory

- Armv8-M架构参考手册详述了异常处理的架构规则。
- 第3.8.4节描述了标准RISC-V陷阱处理机制。
- 第3.8.4.2节介绍了标准RISC-V的外部中断、定时器中断及软件中断请求，以及它们在RP2350上的连接方式。
- 第3.8.6.1节介绍了Xh3irq中断控制器，该控制器为Hazard3上的系统级中断提供优先级控制支持。
- 每个外设都有其各自的中断寄存器，用于控制其系统级中断的触发，详见表95—更多信息请参阅外设文档

### 3.3. 事件信号 (Arm)

通过使用 `WFE` 指令，Cortex-M33可进入睡眠状态，直到发生“事件”（或中断）它还可使用 `SEV` 指令产生事件RP2350在两个处理器之间交叉传递事件信号：一个处理器发送的事件将在另一个处理器接收

#### 注意

事件标志为“粘滞”状态：若两个处理器同时发送事件（`SEV`）后进入睡眠状态（`WFE`），将会立即被唤醒该机制防止处理器在此情况下陷入无法唤醒的睡眠状态

当因其他主设备写操作导致其保留失效时，处理器将依照Armv8-M架构要求，接收来自全局监视器的事件信号

在 `WFE`（或 `WFI`）睡眠状态下，处理器关闭内部时钟门控以降低功耗当两个处理器均处于睡眠状态且DMA处于非活动状态时，整个RP2350可进入睡眠状态，禁用未使用的基础设施时钟，例如总线结构。任一处理器唤醒时，其余RP2350将自动唤醒。详见第6.5.2节。

### 3.4. 事件信号 (RISC-V)

Hazard3 `h3.block` 指令会暂停处理器执行，直到接收到解除阻塞信号。`h3.unblock` 指令向其他处理器发送解除阻塞信号。这些与NOP兼容的提示指令载于第3.8.6.3节。

在RP2350上，Hazard3解除阻塞输入/输出信号在两个处理器之间交叉连接，每个处理器的解除阻塞输出也反馈至其输入端。当核心因其他核心或系统DMA访问而失去预留权时，全局监视器也会向该核心发送解除阻塞信号。

Hazard3 MSLEEP CSR定义了处理器执行 `h3.block` 指令时进入的睡眠深度。默认情况下，这只是一个简单的流水线停滞，但处理器也可以自行门控时钟，并与时钟模块（第6.5.2节）协商系统级时钟的唤醒/睡眠状态。

`h3.unblock` 指令是“粘滞”的：如果处理器自上一次执行`h3.block`指令以来接收到任何`unblock`信号，则任何`h3.block`指令会立即生效。

### 3.5. 调试

串行线调试（SWD）总线提供对硬件和软件调试功能的访问，包括：

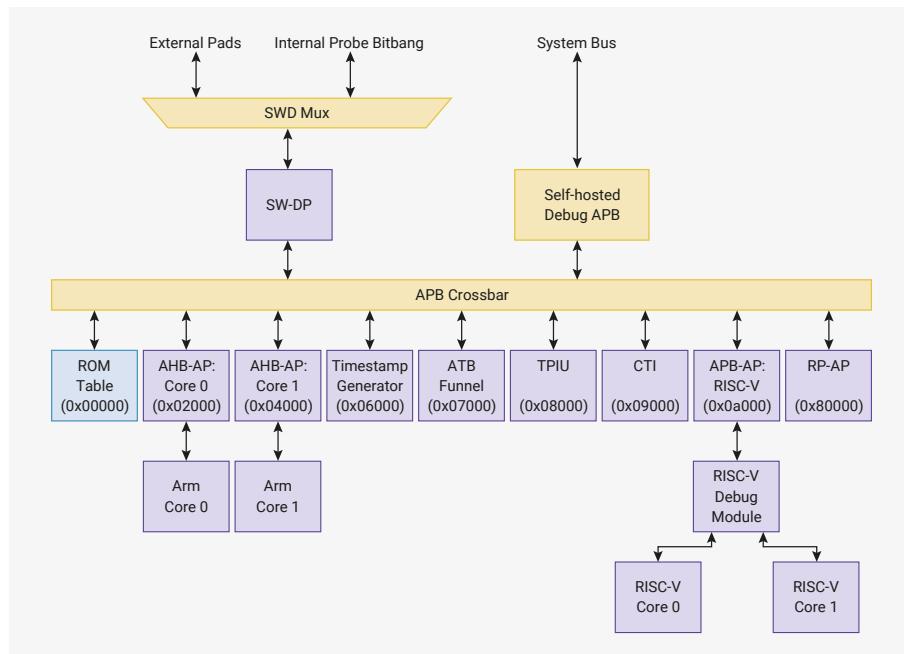

- 将固件加载到SRAM或外部闪存

- Control of processor execution: run/halt, step, set breakpoints, other standard debug functionality
- Access to processor architectural state
- Access to memory and memory-mapped IO via the system bus
- Configuring the CoreSight trace hardware (Arm processors only)

The SWD bus is exposed on two dedicated pins, SWCLK and SWDIO. See [Table 1430](#) for the pin definitions for SWCLK and SWDIO, and see [Table 1440](#) for additional information on their specifications.

A single SW-DP provides access to RP2350's debug subsystem from the external SWCLK and SWDIO pins. The DP is multidrop-capable, but use of multidrop SWD is not mandatory. All hardware in the debug subsystem, with the exception of the RP-AP, can also be accessed directly from the system bus using the self-hosted debug window starting at [CORESIGHT\\_PERIPH\\_BASE](#).

**Figure 10. RP2350 debug topology.** An SW-DP connects the external SWD pins to internal debug hardware. The ROM table lists debug components, for automatic discovery. AHB-APs provide debug access to Arm processors, and an APB-AP provides access to a standard RISC-V Debug Module. The RP-AP provides Raspberry Pi-specific controls such as rescue reset and debug key entry. Remaining components are for Arm trace.

The numbers in brackets in [Figure 10](#) are the addresses of the debug components within the debug address space. These correspond to values written to the SW-DP SELECT register for SWD accesses, or offsets from [CORESIGHT\\_PERIPH\\_BASE](#) for self-hosted debug access. All APs are accessible through the SW-DP, and all except the RP-AP are also accessible through self-hosted debug.

The SW-DP and RP-AP are in the always-on power domain, and are available once external power is applied and the power-on reset (POR) time has elapsed. All other APs in [Figure 10](#) are available only once:

1. the power manager (POWMAN) has sequenced the first power up of the switched core domain
2. the OTP PSM has read critical hardware configuration flags from OTP
3. the system clock (`clk_sys`) is running

### 3.5.1. Connecting to the SW-DP

The SW-DP defaults to the Dormant state at power-up or assertion of the external reset (RUN) pin. A Dormant-to-SWD sequence must be issued before beginning SWD operations. See the Arm Debug Interface specification, version 6, for details of Dormant/SWD state switching: <https://developer.arm.com/documentation/ihi0074/latest/>

After a power-on, the following sequence can be used to connect to the SW-DP:

1. At least 8 × SWCLK cycles with SWDIO high.

- 处理器执行控制：运行/停止、单步执行、设置断点及其他标准调试功能
- 访问处理器体系结构状态
- 通过系统总线访问内存及内存映射IO
- 配置CoreSight跟踪硬件（仅限Arm处理器）

SWD总线通过两个专用引脚SWCLK和SWDIO暴露。SWCLK和SWDIO的引脚定义见表1430；其规格的详细信息见表1440。

单个SW-DP通过外部SWCLK和SWDIO引脚访问RP2350的调试子系统。该DP支持多点连接，但多点SWD并非强制使用。调试子系统中的所有硬件（RP-AP除外）亦可通过自托管调试窗口（起始地址为CORESIGHT\_PERIPH\_BASE）直接从系统总线访问。

图10. RP2350调试拓扑图。SW-DP将外部SWD引脚连接至内部调试硬件。只读存储器表列出了调试组件，用于自动发现。

AHB-AP提供对Arm处理器的调试访问，APB-AP则提供对标准RISCV调试模块的访问。  
RP-AP提供树莓派特定的控制功能，如紧急复位和调试密钥输入。  
剩余组件用于Arm跟踪。

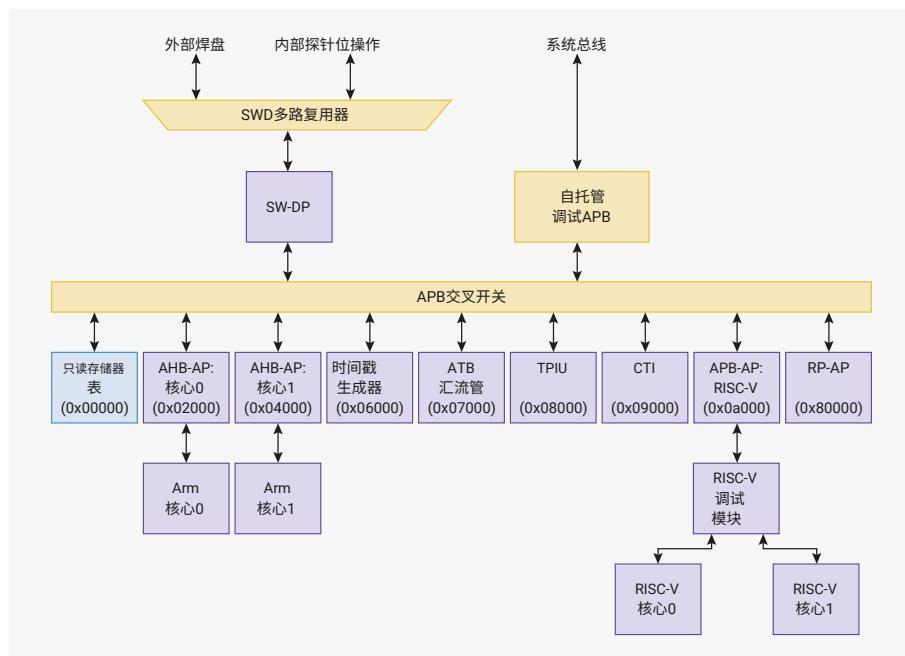

图10中括号内的数字表示调试组件在调试地址空间中的地址。

这些地址对应写入SW-DP SELECT寄存器的值（用于SWD访问），或是自托管调试访问时相对于CORESIGHT\_PERIPH\_BASE的偏移量。所有调试端口（AP）均可通过软件调试端口（SW-DP）访问，且除RP-AP外，所有AP也可通过自托管调试访问。

软件调试端口（SW-DP）和RP-AP位于始终通电的电源域，一旦外部电源接通且上电复位（POR）时间已过即开始可用。图10中的所有其他调试端口仅在满足以下条件后方可使用：

1. 电源管理器（POWMAN）已完成切换内核域的首次加电序列
2. OTP电源管理状态机（PSM）已从只读存储器（OTP）读取关键硬件配置标志
3. 系统时钟（clk\_sys）正在运行

### 3.5.1. 连接至 SW-DP

软件调试端口（SW-DP）在上电或外部复位信号（RUN引脚）断言时默认处于休眠状态。开始串行线调试（SWD）操作前，必须先执行休眠态到SWD态的转换序列。有关休眠态与SWD态切换的详细信息，请参阅Arm调试接口规范第6版：<https://developer.arm.com/documentation/ihi0074/latest/>

上电后，可使用以下序列连接到软件调试端口（SW-DP）：

1. 至少进行8个SWCLK周期，且SWDIO保持高电平。

2. The 128-bit Selection Alert sequence: `0x19bc0ea2, 0xe3ddafe9, 0x86852d95, 0x6209f392`, LSB-first.
3. Four SWCLK cycles with SWDIO low.
4. SWD activation code sequence : `0x1a`, LSB first.
5. At least 50 × SWCLK cycles with SWDIO high (line reset).
6. A DPIDR read to exit the Reset state

In order to wake up the system from a low power (P1.x) state, set the CDBGWRUPREQ in the DP CTRL/STAT register, then poll CDBGWRUPACK in the same register until set. In low-power states, only the SW-DP and RP-AP are accessible, as the remaining debug logic is unpowered.

### 3.5.2. Arm debug

There are two AHB5 Mem-APs, at offsets `0x02000` and `0x04000` in the debug address space, which are used to debug the two Arm Cortex-M33 processors. Each Mem-AP is an AHB5 manager which accesses a 32-bit downstream address space. This is the same address space accessed by a processor's load/store instructions, which includes system-level hardware such as memory and peripherals, and processor-internal hardware on the processor's private peripheral bus (PPB). Certain PPB registers are visible only when accessed from the Mem-AP, not when accessed by software running on the processor.

The AHB5 Mem-AP's own register map is defined in Arm's ADIV6 specification. Generally this is only of interest to those implementing their own debug translator, and the Mem-AP can be thought of simply as a bridge between a DP (such as RP2350's SW-DP) and a downstream address space.

The standard Arm debug registers used to debug software running on the Cortex-M33 can be found documented in the [Armv8-M Architecture Reference Manual](#), or the Cortex-M33 Technical Reference Manual, available from Arm Ltd. This datasheet also documents the core's internal registers in [Section 3.7.5](#).

The Mem-APs can access system peripherals and memory at exactly the same addresses they would be accessed by software running on the processor. However, the privilege and security of Mem-AP accesses may be different from the security state of the software running on the processor at the point it halted: the privilege and security of Mem-AP accesses is configured explicitly via its control and status word (CSW) register. Care must be taken when debugging Non-secure software which accesses the SIO, for example, because by default the debugger may access the Secure alias of the SIO, not the Non-secure alias which software will have been accessing.

The bus filters configured by the ACCESSCTRL bus access permission registers ([Section 10.6.2](#)) treat bus accesses originating from the Mem-APs as distinct from bus accesses originating from software running on the processor. This means it is possible to lock software out from a peripheral, whilst still allowing debugger access.

### 3.5.3. RISC-V debug

There is a single APB Mem-AP, at offset `0x0a000` in the debug address space, which provides access only to the RISC-V Debug Module (DM). The DM is a standard component which the debugger uses to enumerate RISC-V harts present in the system, debug software running on each hart, and access the system bus. It is defined in the RISC-V debug specification, of which RP2350 implements version 0.13.2.

From the point of view of the RISC-V debug specification, the SW-DP and APB Mem-AP function jointly as the Debug Transport Module for this system. The DM is located at offset `0x0` in the APB-AP's downstream address space, and the registers are word-sized and byte-addressed, meaning the DM register addresses in the debug specification must be multiplied by 4 to get the correct APB address.

On RP2350, each core possesses exactly one hardware thread (hart). Core 0 has a hart ID of 0, and core 1 has a hart ID of 1. These hart IDs match the hart index used in the DM. This DM is also equipped with the hart array mask select extension, which allows multiple cores to be reset/halted/resumed simultaneously.

The DM is equipped with the System Bus Access (SBA) extension, which allows the debugger to access the system bus without halting either core. This can be used for minimally intrusive debug techniques like Segger RTT. SBA accesses

2. 128位选择警报序列: `0x19bc0ea2, 0xe3ddafe9, 0x86852d95, 0x6209f392`, 最低有效位优先。
3. 进行4个SWCLK周期, 且SWDIO保持低电平。
4. SWD激活码序列: `0x1a`, 最低有效位优先。
5. 至少进行50个SWCLK周期, 且SWDIO保持高电平(线路复位)。
6. 读取DPIDR以退出复位状态。

为使系统从低功耗(P1.x)状态唤醒, 请设置DP CTRL/STAT寄存器中的CDBGWRUPREQ位, 随后轮询同一寄存器中的CDBGWRUPACK位, 直到该位被置位。在低功耗状态下, 仅可访问SW-DP和RP-AP, 因其余调试逻辑未通电。

### 3.5.2. Arm 调试

在调试地址空间偏移量 `0x02000` 和 `0x04000` 处有两个 AHB5 Mem-AP, 用于调试两颗Arm Cortex-M33处理器。每个 Mem-AP 是一个 AHB5 管理器, 可以访问 32 位下游地址空间。该地址空间与处理器的加载/存储指令所访问的地址空间相同, 包含系统级硬件(如内存和外设)以及处理器私有外设总线(PPB)上的处理器内部硬件。部分 PPB 寄存器仅在通过 Mem-AP 访问时可见, 处理器上运行的软件访问时则不可见。

AHB5 Mem-AP 自身的寄存器映射由 Arm 的 ADIV6 规范定义。通常此内容仅对自行实现调试转换器的人员有意义, Mem-AP 可简化理解为 DP(例如 RP2350 的 SW-DP)与下游地址空间之间的桥接器。

用于调试运行于 Cortex-M33 上软件的标准 Arm 调试寄存器, 可在 Armv8-M 架构参考手册或由 Arm Ltd. 提供的 Cortex-M33 技术参考手册中查阅。本数据手册第 3.7.5 节亦对核心内部寄存器进行了说明。

Mem-AP 可以在与处理器上运行的软件访问系统外设和内存完全相同的地址中进行访问。然而, Mem-AP 访问的权限和安全性可能不同于处理器停止时运行的软件的安全状态: Mem-AP 访问的权限和安全性通过其控制和状态字(CSW)寄存器进行明确配置。调试访问 SIO 的非安全软件时必须谨慎, 例如, 默认情况下调试器可能会访问 SIO 的安全别名, 而非软件实际访问的非安全别名。

由 ACCESSCTRL 总线访问权限寄存器(第 10.6.2 节)配置的总线过滤器将 Mem-AP 发起的总线访问与处理器上运行的软件发起的总线访问视为不同访问。这意味着可以禁止软件访问某外设, 同时仍允许调试器访问。

### 3.5.3. RISC-V 调试

调试地址空间偏移 `0x0a000` 处有一个单一的 APB Mem-AP, 仅提供对 RISC-V 调试模块(DM)的访问。DM 是调试器用于枚举系统中存在的 RISC-V hart、调试运行于各 hart 上的软件以及访问系统总线的标准组件。该组件定义于 RISC-V 调试规范中, RP2350 实现了该规范的 0.13.2 版本。

从 RISC-V 调试规范的视角来看, SW-DP 与 APB Mem-AP 共同构成系统的调试传输模块(Debug Transport Module)。DM 位于 APB-AP 下游地址空间的偏移 `0x0` 处, 其寄存器为字长大小且按字节寻址, 这意味着调试规范中的 DM 寄存器地址须乘以 4, 方能获得正确的 APB 地址。

在 RP2350 中, 每个核心仅拥有一个硬件线程(hart)。核心 0 的 hart ID 为 0, 核心 1 的 hart ID 为 1。这些 hart ID 与 DM 中所使用的 hart 索引对应。此 DM 亦配备了 hart 数组掩码选择扩展, 允许多核心同时执行重置、暂停或恢复操作。

调试模块(DM)配备了系统总线访问(SBA)扩展, 允许调试器在不停止任何核心的情况下访问系统总线。这可用于类似 Segger RTT 的最小侵入性调试技术。SBA 访问

arbitrate with core 1's load/store port to access the system bus, but they are treated as distinct from core 1's accesses for the purpose of bus filtering (Section 10.6.2), which means it is possible to lock software out of a peripheral whilst retaining debug access. Processor load/stores in Debug mode are also treated as debug accesses for the purpose of bus filtering.

The DM is able to reset each core individually using the `dmcontrol.hartreset` control. This resets *only* the selected processor. The `dmcontrol.ndmreset` resets both processors *only*, which is the minimum requirement in the RISC-V debug specification. A full system reset, which includes the DM, can be performed using the SYSRESETREQ control in the SW-DP, a switched core domain reset configured in POWMAN and initiated by the watchdog, or any full-system reset such as the RUN pin. A PSM reset initiated by the watchdog can reset almost all system-level hardware except for the DM, but note that the DM becomes momentarily inaccessible whilst the system clock's clock generator is reset, which is the reason for `dmcontrol.ndmreset` resetting the processors only.

For details on the processor side of RISC-V debug, see Section 3.8.5. See also the Hazard3 source code at [github.com/Wren6991/Hazard3](https://github.com/Wren6991/Hazard3), which includes the DM implementation under the `hdl/debug/dm/` directory.

### 3.5.4. Debug power domains

The SW-DP and the RP-AP are in the always-on power domain. This means they are available even when the system is in its lowest-power state, with the switched core domain (which includes the processors) fully powered down.

The remainder of the debug hardware is in the switched core domain. This is the same domain as the processors and system peripherals.

Setting the CDBGPRUPREQ bit in the SW-DP's CTRL/STAT register will force a power up of the switched core domain, making the remaining debug hardware available. This power up takes some time, as it is sequenced by the 32 kHz low-power oscillator (Section 8.4), so the CDBGPRUPACK bit must be polled to wait for the system to power up before attempting to access any APs other than the RP-AP. See Arm's ADIV6 specification for the SW-DP's register listing.

Note that the RP-AP is accessible without asserting CDBGPRUPREQ, as it is always powered.

### 3.5.5. Software control of SWD pins

The `DBGFORCE` register in SYSCFG can be used to detach the SW-DP from the external debug pads, and instead bitbang the internal SWD signals directly from software. This is intended for a debug probe running on one core being used to debug the other core. For other use cases it is generally cleaner to use the self-hosted debug access to interface with the APs directly from the system bus.

### 3.5.6. Self-hosted debug

All APs shown in Figure 10, except for the RP-AP, have direct memory-mapped access from the system bus. This is known as self-hosted debug, because with care it allows running a debug host (i.e. a debugger) directly on-system. It can also be used to access the trace hardware, which can be used for self-hosted trace using the trace DMA FIFO. By default only Secure access is permitted, as the processor debug presents an opportunity for Non-secure code to interfere with the Secure context and/or perform Secure bus accesses.

The self-hosted debug window starts at address `0x40140000` (`CORESIGHT_PERIPH_BASE`). The offsets of the APs within this window are the same as the APs' addresses when accessed from the SW-DP.

Because of the blocking nature of the AHB-AP's DRW register, and its interactions with the Cortex-M33's arbitration of AHB-AP accesses with load/stores, certain accesses have potential to cause bus lockup due to circular bus stall dependencies. In particular, cores may not access their own AHB-APs through the self-hosted debug window, and AHB-APs may not access AHB-APs through the self-hosted debug window – attempting to do so will immediately return a bus fault. To reduce the opportunities for deadlock, a full APB crossbar is used to connect the SW-DP and the self-hosted debug port to the APs, so that for example self-hosted use of the Arm trace hardware will not interfere with an external debugger attaching via the AHB-APs.

与核心 1 的加载/存储端口竞争访问系统总线，但在总线过滤（第 10.6.2 节）中被视为与核心 1 的访问不同，这意味着可以在保留调试访问的同时锁定软件对外设的访问权限。调试模式下处理器的加载/存储同样被视为调试访问，用于总线过滤。

DM 能通过`dmcontrol.hartreset`控制单独重置各核心。仅重置所选的处理器。`dmcontrol.ndmreset`则仅重置两个处理器，这是 RISC-V 调试规范的最低要求。可通过 SW-DP 中的 SYSRESETREQ 控制执行包含 DM 在内的全系统复位；也可通过 POWMAN 配置并由看门狗触发的切换核心域复位，或任何全系统复位，如 RUN 引脚触发。看门狗触发的 PSM 复位能复位几乎所有系统级硬件，但不包括 DM；需注意的是，系统时钟的时钟发生器复位时，DM 会暂时无法访问，这也是`dmcontrol.ndmreset`仅重置处理器的原因。

关于 RISC-V 调试处理器部分的详细信息，请参见第 3.8.5 节。另请参阅 Hazard3 源代码，地址为 [github.com/Wren6991/Hazard3](https://github.com/Wren6991/Hazard3)，其中包含位于 `hdl/debug/dm/` 目录下的 DM 实现。

### 3.5.4. 调试电源域

SW-DP 和 RP-AP 位于始终通电的电源域中。这意味着即使系统处于最低功耗状态，且切换核心域（包含处理器）完全断电时，它们仍然可用。

其余调试硬件位于切换核心域中。该电源域与处理器及系统外设相同。

在 SW-DP 的 CTRL/STAT 寄存器中设置 CDBGPWRUPREQ 位，将强制切换核心域上电，使其余调试硬件变得可用。该上电过程需要一定时间，由 32 kHz 低功耗振荡器（第 8.4 节）进行序列控制，因此必须轮询 CDBGPWRUPACK 位，等待系统完成上电，方可尝试访问除 RP-AP 之外的任何 AP。有关 SW-DP 寄存器列表，请参阅 Arm 的 ADIV6 规范。

请注意，RP-AP 无需断言 CDBGPWRUPREQ 即可访问，因为它始终供电。

### 3.5.5. SWD 引脚的软件控制

SYSCFG 中的 DBGFORCE 寄存器可用于将 SW-DP 与外部调试引脚分离，转而由软件直接比特操作内部 SWD 信号。该功能旨在让一个核心上运行的调试探针用于调试另一核心。对于其他使用场景，通常更为妥当的做法是使用自托管调试访问，直接从系统总线与 AP 进行接口。

### 3.5.6. 自托管调试

图 10 中所示的所有 AP（除 RP-AP 外）均支持通过系统总线的直接内存映射访问。这称为自托管调试，因为经妥善操作，它允许在系统内直接运行调试主机（即调试器）。该功能还可用于访问跟踪硬件，从而借助跟踪 DMA FIFO 实现自托管跟踪。默认仅允许安全访问，因为处理器调试为非安全代码提供了干扰安全上下文及/或执行安全总线访问的可能。

自托管调试窗口起始地址为 `0x40140000` (CORESIGHT\_PERIPH\_BASE)。该窗口内的 AP 偏移量与从 SW-DP 访问 AP 时的地址相同。

由于 AHB-AP 的 DRW 寄存器具有阻塞特性，且其与 Cortex-M33 对 AHB-AP 访问的仲裁机制以及 load/store 操作相互作用，部分访问可能引发因总线循环阻塞依赖而导致的总线死锁。特别地，核心不得通过自托管调试窗口访问其自身的 AHB-AP，且 AHB-AP 不得通过自托管调试窗口访问其他 AHB-AP——尝试这样做将立即返回总线故障。为减少死锁风险，采用完整的 APB 交叉开关，将 SW-DP 和自托管调试端口连接至 AP；例如，自托管使用 Arm 跟踪硬件时，不会干扰通过 AHB-AP 连接的外部调试器。

There are some cases where a bus deadlock can not be avoided, such as a core using the other core's AHB-AP, via the self-hosted debug window, to access some other APB peripheral:

1. The access upstream of the APB's DRW register will not complete until the downstream access completes
2. The downstream access will not complete until it is granted access to the system APB bridge
3. Access to the APB bridge will not be granted until the upstream access, which is occupying the system APB bridge, completes
4. See point 1.

This situation can arise when running a self-hosted debugger on one core, and debugging code on the other core which accesses APB addresses. The deadlock is eventually broken when the APB bridge's 65536-cycle timeout expires, abandoning the transfer and returning a bus error to the origin of the upstream access. To avoid this, software should detect when it is about to use an AP to access an APB address (an address starting with `0x4`), and perform the access directly instead of using the Mem-AP.

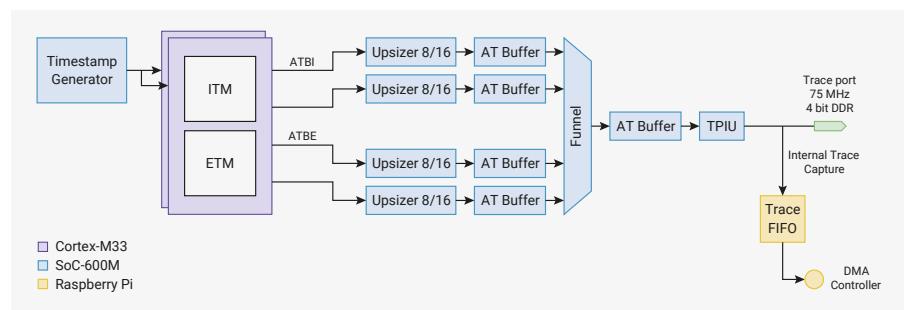

This type of deadlock does not occur when the debugger accesses the bus with RISC-V System Bus Access, because the bus transfer upstream of the DM does not block on completion of the downstream access.

### 3.5.7. Trace

#### 3.5.7.1. Overview

The ATB trace subsystem is based on the Coresight SoC-600M architecture, as shown in [Figure 11](#).

Figure 11. Trace Subsystem

The trace subsystem captures trace messages from each of the Cortex-M33 ITM/ETM components, merges them into a single trace bus, and sends off-chip through the 4-bit DDR trace port for subsequent capture and analysis by a trace port analyser.

This allows the developer to review a detailed log of software executed on the processors. The advantage over conventional hardware debug is that it does this without halting the processors or affecting their execution timing, so you can diagnose software issues that are hard to reproduce under a debugger.

The trace subsystem comprises the following main components:

- **Timestamp Generator:** Timestamps propagate to both Cortex-M33 processors, and are applied to ETM and ITM output so that the relative timing of their trace streams can be recovered.
- **Cortex-M33 ETM:** Embedded Trace Macrocell, for real-time instruction flow messages generated from observations of the Cortex-M33's execution.
- **Cortex-M33 ITM:** Instruction Trace Macrocell, for software-generated messages.
- **ATB Funnel:** Merges the Cortex-M33 trace sources into a single trace stream using the timestamps from the Timestamp Generator.
- **TPIU:** Trace Port Interface Unit, outputs trace data over trace port pins. The source-synchronous trace interface is 4-bits DDR, up to 75 MHz clock, giving a maximum trace data rate of up to 600 Mb/s.

在某些情况下，无法避免总线死锁，例如一个核心通过自托管调试窗口，使用另一个核心的 AHB-AP 访问其他 APB 外设时：

1. APB 的 DRW 寄存器上游访问在下游访问完成之前不会完成。
2. 下游访问在获得系统 APB 桥访问权限之前不会完成。
3. 访问 APB 桥的权限在占用系统 APB 桥的上游访问完成之前不会被授予。
4. 参见第 1 点。

当在一个核心上运行自托管调试器，调试访问 APB 地址的另一个核心上的代码时，可能会出现这种情况。当 APB 桥的 65536 周期超时到期，放弃传输并向上游访问发起方返回总线错误后，死锁最终被解除。为避免此情况，软件应在即将使用 AP 访问 APB 地址（以 `0x4` 开头的地址）时进行检测，并直接执行访问，而非使用 Mem-AP。

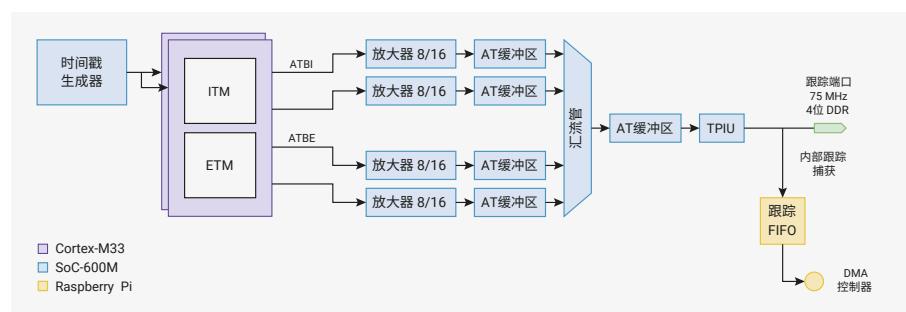

当调试器通过 RISC-V 系统总线访问总线时，不会发生此类死锁，因为 DM 上游的总线传输不会因下游访问完成而阻塞。

### 3.5.7. 跟踪

#### 3.5.7.1 概述

ATB 跟踪子系统基于 Coresight SoC-600M 架构，如图 11 所示。

图 11 跟踪子系统

跟踪子系统捕获来自每个 Cortex-M33 ITM/ETM 组件的跟踪消息，将其合并为单一跟踪总线，并通过 4 位 DDR 跟踪端口发送至片外，供跟踪端口分析仪进行后续捕获和分析。

这使开发人员能够审查处理器上执行的软件的详细日志。与传统硬件调试相比，其优点在于无需暂停处理器或影响其执行时序，从而能够诊断在调试器下难以重现的软件问题。

跟踪子系统包含以下主要组件：

- 时间戳生成器：时间戳传播至两个 Cortex-M33 处理器，并且应用于 ETM 和 ITM 输出，以便恢复其跟踪流的相对时序。
- Cortex-M33 ETM：嵌入式跟踪宏单元，用于基于对 Cortex-M33 执行过程观察生成的实时指令流消息。
- Cortex-M33 ITM：指令跟踪宏单元，用于软件生成的消息。
- ATB 汇聚器：利用时间戳生成器的时间戳，将 Cortex-M33 的跟踪源合并为单一跟踪流。
- TPIU：跟踪端口接口单元，通过跟踪端口引脚输出跟踪数据。源同步跟踪接口为 4 位 DDR，最高时钟频率 75 MHz，最大跟踪数据速率可达 600 Mb/s。

- Trace FIFO: Optionally captures the 32-bit TPIU trace stream on-device, from which point the DMA can transfer to main system SRAM.

See the [Arm CoreSight ETM-M33 Technical Reference Manual](#) for information about the Cortex-M33 ETM. See the [SoC-600M Technical Reference Manual](#) for information about the other trace components in [Figure 11](#)

The trace output clock is fixed at one half of `clk_sys`. At the maximum system frequency of 150 MHz this yields a 75 MHz TPIU output clock. The trace throughput is reduced at lower system clock frequencies, though this is rarely an issue in practice as the processor instruction throughput (and therefore the demand for trace output bandwidth) scales accordingly.

### 3.5.7.2. Trace FIFO

Trace output goes to one of two data sinks:

- The four-bit TPIU interface streams data out of the chip through GPIOs, for capture by an external probe
- The trace FIFO streams data into SRAM via the system DMA

The bandwidth of the DMA is greater than the bandwidth of the TPIU interface. Capturing into an on-chip buffer also allows trace to operate through a comparatively low-speed SWD probe without restricting trace bandwidth.

The operation is similar to a micro-trace buffer (MTB). However, all of system SRAM is available for trace. You can also use other DMA endpoints like the PIO and HSTX to implement your own trace data sinks, for example if you would prefer a wider and lower-frequency bus than the TPIU provides.

You must enable DMA access to the trace FIFO registers by setting the `DMA` bit in the ACCESSCTRL `CORESIGHT_TRACE` register before attempting to DMA from this FIFO. Configure the DMA for DREQ [53](#) to select the trace FIFO.

### 3.5.7.3. List of trace FIFO registers

The trace FIFO registers start at a base address of `0x50700000` (defined as `CORESIGHT_TRACE_BASE` in the SDK).

**Offset:** 0x0

### Description

Control and status register

*Table 97. CTRL\_STATUS Register*

| Bits | Description                                                                                                                                                                                                 | Type | Reset |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:2 | Reserved.                                                                                                                                                                                                   | -    | -     |
| 1    | <b>TRACE_CAPTURE_FIFO_OVERFLOW:</b> This status flag is set high when trace data has been dropped due to the FIFO being full at the point trace data was sampled. Write 1 to acknowledge and clear the bit. | RW   | 0x0   |

- 跟踪FIFO：可选地在设备上捕获32位TPIU跟踪流，从此处开始，DMA可将数据传输至主系统SRAM。

有关Cortex-M33 ETM的详细信息，请参见Arm CoreSight ETM-M33技术参考手册。有关图11中其他跟踪组件的详细信息，请参见SoC-600M技术参考手册。

跟踪输出时钟固定为 `clk_sys` 的一半。在系统最高频率150 MHz时，TPIU输出时钟为75 MHz。在较低系统时钟频率时，跟踪吞吐量会降低，但实际应用中很少成为问题，因为处理器指令吞吐量（及对跟踪输出带宽的需求）会相应调整。

### 3.5.7.2. 跟踪FIFO

跟踪输出传输至两个数据接收端之一：

- 四位TPIU接口通过GPIO将数据从芯片中发送出去，以供外部探针捕获。
- 跟踪FIFO通过系统DMA将数据流入SRAM。

DMA的带宽高于TPIU接口的带宽。捕获至片上缓冲区亦允许跟踪通过相对低速的SWD探针运行，且不会限制跟踪带宽。

其操作方式类似于微追踪缓冲器（MTB）。然而，系统SRAM全部可用于跟踪。您亦可利用其他DMA端点，如PIO和HST X，实现自定义跟踪数据接收端，例如当您希望使用比TPIU提供更宽且频率更低的总线时。

在尝试使用DMA从该FIFO读取数据前，必须通过设置ACCESSCTRL CORESIGHT\_TRACE寄存器中的 `DMA` 位来启用对跟踪FIFO寄存器的DMA访问。配置DMA的DREQ为 [53](#) 以选择跟踪FIFO。

### 3.5.7.3. 跟踪FIFO寄存器列表

跟踪FIFO寄存器的基地址起始于 [0x50700000](#)（在SDK中定义为CORESIGHT\_TRACE\_BASE）。

### 3.5.8. Rescue reset

A rescue reset is a full system reset, similar to asserting the RUN pin low, which also sets a flag telling the bootrom to halt before running any user software. This is performed over the SWD bus using the RP-AP, and can be performed even when system clocks are stopped and the switched core power domain is powered down. This is used in the case where the chip has locked up, for example if code has been programmed into flash which permanently halts the system clock: since the debugger can no longer communicate with the processors to return the system to a working state, more drastic action is needed. This functionality was provided by the Rescue DP on RP2040, but on RP2350 it is provided by the RP-AP, to avoid mandatory use of multidrop SWD.

A rescue is invoked by setting and then clearing the [CTRL.RESCUE\\_RESTART](#) bit in the RP-AP. This causes a hard reset of the chip, and sets [CHIP\\_RESET.RESCUE\\_FLAG](#) to indicate that a rescue reset took place. The bootrom checks this flag almost immediately in the initial boot process (before watchdog, flash or USB boot), acknowledges by clearing the bit, then halts the processor. This leaves the system in a safe state, with the system clock running, so that the debugger can reattach to the cores and load fresh code.

### 3.5.8. 救援重置

救援复位是一种完整的系统复位，类似于使RUN引脚拉低，同时设置一个标志，指示只读存储器在执行任何用户软件之前停止运行。该操作通过RP-AP在SWD总线上完成，即使系统时钟停止且切换核心电源域断电时也能执行。当芯片锁死时使用此功能，例如代码已被编程进闪存，导致系统时钟永久停止：

由于调试器无法再与处理器通信以恢复系统正常状态，因此需要采取更为严厉的措施。此功能由RP2040上的Rescue DP提供，而在RP2350上则由RP-AP提供，以避免强制使用多点SWD。

通过在RP-AP中设置并随后清除CTRL.RESCUE\_RESTART位来调用救援功能。此操作将导致芯片硬复位，并设置CHIP\_RESET.RESCUE\_FLAG，表明已执行救援复位。只读存储器引导程序在初始启动过程中几乎立即检查此标志（位于看门狗、闪存或USB启动之前），通过清除此位确认，然后停止处理器。这使系统保持在安全状态，系统时钟继续运行，以便调试器能够重新连接核心并加载新的代码。

### 3.5.9. Security

By default, the SWD debug access port allows an external debugger to access all system memory and peripherals, and to observe and change the execution of software running on the processors. If boot signature enforcement is enabled ([Section 10.1.1](#)), debug access becomes a security concern, as it is able to sidestep this protection. To account for this, RP2350 supports progressively locking down the debug port using configuration in on-chip OTP storage.

Conceptually there are two control bits: debug disable, and secure debug disable. Debug disable is intended to completely cut off debug access to the processors and the system bus, whilst the secure debug disable forbids Secure bus accesses, and halting of processors in the Secure state, but still allows Non-secure software to be debugged as normal. There are two ways to set these control bits:

- Setting the relevant OTP critical flag: `CRIT1.DEBUG_DISABLE` or `CRIT1.SECURE_DEBUG_DISABLE` to set the debug disable or secure debug disable, respectively
- Installing a 128-bit fixed debug key as OTP key 5 or 6 ([Section 3.5.9.2](#))

OTP configuration changes take effect at the next reset of the OTP block.

Once debug has been disabled, software can re-enable debug using the OTP `DEBUGEN` register, which allows the secure and overall debug enable to be cleared individually for each processor. For example, Secure software may implement a shell where users can authenticate using a cryptographic challenge to enable debug on systems where it is disabled by default. The `DEBUGEN` register belongs to the processor cold reset domain, so it is preserved over a PSM reset starting from as early as OTP (the second PSM stage). This allows almost a full system reset without losing debug access.

To avoid accidental writes of the `DEBUGEN` register, its bits can be individually locked using the matching bits in `DEBUGEN_LOCK`.

This offers increasing levels of debug protection:

1. Fully open: no keys installed and no OTP debug disable flags are set. This is the most convenient configuration for product development.
2. Access with key only: at least one key is installed, but no OTP debug disable flags are set.
3. No access even with key (an OTP debug disable flag is set), but Secure code can enable debug access by writing to `DEBUGEN`.
4. No access even with key (an OTP debug disable flag is set), and `DEBUGEN` is locked by `DEBUGEN_LOCK`.

#### 3.5.9.1. Effects of debug disables

The secure debug disable flag (`CRIT1.SECURE_DEBUG_DISABLE`) has the following effects:

- Set Secure AP enable signals for Arm core 0 and core 1 AHB-APs to `0`.
  - This prevents the APs from performing Secure bus accesses (including to the PPB).
  - Status is reported in the `SDeviceEn` flag of the AHB-AP `CSW` register.
- Set the Cortex-M33 `SPIDEN` and `SPNIDEN` signals for both cores to `0`.
  - This prevents the cores from being halted or traced whilst in the Secure state.
- Disable the factory test JTAG interface ([Section 10.10](#)).

### 3.5.9. 安全

默认情况下，SWD调试访问端口允许外部调试器访问全部系统内存和外设，观察并修改处理器上执行的软件。如果启用了引导签名强制（参见第10.1.1节），调试访问将成为安全隐患，因为它能够绕过该保护。为此，RP2350通过片上OTP存储中的配置支持逐步锁定调试端口。

概念上存在两个控制位：调试禁用和安全调试禁用。调试禁用旨在完全切断对处理器及系统总线的调试访问，而安全调试禁用禁止安全总线访问及在安全状态下暂停处理器，但仍允许对非安全软件进行正常调试。设置这些控制位有两种方式：

- 设置相关的OTP关键标志：CRIT1.DEBUG\_DISABLE或CRIT1.SECURE\_DEBUG\_DISABLE，分别用于配置调试禁用或安全调试禁用。
- 将128位固定调试密钥安装为OTP密钥5或6（详见第3.5.9.2节）。

OTP配置的变更将在下一次OTP块复位时生效。

一旦调试被禁用，软件可以使用OTP DEBUGEN寄存器重新启用调试，该寄存器允许针对每个处理器单独清除安全调试和整体调试启用标志。例如，安全软件可实现一个shell，用户通过加密挑战进行身份验证，从而在默认禁用调试的系统上启用调试功能。DEBUGEN寄存器属于处理器冷复位域，因此从OTP（第二PSM阶段）开始，它可在PSM复位期间保持不变。这允许几乎完整的系统复位而不丢失调试访问权限。

为防止DEBUGEN寄存器发生意外写入，其各位可通过DEBUGEN\_LOCK寄存器中的对应位单独加锁。

本产品提供以下逐级增强的调试保护级别：

1. 完全开放：未安装任何密钥，且未设置任何OTP调试禁用标志。此配置最适合产品开发阶段。
2. 仅限持密钥访问：已安装至少一个密钥，但未设置任何OTP调试禁用标志。
3. 即使持有密钥也无法访问（已设置OTP调试禁用标志），但安全代码可通过写入DEBUGEN启用调试访问。
4. 即使持有密钥也无法访问（已设置OTP调试禁用标志），且DEBUGEN已被DEBUGEN\_LOCK锁定。

#### 3.5.9.1. 调试禁用的影响

安全调试禁用标志（CRIT1.SECURE\_DEBUG\_DISABLE）具有以下效用：

- 将Arm核0和核1的AHB-AP安全AP启用信号设为0。
  - 此操作阻止AP进行安全总线访问（包括访问PPB）。
  - 状态通过AHB-AP的CSW寄存器中的SDeviceEn标志反映。
- 将两个核的Cortex-M33 SPIDEN和SPNIDEN信号设为0。
  - 这会防止内核在安全状态下被暂停或跟踪。
- 禁用工厂测试JTAG接口（第10.10节）。

### NOTE

Both AHB-APs' `CSW.HNONSEC` bits default to 0, generating Secure bus accesses. If the secure debug disable flag is set, these bits must be set to 1 to generate Non-Secure bus accesses.

The debug disable flag (`CRIT1.DEBUG_DISABLE`) has all of the effects of the secure debug disable flag. It also has the following additional effects:

- Set AP enable signals for Arm core 0 and core 1 AHB-APs to 0.
  - This prevents the APs from performing any bus accesses at all (including to the PPB).
  - Status is reported in the `DeviceEn` flag of the AHB-AP `CSW` register.
- Set AP enable signal for RISC-V DM APB-AP to 0.
  - This prevents the AP from accessing the RISC-V Debug Module.
  - Status is reported in the `DeviceEn` flag of the APB-AP `CSW` register.
- Set `DBGEN` and `NIDEN` signals for the CTI to 0.

On RISC-V `CRIT1.SECURE_DEBUG_DISABLE` has no useful effect. Debug-mode accesses from the cores always have Secure and Privileged bus attributes, except when reduced by `FORCE_CORE_NS`. Likewise, System Bus Access via the Debug Module is always Secure and Privileged, unless `FORCE_CORE_NS.CORE1` is set, in which case it is Non-secure and Privileged. Use the `CRIT1.DEBUG_DISABLE` flag on RISC-V.

#### 3.5.9.2. Debug keys

Section 13.5.2 describes the OTP hardware access keys. Hardware reads OTP access keys into hidden registers as part of the OTP power-up sequence which takes place after an OTP reset, and the corresponding OTP locations then become inaccessible. OTP keys 5 and 6 are special in that they control access to the SWD debug hardware in addition to functioning as normal OTP page keys.

A debug key is a 128-bit fixed challenge. Installing a debug key in OTP locks down debug access, and it remains locked until the debug host writes a matching key value through the RP-AP `DBGKEY` register. This is a write-only interface.

To install a debug key, first program the OTP locations starting from `KEY5_0` or `KEY6_0`. These locations are ECC-protected. Once you have programmed the 128-bit key value and read it back to confirm the correct value is programmed, write the raw bit pattern `0x010101` to `KEY5_VALID` or `KEY6_VALID` to mark the key as valid. The validity takes effect at the next reset of the OTP block.

Once a key is valid, the OTP storage locations for that key become inaccessible for both reads and writes. Only the OTP power-up state machine (Section 13.3.4) can read the key.

The effect of installing debug keys depends on which of key 5 and 6 are installed:

- If key 5 or key 6 is valid, and no matching key (either) has been entered through the RP-AP, all debug is disabled. This has the same effect as setting `CRIT1.DEBUG_DISABLE`.
- If key 5 is valid, and no matching key (key 5 specifically) has been entered through the RP-AP, Secure debug is disabled. This has the same effect as writing `CRIT1.SECURE_DEBUG_DISABLE`.

When both keys are installed, key 5 provides both Secure and Non-secure debug access, and key 6 provides Non-secure debug access only. When only a single key is installed, that key provides both Secure and Non-secure debug access.

To enter a key over SWD, first write a 1 to `DBGKEY.RESET`. Then sequentially write 128 bits to `DBGKEY.DATA`, each accompanied by a 1 written to `DBGKEY.PUSH`. Write the data LSB-first, starting with the lowest-numbered OTP row.

Assuming you wrote a value that matched one of the installed debug keys, debug unlocks after the 128th push. The `SDeviceEn` and `DeviceEn` flags in the Mem-AP `CSW` registers indicate success or failure.

Failure to supply a matching key through the RP-AP disables debug if it would otherwise be enabled. However, supplying a key does not enable if it is already disabled for other reasons. For example, if `CRIT1.DEBUG_DISABLE` is set, and

### 注意

两个AHB-AP的`CSW.HNONSEC`位默认均为0，产生安全总线访问。若设置了安全调试禁用标志，则这些位必须设置为1，以产生非安全总线访问。

调试禁用标志（CRIT1.DEBUG\_DISABLE）具备与安全调试禁用标志相同的所有效应。其还具有以下附加效应：

- 将Arm核心0和核心1的AHB-AP使能信号设为0。
  - 这将阻止AP执行任何总线访问（包括对PPB的访问）。
  - 状态通过AHB-AP `CSW`寄存器中的 `DeviceEn`标志进行报告。
- 将RISC-V DM APB-AP的AP使能信号设为0。
  - 这将阻止AP访问RISC-V调试模块。
  - 状态由APB-AP `CSW`寄存器中的 `DeviceEn`标志报告。
- 将CTI的 `DBGEN`和 `NIDEN`信号置为0。

在RISC-V中，CRIT1.SECURE\_DEBUG\_DISABLE无实际效果。核心的调试模式访问始终具有安全且特权的总线属性，除非被FORCE\_CORE\_NS降低。同样，系统总线通过调试模块的访问始终为安全且特权，除非设置了FORCE\_CORE\_NS.CORE1，此时为非安全且特权。请使用RISC-V上的CRIT1.DEBUG\_DISABLE标志。

#### 3.5.9.2. 调试密钥

第13.5.2节描述了OTP硬件访问密钥。硬件在OTP复位后的OTP上电序列中，将OTP访问密钥加载到隐藏寄存器，随后相应的OTP位置变为不可访问。OTP密钥 5和 6具有特殊作用，除作为普通OTP页密钥外，还控制对SWD调试硬件的访问权限。

调试密钥为一个128位固定挑战值。在OTP中安装调试密钥将锁定调试访问，且该状态将持续，直至调试主机通过RP-AP `DBGKEY`寄存器写入匹配密钥值。此接口为只写。

要安装调试密钥，需先从`KEY5_0`或`KEY6_0`开始编程OTP位置，这些位置受ECC保护。编程完128位密钥值并读取确认无误后，写入原始位模式 `0x010101`至`KEY5_VALID`或`KEY6_VALID`，以标记密钥为有效。该有效性将在OTP块的下一次复位时生效。

一旦密钥生效，该密钥对应的OTP存储位置将无法再被读写。仅OTP上电状态机（第13.3.4节）可读取该密钥。

调试密钥安装的作用取决于已安装的密钥 5和/或 6：

- 如果密钥5或密钥6有效，且通过RP-AP未输入任何匹配密钥，则所有调试功能均被禁用。  
此操作等同于设置CRIT1.DEBUG\_DISABLE。
- 如果密钥5有效，且通过RP-AP未输入匹配密钥（特别是密钥5），则安全调试被禁用。此操作等同于写入CRIT1.SECURE\_DEBUG\_DISABLE。

当同时安装密钥时，密钥 5同时提供安全和非安全调试访问；密钥 6仅提供非安全调试访问。当仅安装单个密钥时，该密钥同时提供安全和非安全调试访问。

通过SWD输入密钥时，首先向`DBGKEY.RESET`写入 1。然后依次向`DBGKEY.DATA`写入128位数据，每写入一位，同时向`DBGKEY.PUSH`写入 1。数据应以LSB优先顺序写入，起始于编号最低的OTP行。

假设您写入的值匹配已安装的某个调试密钥，则在第128次按压后，调试功能将被解锁。Mem-APCSW寄存器中的`SDeviceEn`和`DeviceEn`标志指示操作的成功或失败。

若未通过RP-AP提供匹配的密钥，则调试功能将被禁用（若原本应启用）。然而，若因其他原因已被禁用，则即使提供密钥，调试功能也不会启用。例如，当CRIT1.DEBUG\_DISABLE被设置，且

**DEBUGEN** is clear, debug is be disabled no matter the state of the debug keys and the RP-AP.

### 3.5.10. RP-AP

The RP-AP is a small register block which is always accessible over SWD. RP-AP access does not require the switched core domain to be powered up, or any internal system clock generators to be running.

#### 3.5.10.1. List of registers

The RP-AP registers start at offset **0x80000** in the debug address space, which is accessed via address **0x80000** in the SW-DP's SELECT register. Unlike the other APs, it can not be accessed directly from the system bus.

Table 99. List of RP\_AP registers

| Offset | Name                                 | Info                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

DEBUGEN位被清除时，无论调试密钥和RP-AP的状态如何，调试功能均被禁用。

### 3.5.10. RP-AP

RP-AP为一个小型寄存器块，始终可通过SWD访问。访问RP-AP无需切换核心域供电，也无需任何内部系统时钟发生器运行。

#### 3.5.10.1. 寄存器列表

RP-AP寄存器起始于调试地址空间偏移量 `0x80000`，访问地址位于SW-DP的SELECT寄存器中的 `0x80000`。与其他AP不同，无法直接通过系统总线访问。

表99.  
RP\_AP寄存器列表

| 偏移量   | 名称                                   | 说明                                                                                                                                                                                                                                                                                                                                             |

## RP\_AP: CTRL Register

**Offset:** 0x000

### Description

This register is primarily used for DFT but can also be used to overcome some power up problems. However, it should not be used to force power up of domains. Use DBG\_POW\_OVRD for that.

Table 100. CTRL Register

| 偏移量   | 名称                     | 说明                                                                                                                                                                                                                                                                                                                              |

## RP\_AP: CTRL 寄存器

偏移：0x000

### 描述

该寄存器主要用于DFT，也可用于解决部分上电问题。但不应使用该寄存器强制域的上电。请使用DBG\_POW\_OVRD实现此功能。

表 100. CTRL  
寄存器

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Type | Reset |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31   | <b>RESCUE_RESTART</b> : Allows debug of boot problems by restarting the chip with minimal boot code execution. Write to 1 to put the chip in reset then write to 0 to restart the chip with the rescue flag set. The rescue flag is in the POWMAN_CHIP_RESET register and is read by boot code. The rescue flag is cleared by writing 0 to POWMAN_CHIP_RESET_RESCUE_FLAG or by resetting the chip by any means other than RESCUE_RESTART.                                                                                                                                                                                          | RW   | 0x0   |
| 30   | <b>SPARE</b> : Unused                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | RW   | 0x0   |
| 29:7 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | -    | -     |
| 6    | <b>DBG_FRCE_GPIO_LPCK</b> : Allows chip start-up when the Low Power Oscillator (LPOSC) is inoperative or malfunctioning and also allows the initial power sequencing rate to be adjusted. Write to 1 to force the LPOSC output to be driven from a GPIO (gpio20 on 80-pin package, gpio34 on the 60-pin package). If the LPOSC is inoperative or malfunctioning it may also be necessary to set the LPOSC_STABLE_FRCE bit in this register. The user must provide a clock on the GPIO. For normal operation use a clock running at around 32kHz. Adjusting the frequency will speed up or slow down the initial power-up sequence. | RW   | 0x0   |
| 5    | <b>LPOSC_STABLE_FRCE</b> : Allows the chip to start-up even though the Low Power Oscillator (LPOSC) is failing to set its stable flag. Initial power sequencing is clocked by LPOSC at around 32kHz but does not start until the LPOSC declares itself to be stable. If the LPOSC is otherwise working correctly the chip will boot when this bit is set. If the LPOSC is not working then DBG_FRCE_GPIO_LPCK must be set and an external clock provided.                                                                                                                                                                          | RW   | 0x0   |
| 4    | <b>POWMAN_DFT_ISO_OFF</b> : Holds the isolation gates between power domains in the open state. This is intended to hold the gates open for DFT and power manager debug. It is not intended to force the isolation gates open. Use the overrides in DBG_POW_OVRD to force the isolation gates open or closed.                                                                                                                                                                                                                                                                                                                       | RW   | 0x0   |
| 3    | <b>POWMAN_DFT_PWRON</b> : Holds the power switches on for all domains. This is intended to keep the power on for DFT and debug, rather than for switching the power on. The power switches are not sequenced and the sudden demand for current could cause the always-on power domain to brown out. This register is in the always-on domain therefore chaos could ensue. It is recommended to use the DBG_POW_OVRD controls instead.                                                                                                                                                                                              | RW   | 0x0   |
| 2    | <b>POWMAN_DBGMODE</b> : This prevents the power manager from powering down and resetting the switched-core power domain. It is intended for DFT and for debugging the power manager after the chip has booted. It cannot be used to force initial power on because it simultaneously deasserts the reset.                                                                                                                                                                                                                                                                                                                          | RW   | 0x0   |
| 1    | <b>JTAG_FUNCSEL</b> : Multiplexes the JTAG ports onto GPIO0-3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | RW   | 0x0   |
| 0    | <b>JTAG_TRSTN</b> : Resets the JTAG module. Active low.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | RW   | 0x0   |

## RP\_AP: DBGKEY Register

Offset: 0x004

### Description

Serial key load interface (write-only)

Table 101. DBGKEY Register

| Bits | Description | Type | Reset |
|------|-------------|------|-------|
| 31:3 | Reserved.   | -    | -     |

| 位    | 描述                                                                                                                                                                                                                                                 | 类型 | 复位  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31   | <b>RESCUE_RESTART</b> : 通过以最小引导代码执行重启芯片，允许对引导问题进行调试。写入1以将芯片置于复位状态，随后写入0，在设定救援标志后重新启动芯片。救援标志位于POWMAN_CHIP_RESET寄存器，由引导程序读取。通过向POWMAN_CHIP_RESET_RESCUE_FLAG写入0，或通过除RESCUE_RESTART以外的任何方式复位芯片，可清除救援标志。                                               | 读写 | 0x0 |
| 30   | <b>SPARE</b> : 未使用                                                                                                                                                                                                                                 | 读写 | 0x0 |
| 29:7 | 保留。                                                                                                                                                                                                                                                | -  | -   |
| 6    | <b>DBG_FRCE_GPIO_LPCK</b> : 当低功耗振荡器 (LPOSOC) 失效或异常时，允许芯片启动，并允许调整初始电源序列速率。写入1以强制将LPOSOC输出驱动切换至GPIO（80针封装为gpio20，60针封装为gpio34）。<br><br>若LPOSOC失效或异常，可能还需设置此寄存器中的LPOSOC_STABLE_FRCE位。用户必须在GPIO上提供时钟信号。正常运行时，时钟频率应约为32kHz。<br><br>调整频率将加快或减慢初始上电序列的速度。 | 读写 | 0x0 |
| 5    | <b>LPOSOC_STABLE_FRCE</b> : 允许芯片启动，即使低功耗振荡器 (LPOSOC) 未能设置其稳定标志。初始上电时序由约32kHz的LPOSOC提供时钟，但直到LPOSOC声明稳定前，此时序不会启动。如果LPOSOC正常工作，设置此位后芯片将启动；若LPOSOC异常，则必须设置DBG_FRCE_GPIO_LPCK并提供外部时钟。                                                                   | 读写 | 0x0 |
| 4    | <b>POWMAN_DFT_ISO_OFF</b> : 保持电源域之间的隔离门处于打开状态。此功能用于为DFT和电源管理调试保持隔离门开启。该功能并非用于强制隔离门开启。可使用DBG_POW_OVRD中的覆盖功能强制隔离门开启或关闭。                                                                                                                              | 读写 | 0x0 |
| 3    | <b>POWMAN_DFT_PWRON</b> : 保持所有电源域的电源开关处于开启状态。此功能旨在保持电源供给以支持DFT和调试，而非用于开启电源。电源开关未按顺序切换，突发的电流需求可能导致始终通电域电压下降。该寄存器位于始终通电域，故可能引发混乱。建议使用DBG_POW_OVRD控制。                                                                                                 | 读写 | 0x0 |
| 2    | <b>POWMAN_DBGMODE</b> : 防止电源管理器关闭电源及重置切换核心电源域。设计用于芯片启动后对电源管理器进行DFT及调试。不可用于强制初始通电，因为该操作会同时解除复位信号。                                                                                                                                                   | 读写 | 0x0 |
| 1    | <b>JTAG_FUNCSEL</b> : 将JTAG端口复用至GPIO0-3。                                                                                                                                                                                                           | 读写 | 0x0 |
| 0    | <b>JTAG_TRSTN</b> : 复位JTAG模块，低电平有效。                                                                                                                                                                                                                | 读写 | 0x0 |

## RP\_AP: DBG\_POW\_STATE\_SWCORE Register

Offset: 0x008

### Description

This register indicates the state of the power sequencer for the switched-core domain.

The sequencer timing is managed by the POWMAN\_SEQ\_\* registers. See the header file for those registers for more information on the timing.

Power up of the domain commences by clearing bit 0 (IS\_PD) then bits 1-8 are set in sequence. Bit 8 (IS\_PU) indicates the sequence is complete.

Power down of the domain commences by clearing bit 8 (IS\_PU) then bits 7-1 are cleared in sequence. Bit 0 (IS\_PU) is then set to indicate the sequence is complete.

Bits 9-11 describe the states of the power manager clocks which change as clock generators in the switched-core become available following switched-core power up.

This bus can be sent to GPIO for debug. See DBG\_POW\_OUTPUT\_TO\_GPIO in the DBG\_POW\_OVRD register.

Table 102.  
DBG\_POW\_STATE\_SW  
CORE Register

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Type | Reset |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:12 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | -    | -     |
| 11    | <b>USING_FAST_POWCK</b> : Indicates the source of the power manager clock. On switched-core power up the clock switches from the LPOSC to clk_ref and this flag will be set. clk_ref will be running from the ROSC initially but will switch to XOSC when it comes available. On switched-core power down the clock switches to LPOSC and this flag will be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | RO   | 0x0   |
| 10    | <b>WAITING_POWCK</b> : Indicates the switched-core power sequencer is waiting for the power manager clock to update. On switched-core power up the clock switches from the LPOSC to clk_ref. clk_ref will be running from the ROSC initially but will switch to XOSC when it comes available. On switched-core power down the clock switches to LPOSC.<br><br>If the switched-core power up sequence stalls with this flag active then it means clk_ref is not running which indicates a problem with the ROSC. If that happens then set DBG_POW_RESTART_FROM_XOSC in the DBG_POW_OVRD register to avoid using the ROSC.<br><br>If the switched-core power down sequence stalls with this flag active then it means LPOSC is not running. The solution is to not stop LPOSC when the switched-core power domain is powered. | RO   | 0x0   |
| 9     | <b>WAITING_TIMCK</b> : Indicates that the switched-core power sequencer is waiting for the AON-Timer to update. On switched-core power-up there is nothing to be done. The AON-Timer continues to run from the LPOSC so this flag will not be set. Software decides whether to switch the AON-Timer clock to XOSC (via clk_ref). On switched-core power-down the sequencer will switch the AON-Timer back to LPOSC if software switched it to XOSC. During the switchover the WAITING_TIMCK flag will be set. If the switched-core power down sequence stalls with this flag active then the only recourse is to reset the chip and change software to not select XOSC as the AON-Timer source.                                                                                                                             | RO   | 0x0   |
| 8     | <b>IS_PU</b> : Indicates the power domain is fully powered up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | RO   | 0x0   |

## RP\_AP: DBG\_POW\_STATE\_SWCORE寄存器

偏移: 0x008

### 描述

该寄存器指示切换核心域电源序列器的状态。

序列器的时序由POWMAN\_SEQ\_\*寄存器控制。有关时序的更多信息，请参阅这些寄存器的头文件。

域的上电通过清除第0位 (IS\_PD) , 随后依次设置第1至第8位开始。第8位 (IS\_PU) 指示序列完成。

域断电通过清除第8位 (IS\_PU) 开始, 然后依次清除第7至第1位。随后将位0 (IS\_PU) 设置, 以指示序列已完成。

位9至11描述电源管理时钟的状态, 该状态随着切换核心电源启动后切换核心中时钟发生器的可用性而变化。

该总线可通过GPIO进行调试。详见DBG\_POW\_OVRD寄存器中的DBG\_POW\_OUTPUT\_TO\_GPIO。

| 位     | 描述                                                                                                                                                                                                                                                                                                                               | 类型 | 复位  |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31:12 | 保留。                                                                                                                                                                                                                                                                                                                              | -  | -   |
| 11    | <b>USING_FAST_POWCK</b> : 指示电源管理时钟的来源。在切换核心上电时, 时钟由LPOSOC切换至clk_ref, 该标志置位。clk_ref最初由ROSC提供, 但在XOSC可用后切换至XOSC。在切换核心断电时, 时钟切换至LPOSOC, 该标志被清除。                                                                                                                                                                                     | 只读 | 0x0 |
| 10    | <b>WAITING_POWCK</b> : 指示切换核心电源序列器正在等待电源管理时钟更新。切换核心上电时, 时钟由LPOSOC切换至clk_ref。clk_ref初始由ROSC驱动运行, 但当XOSC可用时将切换至XOSC。切换核心断电时, 时钟切换至LPOSOC。<br><br>若切换核心上电序列在该标志激活时停止, 表示clk_ref未运行, 说明ROSC存在问题。发生此情况时, 应在DBG_POW_OVRD寄存器中设置DBG_POW_RSTSTART_FROM_XOSC, 以避免使用ROSC。<br><br>若切换核心断电序列在该标志激活时停止, 表示LPOSOC未运行。解决方案是在切换核心电源域供电时不停止LPOSOC。 | 只读 | 0x0 |
| 9     | <b>WAITING_TIMCK</b> : 指示切换核心电源顺序器正在等待AON计时器更新。切换核心上电时无需执行任何操作。AON计时器继续由LPOSOC驱动运行, 因此该标志不会被设置。软件决定是否将AON计时器时钟切换至XOSC (通过clk_ref)。在切换核心断电时, 序列器将把AON计时器切换回LPOSOC, 若软件已将其切换至XOSC。切换过程中, WAITING_TIMCK标志将被置位。如切换核心断电序列在此标志激活时停滞, 唯一方案是重置芯片, 并调整软件以避免选择XOSC作为AON计时器时钟源。                                                             | 只读 | 0x0 |
| 8     | <b>IS_PU</b> : 表示电源域已完全上电。                                                                                                                                                                                                                                                                                                       | 只读 | 0x0 |
| 7     | <b>RESET_FROM_SEQ</b> : 表示对电源域的复位状态。                                                                                                                                                                                                                                                                                             | 只读 | 0x0 |

| Bits | Description                                                                                                                                                                                                                                                                                                                                    | Type | Reset |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 6    | <b>ENAB_ACK</b> : Indicates the state of the enable to the power domain.                                                                                                                                                                                                                                                                       | RO   | 0x0   |
| 5    | <b>ISOLATE_FROM_SEQ</b> : Indicates the state of the isolation control to the power domain.                                                                                                                                                                                                                                                    | RO   | 0x0   |
| 4    | <b>LARGE_ACK</b> : Indicates the state of the large power switches for the power domain.                                                                                                                                                                                                                                                       | RO   | 0x0   |
| 3    | <b>SMALL_ACK2</b> : The small switches are split into 3 chains. In the power up sequence they are switched on separately to allow management of the VDD rise time. In the power down sequence they switch off simultaneously with the large power switches.<br>This bit indicates the state of the last element in small power switch chain 2. | RO   | 0x0   |
| 2    | <b>SMALL_ACK1</b> : This bit indicates the state of the last element in small power switch chain 1.                                                                                                                                                                                                                                            | RO   | 0x0   |

## RP\_AP: DBG\_POW\_STATE\_XIP Register

Offset: 0x00c

### Description

This register indicates the state of the power sequencer for the XIP domain.

The sequencer timing is managed by the POWMAN\_SEQ\_\* registers. See the header file for those registers for more information on the timing.

Power up of the domain commences by clearing bit 0 (IS\_PD) then bits 1-8 are set in sequence. Bit 8 (IS\_PU) indicates the sequence is complete.

Power down of the domain commences by clearing bit 8 (IS\_PU) then bits 7-1 are cleared in sequence. Bit 0 (IS\_PU) is then set to indicate the sequence is complete.

Table 103.  
DBG\_POW\_STATE\_XIP  
Register

| Bits | Description                                                                                                                                                                                                                                                                                                                                    | Type | Reset |

## RP\_AP: DBG\_POW\_STATE\_XIP 寄存器

偏移量: 0x00c

### 描述

此寄存器指示XIP域电源顺序器的状态。

序列器的时序由POWMAN\_SEQ\_\*寄存器控制。有关时序的更多信息，请参阅这些寄存器的头文件。

域的上电通过清除第0位 (IS\_PD) ，随后依次设置第1至第8位开始。第8位 (IS\_PU) 指示序列完成。

域断电通过清除第8位 (IS\_PU) 开始，然后依次清除第7至第1位。随后将位0 (IS\_PU) 设置，以指示序列已完成。

## RP\_AP: DBG\_POW\_STATE\_SRAM0 Register

Offset: 0x010

### Description

This register indicates the state of the power sequencer for the SRAM0 domain.

The sequencer timing is managed by the POWMAN\_SEQ\_\* registers. See the header file for those registers for more information on the timing.

Power up of the domain commences by clearing bit 0 (IS\_PD) then bits 1-8 are set in sequence. Bit 8 (IS\_PU) indicates the sequence is complete.

Power down of the domain commences by clearing bit 8 (IS\_PU) then bits 7-1 are cleared in sequence. Bit 0 (IS\_PU) is then set to indicate the sequence is complete.

## RP\_AP: DBG\_POW\_STATE\_SRAM1 Register

Offset: 0x014

### Description

This register indicates the state of the power sequencer for the SRAM1 domain.

The sequencer timing is managed by the POWMAN\_SEQ\_\* registers. See the header file for those registers for more information on the timing.

Power up of the domain commences by clearing bit 0 (IS\_PD) then bits 1-8 are set in sequence. Bit 8 (IS\_PU) indicates the sequence is complete.

Power down of the domain commences by clearing bit 8 (IS\_PU) then bits 7-1 are cleared in sequence. Bit 0 (IS\_PU) is then set to indicate the sequence is complete.

| 位 | 描述                         | 类型 | 复位  |
|---|----------------------------|----|-----|
| 0 | <b>IS_PD</b> : 指示电源域已完全断电。 | 只读 | 0x0 |

## RP\_AP: DBG\_POW\_STATE\_SRAM0 寄存器

偏移量: 0x010

### 描述

此寄存器指示SRAM0域电源顺序器的状态。

序列器的时序由POWMAN\_SEQ\_\*寄存器控制。有关时序的更多信息，请参阅这些寄存器的头文件。

域的上电通过清除第0位 (IS\_PD) , 随后依次设置第1至第8位开始。第8位 (IS\_PU) 指示序列完成。

域断电通过清除第8位 (IS\_PU) 开始, 然后依次清除第7至第1位。随后将位0 (IS\_PU) 设置, 以指示序列已完成。

## RP\_AP: DBG\_POW\_STATE\_SRAM1 寄存器

偏移量: 0x014

### 描述

此寄存器指示SRAM1域电源顺序器的状态。

序列器的时序由POWMAN\_SEQ\_\*寄存器控制。有关时序的更多信息，请参阅这些寄存器的头文件。

域的上电通过清除第0位 (IS\_PD) , 随后依次设置第1至第8位开始。第8位 (IS\_PU) 指示序列完成。

域断电通过清除第8位 (IS\_PU) 开始, 然后依次清除第7至第1位。随后将位0 (IS\_PU) 设置, 以指示序列已完成。

## RP\_AP: DBG\_POW\_OVRD Register

Offset: 0x018

### Description

This register allows external control of the power sequencer outputs for all the switched power domains. If any of the power sequencers stall at any stage then force power up operation of all domains by running this sequence:

- set DBG\_POW\_OVRD = 0x3b to force small power switches on, large power switches off, resets on and isolation on
- allow time for the domain power supplies to reach full rail
- set DBG\_POW\_OVRD = 0x3b to force large power switches on
- set DBG\_POW\_OVRD = 0x37 to remove isolation
- set DBG\_POW\_OVRD = 0x17 to remove resets

| 6    | <b>DBG_POW_RESTART_FROM_XOSC</b> : By default the system begins boot as soon as a clock is available from the ROSC, then it switches to the XOSC when it is available. This is done because the XOSC takes several ms to start up. If there is a problem with the ROSC then the default behaviour can be changed to not use the ROSC and wait for XOSC. However, this requires a mask change to modify the reset value of the Power Manager START_FROM_XOSC register. To allow experimentation the default can be temporarily changed by setting this register bit to 1. After setting this bit the core must be reset by a Coresight dprst or a rescue reset (see RESCUE_RESTART in the RP_AP_CTRL register above). A power-on reset, brown-out reset or RUN pin reset will reset this control and revert to the default behaviour. | RW   | 0x0   |

| 0    | <b>IS_PD</b> : 指示电源域已完全断电。                                                                                        | 只读 | 0x0 |

## RP\_AP: DBG\_POW\_OVRD 寄存器

偏移量: 0x018

### 描述

该寄存器允许对所有切换电源域的电源顺序器输出进行外部控制。如果任何电源顺序器在任一阶段停滞，则通过执行以下序列强制所有域的电源开启：

- 设置 **DBG\_POW\_OVRD** = 0x3b，强制小功率开关闭合，大功率开关断开，复位开启，并启用隔离
- 等待电源域电源达到满电压
- 设置 **DBG\_POW\_OVRD** = 0x3b，强制大功率开关闭合
- 设置 **DBG\_POW\_OVRD** = 0x37，取消隔离
- 设置 **DBG\_POW\_OVRD** = 0x17，取消复位

|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31:7 | 保留。                                                                                                                                                                                                                                                                                                                             | -  | -   |
| 6    | <b>DBG_POW_RESTART_FROM_XOSC</b> : 系统默认在 ROSC 提供时钟后立即启动，待 XOSC 可用时切换至 XOSC。之所以如此，是因为 XOSC 启动需数毫秒。如 ROSC 出现问题，可更改默认行为，停止使用 ROSC，改为等待 XOSC。但这需修改电源管理器 START_FROM_XOSC 寄存器的复位值掩码。<br><br>为了允许实验，默认值可以通过将此寄存器位设置为1来临时更改。设置此位后，必须通过Coresight dprst或救援复位（参见上述RP_AP_CTRL寄存器中的RESCUE_RESTART）对内核进行复位。上电复位、欠压复位或RUN引脚复位将复位该控制位，并恢复为默认行为。 | 读写 | 0x0 |

| Bits | Description                                                                                                                                                                                                                                                                                                             | Type | Reset |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 5    | <b>DBG_POW_RESET</b> : When DBG_POW_OVRD_RESET=1 this register bit controls the resets for all domains. 1 = reset. 0 = not reset.                                                                                                                                                                                       | RW   | 0x0   |
| 4    | <b>DBG_POW_OVRD_RESET</b> : Enables DBG_POW_RESET to control the resets for the power manager and the switched-core. Essentially that is everything except the Coresight 2-wire interface and the RP_AP registers.                                                                                                      | RW   | 0x0   |
| 3    | <b>DBG_POW_ISO</b> : When DBG_POW_OVRD_ISO=1 this register bit controls the isolation gates for all domains. 1 = isolated. 0 = not isolated.                                                                                                                                                                            | RW   | 0x0   |
| 2    | <b>DBG_POW_OVRD_ISO</b> : Enables DBG_POW_ISO to control the isolation gates between domains.                                                                                                                                                                                                                           | RW   | 0x0   |
| 1    | <b>DBG_POW_OVRD_LARGE_REQ</b> : Turn on the large power switches for all domains. This should not be done until sufficient time has been allowed for the small switches to bring the supplies up. Switching the large switches on too soon risks browning out the always-on domain and corrupting these very registers. | RW   | 0x0   |
| 0    | <b>DBG_POW_OVRD_SMALL_REQ</b> : Turn on the small power switches for all domains. This switches on chain 0 for each domain and switches off chains 2 & 3 and the large power switch chain. This will bring the power up for all domains without browning out the always-on power domain.                                | RW   | 0x0   |

## RP\_AP: DBG\_POW\_OUTPUT\_TO\_GPIO Register

Offset: 0x01c

### Description

Send some, or all, bits of DBG\_POW\_STATE\_SWCORE to gpios.

Bit 0 sends bit 0 of DBG\_POW\_STATE\_SWCORE to GPIO 34

Bit 1 sends bit 1 of DBG\_POW\_STATE\_SWCORE to GPIO 35

Bit 2 sends bit 2 of DBG\_POW\_STATE\_SWCORE to GPIO 36

1. +

2. + Bit 11 sends bit 11 of DBG\_POW\_STATE\_SWCORE to GPIO 45

Table 107.  
DBG\_POW\_OUTPUT\_TO\_GPIO Register

| Bits  | Description   | Type | Reset |

| 31:0 | Standard Coresight ID Register | RO   | -     |

## 3.6. Cortex-M33 coprocessors

The Cortex-M33 features a coprocessor port which transfers up to 64 bits per cycle between the processor and certain closely-coupled hardware. The Cortex-M33's built-in floating-point unit is an example of such a coprocessor, but RP2350 adds three device-specific coprocessors to this interface. The following sections document these coprocessors.

| 位 | 描述                                                                                                        | 类型 | 复位  |
|---|-----------------------------------------------------------------------------------------------------------|----|-----|
| 5 | <b>DBG_POW_RESET:</b> 当DBG_POW_OVRD_RESET=1时，此寄存器位控制所有域的复位。1=复位，0=不复位。                                    | 读写 | 0x0 |
| 4 | <b>DBG_POW_OVRD_RESET:</b> 使DBG_POW_RESET能够控制电源管理器和切换内核的复位。基本上，除了Coresight双线接口和RP_AP寄存器外，涵盖所有内容。          | 读写 | 0x0 |
| 3 | <b>DBG_POW_ISO:</b> 当DBG_POW_OVRD_ISO=1时，此寄存器位控制所有域的隔离闸门。1=隔离，0=未隔离。                                      | 读写 | 0x0 |
| 2 | <b>DBG_POW_OVRD_ISO:</b> 使能DBG_POW_ISO以控制域间隔离门。                                                           | 读写 | 0x0 |
| 1 | <b>DBG_POW_OVRD_LARGE_REQ:</b> 开启所有域的大功率开关。应在小功率开关充分升压后进行此操作。过早开启大功率开关会导致始终开启域电压降低，进而损坏相关寄存器。             | 读写 | 0x0 |
| 0 | <b>DBG_POW_OVRD_SMALL_REQ:</b> 开启所有域的小功率开关。此操作开启每个域的链路0，同时关闭链路2、链路3及大功率开关链路。该操作将提升所有域的电源，且不会使始终开启电源域电压下降。 | 读写 | 0x0 |

## RP\_AP: DBG\_POW\_OUTPUT\_TO\_GPIO 寄存器

偏移量: 0x01c

### 描述

将DBG\_POW\_STATE\_SWCORE的部分或全部位发送至GPIO。

位0 将DBG\_POW\_STATE\_SWCORE的第0位发送至GPIO 34

位1 将DBG\_POW\_STATE\_SWCORE的第1位发送至GPIO 35

位2 将DBG\_POW\_STATE\_SWCORE的第2位发送至GPIO 36

1. +

2. + 位11将DBG\_POW\_STATE\_SWCORE的第11位信号输出至GPIO 45

表107。

## 3.6. Cortex-M33 协处理器

Cortex-M33 配备一个协处理器端口，能够在处理器与某些紧密耦合的硬件之间每个周期传输最多64位数据。Cortex-M33 内置的浮点单元即为此类协处理器的示例，RP2350 在该接口上新增了三个设备专用协处理器。以下章节对这些协处理器进行详尽说明。

Before accessing a coprocessor from Secure code, that coprocessor must first be enabled by setting the corresponding bit in the CPACR. Before accessing from the Non-secure state, the corresponding bits in the NSACR and CPACR\_NS registers must be set.

The RISC-V processors on RP2350 do not have access to the Cortex-M33 coprocessors.

### 3.6.1. GPIO coprocessor (GPIOC)

Coprocessor port 0 provides low-overhead access from the Cortex-M33 processors to the GPIO registers in the SIO ([Section 3.1.3](#)). This enables a single coprocessor instruction to sample all 48 GPIOs, or to set/clear/write any single GPIO, among other functionality.

Non-secure accesses are filtered according to the [GPIO\\_NSMASK0](#) and [GPIO\\_NSMASK1](#) registers in ACCESSCTRL. GPIOs not granted for Non-secure use will ignore writes from the Non-secure state, and read back as zero when read from the Non-secure state.

#### 3.6.1.1. OUT mask write instructions

These instructions write to multiple bits in the SIO [GPIO\\_OUT](#) and [GPIO\\_HI\\_OUT](#) registers.

| Mnemonic           | Armv8-M Instruction                   | Operation                                                                            |
|--------------------|---------------------------------------|--------------------------------------------------------------------------------------|
| gpioc_lo_out_put   | <code>mcr p0, #0, Rt, c0, c0</code>   | <code>sio_hw&gt;gpio_out = Rt;</code>                                                |
| gpioc_lo_out_xor   | <code>mcr p0, #1, Rt, c0, c0</code>   | <code>sio_hw&gt;gpio_togl = Rt;</code>                                               |
| gpioc_lo_out_set   | <code>mcr p0, #2, Rt, c0, c0</code>   | <code>sio_hw&gt;gpio_set = Rt;</code>                                                |
| gpioc_lo_out_clr   | <code>mcr p0, #3, Rt, c0, c0</code>   | <code>sio_hw&gt;gpio_clr = Rt;</code>                                                |
| gpioc_hi_out_put   | <code>mcr p0, #0, Rt, c0, c1</code>   | <code>sio_hw&gt;gpio_hi_out = Rt;</code>                                             |
| gpioc_hi_out_xor   | <code>mcr p0, #1, Rt, c0, c1</code>   | <code>sio_hw&gt;gpio_hi_togl = Rt;</code>                                            |
| gpioc_hi_out_set   | <code>mcr p0, #2, Rt, c0, c1</code>   | <code>sio_hw&gt;gpio_hi_set = Rt;</code>                                             |
| gpioc_hi_out_clr   | <code>mcr p0, #3, Rt, c0, c1</code>   | <code>sio_hw&gt;gpio_hi_clr = Rt;</code>                                             |
| gpioc_hilo_out_put | <code>mcrr p0, #0, Rt, Rt2, c0</code> | Simultaneously: <code>sio_hw&gt;gpio_out = Rt; sio_hw&gt;gpio_hi_out = Rt2;</code>   |
| gpioc_hilo_out_xor | <code>mcrr p0, #1, Rt, Rt2, c0</code> | Simultaneously: <code>sio_hw&gt;gpio_togl = Rt; sio_hw&gt;gpio_hi_togl = Rt2;</code> |
| gpioc_hilo_out_set | <code>mcrr p0, #2, Rt, Rt2, c0</code> | Simultaneously: <code>sio_hw&gt;gpio_set = Rt; sio_hw&gt;gpio_hi_set = Rt2;</code>   |
| gpioc_hilo_out_clr | <code>mcrr p0, #3, Rt, Rt2, c0</code> | Simultaneously: <code>sio_hw&gt;gpio_clr = Rt; sio_hw&gt;gpio_hi_clr = Rt2;</code>   |

#### 3.6.1.2. OE mask write instructions

These instructions write to multiple bits in the SIO [GPIO\\_OE](#) and [GPIO\\_HI\\_OE](#) registers.

| Mnemonic        | Armv8-M Instruction                 | Operation                                    |
|-----------------|-------------------------------------|----------------------------------------------|
| gpioc_lo_oe_put | <code>mcr p0, #0, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe = Rt;</code>         |
| gpioc_lo_oe_xor | <code>mcr p0, #1, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe_togl = Rt;</code>    |
| gpioc_lo_oe_set | <code>mcr p0, #2, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe_set = Rt;</code>     |
| gpioc_lo_oe_clr | <code>mcr p0, #3, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe_clr = Rt;</code>     |
| gpioc_hi_oe_put | <code>mcr p0, #0, Rt, c0, c5</code> | <code>sio_hw&gt;gpio_hi_oe = Rt;</code>      |
| gpioc_hi_oe_xor | <code>mcr p0, #1, Rt, c0, c5</code> | <code>sio_hw&gt;gpio_hi_oe_togl = Rt;</code> |

在安全代码中访问协处理器之前，必须先通过设置 CPACR 中相应位启用该协处理器。非安全状态下访问时，须设置 NSA CR 和 CPACR\_NS 寄存器中的对应位。

RP2350 上的 RISC-V 处理器无法访问 Cortex-M33 协处理器。

### 3.6.1. GPIO 协处理器 (GPIOC)

协处理器端口 0 为 Cortex-M33 处理器对 SIO 中 GPIO 寄存器（第 3.1.3 节）提供低开销访问。该端口支持单条协处理器指令采样所有 48 个 GPIO，或设置、清除、写入任一单个 GPIO，及其他功能。

根据 ACCESSCTRL 中的 GPIO\_NSMASK0 和 GPIO\_NSMASK1 寄存器，非安全访问将被过滤。

未授权非安全使用的 GPIO 将忽略来自非安全状态的写入操作，且在非安全状态读取时返回零。

#### 3.6.1.1. OUT 掩码写入指令

这些指令写入 SIO GPIO\_OUT 和 GPIO\_HI\_OUT 寄存器中的多个位。

| 助记符                | Armv8-M 指令                           | 操作                                                                       |
|--------------------|--------------------------------------|--------------------------------------------------------------------------|
| gpioc_lo_out_put   | <code>mcr p0, #0, Rt, c0, c0</code>  | <code>sio_hw&gt;gpio_out = Rt;</code>                                    |
| gpioc_lo_out_xor   | <code>mcr p0, #1, Rt, c0, c0</code>  | <code>sio_hw&gt;gpio_togl = Rt;</code>                                   |
| gpioc_lo_out_set   | <code>mcr p0, #2, Rt, c0, c0</code>  | <code>sio_hw&gt;gpio_set = Rt;</code>                                    |
| gpioc_lo_out_clr   | <code>mcr p0, #3, Rt, c0, c0</code>  | <code>sio_hw&gt;gpio_clr = Rt;</code>                                    |
| gpioc_hi_out_put   | <code>mcr p0, #0, Rt, c0, c1</code>  | <code>sio_hw&gt;gpio_hi_out = Rt;</code>                                 |
| gpioc_hi_out_xor   | <code>mcr p0, #1, Rt, c0, c1</code>  | <code>sio_hw&gt;gpio_hi_togl = Rt;</code>                                |
| gpioc_hi_out_set   | <code>mcr p0, #2, Rt, c0, c1</code>  | <code>sio_hw&gt;gpio_hi_set = Rt;</code>                                 |
| gpioc_hi_out_clr   | <code>mcr p0, #3, Rt, c0, c1</code>  | <code>sio_hw&gt;gpio_hi_clr = Rt;</code>                                 |
| gpioc_hilo_out_put | <code>mcr p0, #0, Rt, Rt2, c0</code> | 同时： <code>sio_hw&gt;gpio_out = Rt; sio_hw&gt;gpio_hi_out = Rt2;</code>   |
| gpioc_hilo_out_xor | <code>mcr p0, #1, Rt, Rt2, c0</code> | 同时： <code>sio_hw&gt;gpio_togl = Rt; sio_hw&gt;gpio_hi_togl = Rt2;</code> |
| gpioc_hilo_out_set | <code>mcr p0, #2, Rt, Rt2, c0</code> | 同时： <code>sio_hw&gt;gpio_set = Rt; sio_hw&gt;gpio_hi_set = Rt2;</code>   |
| gpioc_hilo_out_clr | <code>mcr p0, #3, Rt, Rt2, c0</code> | 同时执行： <code>sio_hw&gt;gpio_clr = Rt; sio_hw&gt;gpio_hi_clr = Rt2;</code> |

#### 3.6.1.2. OE 掩码写入指令

这些指令用于写入 SIO GPIO\_OE 及 GPIO\_HI\_OE 寄存器的多个位。

| 助记符             | Armv8-M 指令                          | 操作                                           |
|-----------------|-------------------------------------|----------------------------------------------|
| gpioc_lo_oe_put | <code>mcr p0, #0, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe = Rt;</code>         |
| gpioc_lo_oe_xor | <code>mcr p0, #1, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe_togl = Rt;</code>    |
| gpioc_lo_oe_set | <code>mcr p0, #2, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe_set = Rt;</code>     |
| gpioc_lo_oe_clr | <code>mcr p0, #3, Rt, c0, c4</code> | <code>sio_hw&gt;gpio_oe_clr = Rt;</code>     |
| gpioc_hi_oe_put | <code>mcr p0, #0, Rt, c0, c5</code> | <code>sio_hw&gt;gpio_hi_oe = Rt;</code>      |

### 3.6.1.3. Single-bit write instructions

These instructions write to a single, indexed bit in either the `GPIO_OUT` and `GPIO_HI_OUT` registers, or the `GPIO_OE` and `GPIO_HI_OE` registers.

| Mnemonic           | Armv8-M Instruction                   | Operation                                                                                                                                                             |
|--------------------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| gpioc_bit_out_put  | <code>mcrr p0, #4, Rt, Rt2, c0</code> | Write a 1-bit value to any output. Equivalent to: <code>if (Rt2 &amp; 1) gpioc_hilo_out_set(1ull &lt;&lt; Rt); else gpioc_hilo_out_clr(1ull &lt;&lt; Rt);</code>      |
| gpioc_bit_out_xor  | <code>mcr p0, #5, Rt, c0, c0</code>   | Unconditionally toggle any single output. Equivalent to: <code>gpioc_hilo_out_xor(1ull &lt;&lt; Rt);</code>                                                           |
| gpioc_bit_out_set  | <code>mcr p0, #6, Rt, c0, c0</code>   | Unconditionally set any single output. Equivalent to: <code>gpioc_hilo_out_set(1ull &lt;&lt; Rt);</code>                                                              |
| gpioc_bit_out_clr  | <code>mcr p0, #7, Rt, c0, c0</code>   | Unconditionally clear any single output. Equivalent to: <code>gpioc_hilo_out_clr(1ull &lt;&lt; Rt);</code>                                                            |
| gpioc_bit_out_xor2 | <code>mcrr p0, #5, Rt, Rt2, c0</code> | Conditionally toggle any single output. Equivalent to: <code>gpioc_hilo_out_xor((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                          |
| gpioc_bit_out_set2 | <code>mcrr p0, #6, Rt, Rt2, c0</code> | Conditionally set any single output. Equivalent to: <code>gpioc_hilo_out_set((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                             |
| gpioc_bit_out_clr2 | <code>mcrr p0, #7, Rt, Rt2, c0</code> | Conditionally clear any single output. Equivalent to: <code>gpioc_hilo_out_clr((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                           |
| gpioc_bit_oe_put   | <code>mcrr p0, #4, Rt, Rt2, c4</code> | Write a 1-bit value to any output enable. Equivalent to: <code>if (Rt2 &amp; 1) gpioc_hilo_oe_set(1ull &lt;&lt; Rt); else gpioc_hilo_oe_clr(1ull &lt;&lt; Rt);</code> |
| gpioc_bit_oe_xor   | <code>mcr p0, #5, Rt, c0, c4</code>   | Unconditionally toggle any output enable. Equivalent to: <code>gpioc_hilo_oe_xor(1ull &lt;&lt; Rt);</code>                                                            |
| gpioc_bit_oe_set   | <code>mcr p0, #6, Rt, c0, c4</code>   | Unconditionally set any output enable (set to output). Equivalent to: <code>gpioc_hilo_oe_set(1ull &lt;&lt; Rt);</code>                                               |
| gpioc_bit_oe_clr   | <code>mcr p0, #7, Rt, c0, c4</code>   | Unconditionally clear any output enable (set to input). Equivalent to: <code>gpioc_hilo_oe_clr(1ull &lt;&lt; Rt);</code>                                              |
| gpioc_bit_oe_xor2  | <code>mcrr p0, #5, Rt, Rt2, c4</code> | Conditionally toggle any output enable. Equivalent to: <code>gpioc_hilo_oe_xor((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                           |
| gpioc_bit_oe_set2  | <code>mcrr p0, #6, Rt, Rt2, c4</code> | Conditionally set any output enable (set to output). Equivalent to: <code>gpioc_hilo_oe_set((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                              |
| gpioc_bit_oe_clr2  | <code>mcrr p0, #7, Rt, Rt2, c4</code> | Conditionally clear any output enable (set to input). Equivalent to: <code>gpioc_hilo_oe_clr((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                             |

| 助记符               | Armv8-M 指令                            | 操作                                                                                 |
|-------------------|---------------------------------------|------------------------------------------------------------------------------------|
| gpioc_hi_oe_set   | <code>mcr p0, #2, Rt, c0, c5</code>   | <code>sio_hw-&gt;gpio_hi_oe_set = Rt;</code>                                       |
| gpioc_hi_oe_clr   | <code>mcr p0, #3, Rt, c0, c5</code>   | <code>sio_hw-&gt;gpio_hi_oe_clr = Rt;</code>                                       |
| gpioc_hilo_oe_put | <code>mcrr p0, #0, Rt, Rt2, c4</code> | 同时执行: <code>sio_hw-&gt;gpio_oe = Rt; sio_hw-&gt;gpio_hi_oe = Rt2;</code>           |
| gpioc_hilo_oe_xor | <code>mcrr p0, #1, Rt, Rt2, c4</code> | 同时执行: <code>sio_hw-&gt;gpio_oe_togl = Rt; sio_hw-&gt;gpio_hi_oe_togl = Rt2;</code> |
| gpioc_hilo_oe_set | <code>mcrr p0, #2, Rt, Rt2, c4</code> | 同时执行: <code>sio_hw-&gt;gpio_oe_set = Rt; sio_hw-&gt;gpio_hi_oe_set = Rt2;</code>   |
| gpioc_hilo_oe_clr | <code>mcrr p0, #3, Rt, Rt2, c4</code> | 同时执行: <code>sio_hw-&gt;gpio_oe_clr = Rt; sio_hw-&gt;gpio_hi_oe_clr = Rt2;</code>   |

### 3.6.1.3 单位比特写入指令

这些指令写入GPIO\_OUT和GPIO\_HI\_OUT寄存器，或GPIO\_OE和GPIO\_HI\_OE寄存器中单一索引位。

| 助记符                | Armv8-M 指令                            | 操作                                                                                                                              |
|--------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| gpioc_bit_out_put  | <code>mcrr p0, #4, Rt, Rt2, c0</code> | 向任意输出写入单比特值。等同于: <code>if (Rt2 &amp; 1) gpioc_hilo_out_set(1ull &lt;&lt; Rt); else gpioc_hilo_out_clr(1ull &lt;&lt; Rt);</code> |
| gpioc_bit_out_xor  | <code>mcr p0, #5, Rt, c0, c0</code>   | 无条件切换任意单个输出。等同于:<br><code>gpioc_hilo_out_xor(1ull &lt;&lt; Rt);</code>                                                          |
| gpioc_bit_out_set  | <code>mcr p0, #6, Rt, c0, c0</code>   | 无条件设置任意单个输出。等同于:<br><code>gpioc_hilo_out_set(1ull &lt;&lt; Rt);</code>                                                          |
| gpioc_bit_out_clr  | <code>mcr p0, #7, Rt, c0, c0</code>   | 无条件清除任意单个输出。等同于:<br><code>gpioc_hilo_out_clr(1ull &lt;&lt; Rt);</code>                                                          |
| gpioc_bit_out_xor2 | <code>mcrr p0, #5, Rt, Rt2, c0</code> | 有条件切换任意单个输出。等同于:<br><code>gpioc_hilo_out_xor((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                       |
| gpioc_bit_out_set2 | <code>mcrr p0, #6, Rt, Rt2, c0</code> | 有条件设置任意单个输出。等同于:<br><code>gpioc_hilo_out_set((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                       |
| gpioc_bit_out_clr2 | <code>mcrr p0, #7, Rt, Rt2, c0</code> | 有条件清除任意单个输出。等同于:<br><code>gpioc_hilo_out_clr((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                       |
| gpioc_bit_oe_put   | <code>mcrr p0, #4, Rt, Rt2, c4</code> | 向任意输出使能写入1位值。等同于: <code>if (Rt2 &amp; 1) gpioc_hilo_oe_set(1ull &lt;&lt; Rt); else gpioc_hilo_oe_clr(1ull &lt;&lt; Rt);</code>  |
| gpioc_bit_oe_xor   | <code>mcr p0, #5, Rt, c0, c4</code>   | 无条件切换任意输出使能。等同于:<br><code>gpioc_hilo_oe_xor(1ull &lt;&lt; Rt);</code>                                                           |
| gpioc_bit_oe_set   | <code>mcr p0, #6, Rt, c0, c4</code>   | 无条件设置任意输出使能（设为输出）。等同于:<br><code>gpioc_hilo_oe_set(1ull &lt;&lt; Rt);</code>                                                     |
| gpioc_bit_oe_clr   | <code>mcr p0, #7, Rt, c0, c4</code>   | 无条件清除任意输出使能（设为输入）。等同于:<br><code>gpioc_hilo_oe_clr(1ull &lt;&lt; Rt);</code>                                                     |
| gpioc_bit_oe_xor2  | <code>mcrr p0, #5, Rt, Rt2, c4</code> | 有条件地切换任意输出使能。等同于:<br><code>gpioc_hilo_oe_xor((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                       |
| gpioc_bit_oe_set2  | <code>mcrr p0, #6, Rt, Rt2, c4</code> | 有条件地设置任意输出使能（设为输出）。等同于:<br><code>gpioc_hilo_oe_set((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                 |
| gpioc_bit_oe_clr2  | <code>mcrr p0, #7, Rt, Rt2, c4</code> | 有条件地清除任意输出使能（设为输入）。等同于:<br><code>gpioc_hilo_oe_clr((uint64_t)(Rt2 &amp; 1) &lt;&lt; Rt);</code>                                 |

### 3.6.1.4. Indexed mask write instructions

These instructions write to a single, dynamically selected 32-bit GPIO register.

| Mnemonic                         | Armv8-M Instruction                     | Operation                                                                                                     |
|----------------------------------|-----------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>gpioc_index_out_put</code> | <code>mcr r p0, #8, Rt, Rt2, c0</code>  | Write <code>Rt</code> to a GPIO output register selected by <code>Rt2</code> .                                |
| <code>gpioc_index_out_xor</code> | <code>mcr r p0, #9, Rt, Rt2, c0</code>  | Toggle bits <code>Rt</code> in a GPIO output register selected by <code>Rt2</code> .                          |
| <code>gpioc_index_out_set</code> | <code>mcr r p0, #10, Rt, Rt2, c0</code> | Set bits <code>Rt</code> in a GPIO output register selected by <code>Rt2</code> .                             |
| <code>gpioc_index_out_clr</code> | <code>mcr r p0, #11, Rt, Rt2, c0</code> | Clear bits <code>Rt</code> in a GPIO output register selected by <code>Rt2</code> .                           |
| <code>gpioc_index_oe_put</code>  | <code>mcr r p0, #8, Rt, Rt2, c4</code>  | Write <code>Rt</code> to a GPIO output enable register selected by <code>Rt2</code> .                         |
| <code>gpioc_index_oe_xor</code>  | <code>mcr r p0, #9, Rt, Rt2, c4</code>  | Toggle bits <code>Rt</code> in a GPIO output enable register selected by <code>Rt2</code> .                   |
| <code>gpioc_index_oe_set</code>  | <code>mcr r p0, #10, Rt, Rt2, c4</code> | Set bits <code>Rt</code> in a GPIO output enable register selected by <code>Rt2</code> (i.e. set to output).  |
| <code>gpioc_index_oe_clr</code>  | <code>mcr r p0, #11, Rt, Rt2, c4</code> | Clear bits <code>Rt</code> in a GPIO output enable register selected by <code>Rt2</code> (i.e. set to input). |

### 3.6.1.5. Read instructions

These instructions read from either the `GPIO_OUT` and `GPIO_HI_OUT` registers; the `GPIO_OE` and `GPIO_HI_OE` registers; or the `GPIO_IN` and `GPIO_HI_IN` registers.

| Mnemonic                        | Armv8-M Instruction                   | Operation                                                                                                                                                                                       |
|---------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gpioc_lo_out_get</code>   | <code>mrc p0, #0, Rt, c0, c0</code>   | Read back the lower 32-bit output register. Equivalent to: <code>Rt = sio_hw&gt;gpio_out;</code>                                                                                                |
| <code>gpioc_hi_out_get</code>   | <code>mrc p0, #0, Rt, c0, c1</code>   | Read back the upper 32-bit output register. Equivalent to: <code>Rt = sio_hw&gt;gpio_hi_out;</code>                                                                                             |
| <code>gpioc_hilo_out_get</code> | <code>mrrc p0, #0, Rt, Rt2, c0</code> | Read back two 32-bit output registers in a single operation. Equivalent to: <code>Rt = sio_hw&gt;gpio_out;</code> and simultaneously <code>Rt2 = sio_hw&gt;gpio_hi_out &lt;&lt; 32;</code>      |
| <code>gpioc_lo_oe_get</code>    | <code>mrc p0, #0, Rt, c0, c4</code>   | Read back the lower 32-bit output enable register. Equivalent to: <code>Rt = sio_hw&gt;gpio_oe;</code>                                                                                          |
| <code>gpioc_hi_oe_get</code>    | <code>mrc p0, #0, Rt, c0, c5</code>   | Read back the upper 32-bit output enable register. Equivalent to: <code>Rt = sio_hw&gt;gpio_hi_oe;</code>                                                                                       |
| <code>gpioc_hilo_oe_get</code>  | <code>mrrc p0, #0, Rt, Rt2, c4</code> | Read back two 32-bit output enable registers in a single operation. Equivalent to: <code>Rt = sio_hw&gt;gpio_oe;</code> and simultaneously <code>Rt2 = sio_hw&gt;gpio_hi_oe &lt;&lt; 32;</code> |
| <code>gpioc_lo_in_get</code>    | <code>mrc p0, #0, Rt, c0, c8</code>   | Sample the lower 32 GPIOs. Equivalent to: <code>Rt = sio_hw&gt;gpio_in;</code>                                                                                                                  |
| <code>gpioc_hi_in_get</code>    | <code>mrc p0, #0, Rt, c0, c9</code>   | Sample the upper 32 GPIOs. Equivalent to: <code>Rt = sio_hw&gt;gpio_hi_in;</code>                                                                                                               |
| <code>gpioc_hilo_in_get</code>  | <code>mrrc p0, #0, Rt, Rt2, c8</code> | Sample 64 GPIOs on the same cycle. Equivalent to: <code>Rt = sio_hw&gt;gpio_in;</code> and simultaneously <code>Rt2 = sio_hw&gt;gpio_hi_in &lt;&lt; 32;</code>                                  |

### 3.6.1.6. Interpreting instruction fields

The type of coprocessor instruction — `mrc`, `mrrc`, `mcr` and `mcrr` — specifies the direction of the transfer (read/write) and the number of Arm registers being transferred (one or two).

Bits 3:2 of the first coprocessor register number field, `CRm`, identify the group of registers being accessed. Values 0, 1 and

### 3.6.1.4. 索引掩码写入指令

这些指令写入单个动态选择的32位GPIO寄存器。

| 助记符                              | Armv8-M 指令                              | 操作                                                                   |
|----------------------------------|-----------------------------------------|----------------------------------------------------------------------|

### 3.6.1.5. 读取指令

这些指令从GPIO\_OUT与GPIO\_HI\_OUT寄存器读取；GPIO\_OE与GPIO\_HI\_OE寄存器；或GPIO\_IN与GPIO\_HI\_IN寄存器。

| 助记符                             | Armv8-M 指令                            | 操作                                                                                                                            |
|---------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>gpioc_lo_out_get</code>   | <code>mrc p0, #0, Rt, c0, c0</code>   | 读取低32位输出寄存器的值。等价于： <code>Rt = sio_hw-&gt;gpio_out;</code>                                                                     |
| <code>gpioc_hi_out_get</code>   | <code>mrc p0, #0, Rt, c0, c1</code>   | 读取高32位输出寄存器的值。等价于： <code>Rt = sio_hw-&gt;gpio_hi_out;</code>                                                                  |
| <code>gpioc_hilo_out_get</code> | <code>mrrc p0, #0, Rt, Rt2, c0</code> | 在一次操作中读回两个32位输出寄存器。<br>等同于： <code>Rt = sio_hw-&gt;gpio_out;</code> 并同时 <code>Rt2 = sio_hw-&gt;gpio_hi_out &lt;&lt; 32;</code> |
| <code>gpioc_lo_oe_get</code>    | <code>mrc p0, #0, Rt, c0, c4</code>   | 读回低32位输出使能寄存器。等同于： <code>Rt = sio_hw-&gt;gpio_oe;</code>                                                                      |
| <code>gpioc_hi_oe_get</code>    | <code>mrc p0, #0, Rt, c0, c5</code>   | 读回高32位输出使能寄存器。等同于： <code>Rt = sio_hw-&gt;gpio_hi_oe;</code>                                                                   |
| <code>gpioc_hilo_oe_get</code>  | <code>mrrc p0, #0, Rt, Rt2, c4</code> | 在一次操作中读回两个32位输出使能寄存器。<br>等同于： <code>Rt = sio_hw-&gt;gpio_oe;</code> 并同时 <code>Rt2 = sio_hw-&gt;gpio_hi_oe &lt;&lt; 32;</code> |
| <code>gpioc_lo_in_get</code>    | <code>mrc p0, #0, Rt, c0, c8</code>   | 采样低 32 个 GPIO。等同于： <code>Rt = sio_hw-&gt;gpio_in;</code>                                                                      |
| <code>gpioc_hi_in_get</code>    | <code>mrc p0, #0, Rt, c0, c9</code>   | 采样高 32 个 GPIO。等同于： <code>Rt = sio_hw-&gt;gpio_hi_in;</code>                                                                   |
| <code>gpioc_hilo_in_get</code>  | <code>mrrc p0, #0, Rt, Rt2, c8</code> | 在同一周期采样 64 个 GPIO。等同于： <code>Rt = sio_hw-&gt;gpio_in;</code> 且同时 <code>Rt2 = sio_hw-&gt;gpio_hi_in &lt;&lt; 32;</code>        |

### 3.6.1.6. 指令字段的解析

协处理器指令类型 – `mrc`、`mrrc`、`mcr` 和 `mrr` – 指明传输方向（读/写）及所传输的 Arm 寄存器数量（一或两个）。

第一个协处理器寄存器号字段CRm的第 3 至 2 位指定所访问的寄存器组。数值 0、1 及

2 refer to the output, output enable and input registers respectively.

Bit 0 of the first coprocessor register number field, **CRm**, may be used to distinguish which register in a group is being accessed. Bit 1 is reserved to allow more registers to be indexed on future chips with more GPIOs.

For writes, bits 1:0 of the instruction's **opc1** field specify the type of write operation: values 0, 1, 2, 3 map to normal write, XOR, set and clear operations respectively. Bits 3:2 of the **opc1** field are used to indicate the addressing mode for the register or individual bit being accessed. Their exact interpretation depends on the instruction.

Any combinations not listed in the preceding tables are reserved for future use.

### 3.6.2. Double-precision coprocessor (DCP)

Each Cortex-M33 CPU core is equipped with two instances of a double-precision coprocessor that provides acceleration of double-precision floating point operations including add, subtract, multiply, divide and square root. The design is implemented in just a few thousand gates and so occupies much less silicon die area than a full double-precision floating-point unit.

Nevertheless, these coprocessors considerably speed up basic double-precision operations compared to pure software implementations. The coprocessors also offer support for some single-precision operations and conversions.

The two coprocessor instances are assigned to the Secure and Non-secure domains. Coprocessor number 4 always maps to the coprocessor used for the current processor security state. Coprocessor number 5 always maps to the Non-secure coprocessor instance, but is accessible only from Secure code. This duplication avoids saving and restoring the coprocessor context during Secure/Non-secure state transitions.

#### 3.6.2.1. CPU interface

As with the other coprocessors, the accelerator connects to the CPU over a 64-bit bus. Two words of data can be transferred per cycle over that bus using the following instructions:

- **MCRR**: move two integer registers to coprocessor
- **MRRC**: move two integer registers from coprocessor

There are also single-register versions of these instructions, including ones that allow the CPU's flags to be loaded from the coprocessor. The CPU issues **CDP** instructions to trigger operations within the coprocessor without transferring any data.

#### 3.6.2.2. Internal architecture

A block diagram of the accelerator is shown in [Figure 12](#).

2 分别指向输出寄存器、输出使能寄存器和输入寄存器。

第一个协处理器寄存器编号字段CRm的第0位可用于区分正在访问的寄存器组中的具体寄存器。第1位予以保留，以便未来拥有更多GPIO的芯片能够索引更多寄存器。

对于写操作，指令的opc1字段的第1:0位指定写入操作的类型：数值0、1、2、3分别对应普通写、异或（XOR）、置位和清除操作。opc1字段的第3:2位用于指示所访问寄存器或单个位的寻址模式。该字段的具体含义依赖于指令本身的定义。

前述表格未列举的所有组合均保留供将来使用。

### 3.6.2. 双精度协处理器（DCP）

每个Cortex-M33 CPU内核均配备两个双精度协处理器实例，用于加速包括加法、减法、乘法、除法和平方根在内的双精度浮点运算。该设计仅由几千个逻辑门实现，因此占用的硅晶片面积远小于完整的双精度浮点单元。

尽管如此，这些协处理器相比纯软件实现，大幅加速了基本双精度运算。协处理器还支持部分单精度运算及相应的转换。

这两个协处理器实例分别分配至安全域与非安全域。协处理器编号 4始终映射至当前处理器安全状态所对应的协处理器。协处理器编号 5始终映射至非安全协处理器实例，但仅限安全代码访问。此重复配置避免了安全/非安全状态切换时协处理器上下文的保存与恢复。

#### 3.6.2.1. CPU接口

与其他协处理器一样，加速器通过64位总线连接CPU。可通过以下指令在该总线上每周期传输两个字的数据：

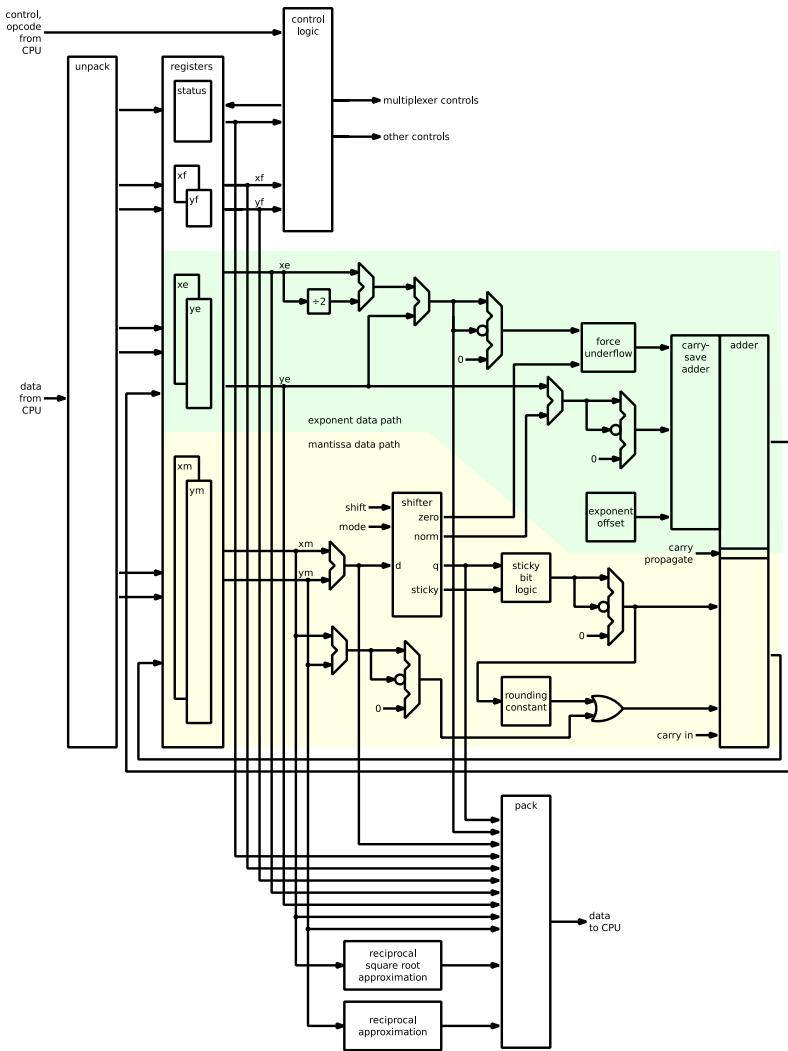

- **MCRR**：将两个整数寄存器传送到协处理器
- **MRRC**：从协处理器传送两个整数寄存器

这些指令还有单寄存器版本，包括允许从协处理器加载CPU标志的指令。CPU发出 **COP** 指令以触发协处理器内的操作，且不传输任何数据。

#### 3.6.2.2 内部架构

加速器的框图如图12所示。

Figure 12. Block diagram of double-precision accelerator

At the heart of the design are:

- two sets of registers, each designed to hold an unpacked double-precision value
- a 9-bit status register

Unlike a conventional FPU, the accelerator does not contain a full register bank. Not only does this save die area, it also means that saving and restoring the coprocessor's state is very fast: in fact, the entire state fits within six 32-bit words and hence can be saved to, or restored from, the CPU in three instructions.

The accelerator contains a wide adder, capable of adding two mantissa values and three exponent values simultaneously. There is also a shifter that can either perform a logical right shift by a given amount, or normalise a denormalised mantissa and report the amount of shift required to do so. A considerable amount of hardware in the shifter is shared between these two operating modes.

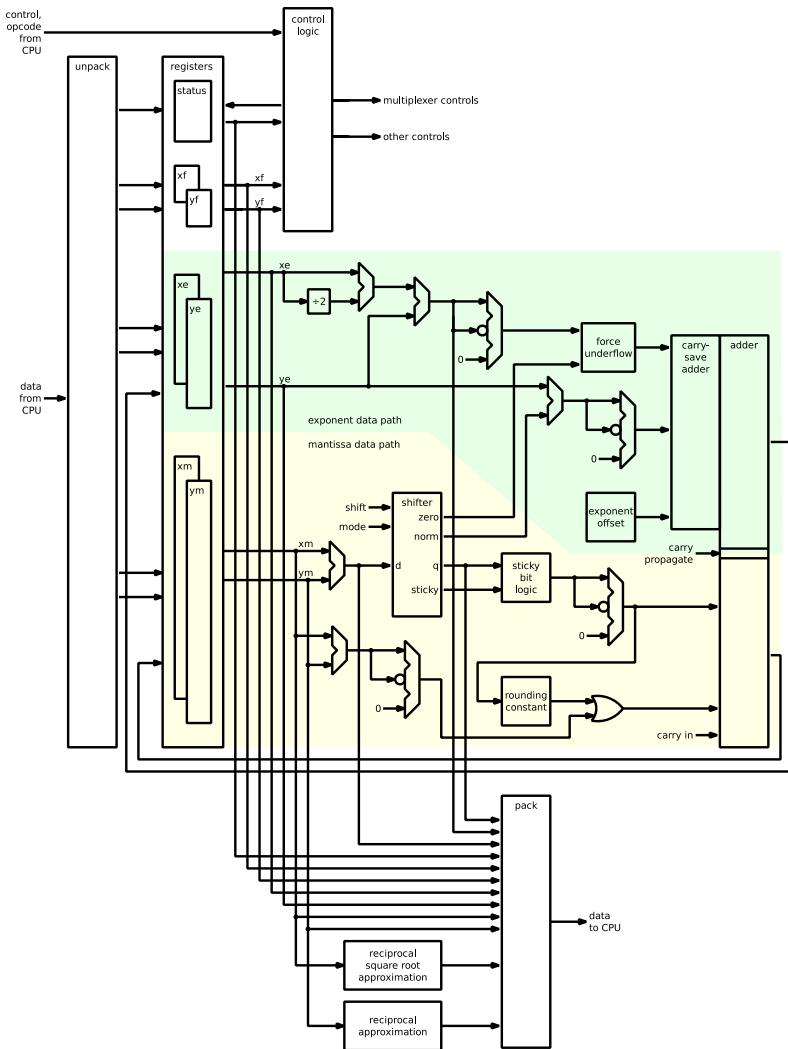

Control logic, shown at the top of the diagram, decodes coprocessor instructions and configures the accelerator's functional units and datapath multiplexers in order to execute the desired operation. Each coprocessor instruction takes a single cycle, so coprocessor operations cannot stall the CPU.

A floating-point operation such as addition or subtraction is carried out by executing a fixed (or 'canned') sequence of instructions as follows:

1. One or two **MCRR** instructions to write the operands to the coprocessor.
2. A number of **CDP** (and possibly other) instructions that together perform the operation itself.
3. An **MRRC** or **MRC** instruction to read back the result.

The hardware handles special cases involving zeroes, NaNs, and infinities, as well as rounding, underflow and overflow.

图12。双精度  
加速器框图

设计核心包括：

- 两组寄存器，每组设计用于存放一个拆包的双精度数值
- 一个9位状态寄存器

与传统的FPU不同，加速器不包含完整的寄存器组。这不仅节省了芯片面积，而且意味着保存和恢复协处理器状态非常快速：实际上，整个状态仅占六个32位字，因而可通过三条指令保存到CPU或从CPU恢复。

该加速器包含一台宽加法器，能够同时对两个尾数值和三个指数值进行加法运算。此外，还配备了一台移位器，可执行逻辑右移指定位数，或对非规格化尾数进行规格化并报告所需的移位量。移位器的相当部分硬件在这两种操作模式之间共享。

图示顶部的控制逻辑解码协处理器指令，并配置加速器的功能单元和数据路径多路复用器，以执行指定操作。每条协处理器指令占用单个周期，因此协处理器操作不会导致CPU停顿。

执行浮点运算（例如加法或减法）时，采用以下固定（或称“预设”）指令序列：

1. 一条或两条 **MCRR** 指令，用于向协处理器写入操作数。
2. 若干条 **CDP** 指令（以及可能的其他指令）共同完成运算操作。
3. 一个 **MRRC** 或 **MRC** 指令，用于读取返回结果。

硬件处理涉及零值、NaN（非数字）和无穷大等特殊情况，以及舍入、下溢和上溢情况。

The accelerator does not contain a multiplier array, as that would occupy a considerable amount of die area. Instead, the mantissas of the operands of a multiplication operation are brought back into the CPU to take advantage of the fast long multiply instructions available there. The coprocessor handles the processing of exponents.

Division and square root operations also involve data moving back and forth between coprocessor and CPU. To assist with these operations, the coprocessor contains two small lookup tables (implemented as random logic) that provide initial approximations used in the divide and square root algorithms. The coprocessor handles the processing of exponents.

The accelerator is only meant to be used with the canned instruction sequences that implement basic floating-point operations. The state of the accelerator is not guaranteed to be preserved from the end of one canned sequence to the beginning of the next: see the discussion of the 'engaged' flag in the status register below.

### 3.6.2.3. Registers

#### X and Y mantissa registers

The X and Y mantissa registers (`xm` and `ym`) are each 64 bits wide. They can be read and written directly by the CPU; the `xm` register can also store the lower part of the result from the adder. When a value is written to the coprocessor using a 'write unpacked' `MCRR` instruction, the top two bits of the mantissa register are set to `01` and the next most significant bits are filled from the mantissa field of the floating-point operand. The low-order bits of the mantissa register are cleared.

#### X and Y exponent registers

The X and Y exponent registers (`xe` and `ye`) are each 14 bits wide. They can be read and written directly by the CPU; the `xe` register can also store the higher part of the result from the adder. When a value is written to the coprocessor using a 'write unpacked' `MCRR` instruction, the exponent register is set from the exponent field of the floating-point operand.

#### X and Y flag registers

The X and Y flag registers (`xf` and `yf`) are each four bits wide. They can be read and written directly by the CPU. The flag register stores information about the type of floating-point number represented in the corresponding mantissa and exponent registers: its sign, whether it is a zero, whether it is an infinity, and whether it is a NaN. When a value is written to the coprocessor using a 'write unpacked' `MCRR` instruction, the bits of the flag register are updated according to the type of the floating-point operand.

#### Status register

The status register contains nine bits. It can be read and written directly by the CPU. The least significant six bits of the register store the shift required to align the two operands of an addition or subtraction; the next two bits indicate whether the value represented by (`xe`, `xm`) is greater than, equal to, or less than the value represented by (`ye`, `ym`) - in other words, whether the magnitude of the value stored in the X registers is greater than, equal to, or less than the magnitude of the value stored in the Y registers. These status bits are set in the first step of an addition, subtraction or comparison operation after the operands have been loaded.

The final bit of the status register indicates whether the coprocessor is 'engaged'. The engaged flag is set by all coprocessor instructions that occur at the beginning or in the middle of the canned instruction sequences. It is cleared by those instructions used at the end of a canned sequence to read back a final result.

### 3.6.2.4. State save and restore

An interrupt handler can test the engaged flag to determine whether it has pre-empted an in-progress operation on the same coprocessor. If the engaged flag is set, the handler can save (and restore) the coprocessor state before using the coprocessor. If the engaged flag is clear, the save (and restore) step can be skipped. If this approach is implemented, the state of the accelerator must be regarded as undefined when not within one of the canned instruction sequences.

Three `MRRC` instructions are provided to copy the six words of state in the coprocessor into integer registers in the CPU, from where they can, for example, be pushed onto the stack. The last of these instructions clears the engaged flag.

该加速器不包含乘法器阵列，因为那将占用相当大的一块芯片面积。相反，乘法操作数的尾数被送回CPU，以利用CPU中可用的高速长乘指令。协处理器负责指数部分的处理。

除法和平方根操作同样涉及协处理器与CPU之间的数据来回传输。为辅助这些操作，协处理器包含两个小型查找表（以随机逻辑实现），用于提供除法和平方根算法中的初始近似值。协处理器负责指数部分的处理。

该加速器仅用于执行实现基本浮点运算的预设指令序列。加速器状态不保证从一个预设序列结束时至下一个序列开始时保持不变：详见下文状态寄存器中“engaged”标志的说明。

### 3.6.2.3. 寄存器

#### X 和 Y 尾数寄存器

X 和 Y 尾数寄存器 ( $xm$  和  $ym$ ) 各为 64 位宽。它们可以被 CPU 直接读取和写入；  
 $xm$  寄存器还可存储加法器结果的低位部分。当使用“写入非打包” MCRR 指令向协处理器写入值时，尾数寄存器的最高两位被设为 01，次高位从浮点操作数的尾数字段填充。尾数寄存器的低位被清零。

#### X 和 Y 指数寄存器

X 和 Y 指数寄存器 ( $xe$  和  $ye$ ) 各为 14 位宽。它们可以被 CPU 直接读取和写入；  
 $xe$  寄存器还可存储加法器结果的高位部分。当使用“写入非打包” MCRR 指令向协处理器写入值时，指数寄存器从浮点操作数的指数组合字段设定。

#### X 和 Y 标志寄存器

X 和 Y 标志寄存器 ( $xf$  和  $yf$ ) 各为四位宽。它们可被 CPU 直接读取和写入。标志寄存器存储有关对应尾数寄存器和指数寄存器中所表示浮点数类型的信息：其符号、是否为零、是否为无穷大以及是否为 NaN。当使用“写入未封装” MCRR 指令向协处理器写入值时，标志寄存器的各位将根据浮点操作数类型进行更新。

#### 状态寄存器

状态寄存器包含九位。它可被 CPU 直接读取和写入。寄存器的最低六位存储对两个加法或减法操作数进行对齐所需的移位数；接下来的两位指示由 ( $xe$ ,  $xm$ ) 表示的值是否大于、等于或小于由 ( $ye$ ,  $ym$ ) 表示的值——即指示存储于 X 寄存器中的值的幅度是否大于、等于或小于存储于 Y 寄存器中的值的幅度。这些状态位在加法、减法或比较操作的第一步中，于操作数加载后被设置。

状态寄存器的最后一位指示协处理器是否处于“启用”状态。所有位于预设指令序列开头或中间的协处理器指令均会设置启用标志。该标志会被用于读取最终结果、处于预设序列末尾的指令清除。

### 3.6.2.4. 状态保存与恢复

中断处理程序可以检测启用标志，以确认是否抢占了同一协处理器上正在进行的操作。若启用标志被设置，处理程序可在使用协处理器前保存（及恢复）协处理器状态。若启用标志被清除，则可跳过保存（及恢复）步骤。若采用此方法，则在不处于任何预设指令序列内时，必须将加速器状态视为未定义。

提供三条 MRRC 指令，用于将协处理器中的六个状态字复制到 CPU 的整数寄存器中，例如，可以将其推入堆栈。其中最后一条指令用于清除 engaged 标志。

Similarly, three **MCRR** instructions are provided to restore the state of the coprocessor from integer registers, including the state of the engaged flag.

### 3.6.2.5. Instruction summary

As mentioned above, it is intended that the coprocessor instructions are only used as part of canned sequences. Nevertheless, for completeness, a list of the available instructions is given here with an outline of their effects.

**MCRR** instructions are shown in [Table 109](#).

Table 109. MCRR instructions

| Mnemonic    | Effect                                                       | Used by                            |
|-------------|--------------------------------------------------------------|------------------------------------|
| <b>WXMD</b> | write $xm$ direct                                            | restore status                     |
| <b>WYMD</b> | write $ym$ direct                                            | restore status                     |
| <b>WEFD</b> | write $xe, xf, ye, yf, \text{other status}$ direct           | restore status                     |
| <b>WXUP</b> | write $xm, xe, xf$ unpacked double-precision                 | double-precision binary operations |
| <b>WYUP</b> | write $ym, ye, yf$ unpacked double-precision                 | double-precision binary operations |
| <b>WXYU</b> | write $xm, xe, xf, ym, ye, yf$ two unpacked single-precision | single-precision binary operations |
| <b>WXMS</b> | write $xm$ bit 0=0/1 if data zero/nonzero                    | dmul                               |
| <b>WXMO</b> | write $xm$ direct OR into b0, add exponents, XOR signs       | dmul                               |
| <b>WXDD</b> | write $xm$ direct; subtract exponents, XOR signs             | ddiv                               |
| <b>WDXQ</b> | write $xm$ direct, offset exponent                           | dsqrt                              |
| <b>WXUC</b> | write X unsigned int $+2^{52}+2^{32}$ , Y $=2^{52}+2^{32}$   | conversions from unsigned int      |
| <b>WXIC</b> | write X signed int $+2^{52}+2^{32}$ , Y $=2^{52}+2^{32}$     | conversions from signed int        |
| <b>WXOC</b> | write X unpacked double-precision, Y $=2^{52}+2^{32}$        | conversions from double-precision  |
| <b>WXFC</b> | write X unpacked single-precision, Y $=2^{52}+2^{32}$        | conversions from single-precision  |
| <b>WXFM</b> | write $xm$ direct, add exponents, XOR signs                  | fmul                               |
| <b>WXML</b> | write $xm$ direct, subtract exponents, XOR signs             | fdiv                               |
| <b>WXFQ</b> | write $xm$ direct, offset exponent                           | fsqrt                              |

**CDP** instructions are shown in [Table 110](#).

Table 110. CDP instructions

| Mnemonic    | Effect                                                 | Used by       |
|-------------|--------------------------------------------------------|---------------|
| <b>INIT</b> | zero all registers                                     |               |
| <b>ADD0</b> | compare X-Y, set status                                | add, sub, cmp |
| <b>ADD1</b> | $xm := \pm xm + \pm ym >> s$ or $\pm ym + \pm xm >> s$ | add           |
| <b>SUB1</b> | $xm := \pm xm - \pm ym >> s$ or $-\pm ym \pm xm >> s$  | sub           |
| <b>SQR0</b> | $xe = xe / 2$ , $xm = xm << 0:1$                       | sqrt          |

类似地，提供三条 MCRR 指令，用于从整数寄存器恢复协处理器状态，包括 engaged 标志的状态。

### 3.6.2.5. 指令概要

如前所述，协处理器指令仅应作为预定义序列的一部分使用。

然而，为完整起见，现列出可用指令及其功能概要。

MCRR 指令详见表 109。

表 109. MCRR  
指令

| 助记符  | 效果                                           | 使用者      |
|------|----------------------------------------------|----------|
| WXMD | 写入 $xm$ 直接                                   | 恢复状态     |
| WYMD | 写入 $ym$ 直接                                   | 恢复状态     |
| WEFD | 写入 $xe$ 、 $xf$ 、 $ye$ 、 $yf$ 及其他状态（直接）       | 恢复状态     |
| WXUP | write $xm, xe, xf$ 拆包双精度                     | 双精度二进制运算 |
| WYUP | write $ym, ye, yf$ 拆包双精度                     | 双精度二进制运算 |
| WXYU | write $xm, xe, xf, ym, ye, yf$ 两个拆包单精度       | 单精度二进制运算 |
| WXMS | write $xm$ 第 0 位 = 0/1，表示数据为零/非零             | dmul     |
| WXMO | write $xm$ 直接对 b0 进行 OR 运算，指数相加，符号执行 XOR     | dmul     |
| WXDD | write $xm$ 直接写入；指数相减，符号执行 XOR                | ddiv     |
| WDXQ | 写入 $xm$ 直接，偏移指数                              | dsqrt    |
| WXUC | 写入 X 无符号整数 $+2^{52}+2^{32}$ , $Y=252+2^{32}$ | 从无符号整数转换 |
| WXIC | 写入 X 有符号整数 $+2^{52}+2^{32}$ , $Y=252+2^{32}$ | 从有符号整数转换 |
| WXOC | 写入 X 未打包双精度， $Y=2^{52}+2^{32}$               | 从双精度转换   |
| WXFC | 写入 X 未打包单精度， $Y=2^{52}+2^{32}$               | 从单精度转换   |
| WXML | 写入 $xm$ 直接，指数相加，符号异或                         | fmul     |
| WXFD | 写入 $xm$ 直接，指数相减，异或符号                         | fdiv     |
| WXFQ | 写入 $xm$ 直接，偏移指数                              | fsqrt    |

CDP 指令见表 110。

表 110. CDP  
指令

| 助记符  | 效果                                          | 使用者    |
|------|---------------------------------------------|--------|
| 初始化  | 清零所有寄存器                                     |        |
| ADD0 | 比较 $X-Y$ ，设置状态                              | 加、减、比较 |
| ADD1 | $xm:=\pm xm+\pm ym>>s$ 或 $\pm ym+\pm xm>>s$ | 加      |
| SUB1 | $xm:=\pm xm-\pm ym>>s$ 或 $-\pm ym\pm xm>>s$ | 减      |
| SQR0 | $xe=xe/2$ , $xm=xm<<0:1$                    | sqrt   |

| Mnemonic    | Effect                                                         | Used by                                                      |

| REFD | 读取 <b>xe</b> , <b>xf</b> , <b>ye</b> , <b>yf</b> , 其他状态直接 | 保存状态              |
| RXMS | 读取 <b>xm</b> Q62-s                                        | dmul, ddiv, dsqrt |
| RYMS | 读 <b>ym</b> Q62-s                                         | dmul, ddiv        |
| RXYH | 读 <b>ym</b> hi, <b>xm</b> hi                              | fmul, fdiv        |
| RYMR | 读 <b>ym</b> hi, 倒数近似低位                                    | fdiv, ddiv        |
| RXMQ | 读 <b>xm</b> hi, 平方根倒数近似低位                                 | fsqrt, dsqrt      |
| RDDA | 读取从 X 打包的 DADD 结果                                         | dadd              |
| RDDS | 读取从 X 打包的 DSUB 结果                                         | dsub              |
| RDDM | 从 X 读取 DMUL 结果的打包数据                                       | dmul              |
| RDDD | 从 X 读取 DDIV 结果的打包数据                                       | ddiv              |

| Mnemonic | Effect                                   | Used by                                         |
|----------|------------------------------------------|-------------------------------------------------|
| RDDQ     | read DSQRT result packed from X          | dsqrt                                           |
| RDDG     | read general double result packed from X | single-precision to double-precision conversion |

Alongside each `MRRC` and `MRC` instruction is a variant starting `P` (for 'peek') instead of `R` that has the same function but preserves the engaged flag. `RXMD` is identical to `PXMD`; `REFD` is identical to `PEFD`.

The SDK includes macros to generate Arm assembler from the mnemonics above in the file `dcp_instr.inc.S` in the SDK, for example turning `WXUP r0,r1` into `mrrr p4,#1,r0,r1,c0`.

### 3.6.2.6. Example canned sequence

The assembly code sequence to implement a callable double-precision addition operation is shown in [Table 112](#).

Table 112. Assembly code sequence to implement a callable double-precision addition operation

| Arm assembler                      | Coprocessor mnemonic    | Action                                                                                                                                 |
|------------------------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>mrrr p4,#1,r0,r1,c0</code>   | <code>WXUP r0,r1</code> | write <code>R0</code> and <code>R1</code> unpacked double-precision into <code>X</code>                                                |
| <code>mrrr p4,#1,r2,r3,c1</code>   | <code>WYUP r2,r3</code> | write <code>R2</code> and <code>R3</code> unpacked double-precision into <code>Y</code>                                                |
| <code>cdp p4,#0,c0,c0,c1,#0</code> | <code>ADD0</code>       | compare <code>X</code> and <code>Y</code> ; set status and alignment shift                                                             |
| <code>cdp p4,#1,c0,c0,c1,#0</code> | <code>ADD1</code>       | add/subtract (depending on status and signs) <code>xm</code> and <code>ym</code> aligned, write result to <code>xm</code>              |
| <code>cdp p4,#8,c0,c0,c0,#1</code> | <code>NRDD</code>       | normalise and round double-precision result                                                                                            |
| <code>mrrc p4,#1,r0,r1,c0</code>   | <code>RDDA r0,r1</code> | read <code>R0</code> and <code>R1</code> packed double-precision from <code>X</code> , including special-value processing for addition |
| <code>bx r14</code>                |                         | return from function                                                                                                                   |

Logic in the coprocessor ensures, for example, that the `ADD1` instruction shifts the smaller argument, that `xm` and `ym` are negated as required before being sent to the adder, and that the larger exponent is used as the basis for the subsequent normalisation.

### 3.6.2.7. Using the coprocessor via the SDK library

The SDK `pico_double` library automatically uses the coprocessor for double-precision floating-point calculations. This is the simplest way to take advantage of the coprocessor, but it entails a few cycles of overhead for each operation. Not only is there the overhead involved in a function call and return, but for safety the general-purpose implementations in the SDK always test the engaged flag, saving and restoring the coprocessor state to and from the stack as needed. That ensures that the functions work correctly if used in interrupt handlers, without additional intervention.

### 3.6.2.8. Using the coprocessor directly

The SDK includes macros to generate canned sequences for standard operations in the file `dcp_canned.inc.S` in the SDK.

These allow the callable double-precision addition operation listed above, for example, to be written as:

```
dcp_dadd_m r0,r1, r0,r1,r2,r3 @ result in r0,r1; operands in r0,r1 and r2,r3
bx r14
```

| 助记符  | 效果               | 使用者       |
|------|------------------|-----------|
| RDDQ | 从X读取DSQRT结果的打包数据 | dsqrt     |
| RDDG | 从X读取通用双精度结果的打包数据 | 单精度到双精度转换 |

每个 **MRRC** 和 **MRC** 指令旁均有一个变体，使用 **P**（代表“peek”）替代 **R**，功能相同但保留已置位的标志。**RXMD** 与 **PXMD** 完全相同；**REFD** 与 **PEFD** 完全相同。

SDK 包含宏，可根据上述助记符生成 Arm 汇编，宏定义位于 SDK 中的文件 **dcp\_instr.inc.S** 中，例如，将 **WXUP r0,r1** 转换为 **mcrr p4,#1,r0,r1,c0**。

### 3.6.2.6. 示例预设序列

表 112 展示了实现可调用双精度加法操作的汇编代码序列。

表 112。实现可调用双精度加法操作的汇编代码序列

| Arm 汇编                       | 协处理器助记符           | 操作                                  |
|------------------------------|-------------------|-------------------------------------|
| <b>mcrr p4,#1,r0,r1,c0</b>   | <b>WXUP r0,r1</b> | 将拆包的双精度数 R0 和 R1 写入 X               |
| <b>mcrr p4,#1,r2,r3,c1</b>   | <b>WYUP r2,r3</b> | 将拆包的双精度数 R2 和 R3 写入 Y               |
| <b>cdp p4,#0,c0,c0,c1,#0</b> | <b>ADD0</b>       | 比较 X 和 Y；设置状态和对齐移位                  |
| <b>cdp p4,#1,c0,c0,c1,#0</b> | <b>ADD1</b>       | 根据状态及符号执行加/减操作，xm 和 ym 对齐，结果写入 xm   |
| <b>cdp p4,#8,c0,c0,c0,#1</b> | <b>NRDD</b>       | 归一化并四舍五入双精度结果                       |
| <b>mrrc p4,#1,r0,r1,c0</b>   | <b>RDDA r0,r1</b> | 从 X 读取 R0 与 R1 打包的双精度值，包括针对加法的特殊值处理 |
| <b>bx r14</b>                |                   | 函数返回                                |

协处理器中的逻辑确保，例如，**ADD1** 指令会对较小的参数进行移位，且在送入加法器之前，**xm** 和 **ym** 会根据要求被取反，同时使用较大的指数作为后续规格化的基础。

### 3.6.2.7. 通过 SDK 库使用协处理器

SDK **pico\_double** 库会自动调用协处理器以执行双精度浮点运算。这是利用协处理器的最简便方式，但每个操作都会带来数个周期的开销。不仅存在函数调用和返回的开销，且为保证安全，SDK 中的通用实现总是检测使能标志，并根据需要将协处理器状态保存至堆栈或从堆栈恢复。此措施确保若在中断处理程序中使用函数，其功能能正确执行，无需额外介入。

### 3.6.2.8. 直接使用协处理器

SDK 包含用于在文件 **dcp\_canned.inc.S**（位于 SDK 中）生成标准操作预定义序列的宏。

例如，上述可调用双精度加法操作可写为：

```
dcp_dadd_m r0, r1, r0, r1, r2, r3 @ 结果存放于 r0, r1；操作数位于 r0, r1 和 r2, r3
bx r14
```

`dcp_dadd_m` is a macro which expands into the sequence of coprocessor instructions given above. This macro allows you to specify the integer registers to be used for the operands and the result, which means that using these macros directly not only avoids function call and return overhead, it also avoids the extra overhead associated with argument marshalling.

The more complex macros also require you to specify 'scratch' registers that they can use for storing intermediate results. The following function, which calculates the dot product of two three-element vectors of doubles pointed to by `R0` and `R1`, illustrates this:

```

push {r4-r9,r14}
ldrd r3,r4,[r0],#8 @ load x0
ldrd r5,r6,[r1],#8 @ load y0
dcp_dmull_m r7,r8, r3,r4,r5,r6, r3,r4,r5,r6,r12,r14,r9 @ compute x0y0 ①
ldrd r3,r4,[r0],#8 @ load x1
ldrd r5,r6,[r1],#8 @ load y1
dcp_dmull_m r3,r4, r3,r4,r5,r6, r3,r4,r5,r6,r12,r14,r9 @ compute x1y1 ①
dcp_dadd_m r7,r8, r3,r4,r7,r8 @ compute x0y0+x1y1
ldrd r3,r4,[r0],#8 @ load x2
ldrd r5,r6,[r1],#8 @ load y2
dcp_dmull_m r3,r4, r3,r4,r5,r6, r3,r4,r5,r6,r12,r14,r9 @ compute x2y2 ①
dcp_dadd_m r0,r1, r3,r4,r7,r8 @ compute x0y0+x1y1+x2y2 ②
pop {r4-r9,r15}

```

1. `r3, r4, r5, r6, r12, r14`, and `r9` are scratch registers.

2. stores the result in `r0, r1`.

### NOTE

This example does not check the engaged flag. If used in interrupt handlers or in multi-threaded applications, a suitable test would have to be added. For example, see the [SDK implementation of `\_aeabi\_dadd`](#) for an efficient way to do this. The test only needs to be performed once, at the beginning of the function, so the overhead in this case would be relatively small.

The following example demonstrates how to use the coprocessor:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/dcp/hello\\_dcp/hello\\_dcp.c](https://github.com/raspberrypi/pico-examples/blob/master/dcp/hello_dcp/hello_dcp.c) Lines 18 - 109

```

18 extern double dcp_dot (double*p,double*q,int n);
19 extern double dcp_dotx (float*p,float*q,int n);
20 extern float dcp_iirx (float x,float*temp,float*coeff,int order);
21 extern void dcp_butterfly_radix2 (double*x,double*y);
22 extern void dcp_butterfly_radix2_twiddle_dif (double*x,double*y,double*tf);
23 extern void dcp_butterfly_radix2_twiddle_dit (double*x,double*y,double*tf);
24 extern void dcp_butterfly_radix4 (double*w,double*x,double*y,double*z);

25
26 static void dcp_test0() {
27 double u[3]={1,2,3};
28 double v[3]={4,5,6};
29 double w;
30 w=dcp_dot(u,v,3);
31 printf("(1,2,3).(4,5,6)=%g\n",w);
32 }
33
34 static void dcp_test1() {
35 float u[3]={1+pow(2,-20),2,3};
36 float v[3]={1-pow(2,-20),5,6};
37 double w;
38 w=dcp_dotx(u,v,3);

```

`dcp_dadd_m`为宏，展开后形成上述协处理器指令序列。该宏允许指定用于操作数和结果的整型寄存器，既避免函数调用与返回开销，又消除参数封送处理的额外负担。

较复杂的宏还要求指定‘临时’寄存器，用于保存中间结果。以下函数通过计算由 `R0` 和 `R1` 指向的两个三元素双精度向量的点积予以说明：

```

push {r4-r9, r14}
lrd r3, r4, [r0], #8 @ 加载 x0
lrd r5, r6, [r1], #8 @ 加载 y0
dcp_dmull_m r7, r8, r3, r4, r5, r6, r3, r4, r5, r6, r12, r14, r9 @ 计算 x0y0 ①
lrd r3, r4, [r0], #8 @ 加载 x1
lrd r5, r6, [r1], #8 @ 加载 y1
dcp_dmull_m r3, r4, r3, r4, r5, r6, r3, r4, r5, r6, r12, r14, r9 @ 计算 x1y1 ①
dcp_dadd_m r7, r8, r3, r4, r7, r8 @ 计算 x0y0+x1y1
lrd r3, r4, [r0], #8 @ 加载 x2
lrd r5, r6, [r1], #8 @ 加载 y2
dcp_dmull_m r3, r4, r3, r4, r5, r6, r3, r4, r5, r6, r12, r14, r9 @ 计算 x2y2 ①
dcp_dadd_m r0, r1, r3, r4, r7, r8 @ 计算 x0y0+x1y1+x2y2②
出栈 {r4-r9, r15}

```

1. `r3`、`r4`、`r5`、`r6`、`r12`、`r14` 及 `r9` 为临时寄存器。

2. 结果存储于 `r0`、`r1`。

### 注意

该示例未检查激活标志。若在中断处理程序或多线程应用中使用，须添加适当检测。例如，参阅 SDK 中 `_aeabi_dadd` 的实现，以获得高效的方法。该测试仅需在函数开始时执行一次，因此在此情况下的开销相对较小。

以下示例演示如何使用协处理器：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/dcp/hello\\_dcp/hello\\_dcp.c](https://github.com/raspberrypi/pico-examples/blob/master/dcp/hello_dcp/hello_dcp.c) 第 18 行至第 109 行

106
107 return 0;
108 }

```

There are also further examples in the `dcp/` directory in the [Pico Examples](#) repository.

### 3.6.2.9. IEEE 754 compliance

The canned instruction sequences provide IEEE-compliant operations with the exception that denormals are flushed to zero on input and output. Zeroes, NaNs and infinities are correctly handled. Rounding is to nearest, even on tie.

Faster versions of division and square root operations, named `ddiv_fast` and `dsqrt_fast` respectively, are available. These do not always give correctly rounded results but do have a guaranteed error before rounding of less than 0.5ulp ('units in last place'), which in particular means that if there is an exact representation of the result then that is what is returned.

### 3.6.2.10. Benchmarks

[Table 113](#) gives cycle counts for various floating-point operations using the accelerator with inlined code, compared to some typical ranges of benchmarks for (a) fully-fledged hardware double-precision FPUs; and (b) pure software implementations.

*Table 113. Cycle counts for floating-point operations using the accelerator*

| Operation                           | Using coprocessor | Full hardware (latency) | Software only |
|-------------------------------------|-------------------|-------------------------|---------------|
| <code>dadd</code>                   | 6                 | 2-6                     | 70-90         |
| <code>dsub</code>                   | 6                 | 2-6                     | 70-90         |
| <code>dmul</code>                   | 17                | 3-7                     | 75-90         |
| <code>ddiv</code>                   | 51                | 13-60                   | 135-600       |
| <code>ddiv_fast</code>              | 32                |                         |               |
| <code>dsqrt</code>                  | 49                | 15-62                   | 130-650       |
| <code>dsqrt_fast</code>             | 38                |                         |               |
| <code>dcmp</code>                   | 4                 |                         |               |
| <code>declassify</code>             | 2                 |                         |               |
| <code>integer to/from double</code> | 5                 |                         |               |

### 3.6.3. Redundancy coprocessor (RCP)

```

100 dcp_test1();
101 dcp_test2();
102 dcp_test3();
103 dcp_test4();
104 dcp_test5();
105 dcp_test6();
106
107 return 0;
108 }
```

在 Pico Examples 仓库的 `dcp/` 目录中还有更多示例。

### 3.6.2.9. IEEE 754 合规性

预置指令序列提供符合 IEEE 标准的操作，但输入和输出时非规格化数会被冲零处理。零值、NaN 和无穷大均得到正确处理。舍入到最接近值，遇到平分则舍入至偶数。

提供名为 `ddiv_fast` 和 `dsqrt_fast` 的加速版除法及平方根操作。该版本的结果不总是精确舍入，但保证舍入前误差小于  $0.5u$  Ip（单位最后一位），特别是若结果存在精确表示，则返回该精确值。

### 3.6.2.10. 基准测试

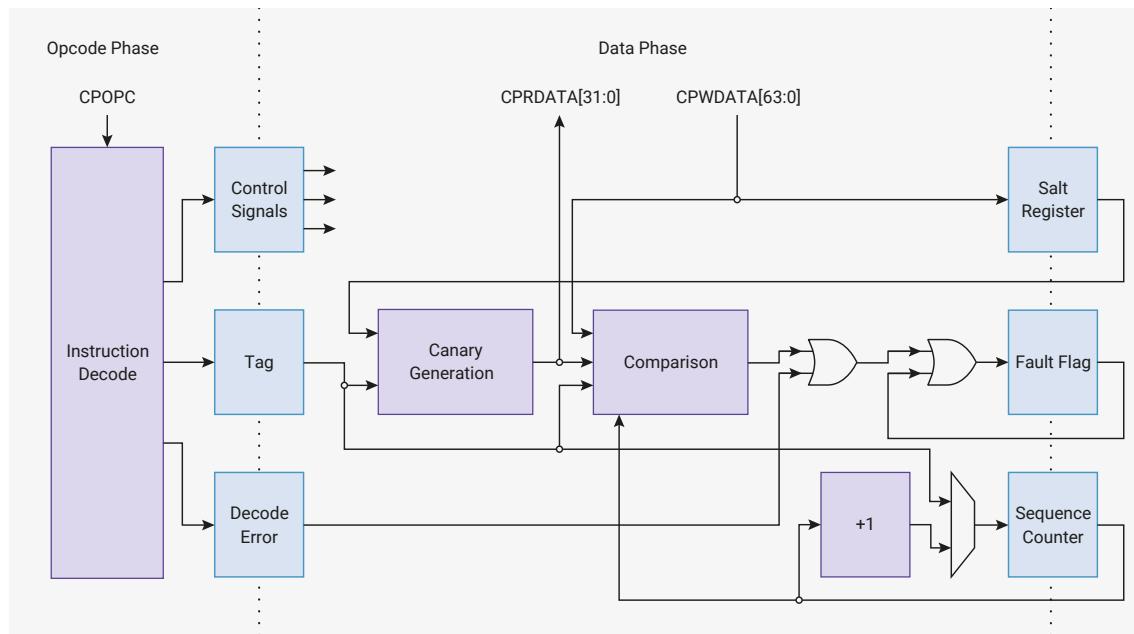

表113列出了使用加速器内联代码执行各种浮点运算的周期数，且将其与（a）完整硬件双精度FPU的典型基准范围进行了比较；以及（b）纯软件实现。

表113。使用  
加速器执行浮点  
运算的周期数

| 操作                          | 使用<br>协处理器 | 完整硬件（延迟） | 仅软件     |
|-----------------------------|------------|----------|---------|
| <code>dadd</code>           | 6          | 2-6      | 70-90   |
| <code>dsub</code>           | 6          | 2-6      | 70-90   |
| <code>dmul</code>           | 17         | 3-7      | 75-90   |
| <code>ddiv</code>           | 51         | 13-60    | 135-600 |
| <code>ddiv_fast</code>      | 32         |          |         |
| <code>dsqrt</code>          | 49         | 15-62    | 130-650 |
| <code>dsqrt_fast</code>     | 38         |          |         |
| <code>dcmp</code>           | 4          |          |         |
| <code>declassify</code>     | 2          |          |         |
| 整数与 <code>double</code> 的转换 | 5          |          |         |

### 3.6.3. 冗余协处理器（RCP）

**Figure 13. The redundancy coprocessor implements hardware-checked assertions, to aid control flow and data flow integrity checking. Its two-phase pipeline is closely coupled to the Cortex-M33 pipeline. A 64-bit salt register holds a once-per-boot random number, which is used to generate and validate stack canary values and generate pseudorandom delay sequences on RCP instructions. Other comparison functions provide more general hardware-checked assertion support.**

The redundancy coprocessor (RCP) is used in the RP2350 bootrom to provide hardware-assisted mitigation against fault injection and return-oriented programming attacks. This includes the following instructions:

- generate and validate stack canary values based on a per-boot random seed
- assert that certain points in the program are executed in the correct order without missing steps
- validate booleans stored as one of two valid bit patterns in a 32-bit word
- validate 32-bit integers stored redundantly in two words with an XOR parity mask
- halt the processor upon reaching a software-detected panic condition

Section 3.6.3.7 lists the RCP instruction set in full. RCP instruction encodings contain a parity bit; executing an invalid instruction or an instruction with bad parity triggers an RCP fault.

Each Cortex-M33 processor is equipped with a single RCP instance, mapped as coprocessor number 7 in the coprocessor opcode space. The two RCP instances are linked: an RCP fault on one core immediately triggers a fault on the other. RCP faults have two steps:

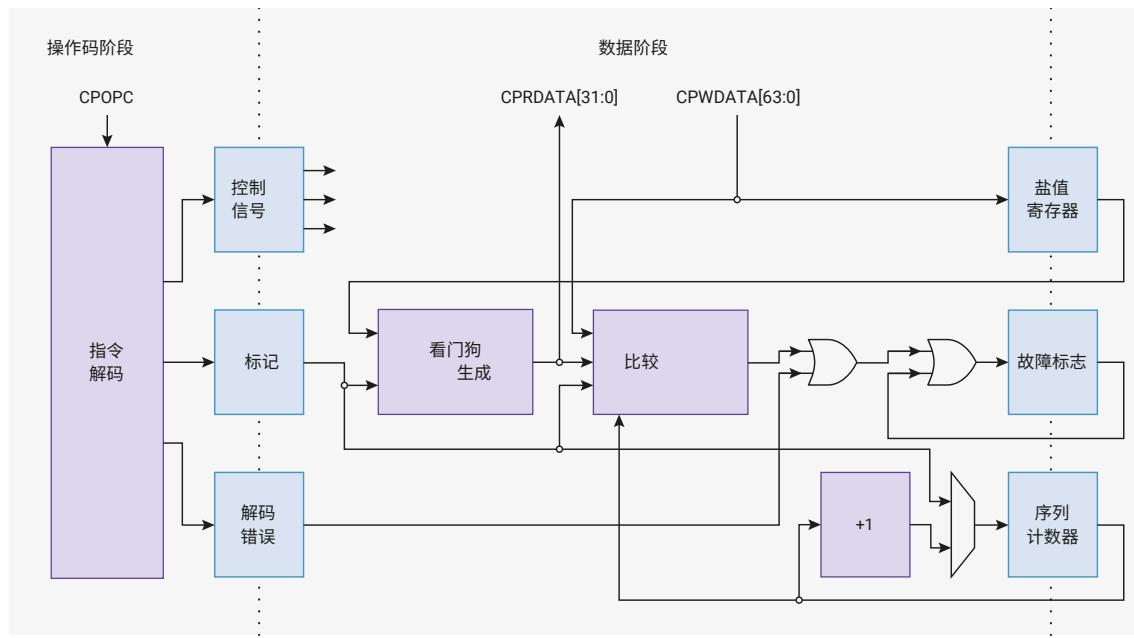

1. The non-maskable interrupt (NMI) is asserted. It remains asserted until a warm reset of the processor.
2. Any further RCP instructions stall the coprocessor port until a warm reset of the processor. This stall cannot be interrupted, as the processor is already in the NMI state.

The RP2350 bootrom implements the NMI and HardFault vectors with an `rcp_panic` instruction. This instruction unconditionally stalls the coprocessor port. This prevents the processor from retiring any more instructions until either a debugger connects to reset the processors, or the processors reset through some other mechanism (such as the system watchdog timer). The processor quickly reaches a quiescent state that reduces vulnerability to further fault injection (deliberate or otherwise).

Each core's RCP has a 64-bit seed value (Section 3.6.3.1). The RCP uses this value to generate stack canary values and to add short pseudorandom delays to RCP instructions. Both RCP instances are seeded by core 0 during the early boot path in the bootrom using the system true-random number generator (Section 12.12). Running any RCP instruction before providing a salt value triggers an RCP fault. The use of random data in stack canary values makes it difficult to reuse return-oriented-programming stack payloads across multiple boots.

Figure 13 gives a dataflow-level overview of the RCP hardware. The RCP is structured as a two-phase pipeline which overlays the Cortex-M33 execution pipeline. It exchanges data with the core via a 64-bit incoming bus (CPWDATA) and a 32-bit outgoing bus (CPRDATA). The Cortex-M33 can issue two register reads to the coprocessor in one cycle through the CPWDATA bus. The RCP leverages this throughput for some of its assertion instructions, such as `rcp_iequal`, which raises a fault when two Arm registers do not contain the same 32-bit value.

。

冗余协处理器（RCP）用于RP2350只读存储器启动程序中，提供针对故障注入及面向返回编程攻击的硬件辅助缓解措施。包括以下指令：

- 基于每次启动的随机种子生成和校验堆栈金丝雀值
- 断言程序中某些点按正确顺序执行且无遗漏步骤
- 校验存储于32位字中、以两种有效位模式之一表示的布尔值
- 验证以异或奇偶校验掩码冗余存储于两个字中的32位整数
- 在检测到软件触发的紧急状况时，停止处理器运行

第3.6.3.7节完整列出了RCP指令集。RCP指令编码包含奇偶校验位；执行无效指令或奇偶校验错误的指令将触发RCP故障。

每个Cortex-M33处理器配备一个RCP实例，映射为协处理器操作码空间中的协处理器编号 7。两个RCP实例相互连接：一个内核发生RCP故障时，立即触发另一内核故障。RCP故障包含两个步骤：

1. 不可屏蔽中断（NMI）被激活。该中断保持激活状态，直至处理器完成热复位。
2. 所有后续RCP指令将使协处理器端口阻塞，直到处理器完成热复位。该阻塞状态不可中断，因处理器已处于NMI状态。

RP2350 只读存储器实现了带有 `rcp_panic` 指令的 NMI 和 HardFault 向量。该指令无条件阻塞协处理器端口。这阻止处理器完成更多指令，直到调试器连接以重置处理器，或处理器通过其他机制（例如系统看门狗定时器）重置。处理器迅速进入静止状态，从而降低了对进一步故障注入（无论故意与否）的脆弱性。

每个核心的RCP均有一个64位种子值（第3.6.3.1节）。RCP使用该值生成栈金丝雀值，并向RCP指令添加短暂的伪随机延迟。两个RCP实例均由核心0在启动只读存储器早期引导路径中，通过系统真随机数生成器（第12.12节）初始化种子。在提供盐值前执行任何RCP指令将触发RCP故障。在栈金丝雀值中使用随机数据，令基于返回导向编程的栈负载难以在多次启动间重用。

图13展示了RCP硬件的数据流级概览。RCP结构为一个叠加于Cortex-M33执行流水线上的两阶段流水线。该模块通过64位输入总线（CPWDATA）和32位输出总线（CPRDATA）与核心交换数据。Cortex-M33可通过CPWDATA总线在一个周期内向协处理器发出两次寄存器读取。RCP利用此吞吐量支持部分断言指令，如 `rcp_iequal`，当两个Arm寄存器的32位值不一致时，该指令会引发故障。

The 8-bit **tag** value in [Figure 13](#) is an 8-bit instruction immediate value encoded by the instruction **CRn** and **CRm** fields. These 8-bit values are used to uniquely identify functions for canary value generation so that stack frames are not interchangeable between functions. They also provide 8-bit counter values for **rcp\_count\_set** and **rcp\_count\_check** instructions. Encoding the tags using the **CRn** and **CRm** fields makes RCP instruction sequences more compact, as it obviates additional instructions to materialise these small constants in registers and pass them through CPWDATA. This also makes the tag values less vulnerable to glitching, because the instruction opcode fields are available earlier in the cycle than the register values passed on CPWDATA.

RCP instructions may also execute in the Non-secure state, with certain differences to prevent Non-secure code from triggering RCP faults or observing the value of the salt register. This supports Non-secure software executing shared ROM routines which contain RCP instructions, but does not allow probing of the RCP's internal state from a Non-secure context. [Section 3.6.3.2](#) gives further details and rationale for Non-secure execution support.

Certain details are elided from [Figure 13](#) for clarity, such as the delay counter used for pseudorandom instruction delays, and the logic for suppressing faults under Non-secure execution. This behaviour is described in full in the following sections.

### 3.6.3.1. Salt register

Each RCP instance is provisioned with a 64-bit **salt register**, which provides a seed for stack canary values and random instruction delays. This is expected to be initialised with a random value early in the boot process: the RP2350 bootrom uses the true random number generator to generate the salt values.

Initially the salt register is in the **invalid** state. This state only allows the following operations:

- Checking the valid state of the salt register, via **rcp\_canary\_status**
- Writing a salt via **rcp\_salt\_core0** or **rcp\_salt\_core1**, which writes a 64-bit value to that core's salt register, and changes its state to **valid**

When the salt register is in the invalid state, *executing any RCP instruction other than those listed above unconditionally triggers an RCP fault*. This makes it difficult to skip RCP initialisation via fault injection, because the RP2350 bootrom contains a high density of RCP instructions.

Similarly, attempting to write to an already-valid RCP salt register triggers an RCP fault. There is no reason to initialise the RCP salt register twice, so this case is detected as an anomaly that indicates loss of control flow integrity.

Core 0's coprocessor port writes the salt registers for both cores' RCP instances to simplify multicore interactions during early boot. In the RP2350 bootrom, core 1's first steps lock down its MPU execute permissions to a small region of the ROM containing its wait-for-launch code, and then poll for its RCP salt to become valid once core 0 has cleared boot memory, performed some minimal hardware setup, and generated the RCP salts.

When core 0 is switched to RISC-V architecture and core 1 is Arm, the core 1 salt register is forcibly marked as valid to permit core 1 to execute the ROM. This has no impact on secure boot because RISC-V cores are only enabled when secure boot is disabled; the ability to set core 0 to RISC-V already implies subversion of secure boot.

### 3.6.3.2. Access from Non-secure

Setting bit 7 of the Cortex-M33 **NSACR** register permits Non-secure code to set bit 7 of **CPACR\_NS**, which in turn enables Non-secure access to the RCP. Non-secure RCP access is useful for executing shared Secure/Non-secure routines which contain RCP instructions. For example, the **memcpy** implementation in the RP2350 bootrom is shared by Secure code in the main boot path, and Non-secure code such as the USB bootloader.

Since an RCP fault is fatal for all software running on the system, Non-secure must not be able to trigger RCP faults at will. Similarly, if Non-secure code were able to read out the RCP salt register, it would make it easier to engineer stack payloads which can control Secure execution without triggering RCP faults. Therefore the RCP handles Non-secure accesses differently from Secure:

- Masks read data to all-zeroes

图13中8位的 **tag** 值是由指令的 **CRn** 和 **CRm** 字段编码的8位立即数。

这些8位值用于唯一标识用于金丝雀值生成的函数，以防止函数之间的堆栈帧被互换。它们还为 **rcp\_count\_set** 和 **rcp\_count\_check** 指令提供8位计数器值。通过使用CRn和CRm字段对标签进行编码，使得RCP指令序列更加紧凑，避免了将这些小常量具体化到寄存器并通过CPWDATA传递而需额外指令的情况。

这也增强了标签值对故障注入攻击的抵抗力，因为指令操作码字段在周期中比通过CPWDATA传递的寄存器值更早可用。

RCP指令亦可在非安全状态下执行，但为防止非安全代码触发RCP故障或观察盐寄存器的值，存在某些差异。此举支持非安全软件执行包含RCP指令的共享只读存储器例程，但不允许从非安全上下文探查RCP的内部状态。第3.6.3.2节详述了非安全执行支持的更多细节及其设计原理。

为保证图13的清晰度，省略了部分细节，如用于伪随机指令延迟的延迟计数器，以及在非安全执行环境下抑制故障的逻辑。此行为在以下章节中有详尽说明。

### 3.6.3.1. 盐寄存器

每个RCP实例均配备一个64位盐寄存器，作为堆栈保护值和随机指令延迟的种子。该寄存器预期在启动过程早期以随机值进行初始化：RP2350只读存储器启动程序使用真随机数发生器生成盐值。

盐寄存器初始处于无效状态。该状态仅允许以下操作：

- 通过 **rcp\_canary\_status** 检查盐寄存器的有效状态
- 通过 **rcp\_salt\_core0** 或 **rcp\_salt\_core1** 写入盐值，向该核的盐寄存器写入64位数值，并将其状态置为有效

当盐寄存器处于无效状态时，执行除上述操作之外的任何RCP指令均会无条件触发RCP故障。由于RP2350只读存储器启动程序中包含大量RCP指令，这使得通过故障注入跳过RCP初始化变得极为困难。

同样，试图向已有效的RCP盐寄存器写入数据会触发RCP故障。没有理由对RCP盐寄存器进行二次初始化，因此此情况被视为表明控制流完整性丧失的异常。

核心0的协处理器端口写入两个核心RCP实例的盐寄存器，以简化多核在早期启动阶段的交互。在RP2350引导只读存储器中，核心1首先将其MPU执行权限锁定在包含等待启动代码的只读存储器小区域内，然后在核心0清理启动内存、执行必要的硬件初始化并生成RCP盐后，轮询其RCP盐的有效状态。

当核心0切换为RISC-V架构且核心1采用Arm架构时，核心1的盐寄存器会被强制标记为有效，以允许核心1执行只读存储器中的代码。由于只有在禁用安全启动时才启用RISC-V核心，此操作不会影响安全启动；将核心0设为RISC-V的能力已意味着对安全启动的破坏。

### 3.6.3.2. 非安全访问

设置Cortex-M33NSACR寄存器的第7位允许非安全代码设置 **CPACR\_NS** 的第7位，从而使非安全访问RCP成为可能。非安全RCP访问对于执行包含RCP指令的共享安全/非安全例程尤为重要。例如，RP2350只读存储器中的memcpy实现由主启动路径中的安全代码与USB引导程序等非安全代码共享。

鉴于RCP故障对系统上运行的所有软件均致命，非安全代码不得任意触发RCP故障。同样，若非安全代码能读取RCP盐寄存器，将更易构造出能控制安全执行且不触发RCP故障的堆栈载荷。因此，RCP对非安全访问的处理方式区别于安全访问：

- 将读取数据屏蔽为全零

- Ignores write data: any instruction which would generate a data-dependent RCP fault becomes a no-op
- Reports coprocessor errors instead of RCP faults for invalid instructions, which the processor maps to the Non-secure UNDEFINSTR UsageFault
- Skips the pseudorandom instruction delay: all RCP instructions execute in one cycle, assuming the Cortex-M33 is able to issue them at one instruction per cycle

The lack of pseudorandom instruction delays makes it more difficult for Non-secure code to extract the seed value used to add delays to Secure execution of RCP instructions.

### 3.6.3.3. Instruction validation

The RCP applies the following rules to all coprocessor instructions which target coprocessor 7:

- The number of 1 bits in the `Opc1` field, plus the instruction parity bit, must be an even number.
  - For `mcr`, `mrc` and `cdp` instructions, bit 0 of the `Opc2` field encodes the parity bit.
  - For `mcrr`, bit 3 of the `CRn` field encodes the parity bit.
- The instruction must not be an `mrrc` (64-bit coprocessor-to-core)
- For `mcr` instructions (32-bit core-to-coprocessor):
  - The `Opc1` field must be in the range 0 through 6.
  - If there is no 8-bit tag (i.e. any other than `rcp_canary_check`, `rcp_count_check`, `rcp_count_set`), the `CRn` and `CRm` opcode fields must be all-zeroes.
- For `mrc` instructions (32-bit coprocessor-to-core):
  - The `Opc1` field must be in the range 0 through 2.
  - For instructions other than `rcp_canary_get` and `rcp_canary_check`, the `CRn` and `CRm` opcode fields must be all-zeroes.
- For `mcrr` instructions (64-bit core-to-coprocessor):
  - The `Opc1` field must be in the range 0 through 8.
  - For `rcp_salt_core*` instructions, bits 2:0 of the `CRm` field must be 0 or 1 (referred to as `rcp_salt_core0` and `rcp_salt_core1` respectively).
  - For all other `mcrr` instructions, bits 2:0 of the `CRm` field must be 0.

The terms `Opc1`, `Opc2`, `CRn` and `CRm` in the description above refer to standard encoding fields in the Arm T32 instruction encoding for coprocessor instructions. See the [Armv8-M Architecture Reference Manual](#) for full details of the encoding and assembler syntax.

Any coprocessor instruction targeting coprocessor 7 that fails these validation rules will result in one of two outcomes, depending on the security domain in which the instruction is executed:

- Secure execution of an invalid instruction is an immediate, unconditional RCP fault. The RCP asserts the core's non-maskable interrupt signal, and any further RCP instructions stall the coprocessor port indefinitely. This continues until the core receives a warm reset. This also triggers RCP faults on other cores: for more information, see [Section 3.6.3.4](#).
- Non-secure execution of an invalid instruction returns an error on the opcode-phase coprocessor interface, which is interpreted as a Non-secure UNDEFINSTR UsageFault by the core. For a full description of this Armv8-M-specific fault, see the [Armv8-M Architecture Reference Manual](#).

### 3.6.3.4. Cross-core triggering

An RCP fault indicates that the integrity of the software environment is compromised. Though the fault may originate on

- 忽略写入数据：任何可能引发数据相关RCP错误的指令均视为无操作
- 对无效指令报告协处理器错误，而非RCP错误，处理器将其映射为非安全的UNDEFINSTR UsageFault
- 跳过伪随机指令延迟：假设Cortex-M33能够以每周期一条指令的速度发出指令，所有RCP指令均在一个周期内执行

伪随机指令延迟的缺失使非安全代码更难提取用于向安全执行RCP指令添加延迟的种子值。

### 3.6.3.3 指令验证

RCP对所有以协处理器7为目标的协处理器指令应用以下规则：

- Opc1字段中1的数量加上指令奇偶校验位，必须为偶数。
  - 对于 mcr、 mrc 和 cdp 指令，Opc2 字段的第0位编码奇偶校验位。
  - 对于 mrr，CRm 字段的第3位编码奇偶校验位。
- 该指令不得为 mrc (64位协处理器到内核指令)。
- 对于 mcr 指令 (32位内核到协处理器)：
  - Opc1 字段的值必须在0至6之间。
  - 如果没有8位标签（即非 rcp\_canary\_check、 rcp\_count\_check 或 rcp\_count\_set），则 CRn 和 CRm 操作码字段必须全部为零。
- 对于 mrc 指令 (32位协处理器到内核)：
  - Opc1 字段的值必须在0至2之间。
  - 对于除 rcp\_canary\_get 和 rcp\_canary\_check 以外的指令，CRn 和 CRm 操作码字段必须全部为零。
- 对于 mrr 指令 (64位核心到协处理器)：
  - Opc1 字段的值必须在0至8之间。
  - 对于 rcp\_salt\_core\* 指令，CRm 字段的第2至0位必须为0或1（分别称为 rcp\_salt\_core0 和 rcp\_salt\_core1）。
  - 对于所有其他 mrr 指令，CRm 字段的第2至0位必须为0。

上述描述中的 Opc1、Opc2、CRm 和 CRn 术语，指的是 Arm T32 架构中协处理器指令的标准编码字段。有关编码和汇编语法的完整细节，请参阅 Armv8-M 架构参考手册。

任何针对协处理器 7 且未通过这些验证规则的协处理器指令，都会导致以下两种结果之一，具体取决于指令执行时所在的全域：

- 无效指令的安全执行将立即导致无条件的RCP故障。RCP会断言核心的不可屏蔽中断信号，任何后续的RCP指令将使协处理器端口无限期阻塞。该状态将持续，直至核心接收到热复位。这也会在其他核心触发RCP故障：更多信息详见第3.6.3.4节。
- 非安全状态下执行无效指令将在操作码阶段协处理器接口返回错误，该错误被核心解释为非安全UNDEFINSTR UsageFault。有关该 Armv8-M 特定故障的完整描述，详见 Armv8-M 架构参考手册。

### 3.6.3.4 跨核心触发

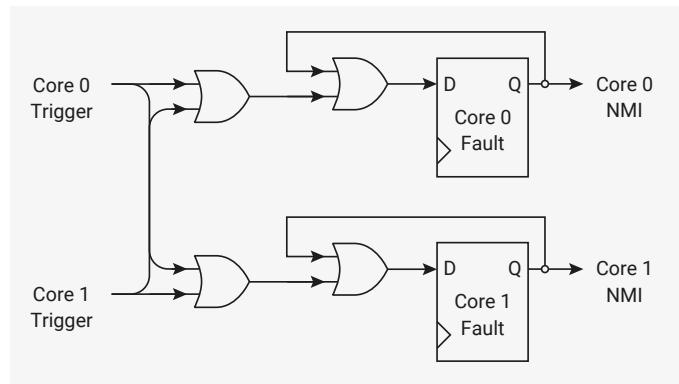

RCP故障表明软件环境的整体性已被破坏。虽故障可能起于

a single processor, all processors which share the same trusted memory may behave unpredictably if they continue to execute, since:

- The physical condition which caused one processor to misexecute in a detectable way, such as low supply voltage, may cause other processors to misexecute in a manner which was not detected.
- The processor which triggered an RCP fault may already have corrupted shared, trusted memory contents in a way that interferes with the other processor's operation, (e.g. corrupting the other core's stack).

Therefore, an RCP fault on one core also triggers an RCP fault on other cores. Because RP2350 has two cores, an RCP fault on core 0 always triggers a fault on core 1, and an RCP fault on core 1 always triggers a fault on core 0.

*Figure 14. Triggering an RCP fault on one core also triggers a fault on the other core. Triggers accumulate into a fault register, which remains set until the core resets. The NMI asserts when the fault register is set.*

Each core locally ORs in the trigger signal from the other core. The outputs of the two OR gates on the left are logically equivalent, but the gates are kept local to the core to minimise delay routing the core's own fault trigger to its own fault register.

### 3.6.3.5. Stack canary values

Canaries are values written to the stack on function entry and validated on function exit, to assure that:

- The exit matches the entry (i.e. when leaving through the back door, you entered through the front door)
- The stack was not completely overwritten in the course of executing the function

This helps to mitigate two classes of attack:

- Fault injection: any physical fault condition which corrupts the program counter or causes a wild indirect branch is likely to cause the processor to execute a function epilogue which does not match the prologue. Any branch into the middle of a function is likely to eventually reach the epilogue.
- Return-oriented programming: deliberate stack corruption can redirect control flow through a sequence of function tails which perform arbitrary operations. The stack may be corrupted by exploiting missing bounds checks on stack buffer operations. Random canary values make it difficult to craft such a stack payload.

Return-oriented programming mitigation is particularly important to account for in the bootrom because the bootrom exposes an API surface that is mapped at a known location at runtime (it is physically always mapped at `0x00000000`). This provides a well-known exploit surface similar to the C standard library.

The RCP supports canary values with two canary-specific instructions:

- `rcp_canary_get` generates a 32-bit value for an 8-bit tag as a function of the salt register
- `rcp_canary_check` validates a 32-bit value for an 8-bit tag and raises an RCP fault if the value does not match that produced by an `rcp_canary_get` for the same tag.

The 32-bit canary value is as follows:

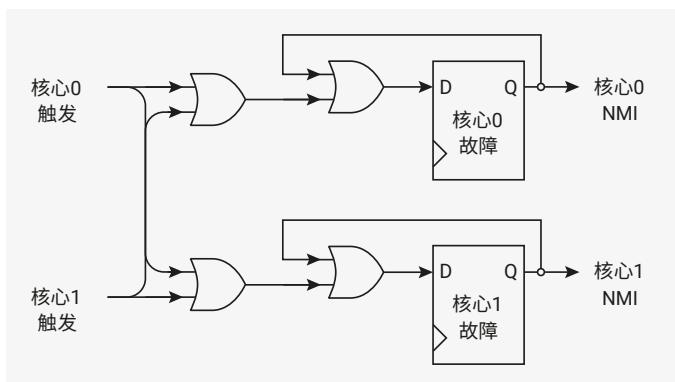

- Bits `7:0`: all-zero
- Bits `15:8`: XOR of bits `7:0` of the salt with (AND of bits `31:24` of the salt with the 8-bit tag)

单个处理器，所有共享相同受信内存的处理器若继续执行，均可能表现出不可预测的行为，因为：

- 导致某个处理器以可检测方式错误执行的物理情况，例如低电压供应，可能导致其他处理器以未被检测的方式错误执行。
- 触发RCP故障的处理器可能已损坏共享且受信任的内存内容，从而干扰其他处理器的运行（例如破坏其他核心的堆栈）。

因此，一个核心上的RCP故障也会引发其他核心上的RCP故障。由于RP2350具有两个核心，核心0上的RCP故障必然触发核心1上的故障，核心1上的RCP故障同样必然触发核心0上的故障。

图14。在一个核心上触发RCP故障也会引发另一个核心上的故障。触发信号累积到故障寄存器，故障寄存器保持设定状态直至核心复位。当故障寄存器被设定时，非屏蔽中断（NMI）

每个核心本地对来自另一核心的触发信号进行逻辑或运算。左侧两个逻辑或门的输出在逻辑上等价，但这两个门保持在核心本地，以尽量减少将核心自身故障触发信号传递至自身故障寄存器的延迟。

### 3.6.3.5. 堆栈金丝雀值

金丝雀值是在函数入口写入堆栈，并在函数退出时验证，以确保：

- 退出与入口状态匹配（即从后门退出时，必须是从前门进入）
- 在函数执行过程中，堆栈未被完全覆盖

此机制有助于防范两类攻击：

- 故障注入：任何导致程序计数器受损或引发异常间接跳转的物理故障，极可能使处理器执行与函数前导代码不匹配的函数尾声。函数中任何中途的跳转最终很可能到达尾声代码段。
- 基于返回的编程（Return-oriented programming）：故意破坏栈结构可通过执行任意操作的函数尾部序列重定向控制流。利用对栈缓冲区操作缺失边界检查可能导致栈的破坏。随机生成的金丝雀值使构造此类栈载荷变得困难。

针对基于返回的编程的缓解措施在只读存储器启动代码（bootrom）中尤为重要，因为启动代码暴露的 API 表面在运行时映射于已知位置（其物理地址始终映射于 `0x00000000`）。

这提供了类似于 C 标准库的知名利用表面。

RCP 支持两条与金丝雀相关的指令，用于管理金丝雀值：

- `rcc_canary_get` 根据盐寄存器为 8 位标签生成一个 32 位值
- `rcc_canary_check` 验证给定 8 位标签的 32 位值，若该值与相同标签通过 `rcc_canary_get` 生成的值不符，将触发 RCP 故障。

32位看门狗值如下：

- 位 `7:0`：全零
- 位 `15:8`：盐的位 `7:0` 与（盐的位 `31:24` 与 8 位标签按位与）的异或

- Bits 23:16: XOR of bits 15:8 of the salt with (AND of bits 39:32 of the salt with the bitwise NOT of the 8-bit tag)
- Bits 31:24: XOR of bits 23:16 of the salt with the 8-bit tag

The following code demonstrates how you might calculate the 32-bit canary value in C:

```
uint32_t canary_value(uint64_t salt, uint8_t tag) {
 uint32_t tag_expanded =
 (uint32_t)tag |
 ((uint32_t)~tag << 8) |
 ((uint32_t)tag << 16);
 tag_expanded &= (0xff0000u | ((salt >> 24) & 0x00ffffu));
 uint32_t result24 = tag_expanded ^ salt;
 return result24 << 8;
}
```

This canary value is chosen such that:

- Different tags are guaranteed to yield different canary values
- For any two different tags, each is a function of at least one salt bit that the other is not a function of (so it is difficult to calculate canaries for different tags even if one value is known)
- Null-terminated string operations on the stack terminate before reading or writing a canary

Each function should use a different canary tag, to prevent a stack frame for one function being used to return through another function's epilogue. Avoid using canary values for purposes other than stack canaries.

The RP2350 bootrom uses 8-bit tags in the range `0x40` through `0xbff`. The remaining tags are free for use in user code.

### 3.6.3.6. Pseudorandom instruction delays

By default, all RCP instructions execute with a pseudorandom delay in the range of 0 to 127 cycles. These delays make it more difficult for an outside observer to precisely time a fault injection event with respect to an RCP instruction, or the critical code path it protects.

**NOTE**

In certain usage situations, RCP delays can expose a side-channel where processor state can be inferred. See [RP2350-E26](#) for details.

Setting bit 12 of the first halfword of an instruction disables the pseudorandom delay for that instruction only. The instruction executes in a single cycle, assuming the Cortex-M33 does not insert stall cycles due to other micro-architectural constraints. To set this bit, assemble the `*2` variant of any given coprocessor instruction (e.g. `mrc2` rather than `mrc`). In the NonSecure state, RCP instructions always execute without delay.

The RCP implements instruction execution delays by stalling the coprocessor opcode interface during the opcode phase (shown in the [Figure 13](#) pipeline diagram). The Cortex-M33 may choose to abandon a stalled coprocessor instruction due to an interrupt. When this happens, the delay counter continues counting down, waiting for the delay period to elapse. If the Cortex-M33 issues another RCP instruction whilst the delay counter is still running (either in the interrupt, or after returning to the interrupted RCP instruction), this instruction executes once the existing countdown completes. However, if the delay counter of an abandoned instruction has already expired before the next RCP instruction executes, the next instruction samples a pseudorandom delay count, and begins a new countdown.

The pseudorandom delay sequence is a function of bits 63:40 of the salt value. As such, the pattern of delays is unique per-boot, provided each boot writes a different 64-bit value to the salt register.

The pseudorandom number generator (PRNG) used for delays implements a number of small linear feedback shift registers (LFSRs) in bits 63:40 of the salt register, and returns a nonlinear function of the 24-bit state. The LFSR feedback functions on the 24-bit state are:

- 位 23:16：盐的位 15:8与（盐的位 39:32与8位标签按位非的按位与）的异或
- 位 31:24：盐的位 23:16与8位标签的异或

以下代码演示了如何在C语言中计算32位看门狗值：

```
uint32_t canary_value(uint64_t salt, uint8_t tag) {
 uint32_t tag_expanded =
 (uint32_t)tag |
 ((uint32_t)~tag << 8) |
 ((uint32_t)tag << 16);
 tag_expanded &= (0xff0000u | ((salt >> 24) & 0x00ffffu));
 uint32_t result24 = tag_expanded ^ salt;
 return result24 << 8;
}
```

该金丝雀值选择的原则如下：

- 不同标签保证产生不同的金丝雀值。
- 对于任意两个不同的标签，每个标签至少依赖一个该标签独有的盐位（因此即使已知一个值，也难以计算不同标签的金丝雀值）。
- 栈上的以空字符结尾的字符串操作在读取或写入金丝雀值之前即终止。

每个函数应使用不同的金丝雀标签，以防止一个函数的栈帧被另一个函数的尾部错误重用。避免将金丝雀值用于堆栈金丝雀以外的其他用途。

RP2350 只读存储器启动程序使用范围为 0x40 至 0xbf 的8位标签。其余标签可自由用于用户代码。

### 3.6.3.6. 伪随机指令延迟

默认情况下，所有RCP指令执行时均带有0到127周期的伪随机延迟。这些延迟使外部观察者难以精确地将故障注入事件与RCP指令或其保护的关键代码路径时间对齐。

#### 注意

在某些使用情况下，RCP延迟可能暴露出侧信道，从而推断处理器状态。详见RP2350-E26。

设置指令首半字的第 12位仅禁用该指令的伪随机延迟。该指令在单个周期内执行，前提是Cortex-M33未因其他微架构约束插入停顿周期。要设置此位，请使用任何协处理器指令的 \*2变体进行汇编（例如使用 mrc2而非 mrc）。在非安全状态下，RCP指令始终无延迟执行。

RCP通过在操作码阶段（如图13流水线图所示）暂停协处理器操作码接口实现指令执行延迟。由于中断，Cortex-M33可能会选择放弃已暂停的协处理器指令。当此情况发生时，延迟计数器将继续倒计时，等待延迟周期届满。若 Cortex-M33 在延迟计数器仍在运行期间（无论是在中断中，还是返回至被中断的 RCP 指令后）发出另一条 RCP 指令，则该指令将在现有倒计时完成后执行。然而，若被废弃指令的延迟计数器在下一条 RCP 指令执行前已到期，则下一条指令将采样伪随机延迟计数，并启动新一轮倒计时。

伪随机延迟序列是盐寄存器第 63 至 40 位的函数。因此，前提是每次启动向盐寄存器写入不同的 64 位值，每次启动的延迟模式均独一无二。

用于延迟的伪随机数生成器（PRNG）在盐寄存器第 63 至 40 位中实现多个小型线性反馈移位寄存器（LFSRs），并返回该 24 位状态的非线性函数。24位状态的LFSR反馈函数为：

- Bits 23:20: 4-bit LFSR with taps 0xc
- Bits 19:15: 5-bit LFSR with taps 0x14
- Bits 14:8: 7-bit LFSR with taps 0x60
- Bits 7:0: 8-bit LFSR with taps 0xb4

The LFSRs are implemented by shifting the XOR reduction of (state AND taps) into the LSB with each state update. When an LFSR's state is all-zeroes, a one bit is shifted into the LSB. The LFSR state advances each time a random number is generated: this happens when executing an instruction with a pseudorandom delay, or when executing a `rcp_random_byte` instruction.

Each bit of the pseudorandom output is the XOR of six bits of the 24-bit state, XORed with the majority-3 vote of three other bits of the state:

| Output Bit | XOR Taps |    |    |    |    |    |    | Majority-3 Taps |    |  |
|------------|----------|----|----|----|----|----|----|-----------------|----|--|
| 7          | 7        | 17 | 6  | 16 | 13 | 8  | 9  | 12              | 21 |  |
| 6          | 14       | 21 | 19 | 6  | 16 | 13 | 4  | 14              | 6  |  |
| 5          | 7        | 5  | 2  | 18 | 11 | 1  | 18 | 14              | 7  |  |
| 4          | 4        | 19 | 17 | 0  | 18 | 7  | 18 | 11              | 3  |  |
| 3          | 23       | 12 | 7  | 16 | 14 | 5  | 17 | 3               | 15 |  |
| 2          | 15       | 13 | 20 | 21 | 8  | 12 | 7  | 22              | 9  |  |
| 1          | 4        | 16 | 11 | 18 | 9  | 6  | 14 | 21              | 16 |  |
| 0          | 11       | 3  | 4  | 19 | 10 | 14 | 1  | 2               | 9  |  |

Bits 6:0 of this function are used for pseudorandom instruction delays, producing delays in the range of 0 to 127 cycles. The delay is applied in addition to the one-cycle base cost of executing a coprocessor instruction. The full 8-bit result is available through the `rcp_random_byte` instruction.

This is a simple pseudorandom number generator which makes it difficult to recover the initial 24-bit state from a small number of observations. It accomplishes this by making the observation size much smaller than the state size and using a non-linear combination function for the output. It has a number of statistical aberrations which make it unsuitable for general random number generation (not to mention its small state size). For high-quality random number generation, either use the system true-random number generator (TRNG) directly, or use a high-quality software PRNG with a large state seeded from the TRNG.

Note that the 24 MSBs of the salt value used to seed the delay PRNG do not overlap with the 40 LSBs used to generate stack canary values. Therefore measuring the random delays externally provides no information on the canary values.

### 3.6.3.7. Instruction listing

The Cortex-M33 processors access the RCP using `mcr`, `mcr2`, `mrc`, and `cdp` instructions. The [Armv8-M Architecture Reference Manual](#) describes the intricacies of these instructions in relation to the processor's architectural state, but from the coprocessor's point of view:

- `mcr` writes a 32-bit value to the coprocessor from a single Arm integer register
- `mcr2` writes a 64-bit value to the coprocessor from a pair of Arm integer registers
- `mrc` reads a 32-bit value from the coprocessor, writing to either a single Arm integer register or to the processor status flags
- `cdp` performs some internal coprocessor operation without exchanging data with the processor

For each `mcr`, `mcr2`, `mrc` and `cdp` instruction, the RCP also accepts the matching `mcr2`, `mcr2`, `mrc2`, and `cdp2` opcode variant. These opcodes differ only in bit 12. The plain versions have a pseudorandom delay of up to 127 cycles on their

- 位 **23:20**: 4位LFSR，抽头为 **0xc**
- 位 **19:15**: 5位LFSR，抽头为 **0x14**
- 位 **14:8**: 7位LFSR，抽头为 **0x60**
- 位 **7:0**: 8位LFSR，抽头为 **0xb4**

LFSRs通过对（状态 AND 抽头）执行异或合并，然后将结果移入最低有效位以实现，每次状态更新时均执行此操作。当LFSR状态全为零时，将一位1移入最低有效位。每次生成随机数时，LFSR状态都会前进：该情况发生于执行带伪随机延迟的指令或执行 `rcc_random_byte` 指令时。

伪随机输出的每一位为24位状态中6个位的异或结果，且与状态中另外3个位的多数投票（三取二）结果异或：

| 输出位 | 异或抽头 |    |    |    |    |    |    | 三数多数抽头 |    |  |
|-----|------|----|----|----|----|----|----|--------|----|--|
| 7   | 7    | 17 | 6  | 16 | 13 | 8  | 9  | 12     | 21 |  |
| 6   | 14   | 21 | 19 | 6  | 16 | 13 | 4  | 14     | 6  |  |
| 5   | 7    | 5  | 2  | 18 | 11 | 1  | 18 | 14     | 7  |  |
| 4   | 4    | 19 | 17 | 0  | 18 | 7  | 18 | 11     | 3  |  |
| 3   | 23   | 12 | 7  | 16 | 14 | 5  | 17 | 3      | 15 |  |
| 2   | 15   | 13 | 20 | 21 | 8  | 12 | 7  | 22     | 9  |  |
| 1   | 4    | 16 | 11 | 18 | 9  | 6  | 14 | 21     | 16 |  |
| 0   | 11   | 3  | 4  | 19 | 10 | 14 | 1  | 2      | 9  |  |

该函数的位 **6:0** 用于伪随机指令延迟，产生0至127周期范围内的延迟。

此延迟是在执行协处理器指令的一个周期基准成本之外额外施加的。完整的8位结果可通过 `rcc_random_byte` 指令获得。

这是一个简单的伪随机数生成器，使从少量观测中恢复初始24位状态变得困难。它通过将观测规模远小于状态规模，并使用非线性组合函数来输出，从而实现此目的。其存在多处统计异常，故不适合用于通用随机数生成（更别提其状态规模较小）。对于高质量随机数生成，建议直接使用系统真实随机数生成器（TRNG），或使用由TRNG播种的大状态高质量软件伪随机数生成器。

请注意，用于为延迟伪随机数生成器（PRNG）设定种子的盐值的最高24位（MSBs）与用于生成栈保护值的最低40位（LSBs）不重叠。因此，外部测量随机延迟无法获取任何关于栈保护值的信息。

### 3.6.3.7. 指令列表

Cortex-M33处理器通过 `mcr`、`mcr2`、`mrc` 及 `cdp` 指令访问RCP。Armv8-M架构参考手册详细描述了这些指令与处理器架构状态的复杂关系，但从协处理器视角来看：

- `mcr` 将一个32位值从单个Arm整数寄存器写入协处理器
- `mcr2` 将一个64位值从一对Arm整数寄存器写入协处理器
- `mrc` 从协处理器读取一个32位值，写入单个Arm整数寄存器或处理器状态标志
- `cdp` 执行某些内部协处理器操作，且不与处理器交换数据

对于每条 `mcr`、`mcr2`、`mrc` 和 `cdp` 指令，RCP同样支持对应的 `mcr2`、`mcr2`、`mrc2` 及 `cdp2` 操作码变体。这些操作码仅在第 12 位上存在差异。普通版本的执行过程中会有最多127个周期的伪随机延迟，

execution, whereas the `2`-suffixed versions have no such delay.

Most RCP instructions are in the form of hardware-checked assertions. The phrase "asserts that" in the following instruction listings means that, if some asserted condition is not true, the coprocessor raises an RCP fault.

### 3.6.3.7.1. Initialisation

#### `rcp_salt_core0`

Asserts that the core 0 salt register is currently invalid. Writes a 64-bit value, and marks it as valid.

Opcode:

```
mcrr p7, #8, Rt, Rt2, c0
```

`Rt` is the 32 LSBs of the salt, `Rt2` is the 32 MSBs.

#### `rcp_salt_core1`

Asserts that the core 1 salt register is currently invalid. Writes a 64-bit value, and marks it as valid.

Opcode:

```
mcrr p7, #8, Rt, Rt2, c1
```

#### `rcp_canary_status`

Returns a `true` or `false` bit pattern (`0xa500a500` or `0x00c300c3` respectively) that indicates whether the salt register for this core has been initialised.

Opcode:

```
mrc p7, #1, Rt, c0, c0, #0
```

Invoking with `Rt = 0xf` sets the Arm `N` and `C` flags if and only if the salt register is valid.

If the salt has not been initialised, any operation other than initialising the salt or checking the canary status triggers an RCP fault.

This opcode is used on core 0 to skip the RCP initialisation sequence if the bootrom has been re-entered without a reset under debugger control, and on core 1 to wait for its RCP salt to be initialised.

### 3.6.3.7.2. Canary

#### `rcp_canary_get`

Gets a 32-bit canary value as a function of the salt register and the 8-bit tag encoded by two 4-bit coprocessor register numbers `CRn` and `CRm`. `CRn` contains the four MSBs, `CRm` the four LSBs.

Opcode:

```
mrc p7, #0, Rt, CRn, CRm, #1
```

Section 3.6.3.5 specifies the 32-bit value returned by this instruction, but you should treat this as an opaque value to be consumed by `rcp_canary_check`.

而带有 `2` 后缀的版本则无此延迟。

大多数RCP指令表现为硬件校验断言形式。下述指令列表中“断言”为”的表达意指：若某断言条件不成立，协处理器将触发RCP故障。

### 3.6.3.7.1. 初始化

#### `rcp_salt_core0`

断言核心0的盐值寄存器当前处于无效状态。写入一个64位数值，并将其标记为有效。

操作码：

```
mcrr p7, #8, Rt, Rt2, c0
```

`Rt` 是盐值的32位最低有效位，`Rt2`是32位最高有效位。

#### `rcp_salt_core1`

断言核心1的盐寄存器当前无效。写入一个64位数值，并将其标记为有效。

操作码：

```
mcrr p7, #8, Rt, Rt2, c1
```

#### `rcp_canary_status`

返回一个 `true`或 `false`的位模式（分别为 `0xa500a500`或 `0x00c300c3`），用于指示该核心的盐寄存器是否已初始化。

操作码：

```
mrc p7, #1, Rt, c0, c0, #0
```

仅当盐寄存器有效时，调用时传入 `Rt = 0xf`会设置Arm的 `N`和 `C`标志位。

如果盐尚未初始化，除初始化盐或检查canary状态外的任何操作都会触发RCP故障。

该操作码在核心0用于跳过RCP初始化序列（当在调试器控制下未复位重新进入bootrom时），核心1用于等待其RCP 盐值初始化完成。

### 3.6.3.7.2. 金丝雀

#### `rcp_canary_get`

获取一个32位金丝雀值，该值基于盐寄存器及由两个4位协处理器寄存器编号 `CRn`和 `CRm`编码的8位标签。`CRn`包含四个最高有效位，`CRm`包含四个最低有效位。

操作码：

```
mrc p7, #0, Rt, CRn, CRm, #1
```

第3.6.3.5节规定了该指令返回的32位值，但应将其视为不透明值，由 `rcp_canary_check` 使用。

**rcp\_canary\_check**

Asserts that a value matches the result of an `rcp_canary_get` with the same 8-bit tag. The tag is encoded by two 4-bit coprocessor register numbers, `CRn` and `CRm`. `CRn` contains the four MSBs, `CRm` the four LSBs.

Opcode:

```
mcr p7, #0, Rt, CRn, CRm, #1
```

**3.6.3.7.3. Boolean validation**

The RCP defines `0xa500a500` as the `true` value for 32-bit booleans, and `0x00c300c3` as the `false` value. All other bit patterns are poison, and trigger an RCP fault when consumed by any RCP boolean instructions. These values are chosen as they are valid immediates in Armv8-M Main.

This provides limited runtime type checking to ensure that boolean values are used in boolean contexts. The RP2350 bootrom occasionally uses redundant operations to generate booleans in a way that results in an invalid bit pattern if the two redundant operations do not return the same value, such as when checking boot flags in OTP.

**rcp\_bvalid**

Asserts that `Rt` is a valid boolean (`0xa500a500` or `0x00c300c3`).

Opcode:

```
mcr p7, #1, Rt, c0, c0, #0
```

**rcp\_btrue**

Asserts that `Rt` is `true` (`0xa500a500`).

Opcode:

```
mcr p7, #2, Rt, c0, c0, #0
```

**rcp\_bfalse**

Asserts that `Rt` is `false` (`0x00c300c3`).

Opcode:

```
mcr p7, #3, Rt, c0, c0, #1
```

**rcp\_b2valid**

Asserts that `Rt` and `Rt2` are both valid booleans.

Opcode:

```
mcrr p7, #0, Rt, Rt2, c8
```

**rcp\_canary\_check**

断言某值与指定相同8位标签的 `rcp_canary_get` 结果一致。标签由两个4位协处理器寄存器编号 CRn 和 CRm 编码。 CRn 包含四个最高有效位， CRm 包含四个最低有效位。

操作码：

```
mcr p7, #0, Rt, CRn, CRm, #1
```

**3.6.3.7.3. 布尔验证**

RCP 将 `0xa500a500` 定义为 32 位布尔值的 `true` 值，将 `0x00c300c3` 定义为 `false` 值。所有其他位模式均为无效，若被任何 RCP 布尔指令使用，将触发 RCP 错误。这些值之所以被选用，是因为它们在 Armv8-M Main 中是有效的立即数。

此机制提供有限的运行时类型检查，以确保布尔值仅在布尔上下文中使用。RP2350 启动只读存储器偶尔使用冗余操作生成布尔值，若两个冗余操作的返回值不一致（例如在 OTP 中检查启动标志时），将产生无效的位模式。

**rcp\_bvalid**

断言 Rt 为有效布尔值（`0xa500a500` 或 `0x00c300c3`）。

操作码：

```
mcr p7, #1, Rt, c0, c0, #0
```

**rcp\_btrue**

断言 Rt 为 `true`（`0xa500a500`）。

操作码：

```
mcr p7, #2, Rt, c0, c0, #0
```

**rcp\_bfalse**

断言 Rt 为 `false`（`0x00c300c3`）。

操作码：

```
mcr p7, #3, Rt, c0, c0, #1
```

**rcp\_b2valid**

断言 Rt 和 Rt2 均为有效布尔值。

操作码：

```
mcrr p7, #0, Rt, Rt2, c8
```

**rcp\_b2and**

Asserts that **Rt** and **Rt2** are both **true**.

Opcode:

```
mcrr p7, #1, Rt, Rt2, c0
```

**rcp\_b2or**

Asserts that both **Rt** and **Rt2** are valid, and at least one is **true**.

```
mcrr p7, #2, Rt, Rt2, c0
```

**rcp\_bxorvalid**

Asserts that **Rt** XOR **Rt2** is a valid boolean. The XOR mask is generally a fixed bit pattern used to validate the origin of the boolean, such as a return value from a critical function.

Opcode:

```
mcrr p7, #3, Rt, Rt2, c8
```

**rcp\_bxortrue**

Asserts that **Rt** XOR **Rt2** is **true**.

Opcode:

```
mcrr p7, #4, Rt, Rt2, c0
```

**rcp\_bxorfalse**

Asserts that **Rt** XOR **Rt2** is **false**.

Opcode:

```
mcrr p7, #5, Rt, Rt2, c8
```

### 3.6.3.7.4. Integer Validation

**rcp\_ivalid**

Asserts that **Rt** XOR **Rt2** is equal to **0x96009600**. This is used to validate 32-bit integers stored redundantly in two memory words. The XOR difference provides assurance that two parallel chains of integer operations have not mixed.

Opcode:

**rcp\_b2and**

断言 Rt 和 Rt2 均为真。

操作码：

```
mcrr p7, #1, Rt, Rt2, c0
```

**rcp\_b2or**

断言 Rt 和 Rt2 均有效，且至少一个为真。

```
mcrr p7, #2, Rt, Rt2, c0
```

**rcp\_bxorvalid**

断言 Rt 异或 Rt2 为有效布尔值。XOR 掩码通常为固定比特模式，用于验证布尔值的来源，例如关键函数返回值。

操作码：

```
mcrr p7, #3, Rt, Rt2, c8
```

**rcp\_bxortrue**

断言 Rt XOR Rt2 为真。

操作码：

```
mcrr p7, #4, Rt, Rt2, c0
```

**rcp\_bxorfalse**

断言 Rt XOR Rt2 为假。

操作码：

```
mcrr p7, #5, Rt, Rt2, c8
```

**3.6.3.7.4. 整数验证****rcp\_ivalid**

断言 Rt XOR Rt2 等于 0x96009600。此方法用于验证冗余存储在两个内存字中的32位整数。XOR 差异确保两条并行的整数运算链未被干扰。

操作码：

```
mcrr p7, #6, Rt, Rt2, c8
```

**rcp\_iequal**

Asserts that **Rt** is equal to **Rt2**. Useful for general software assertions that are worth checking in hardware.

Opcode:

```
mcrr p7, #7, Rt, Rt2, c0
```

**3.6.3.7.5. Random****rcp\_random\_byte**

Returns a random 8-bit value generated from the upper 24 bits of the 64-bit salt value. Bits **31:8** of the result are all-zero.

Opcode:

```
mrc p7, #2, Rt, c0, c0, #0
```

This is the same PRNG used for random delay values. It is mainly exposed for debugging purposes, and should not be used for general software RNG purposes because the 24-bit state space is inadequate for scenarios where the quality and predictability of the random numbers is important.

This instruction never has an execution delay. Once the Cortex-M33 issues the coprocessor access, it always completes in one cycle.

**3.6.3.7.6. Sequence count checking**

These instructions are used to assert that a sequence of operations happens in the correct order. The count is initialised to an 8-bit value at the beginning of such a sequence, then repeatedly checked, incrementing with each check. If the 8-bit check value does not match the current counter value, the coprocessor raises an RCP fault.

**rcp\_count\_set**

Writes an 8-bit count value to the RCP sequence counter. Encodes the 8-bit value using two 4-bit coprocessor numbers: **CRn** provides the MSBs, **CRm** the LSBs.

Opcode:

```
mcr p7, #4, r0, CRn, CRm, #0
```

**rcp\_count\_check**

Asserts that an 8-bit count value matches the current value of the RCP sequence counter. Increments the counter by one, wrapping back to **0x00** after reaching **0xff**. Encodes the 8-bit count value using two 4-bit coprocessor numbers: **CRn** provides the MSBs, **CRm** the LSBs.

Opcode:

```
mcr p7, #6, Rt, Rt2, c8
```

**rcp\_iequal**

断言 **Rt** 等于 **Rt2**。对于值得在硬件中进行检测的一般软件断言，此项极为有用。

操作码：

```
mcr p7, #7, Rt, Rt2, c0
```

**3.6.3.7.5. 随机****rcp\_random\_byte**

返回从64位盐值的高24位生成的随机8位数值。结果的第**31**至第**8**位均为零。

操作码：

```
mrc p7, #2, Rt, c0, c0, #0
```

该伪随机数生成器与用于随机延迟值的相同。此处主要用于调试目的，不应用于一般软件随机数生成，因为24位的状态空间无法满足对随机数质量与不可预测性有较高要求的应用场景。

该指令不会产生执行延迟。Cortex-M33发出协处理器访问请求后，必定在一个周期内完成。

**3.6.3.7.6. 序列计数检查**

这些指令用于断言一系列操作按正确顺序执行。计数在序列开始时初始化为8位值，随后反复检查，每次检查时递增。

如果8位校验值与当前计数器值不符，协处理器将触发RCP故障。

**rcp\_count\_set**

向RCP序列计数器写入8位计数值。使用两个4位协处理器编号编码8位值：**CRn**提供高位，**CRm**提供低位。

操作码：

```
mcr p7, #4, r0, CRn, CRm, #0
```

**rcp\_count\_check**

断言8位计数值与RCP序列计数器当前值相符。计数器递增1，计数达到 **0xff** 后回绕至 **0x00**。使用两个4位协处理器编号编码8位计数值：**CRn**提供高位，**CRm**提供低位。

操作码：

```
mcr p7, #5, r0, CRn, CRm, #1
```

### 3.6.3.7.7. Panic

#### `rcp_panic`

Stalls the coprocessor port forever. If the processor abandons the coprocessor access, asserts NMI and continues stalling the coprocessor port. Also immediately raises an RCP fault on other cores.

Opcode:

```
cdp p7, #0, c0, c0, c0, #1
```

Software executes an `rcp_panic` instruction when it detects a condition that makes it unsafe to continue executing the current program. The RCP responds by stalling the processor's CDP access forever, which should cause the processor to stop fetching and executing instructions.

The processor is allowed to abandon a stalled coprocessor instruction when interrupted, which may cause it to continue executing in an unsafe state. The RCP responds to an abandoned transfer by asserting the non-maskable interrupt, pre-empting the interrupt handler that caused the coprocessor access to be abandoned. This should swiftly encounter another RCP instruction and once again stall the processor, this time without allowing interruption.

Panic is specified in this way, instead of gating the processor clock, so the debugger can still attach cleanly to the processor after a panic.

## 3.6.4. Floating point unit

The Cortex-M33 cores on RP2350 are configured with the standard Arm single-precision floating point unit (FPU). Coprocessor ports 10 and 11 access the FPU.

The Arm floating point extension is documented in the [Armv8-M Architecture Reference Manual](#).

Applications built with the SDK use the FPU automatically by default. For example, calculations with the `float` data type in C automatically use the standard FPU, while calculations with the `double` data type automatically use the RP2350 double-precision coprocessor ([Section 3.6.2](#)).

## 3.7. Cortex-M33 processor

#### Arm Documentation

Much of the following is excerpted from the [Cortex-M33 Technical Reference Manual](#). Used with permission.

The Arm Cortex-M33 processor is a low gate count, highly energy-efficient processor intended for microcontroller and embedded applications. The processor is based on the Armv8-M architecture and is primarily for use in environments where security is an important consideration.

```
mcr p7, #5, r0, CRn, CRm, #1
```

### 3.6.3.7.7. 紧急情况

#### `rcp_panic`

永久阻塞协处理器端口。如果处理器放弃协处理器访问，则断言非屏蔽中断（NMI）并持续阻塞协处理器端口。并立即在其他核心上引发RCP故障。

操作码：

```
cdp p7, #0, c0, c0, c0, #1
```

软件在检测到当前程序继续执行存在安全隐患时，会执行 `rcp_panic` 指令。RCP的响应是永久阻塞处理器对CDP的访问，这应导致处理器停止获取和执行指令。

当处理器被中断时，允许其放弃阻塞的协处理器指令，但这可能导致继续在不安全状态下执行。RCP通过断言非屏蔽中断响应被放弃的传输，抢占触发协处理器访问放弃的中断处理程序。此时应迅速遇到另一个RCP指令，并再次阻塞处理器，且此次不允许中断。

Panic采用这种方式指定，而非通过门控处理器时钟，使调试器在发生panic后仍能清晰地附加至处理器。

## 3.6.4. 浮点运算单元

RP2350上的Cortex-M33内核配备标准的Arm单精度浮点运算单元（FPU）。

协处理器端口 [10](#) 和 [11](#) 可访问FPU。

Arm浮点扩展详见Armv8-M架构参考手册。

使用SDK构建的应用程序默认自动调用FPU。例如，在C语言中，对 `float` 数据类型的计算自动使用标准FPU，而对 `double` 数据类型的计算自动使用RP2350双精度协处理器（见第3.6.2节）。

## 3.7. Cortex-M33 处理器

### Arm文档

下列内容大部分摘自Cortex-M33技术参考手册，经授权使用。

Arm Cortex-M33处理器是一款逻辑门数低、高能效的处理器，适用于微控制器及嵌入式应用。该处理器基于Armv8-M架构，主要应用于对安全性有重要要求的环境。

**NOTE**

Full details of the Arm Cortex-M33 processor can be found in the [Technical Reference Manual](#).

### 3.7.1. Features

The Arm Cortex-M33 processor provides the following features and benefits:

- An in-order issue pipeline
- Thumb-2 technology; for more information, see the [Armv8-M Architecture Reference Manual](#)
- Little-endian data accesses
- A Nested Vectored Interrupt Controller (NVIC) closely integrated with the processor
- A Floating Point Unit (FPU) supporting single-precision arithmetic
- Support for exception-continuable instructions, such as LDM, LDMDB, STM, STMDB, PUSH, POP, VLDM, VSTM, VPUSH, and VPOP
- A low-cost debug solution that provides the ability to implement:
  - Breakpoints
  - Watchpoints
  - Tracing
  - System profiling
  - Support for `printf()` style debugging through an Instrumentation Trace Macrocell (ITM)
- Support for the Embedded Trace Macrocell (ETM) instruction trace option; for more information, see the [Arm CoreSight ETM-M33 Technical Reference Manual](#)
- A coprocessor interface for external hardware accelerators
- Low-power features including architectural clock gating, sleep mode, and a power-aware system with Wake-up Interrupt Controller (WIC)
- A memory system that includes memory protection and security attribution

### 3.7.2. Configuration

Each Arm Cortex-M33 processor in RP2350 is configured with the following features:

- **FPU**: Single precision FPU
- DSP: DSP extension
- **SECEXT**: Security extensions
- CPIF: coprocessor interface
- MPU\_NS: 8 non-secure MPU regions
- MPU\_S: 8 secure MPU regions
- SAU: 8 SAU regions
- IRQ: 52 external interrupts
- IRQLVL: 4 exception priority bits
- DBGLVL: Full debug set: 4 watchpoint, 8 breakpoint comparators, debug monitor

### ⓘ 注意

有关Arm Cortex-M33处理器的完整详情，请参阅技术参考手册。

## 3.7.1. 特性

Arm Cortex-M33处理器提供以下功能与优势：

- 顺序发射流水线
- Thumb-2技术；如需更多信息，请参阅Arm v8-M架构参考手册。
- 小端数据访问
- 与处理器紧密集成的嵌套向量中断控制器（NVIC）
- 支持单精度浮点运算的浮点单元（FPU）
- 支持可异常续发的指令，如LDM、LDMDB、STM、STMDB、PUSH、POP、VLDM、VSTM、VPUSH和VPOP
- 一种低成本调试解决方案，具备实现以下功能的能力：
  - 断点
  - 观察点
  - 跟踪
  - 系统性能分析
  - 通过仪器追踪宏单元（ITM）支持printf()风格的调试
- 支持嵌入式追踪宏单元（ETM）指令追踪选项；如需更多信息，请参阅Arm CoreSight ETM-M33技术参考手册
- 
- 用于外部硬件加速器的协处理器接口
- 低功耗特性，包括架构时钟门控、睡眠模式及具备唤醒中断控制器（WIC）的电源感知系统
- 包括内存保护与安全属性的内存系统

## 3.7.2. 配置

RP2350 中每个 Arm Cortex-M33 处理器均配置以下特性：

- **FPU：单精度浮点运算单元**
- DSP：数字信号处理扩展
- **SECEXT：安全扩展**
- CPIF：协处理器接口
- MPU\_NS：8 个非安全 MPU 区域
- MPU\_S：8 个安全 MPU 区域
- SAU：8 个安全属性单元（SAU）区域
- IRQ：52 个外部中断
- IRQLVL：4 位异常优先级
- DBGLVL：完整调试集，包括 4 个观察点、8 个断点比较器及调试监视器

- ITM: [DWT](#) and ITM trace
- [ETM](#): ETM trace
- [MTB](#): no MTB trace
- WIC: Wake up interrupt controller
- WICLINES: 55: All external interrupts and 3 internal events: NMI, RVEX, Debug
- [CTI](#): Cross trigger interface
- RAR: reset all registers on power up
- [UNCROSS\\_I\\_D](#): Modify internal address map
- SBIST: no SBIST features
- CDE modules not used
- CDERTLID: RTL ID for system with multi Cortex-M33: 16

Architectural clock gating allows the processor core to support SLEEP and DEEPSLEEP power states by disabling the clock to parts of the processor core. Power gating is not supported.

Each Cortex-M33 core has its own interrupt controller that can individually mask out interrupt sources as required. The same interrupts route to both Cortex-M33 cores.

The processor supports the following interfaces:

- Code AHB (C-AHB) interface
- System AHB (S-AHB) interface
- External PPB (EPPB) APB interface
- Debug AHB (D-AHB) interface

The processor implements the following optional interfaces:

- Arm TrustZone technology, using the Armv8-M Security Extension supporting Secure and Non-secure states
- Memory Protection Units (MPUs), which you can configure to protect regions of memory
- Floating-point arithmetic functionality with support for single precision arithmetic
- Support for ETM trace

### 3.7.2.1. Modifications by Raspberry Pi

#### 3.7.2.1.1. [UNCROSS\\_I\\_D](#)

The original Cortex-M33 processor design routes the following operations to either the Code or System port:

- instruction fetch
- load/stores
- debugger accesses

Accesses below address `0x20000000` route to the Code port. All other accesses route to the System port.

This routing strategy makes contention possible on both the internal bus matrix *and* the main system AHB5 crossbar. The *Cortex-M33 Technical Reference Manual* describes this strategy in detail.

In RP2350, Raspberry Pi modified the Cortex-M33 bus matrix to:

- route all instruction fetch operations to the Code port

- ITM：数据观察追踪（DWT）与 ITM 追踪
- ETM：指令追踪（ETM）
- MTB：无 MTB 追踪
- WIC：唤醒中断控制器
- WICLINES: 55：所有外部中断及3个内部事件：NMI、RVEV、调试
- CTI：交叉触发接口
- RAR：上电时复位所有寄存器
- UNCROSS\_I\_D：修改内部地址映射
- SBIST：无SBIST功能
- 未使用CDE模块
- CDERTLID：多Cortex-M33系统的RTL ID：16

架构时钟门控允许处理器核心通过禁用核心部分时钟，支持SLEEP和DEEPSLEEP低功耗状态。不支持电源门控。

每个Cortex-M33核心拥有独立的中断控制器，可以根据需要单独屏蔽中断源。相同的中断会路由到两个Cortex-M33核心。

处理器支持以下接口：

- 代码AHB（C-AHB）接口
- 系统AHB（S-AHB）接口
- 外部PPB（EPPB）APB接口
- 调试AHB（D-AHB）接口

处理器实现了以下可选接口：

- Arm TrustZone 技术，采用支持安全与非安全状态的 Armv8-M 安全扩展
- 内存保护单元（MPU），可配置以保护特定内存区域
- 具备支持单精度算术运算的浮点运算功能
- 支持 ETM 跟踪功能

### 3.7.2.1. Raspberry Pi 的修改内容

#### 3.7.2.1.1. UNCROSS\_I\_D

原始 Cortex-M33 处理器设计将以下操作路由至代码端口或系统端口：

- 指令取指
- 加载/存储
- 调试器访问

地址低于 `0x2` 的访问 `0000000` 路由至代码端口。所有其他访问路由至系统端口。

该路由策略可能引发内部总线矩阵和主系统 AHB5 交叉开关的争用。

Cortex-M33 技术参考手册对此策略有详细描述。

在 RP2350 中，Raspberry Pi 对 Cortex-M33 总线矩阵进行了修改，具体为：

- 将所有指令取指操作路由至代码端口

- route all load/stores and debugger accesses to the System port

This eliminates internal conflicts and improves performance in certain software use cases, e.g. when allocating both code and data from a single unified SRAM pool.

In [Section 3.7.2](#), we refer to this feature as [UNCROSS\\_I\\_D](#).

There are no other modifications to the Cortex-M33 processor.

#### NOTE

This datasheet may refer to the Cortex-M33 Code and System ports as the instruction and data ports respectively (I and D), to reflect this modification to the core's integrated bus matrix.

### 3.7.2.2. Interfaces

The processor has various external interfaces:

#### Code and System AHB interfaces

Harvard AHB bus architecture supporting exclusive transactions and security state.

#### System AHB interface

The System AHB (S-AHB) interface is used for any instruction fetch and data access to the memory-mapped SRAM, Peripheral, External RAM and External device, or Vendor\_SYS regions of the Armv8-M memory map.

#### Code AHB interface

The Code AHB (C-AHB) interface is used for any instruction fetch and data access to the Code region of the Armv8-M memory map.

#### External Private Peripheral Bus

The External PPB (EPPB) APB interface enables access to CoreSight-compatible debug and trace components in a system connected to the processor.

#### Secure attribution interface

The processor has an interface that connects to an external Implementation Defined Attribution Unit (IDAU), which enables your system to set security attributes based on address.

#### ATB interfaces

The ATB interfaces output trace data for debugging. The ATB interfaces are compatible with the CoreSight architecture. See the Arm CoreSight Architecture Specification v2.0 for more information. The instruction ATB interface is used by the ETM, and the instrumentation ATB interface is used by the Instrumentation Trace Macrocell (ITM).

#### Micro Trace Buffer interfaces

The Micro Trace Buffer (MTB) AHB slave interface and SRAM interface are for the CoreSight Micro Trace Buffer.

#### Coprocessor interface

The coprocessor interface is designed for closely coupled external accelerator hardware.

#### Debug AHB interface

The Debug AHB (D-AHB) slave interface allows a debugger access to registers, memory, and peripherals. The D-AHB interface provides debug access to the processor and the complete memory map.

#### Cross Trigger Interface

The processor includes a Cross Trigger Interface (CTI) Unit that has an interface that is suitable for connection to external CoreSight components using a Cross Trigger Matrix (CTM).

#### Power control interface

The processor supports a number of internal power domains that can be enabled and disabled using Q-channel interfaces connected to a Power Management Unit (PMU) in the system.

- 将所有加载/存储和调试器访问路由至系统端口

此举消除内部冲突，并在某些软件使用场景中提升性能，例如当从单一统一的SRAM池分配代码与数据时。

在第3.7.2节中，我们将该功能称为UNCROSS\_I\_D。

Cortex-M33处理器未作其他修改。

### 注意

本数据手册可能将Cortex-M33的代码端口与系统端口分别称为指令端口与数据端口（I与D），以反映对内核集成总线矩阵的该项修改。

## 3.7.2.2 接口

处理器具备多种外部接口：

### 代码与系统 AHB 接口

采用哈佛AHB总线架构，支持排他性事务与安全状态。

### 系统 AHB 接口

系统 AHB（S-AHB）接口用于任何对Armv8-M存储映射的SRAM、外设、外部RAM、外部设备或Vendor\_SYS区域的指令提取和数据访问。

### 代码 AHB 接口

代码 AHB（C-AHB）接口用于对 Armv8-M 存储器映射中的代码区域进行任何指令取指和数据访问。

### 外部私有外设总线

外部 PPB (EPPB) APB 接口使系统能够访问连接至处理器的兼容 CoreSight 调试和追踪组件。

### 安全归因接口

处理器设有连接至外部实现定义归因单元（IDAU）的接口，允许系统基于地址设置安全属性。

### ATB 接口

ATB 接口用于输出调试追踪数据。ATB 接口兼容 CoreSight 架构。更多信息请参阅 Arm CoreSight 架构规范 v2.0。指令 ATB 接口由 ETM 使用，仪表 ATB 接口由仪表追踪宏单元（ITM）使用。

### 微追踪缓冲区接口

微追踪缓冲区（MTB）的 AHB 从接口和 SRAM 接口用于 CoreSight 微追踪缓冲区。

### 协处理器接口

协处理器接口专为紧密耦合的外部加速硬件设计。

### 调试 AHB 接口

调试 AHB（D-AHB）从属接口允许调试器访问寄存器、内存和外设。D-AHB 接口提供对处理器及完整内存映射的调试访问。

### 交叉触发接口

处理器包含一个交叉触发接口（CTI）单元，该接口适用于通过交叉触发矩阵（CTM）连接外部 CoreSight 组件。

### 电源控制接口

处理器支持多个内部电源域，可通过连接至系统中电源管理单元（PMU）的 Q 通道接口启用或禁用。

### 3.7.2.3. Security attribution and memory protection

The Cortex-M33 processor supports the Armv8-M Protected Memory System Architecture (PMSA) that provides programmable support for [memory protection](#) using a number of software controllable regions. RP2350 supports 8 programmable regions.

PMSA allows privileged software to assign access permissions to a memory region. When unprivileged software attempts to access the region, a fault exception is triggered. PMSA includes fault status registers that allow an exception handler to determine the source of the fault, apply corrective action, and notify the system. This reduces the potential impact of incorrectly-written application code.

The Cortex-M33 processor also includes support for defining memory regions as Secure or Non-secure, as defined in the Armv8-M Security Extension. This protects memory regions from accesses with an inappropriate level of security.

### 3.7.2.4. Floating-point unit (FPU)

The FPU provides:

- Instructions for single-precision (C programming language float type) data-processing operations
- Instructions for double-precision (C programming language double type) load and store operations
- Combined multiply-add instructions for increased precision (Fused MAC)
- Hardware support for conversion, addition, subtraction, multiplication, accumulate, division, and square-root
- Hardware support for denormals and all IEEE Standard 754-2008 rounding modes
- Thirty-two 32-bit single-precision registers or sixteen 64-bit double-precision registers
- Lazy floating-point context save

#### 3.7.2.4.1. Lazy floating-point context save

This FPU function delays automated stacking of floating-point state until the ISR attempts to execute a floating-point instruction. This reduces the latency to enter the ISR and removes floating-point context save for ISRs that do not use floating-point.

### 3.7.2.5. NVIC

The Nested Vectored Interrupt Controller NVIC prioritizes external interrupt signals. Software can set the priority of each interrupt. The NVIC and the Cortex-M33 processor core are closely coupled, providing low latency interrupt processing and efficient processing of late arriving interrupts.

#### NOTE

"Nested" refers to the fact that interrupts can themselves be interrupted, by higher-priority interrupts. "Vectored" refers to the hardware dispatching each interrupt to a distinct handler routine specified by a vector table. For more details about nesting and vectoring behaviour, see the [Armv8-M Architecture Reference Manual](#).

All NVIC registers are only accessible using word transfers. Any attempt to read or write a halfword or byte individually is unpredictable.

NVIC registers are always little-endian.

The Nested Vectored Interrupt Controller (NVIC) is closely integrated with the core to achieve low-latency interrupt processing.

Functions of the NVIC include:

### 3.7.2.3 安全归属与内存保护

Cortex-M33 处理器支持 Armv8-M 受保护内存系统架构（PMSA），该架构利用多个软件可控区域实现可编程内存保护。RP2350 支持 8 个可编程区域。

PMSA 允许特权软件为内存区域分配访问权限。当非特权软件尝试访问该区域时，将触发故障异常。PMSA 包含故障状态寄存器，允许异常处理程序确定故障来源，采取纠正措施并通知系统。此机制减少了错误编写的应用程序代码可能造成的潜在影响。

Cortex-M33 处理器还支持根据 Armv8-M 安全扩展，将内存区域定义为安全或非安全状态，从而防止不适当安全级别的访问。

### 3.7.2.4. 浮点单元 (FPU)

FPU 提供以下功能：

- 针对单精度（C 语言 float 类型）数据处理操作的指令
- 针对双精度（C 语言 double 类型）加载与存储操作的指令
- 用于提高精度的乘加合并指令（Fused MAC）
- 支持硬件实现的转换、加法、减法、乘法、累加、除法及平方根操作
- 对非正规数及所有 IEEE Standard 754-2008 舍入模式的硬件支持
- 三十二个 32 位单精度寄存器或十六个 64 位双精度寄存器
- 惰性浮点上下文保存

#### 3.7.2.4.1. 惰性浮点上下文保存

该 FPU 功能延迟自动堆栈保存浮点状态，直至中断服务例程（ISR）尝试执行浮点指令。此举减少了进入 ISR 的时延，并避免了对不使用浮点的 ISR 进行浮点上下文保存。

### 3.7.2.5. NVIC

嵌套向量中断控制器（NVIC）负责对外部中断信号进行优先级排序。软件能够设置各中断的优先级。NVIC 与 Cortex-M3 3 处理器核心紧密耦合，提供低延迟的中断处理及对后续中断的高效响应。

#### 注意

“嵌套”意指中断本身可以被更高优先级的中断打断。“向量化”意指硬件将每个中断分派至矢量表中指定的独立处理程序例程。有关嵌套和矢量行为的详细信息，请参阅 Armv8-M 架构参考手册。

所有 NVIC 寄存器仅能通过字传输访问。任何单独读取或写入半字或字节的尝试行为均为不可预测。

NVIC 寄存器始终采用小端序存储。

嵌套矢量中断控制器（NVIC）与内核紧密集成，以实现低延迟的中断处理。

NVIC 的功能包括：

- External interrupts, configurable from 1 to 480 using a contiguous or non-contiguous mapping. This is configured at implementation.
- Configurable levels of interrupt priority from 8 to 256. This is configured at implementation.
- Dynamic reprioritisation of interrupts.
- Priority grouping. This enables selection of pre-empting interrupt levels and non-pre-empting interrupt levels.
- Support for tail-chaining and late arrival of interrupts. This enables back-to-back interrupt processing without the overhead of state saving and restoration between interrupts.
- Support for the Armv8-M Security Extension. Secure interrupts can be prioritized above any Non-secure interrupt.

### 3.7.2.6. Cross Trigger Interface Unit (CTI)

The CTI enables the debug logic, MTB, and ETM to interact with each other and with other CoreSight™ components.

### 3.7.2.7. ETM

The ETM provides instruction-only capabilities.

### 3.7.2.8. MTB

The MTB provides a simple low-cost execution trace solution for the Cortex-M33 processor.

Trace is written to an SRAM interface, and can be extracted using a dedicated AHB slave interface (M-AHB) on the processor. The MTB can be controlled by memory-mapped registers in the PPB region or by events generated by the DWT or through the CTI.

See the Arm [CoreSight MTB-M33 Technical Reference Manual](#) for more information.

### 3.7.2.9. Debug and trace

Debug and trace components include a configurable Breakpoint Unit (BPU) used to implement breakpoints and a configurable Data Watchpoint and Trace (DWT) unit used to implement watchpoints, data tracing, and system profiling. Other debug and trace components include:

- ITM for support of `printf()` style debugging, using instrumentation trace
- Interfaces suitable for:
  - Passing on-chip data through a Trace Port Interface Unit (TPIU) to a Trace Port Analyzer (TPA) via a 4-bit DDR output selected as a GPIO function (see [Section 3.5.7](#))
  - A ROM table to allow debuggers to determine which components are implemented in the Cortex-M33 processor
  - Debugger access to all memory and registers in the system, including access to memory-mapped devices, access to internal core registers when the core is halted, and access to debug control registers even when reset is asserted

### 3.7.3. Compliance

The processor complies with, or implements, the relevant Arm architectural standards and protocols, and relevant external standards.

- 外部中断，支持1至480个中断，可通过连续或非连续映射进行配置。该配置由具体实现决定。
- 可配置中断优先级级别，范围从8至256。该配置由具体实现决定。
- 支持中断的动态优先级重新排序。
- 优先级分组功能。该功能允许选择抢占式优先级和非抢占式优先级。
- 支持尾部链式和延迟到达中断。该功能使得连续中断处理无需中断间的状态保存与恢复开销。
- 支持 Armv8-M 安全扩展。安全中断的优先级可高于任何非安全中断。

### 3.7.2.6. 交叉触发接口单元（CTI）

CTI使调试逻辑、MTB和ETM能够相互交互，并与其他CoreSight™组件协同工作。

### 3.7.2.7. ETM

ETM仅提供指令执行追踪功能。

### 3.7.2.8. MTB

MTB为Cortex-M33处理器提供一种简易且低成本的执行跟踪解决方案。

跟踪数据写入SRAM接口，并可通过处理器上的专用AHB从属接口（M-AHB）提取。MTB可通过PPB区域的内存映射寄存器控制，或由DWT生成的事件或CTI触发。

更多详情请参阅Arm CoreSight MTB-M33技术参考手册。

### 3.7.2.9. 调试与跟踪

调试与跟踪组件包括可配置断点单元（BPU），用于实现断点；以及可配置数据观察点与跟踪单元（DWT），用于实现观察点、数据跟踪和系统性能分析。

其他调试和追踪组件包括：

- 支持 `printf()` 风格调试的ITM，基于仪表追踪
- 适用的接口包括：
  - 通过追踪端口接口单元（TPIU），利用4位DDR输出作为GPIO功能（参见第3.5.7节），将片上数据传递至追踪端口分析仪（TPA）
  - 只读存储器（ROM）表，允许调试器确定Cortex-M33中已实现的组件处理器
  - 调试器可访问系统中的所有内存和寄存器，包括内存映射设备，在核心停止时访问内部核心寄存器，且即便复位信号被断言，依然可访问调试控制寄存器

### 3.7.3. 合规性

该处理器符合或实现了相关Arm架构标准和协议，以及相关外部标准。

### 3.7.3.1. Arm architecture

The processor is compliant with the following:

- Armv8-M Main Extension
- Armv8-M Security Extension
- Armv8-M Protected Memory System Architecture (PMSA)
- Armv8-M Floating-point Extension
- Armv8-M Digital Signal Processing (DSP) Extension
- Armv8-M Debug Extension
- Armv8-M Flash Patch Breakpoint (FPB) architecture version 2.0

### 3.7.3.2. Bus architecture

The processor provides external interfaces that comply with the AMBA 5 AHB5 protocol. The processor also implements interfaces for CoreSight and other debug components using the APB4 protocol and ATBv1.1 part of the AMBA 4 ATB protocol.

For more information, see the:

- [Arm AMBA 5 AHB Protocol Specification](#)
- [AMBA APB Protocol Version 2.0 Specification](#)
- [Arm AMBA 4 ATB Protocol Specification ATBv1.0 and ATBv1.1](#)

The processor also provides a Q-Channel interface. For more information, see the [AMBA Low Power Interface Specification](#).

### 3.7.3.3. Debug

The debug features of the processor implement the Arm Debug Interface Architecture. For more information, see the [Arm Debug Interface Architecture Specification, ADLv5.0 to ADLv5.2](#).

### 3.7.3.4. Embedded Trace Macrocell

The trace features of the processor implement the Arm Embedded Trace Macrocell (ETM) v4.2 architecture.

For more information, see the [Arm CoreSight ETM-M33 Technical Reference Manual](#).

### 3.7.3.5. Floating-point unit

The Cortex-M33 processor with FPU supports single-precision arithmetic as defined by the FPv5 architecture that is part of the Armv8-M architecture. The FPU provides floating-point computation functionality compliant with ANSI/IEEE Standard 754-2008, IEEE Standard for Binary Floating-Point Arithmetic.

The FPU supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

The FPU provides an extension register file containing 32 single-precision registers.

The registers can be viewed as:

### 3.7.3.1 Arm架构

该处理器符合以下规范：

- Armv8-M主扩展
- Armv8-M安全扩展
- Armv8-M保护内存系统架构（PMSA）
- Armv8-M 浮点扩展
- Armv8-M 数字信号处理（DSP）扩展
- Armv8-M 调试扩展
- Armv8-M 闪存补丁断点（FPB）架构版本 2.0

### 3.7.3.2 总线架构

处理器提供符合 AMBA 5 AHB5 协议的外部接口。处理器还采用 APB4 协议及 AMBA 4 ATB 协议中的 ATBv1.1，为 CoreSight 及其他调试组件实现接口。

更多信息，请参阅：

- [Arm AMBA 5 AHB 协议规范](#)
- [AMBA APB 协议版本 2.0 规范](#)
- [Arm AMBA 4 ATB 协议规范，含 ATBv1.0 与 ATBv1.1](#)

处理器还提供 Q-Channel 接口。更多信息，请参阅 AMBA 低功耗接口规范。

### 3.7.3.3 调试

处理器的调试功能实现了 Arm 调试接口架构。更多信息，请参阅 Arm 调试接口架构规范 ADIv5.0 至 ADIv5.2。

### 3.7.3.4. 嵌入式跟踪宏单元

处理器的跟踪功能实现了 Arm 嵌入式跟踪宏单元（ETM）v4.2 架构。

如需更多信息，请参见 Arm CoreSight ETM-M33 技术参考手册。

### 3.7.3.5. 浮点单元

Cortex-M33 处理器配备的浮点单元（FPU）支持由 Armv8-M 架构中 FPv5 定义的单精度算术运算。该 FPU 提供符合 ANSI/IEEE 标准 754-2008 —— 二进制浮点运算 IEEE 标准的浮点计算功能。

FPU 支持单精度的加、减、乘、除、乘加累积及平方根运算。  
此外，还支持固定点与浮点数据格式之间的转换及浮点常量指令。

FPU 包含一个扩展寄存器文件，含 32 个单精度寄存器。

这些寄存器可视为：

- Thirty-two 32-bit single-word registers, [S0-S31](#)
- Sixteen 64-bit double-word registers, [D0-D15](#)
- A combination of registers from these views

### 3.7.3.5.1. FPU modes

The FPU provides full-compliance, flush-to-zero, and Default NaN modes of operation. In full-compliance mode, the FPU processes all operations according to the IEEE 754 standard in hardware.

Modes of operation are controlled using the Floating-Point Status and Control Register, [FPSCR](#).

Setting the [FPSCR.FZ](#) bit enables Flush-to-Zero (FZ) mode. In FZ mode, the FPU treats all subnormal input operands of arithmetic operations as zeros. Exceptions that result from a zero operand are signalled appropriately. [VABS](#), [VNEG](#), and [VMOV](#) are not considered arithmetic operations and are not affected by FZ mode. When an operation yields a *tiny* result (as described in the IEEE 754 standard, where the destination precision is smaller in magnitude than the minimum normal value before rounding) FZ mode replaces the result with a zero.

The [FPSCR.IDC](#) bit indicates when an input flush occurs.

The [FPSCR.UFC](#) bit indicates when a result flush occurs.

Setting the [FPSCR.DN](#) bit enables Default NaN (DN) mode. In NaN mode, the result of any arithmetic data processing operation that involves an input NaN, or that generates a NaN result, returns the default NaN. All arithmetic operations except for [VABS](#), [VNEG](#), and [VMOV](#) ignore the fraction bits of an input NaN.

Setting neither the [FPSCR.DN](#) bit nor the [FPSCR.FZ](#) bit enables full-compliance mode. In full-compliance mode, FPv5 functionality is compliant with the IEEE 754 standard in hardware.

For more information about the FPU and [FPSCR](#), see the [Armv8-M Architecture Reference Manual](#).

### 3.7.3.5.2. FPU exceptions

The FPU sets the cumulative exception status flag in the [FPSCR](#) register as required for each instruction, in accordance with the FPv5 architecture. The FPU does not support exception traps.

The processor has six output pins. By default, they are disconnected. Each reflect the status of one of the cumulative exception flags:

#### **FPIXC**

Masked floating-point inexact exception.

#### **FPUFC**

Masked floating-point underflow exception.

#### **FPOFC**

Masked floating-point overflow exception.

#### **FPDZC**

Masked floating-point divide by zero exception.

#### **FPIDC**

Masked floating-point input denormal exception.

#### **FPIOC**

Invalid operation.

When a floating-point context is active, the stack frame extends to accommodate the floating-point registers. To reduce the additional interrupt latency associated with writing the larger stack frame on exception entry, the processor supports lazy stacking. This means that the processor reserves space on the stack for the FP state, but does not save that state information to the stack unless the processor executes an FPU instruction inside the exception handler.

- 三十二个 32 位单字寄存器, [S0-S31](#)
- 十六個 64 位双字寄存器, [D0-D15](#)
- 这些视图中寄存器的组合

### 3.7.3.5.1. FPU 模式

FPU 提供完全兼容、零舍入 (Flush-to-Zero) 和默认 NaN 模式的操作。在完全兼容模式下，FPU 通过硬件根据 IEEE 754 标准处理所有操作。

操作模式由浮点状态和控制寄存器 ([FPSCR](#)) 控制。

设置 [FPSCR.FZ](#) 位即可启用零舍入 (Flush-to-Zero, FZ) 模式。在 FZ 模式下，FPU 将所有算术操作的非规格化输入操作数视为零。由零操作数引发的异常会被适当报告。[VABS](#)、[VNEG](#) 和 [VMOV](#) 不被视为算术操作，因此不受 FZ 模式影响。当操作产生 *tiny* 结果时（如 IEEE 754 标准规定，目标精度的数值在舍入前小于最小正规值），FZ 模式将结果替换为零。

[FPSCR.IDC](#) 位指示输入刷新事件的发生。

[FPSCR.UFC](#) 位指示结果刷新事件的发生。

设置 [FPSCR.DN](#) 位以启用默认 NaN (DN) 模式。在 NaN 模式下，任何涉及输入 NaN 或产生 NaN 结果的算术数据处理操作，其结果均返回默认 NaN。除 [VABS](#)、[VNEG](#) 和 [VMOV](#) 外，所有算术操作均忽略输入 NaN 的分数位。

当 [FPSCR.DN](#) 位和 [FPSCR.FZ](#) 位均未设置时，启用全合规模式。在全合规模式下，[FPv5](#) 功能在硬件层面符合 IEEE 754 标准。

有关 FPU 和 FPSCR 的更多信息，请参见 Armv8-M 架构参考手册。

### 3.7.3.5.2 FPU 异常

FPU 根据 FPv5 架构要求，在 FPSCR 寄存器中为每条指令设置累计异常状态标志。FPU 不支持异常陷阱。

处理器具有六个输出引脚。默认情况下，它们处于断开状态。每个引脚反映一个累积异常标志的状态：

#### FPIXC

屏蔽的浮点不精确异常。

#### FPUFC

屏蔽的浮点下溢异常。

#### FPOFC

屏蔽的浮点溢出异常。

#### FPDZC

屏蔽的浮点除零异常。

#### FPIDC

屏蔽的浮点输入非规格化数异常。

#### FPIOC

无效操作。

当浮点上下文处于活动状态时，堆栈帧会扩展以容纳浮点寄存器。为减少异常进入时写入更大堆栈帧所带来的额外中断延迟，处理器支持惰性堆栈技术。这意味着处理器在堆栈上预留了浮点状态的空间，但仅在异常处理程序内执行 FPU 指令时，才将该状态信息保存至堆栈。

The lazy save of the FP state is interruptible by a higher priority exception. The FP state saving operation starts over after that exception returns.

### 3.7.3.5.3. Low power FPU operation

If the FPU is in a separate power domain, the way the FPU domain powers down depends on whether the FPU domain includes state retention logic.

To power down the FPU:

- If FPU domain includes state retention logic, disable the FPU by clearing the `CPACR.CP10` and `CPACR.CP11` bitfields.
- If FPU domain does not include state retention logic, disable the FPU by clearing the `CPACR.CP10` and `CPACR.CP11` bitfields and set both the `CPPWR.SU10` and `CPPWR.SU11` bitfields to 1.

 **WARNING**

Setting the `CPPWR.SU10` and `CPPWR.SU11` bitfields indicates that FPU state can be lost.

## 3.7.4. Programmer's model

The Cortex-M33 programmer's model is an implementation of the Armv8-M Main Extension architecture.

For a complete description of the programmers model, refer to the [Armv8-M Architecture Reference Manual](#), which also contains the Armv8-M Thumb instructions. In addition, other options of the programmers model are described in the System Control, MPU, NVIC, FPU, Debug, DWT, ITM, and TPIU feature topics.

### 3.7.4.1. Modes of operation and execution

The Cortex-M33 processor supports Secure and Non-secure security states, Thread and Handler operating modes, and can run in either Thumb or Debug operating states. In addition, the processor can limit or exclude access to some resources by executing code in privileged or unprivileged mode.

See the [Armv8-M Architecture Reference Manual](#) for more information about the modes of operation and execution.

#### 3.7.4.1.1. Security states

With the Armv8-M Security Extension, the programmer's model includes two orthogonal security states: Secure state and Non-secure state. The processor always resets into Secure state. Each security state includes a set of independent operating modes and supports both privileged and unprivileged user access. Registers in the System Control Space are banked across Secure and Non-secure state, with a Non-secure register view available to Secure state at an aliased address.

#### 3.7.4.1.2. Operating modes

For each security state, the processor can operate in *Thread* or *Handler* mode. The following conditions cause the processor to enter Thread or Handler mode:

- The processor enters Thread mode on reset, or as a result of an exception return to Thread mode. Privileged and Unprivileged code can run in Thread mode.
- The processor enters Handler mode as a result of an exception. In Handler mode, all code is privileged.

The processor can change security state on taking an exception, for example when a Secure exception is taken from Non-secure state, the Thread mode enters the Secure state Handler mode. The processor can also call Secure functions

FP 状态的延迟保存可被更高优先级的异常中断。该异常返回后，FP 状态保存操作将重新执行。

### 3.7.3.5.3. 低功耗 FPU 操作

若 FPU 处于独立电源域，FPU 域的断电方式取决于该域是否含有状态保持逻辑。

关闭 FPU 电源的步骤如下：

- 若 FPU 域包含状态保持逻辑，通过清除 CPACR.CP10 和 CPACR.CP11 位字段以禁用 FPU。
- 若 FPU 域不包含状态保持逻辑，通过清除 CPACR.CP10 和 CPACR.CP11 位字段以禁用 FPU，并将 CPPWR.SU10 和 CPPWR.SU11 位字段均设为 1。

#### — 警告

设置 CPPWR.SU10 和 CPPWR.SU11 位字段即表示可能丢失 FPU 状态。

## 3.7.4. 程序员模型

Cortex-M33 程序员模型是 Armv8-M 主扩展架构的实现。

有关程序员模型的完整描述，请参阅 Armv8-M 架构参考手册，该手册还包含 Armv8-M Thumb 指令。此外，系统控制、MPU、NVIC、FPU、调试、DWT、ITM 和 TPIU 等功能主题中，描述了程序员模型的其他选项。

### 3.7.4.1. 操作模式与执行

Cortex-M33 处理器支持安全状态与非安全状态、安全线程和处理程序模式，并且可在 Thumb 状态或调试执行状态下运行。此外，处理器可以通过在特权模式或非特权模式下执行代码，限制或拒绝对某些资源的访问。

有关操作模式与执行的更多信息，请参阅 Armv8-M 架构参考手册。

#### 3.7.4.1.1. 安全状态

借助 Armv8-M 安全扩展，程序员模型包含两个相互正交的安全状态：安全状态和非安全状态。处理器始终复位进入安全状态。每个安全状态包含一组独立的操作模式，并支持特权级和非特权级用户访问。系统控制空间中的寄存器在安全状态与非安全状态之间采用寄存器组切换，且安全状态通过别名地址访问非安全寄存器视图。

#### 3.7.4.1.2. 操作模式

对于每个安全状态，处理器可在线程（*Thread*）或处理程序（*Handler*）模式下运行。以下条件将导致处理器进入线程模式或处理程序模式：

- 处理器在复位时进入线程模式，或在异常返回至线程模式时进入线程模式。特权级和非特权级代码均可在线程模式下执行。
- 处理器在发生异常时进入处理程序模式。在处理程序模式下，所有代码均具有特权级。

处理器可在响应异常时切换安全状态，例如，当从非安全状态捕获安全异常时，线程模式将进入安全状态的处理程序模式。处理器还可调用安全函数。

from Non-secure state and Non-secure functions from Secure state. The Security Extension includes requirements for these calls to prevent Secure data from being accessed in Non-secure state.

#### 3.7.4.1.3. Operating states

The processor can operate in Thumb or Debug state:

- Thumb state is the state of normal execution running 16-bit and 32-bit halfword-aligned Thumb instructions.
- Debug state is the state when the processor is in Halting debug.

#### 3.7.4.1.4. Privileged access and unprivileged user access

Code can execute as privileged or unprivileged. Unprivileged execution limits resource access appropriate to the current security state. Privileged execution has access to all resources available to the security state. Handler mode is always privileged. Thread mode can be privileged or unprivileged.

#### 3.7.4.2. Instruction set summary

The processor implements the following instruction from Armv8-M:

- All base instructions
- All instructions in the Main Extension
- All instructions in the Security Extension
- All instructions in the DSP Extension
- All single-precision instructions and double precision load/store instructions in the Floating-point Extension

For more information about Armv8-M instructions, see the [Armv8-M Architecture Reference Manual](#).

#### 3.7.4.3. Memory model

The processor contains a bus matrix that arbitrates instruction fetches and memory accesses from the processor core between the external memory system and the internal System Control Space (SCS) and debug components.

Priority is usually given to the processor to keep debug accesses as non-intrusive as possible.

The system memory map is Armv8-M Main Extension compliant, and is common both to the debugger and processor accesses.

The default memory map provides user and privileged access to all regions except for the Private Peripheral Bus (PPB). The PPB space only allows privileged access.

The following table shows the default memory map. This is the memory map used when the included MPUs are disabled. The attributes and permissions of all regions, except that targeting the NVIC and debug components, can be modified using an implemented MPU.

*Table 114. Default memory map*

| Address Range (inclusive) | Region     | Interface                                                                                                                                       |
|---------------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x00000000 - 0x1FFFFFFF   | Code       | Instruction and data accesses.                                                                                                                  |
| 0x20000000 - 0x3FFFFFFF   | SRAM       | Instruction and data accesses.                                                                                                                  |
| 0x40000000 - 0x5FFFFFFF   | Peripheral | Instruction and data accesses. Any attempt to execute instructions from the peripheral and external device region results in a MemManage fault. |

来自非安全态及安全态中的非安全函数。安全扩展包含对这些调用的要求，以防止安全数据在非安全态被访问。

### 3.7.4.1.3. 运行状态

处理器可在Thumb状态或调试状态下工作：

- Thumb状态为正常执行状态，运行16位和32位半字对齐的Thumb指令。
- 调试状态为处理器处于停止调试状态时的状态。

### 3.7.4.1.4. 特权访问与非特权用户访问

代码可以以特权或非特权身份执行。非特权执行限制资源访问，符合当前安全状态。特权执行可访问安全状态下的所有资源。异常处理程序模式始终为特权模式。线程模式可为特权或非特权模式。

### 3.7.4.2. 指令集摘要

处理器实现了Armv8-M架构中的以下指令：

- 所有基础指令
- 主扩展中的所有指令
- 安全扩展中的所有指令
- 数字信号处理扩展中的所有指令
- 浮点扩展中的所有单精度指令及双精度加载/存储指令

有关 Armv8-M 指令的更多信息，请参阅 Armv8-M 架构参考手册。

### 3.7.4.3 内存模型

处理器包含一个总线矩阵，用于在外部内存系统与内部系统控制空间（SCS）及调试组件之间，仲裁处理器核心的指令获取和内存访问。

通常优先保证处理器访问，以尽可能减少调试访问的侵入性。

系统内存映射符合 Armv8-M 主扩展规范，调试器和处理器访问共享该映射。

默认内存映射为除私有外设总线（PPB）外的所有区域提供用户和特权访问权限。

PPB 空间仅允许特权访问。

下表显示默认内存映射。该映射适用于内置 MPU 被禁用的情况。除针对 NVIC 和调试组件的区域外，所有区域的属性和权限均可通过已实现的 MPU 进行修改。

表114. 默认内存映射

| 地址范围（含端点）               | 区域   | 接口                                               |
|-------------------------|------|--------------------------------------------------|
| 0x00000000 - 0x1FFFFFFF | 代码   | 指令和数据访问。                                         |
| 0x20000000 - 0x3FFFFFFF | SRAM | 指令和数据访问。                                         |
| 0x40000000 - 0x5FFFFFFF | 外设   | 指令和数据访问。任何尝试从外设和外部设备区域执行指令的操作，均会导致 MemManage 错误。 |

| Address Range (inclusive) | Region          | Interface                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x60000000 - 0x9FFFFFFF   | External RAM    | Instruction and data accesses. Any attempt to execute instructions from the peripheral and external device region results in a MemManage fault.                                                                                                                                                                                                                                                                                 |
| 0xA0000000 - 0xDFFFFFFF   | External device | Instruction and data accesses. Any attempt to execute instructions from the peripheral and external device region results in a MemManage fault.                                                                                                                                                                                                                                                                                 |
| 0xE0000000 - 0xE00FFFFF   | PPB             | Reserved for system control and debug. Cannot be used for exception vector tables. Data accesses are either performed internally or on EPPB. Accesses in the range 0xE0000000 - 0xE0043FFF are handled within the processor. Accesses in the range 0xE0044000 - 0xE00FFFFF appear as APB transactions on the EPPB interface of the processor. Any attempt to execute instructions from the region results in a MemManage fault. |
| 0xE0100000 - 0xFFFFFFFF   | Vendor_SYS      | Partly reserved for future processor feature expansion. Any attempt to execute instructions from the region results in a MemManage fault.                                                                                                                                                                                                                                                                                       |

The internal Secure Attribution Unit (SAU) determines the security level associated with an address. Some internal peripherals have memory-mapped registers in the PPB region which are banked between Secure and Non-secure state. When the processor is in Secure state, software can access both the Secure and Non-secure versions of these registers. The Non-secure versions are accessed using an aliased address.

For more information about the memory model, see the [Armv8-M Architecture Reference Manual](#).

### 3.7.4.3.1. Private Peripheral Bus (PPB)

The Private Peripheral Bus (PPB) memory region provides access to internal and external processor resources.

The internal PPB provides access to:

- The System Control Space (SCS), including the Memory Protection Unit (MPU), Secure Attribution Unit (SAU), and the Nested Vectored Interrupt Controller (NVIC).
- The Data Watchpoint and Trace (DWT) unit.
- The Breakpoint Unit (BPU).
- The Embedded Trace Macrocell (ETM).
- CoreSight Micro Trace Buffer (MTB).
- Cross Trigger Interface (CTI).
- The ROM table.

The external PPB (EPPB) provides access to implementation-specific external areas of the PPB memory map.

### 3.7.4.3.2. Unaligned accesses

The Cortex-M33 processor supports unaligned accesses. They are converted into two or more aligned AHB transactions on the C-AHB or S-AHB master ports on the processor.

Unaligned support is only available for load/store singles (LDR, LDRH, STR, STRH, TBH) to addresses in Normal memory. Load/store double and load/store multiple instructions already support word aligned accesses, but do not permit other unaligned accesses, and generate a fault if this is attempted. Unaligned accesses in Device memory are not permitted and fault. Unaligned accesses that cross memory map boundaries are architecturally **UNPREDICTABLE**.

| 地址范围（含端点）               | 区域         | 接口                                                                                                                                                                           |
|-------------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x60000000 - 0xFFFFFFFF | 外部 RAM     | 指令和数据访问。任何尝试从外设和外部设备区域执行指令的操作，均会导致 MemManage 错误。                                                                                                                             |
| 0xA0000000 - 0xDFFFFFFF | 外部设备       | 指令和数据访问。任何尝试从外设和外部设备区域执行指令的操作，均会导致 MemManage 错误。                                                                                                                             |
| 0xE0000000 - 0xE00FFFFF | PPB        | 保留用于系统控制和调试。不可用于异常向量表。数据访问要么在内部执行，要么在EPPB上执行。访问范围为 0xE0000000 - 0xE0043FFF 的访问由处理器内部处理。访问范围为 0xE0044000 - 至 0xE0FFFFF 的访问在处理器的EPPB接口上表现为APB事务。任何尝试从该区域执行指令的行为将导致MemManage故障。 |
| 0xE0100000 - 0xFFFFFFFF | Vendor_SYS | 部分保留用于未来处理器功能扩展。任何尝试从该区域执行指令的行为将导致MemManage故障。                                                                                                                               |

内部安全归属单元（SAU）确定与地址相关的安全级别。一些内部外设在PPB区域有内存映射寄存器，这些寄存器在安全状态和非安全状态之间分银行。

当处理器处于安全状态时，软件可访问这些寄存器的安全版本和非安全版本。非安全版本通过别名地址进行访问。

有关内存模型的更多信息，请参见 Armv8-M 架构参考手册。

### 3.7.4.3.1. 私有外设总线（PPB）

私有外设总线（PPB）内存区域提供对内部及外部处理器资源的访问。

内部 PPB 提供对以下内容的访问：

- 系统控制空间（SCS），包括内存保护单元（MPU）、安全归属单元（SAU）以及嵌套向量中断控制器（NVIC）。
- 数据监视点与跟踪单元（DWT）。
- 断点单元（BPU）。
- 嵌入式跟踪宏单元（ETM）。
- CoreSight 微跟踪缓冲区（MTB）。
- 交叉触发接口（CTI）。
- 只读存储器表（ROM table）。

外部 PPB（EPPB）提供对 PPB 内存映射中实现特定外部区域的访问。

### 3.7.4.3.2. 非对齐访问

Cortex-M33 处理器支持非对齐访问。它们会被转换为处理器上的 C-AHB 或 S-AHB 主端口的两个或多个对齐 AHB 事务。

非对齐支持仅适用于普通内存地址上的单次加载/存储指令（LDR、LDRH、STR、STRH、TBH）。加载/存储双字及加载/存储多字指令已经支持字对齐访问，但不允许其他非对齐访问，且若尝试将产生故障。设备内存中的非对齐访问禁止且会引发故障。跨越内存映射边界的非对齐访问在体系结构上为不可预测。

**NOTE**

If `CCR.UNALIGN_TRP` for the current Security state is set, any unaligned accesses generate a fault.

### 3.7.4.4. Exclusive monitor

The Cortex-M33 processor implements a local exclusive monitor. The local monitor within the processor has been constructed so that it does not hold any physical address, but instead treats any store-exclusive access as matching the address of the previous load-exclusive. This means that the implemented exclusives reservation granule is the entire memory address range. For more information about semaphores and the local exclusive monitor, see the [Arm v8-M Architecture Reference Manual](#).

### 3.7.4.5. Processor core registers summary

The following table shows the processor core register set summary. Each of these registers is 32 bits wide. When the Armv8-M Security Extension is included, some of the registers are banked. The Secure view of these registers is available when the Cortex-M33 processor is in Secure state and the Non-secure view when Cortex-M33 processor is in Non-secure state.

*Table 115. Processor core register set summary*

| Name                   | Description                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>R0-R12</code>    | <code>R0-R12</code> are general-purpose registers for data operations.                                                                                                                                                                                                                                                                      |
| <code>MSP (R13)</code> | The Stack Pointer (SP) is register <code>R13</code> . In Thread mode, the CONTROL register indicates the stack pointer to use, Main Stack Pointer (MSP) or Process Stack Pointer (PSP). There are two MSP registers in the Cortex-M33 processor: <code>MSP_NS</code> for the Non-secure state, and <code>MSP_S</code> for the Secure state. |
| <code>PSP (R13)</code> | The Stack Pointer (SP) is register <code>R13</code> . In Thread mode, the CONTROL register indicates the stack pointer to use, Main Stack Pointer (MSP) or Process Stack Pointer (PSP). There are two PSP registers in the Cortex-M33 processor: <code>PSP_NS</code> for the Non-secure state, and <code>PSP_S</code> for the Secure state. |
| <code>MSPLIM</code>    | The stack limit registers limit the extent to which the MSP and PSP registers can descend respectively. There are two MSPLIM registers in the Cortex-M33 processor: <code>MSPLIM_NS</code> for the Non-secure state, and <code>MSPLIM_S</code> for the Secure state.                                                                        |
| <code>PSPLIM</code>    | The stack limit registers limit the extent to which the MSP and PSP registers can descend respectively. There are two PSPLIM registers in the Cortex-M33 processor: <code>PSPLIM_NS</code> for the Non-secure state, and <code>PSPLIM_S</code> for the Secure state.                                                                        |
| <code>LR (R14)</code>  | The Link Register (LR) is register <code>R14</code> . It stores the return information for subroutines, function calls, and exceptions.                                                                                                                                                                                                     |
| <code>PC (R15)</code>  | The Program Counter (PC) is register <code>R15</code> . It contains the current program address.                                                                                                                                                                                                                                            |

### ⓘ 注意

若当前安全状态的`CCR.UNALIGN_TRP`已设置，任何非对齐访问都会引发故障。

#### 3.7.4.4. 排他监视器

Cortex-M33 处理器实现了本地排他监视器。处理器内的本地监视器设计为不保存任何物理地址，而是将所有存储排他访问视为匹配先前加载排他访问的地址。这意味着已实现的独占保留粒度为整个内存地址范围。有关信号量及本地独占监视器的详细信息，请参阅Armv8-M架构参考手册。

#### 3.7.4.5. 处理器内核寄存器汇总

下表展示了处理器内核寄存器集的汇总。每个寄存器宽度均为32位。包含Armv8-M安全扩展时，部分寄存器为分组寄存器。当Cortex-M33处理器处于安全态时，可访问这些寄存器的安全视图；处于非安全态时，则访问非安全视图。

表115。处理器内核寄存器集  
汇总

| 名称                     | 描述                                                                                                                                                                                            |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>R0-R12</code>    | <code>R0-R12</code> 为用于数据操作的通用寄存器。                                                                                                                                                            |
| <code>MSP (R13)</code> | 堆栈指针（SP）对应寄存器 <code>R13</code> 。在线程模式下， <code>CONTR</code> 寄存器指示所用的堆栈指针类型，即主堆栈指针（MSP）或进程堆栈指针（PSP）。<br>Cortex-M33 处理器中存在两个 MSP 寄存器：<br><code>MSP_NS</code> 表示非安全状态， <code>MSP_S</code> 表示安全状态。 |
| <code>PSP (R13)</code> | 堆栈指针（SP）对应寄存器 <code>R13</code> 。在线程模式下， <code>CONTR</code> 寄存器指示所用的堆栈指针类型，即主堆栈指针（MSP）或进程堆栈指针（PSP）。<br>Cortex-M33 处理器中存在两个 PSP 寄存器：<br><code>PSP_NS</code> 表示非安全状态， <code>PSP_S</code> 表示安全状态。 |

| Name      | Description                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PSR       | The Program Status Register (PSR) combines the Application Program Status Register ( <a href="#">APSR</a> ), Interrupt Program Status Register ( <a href="#">IPSR</a> ), and Execution Program Status Register ( <a href="#">EPSR</a> ). These registers provide different views of the PSR.                                                  |
| PRIMASK   | The <a href="#">PRIMASK</a> register prevents activation of exceptions with configurable priority. When the Armv8-M Security Extension is included, there are two <a href="#">PRIMASK</a> registers in the Cortex-M33 processor: <a href="#">PRIMASK_NS</a> for the Non-secure state and <a href="#">PRIMASK_S</a> for the Secure state.      |
| BASEPRI   | The <a href="#">BASEPRI</a> register defines the minimum priority for exception processing. There are two <a href="#">BASEPRI</a> registers in the Cortex-M33 processor: <a href="#">BASEPRI_NS</a> for the Non-secure state, and <a href="#">BASEPRI_S</a> for the Secure state.                                                             |
| FAULTMASK | The <a href="#">FAULTMASK</a> register prevents activation of all exceptions except for <b>NON-MASKABLE INTERRUPT</b> (NMI) and Secure HardFault. There are two <a href="#">FAULTMASK</a> registers in the Cortex-M33 processor: <a href="#">FAULTMASK_NS</a> for the Non-secure state, and <a href="#">FAULTMASK_S</a> for the Secure state. |
| CONTROL   | The <a href="#">CONTROL</a> register controls the stack used, and optionally the privilege level, when the processor is in Thread mode. There are two <a href="#">CONTROL</a> registers in the Cortex-M33 processor: <a href="#">CONTROL_NS</a> for the Non-secure state and <a href="#">CONTROL_S</a> for the Secure state.                  |

### 3.7.4.6. Exceptions

Exceptions are handled and prioritized by the processor and the NVIC. In addition to architecturally defined behaviour, the processor implements advanced exception and interrupt handling that reduces interrupt latency and includes implementation defined behaviour.

The processor core and the Nested Vectored Interrupt Controller (NVIC) together prioritize and handle all exceptions. When handling exceptions:

- All exceptions are handled in Handler mode.
- Processor state is automatically stored to the stack on an exception, and automatically restored from the stack at the end of the Interrupt Service Routine (ISR).
- The vector is fetched in parallel to the state saving, enabling efficient interrupt entry.

The processor supports tail-chaining that enables back-to-back interrupts without the overhead of state saving and restoration.

Software can choose only to enable a subset of the configured number of interrupts, and can choose how many bits of the configured priorities to use.

Exceptions can be specified as either Secure or Non-secure. When an exception occurs the processor switches to the associated security state. The priority of Secure and Non-secure exceptions can be programmed independently. You can deprioritise Non-secure configurable exceptions using the [AIRCR.PRIS](#) bit field to enable Secure interrupts to take priority.

When taking and returning from an exception, the register state is always stored using the stack pointer associated with the background security state. When taking a Non-secure exception from Secure state, all the register state is stacked and then registers are cleared to prevent Secure data being available to the Non-secure handler. The vector base

| 名称        | 描述                                                                                                                                                        |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| PSR       | 程序状态寄存器（PSR）综合了应用程序状态寄存器（APSR）、中断程序状态寄存器（IPSR）以及执行程序状态寄存器（EPSR）。这些寄存器提供了PSR的不同视角。                                                                         |
| PRIMASK   | PRIMASK寄存器防止优先级可配置的异常被激活。在包含Armv8-M安全扩展时，Cortex-M33处理器内设有两个PRIMASK寄存器：非安全状态使用PRIMASK_NS，安全状态使用PRIMASK_S。                                                  |
| BASEPRI   | BASEPRI寄存器定义异常处理的最低优先级门槛。Cortex-M33处理器内设有两个BASEPRI寄存器：非安全状态使用BASEPRI_NS，安全状态使用BASEPRI_S。                                                                  |
| FAULTMASK | FAULTMASK寄存器可防止激活除非屏蔽中断（Non-Maskable Interrupt, NMI）和安全硬故障（Secure HardFault）之外的所有异常。Cortex-M33处理器中设有两个FAULTMASK寄存器：FAULTMASK_NS用于非安全状态，FAULTMASK_S用于安全状态。 |
| CONTROL   | CONTROL寄存器控制处理器在线程模式下所使用的堆栈，并可选择控制特权级别。Cortex-M33处理器中设有两个CONTROL寄存器：CONTROL_NS用于非安全状态，CONTROL_S用于安全状态。                                                    |

### 3.7.4.6. 异常

异常由处理器和嵌套向量中断控制器（NVIC）处理并排序优先级。除架构定义的行为外，处理器实现了先进的异常和中断处理机制，以降低中断延迟，并包含实现定义的行为。

处理器核心与嵌套向量中断控制器（NVIC）共同对所有异常进行优先级排序和处理。

处理异常时：

- 所有异常均在处理程序模式中进行处理。
- 在异常发生时，处理器状态会自动保存到堆栈中，并在中断服务例程（ISR）结束时自动从堆栈恢复。
- 向量在状态保存的同时被并行获取，从而实现高效的中断入口。

处理器支持尾部链式调用，使连续中断无需状态保存和恢复的开销。

软件可选择仅启用配置数量中的部分中断，也可选择使用配置优先级的位数。

异常可指定为安全（Secure）或非安全（Non-secure）。当异常发生时，处理器会切换到相应的安全状态。安全异常与非安全异常的优先级可独立进行编程设置。您可以通过 [AIRCR.PRIS](#)位域降低非安全可配置异常的优先级，以使安全中断优先获得处理。

进入和返回异常时，寄存器状态始终使用与后台安全状态关联的堆栈指针保存。当从安全状态进入非安全异常时，所有寄存器状态都会被压栈，然后寄存器被清零，以防止安全数据被非安全处理程序访问。向量基址

address is banked between Secure and Non-secure state. `VTOR_S` contains the Secure vector base address, and `VTOR_NS` contains the Non-secure vector base address. These registers can be programmed by software, and also initialized at reset by the system.

#### NOTE

Vector table entries are compatible with interworking between Arm and Thumb instructions. This causes bit[0] of the vector value to load into the Execution Program Status Register (EPSR) T-bit on exception entry. All populated vectors in the vector table entries must have bit[0] set. Creating a table entry with bit[0] clear generates an `INVSTATE` fault on the first instruction of the handler corresponding to this vector.

#### 3.7.4.7. Security attribution and memory protection

Security attribution and memory protection in the processor is provided by the Security Attribution Unit (SAU) and the Memory Protection Units (MPUs).

The SAU is a programmable unit that determines the security of an address. RP2350 includes 8 memory regions.

For instructions and data, the SAU returns the security attribute that is associated with the address.

For instructions, the attribute determines the allowable Security state of the processor when the instruction is executed. It can also identify whether code at a Secure address can be called from Non-secure state.

For data, the attribute determines whether a memory address can be accessed from Non-secure state, and also whether the external memory request is marked as Secure or Non-secure.

If a data access is made from Non-secure state to an address marked as Secure, then a SecureFault exception is taken by the processor. If a data access is made from Secure state to an address marked as Non-secure, then the associated memory access is marked as Non-secure.

The security level returned by the SAU is a combination of the region type defined in the internal SAU, if configured, and the type that is returned on the associated Implementation Defined Attribution Unit (IDAU). If an address maps to regions defined by both internal and external attribution units, the region of the highest security level is selected.

The register fields `SAU_CTRL.EN` and `SAU_CTRL.ALLNS` control the enable state of the SAU and the default security level when the SAU is disabled. Both `SAU_CTRL.EN` and `SAU_CTRL.ALLNS` reset to zero disabling the SAU and setting all memory, apart from some specific regions in the PPB space to Secure level. If the SAU is not enabled, and `SAU_CTRL.ALLNS` is zero, then the IDAU cannot set any regions of memory to a security level lower than Secure, for example Secure NSC or NS. If the SAU is enabled, then `SAU_CTRL.ALLNS` does not affect the Security level of memory.

RP2350 supports the Armv8-M Protected Memory System Architecture (PMSA). The MPU provides full support for:

- protection regions
- access permissions
- exporting memory attributes to the system

MPU mismatches and permission violations invoke the MemManage handler. For more information, see the [Armv8-M Architecture Reference Manual](#).

You can use the MPU to:

- enforce privilege rules
- separate processes
- manage memory attributes

The MPU supports 16 memory regions: 8 secure and 8 non-secure. The MPU is banked between Secure and Non-secure states. The number of regions in the Secure and Non-secure MPU can be configured independently and each can be programmed to protect memory for the associated Security state.

地址介于安全态与非安全态之间。`VTOR_S`包含安全向量基地址，`VTOR_NS`包含非安全向量基地址。这些寄存器可以由软件编程，也可由系统在复位时初始化。

### **① 注意**

向量表条目支持Arm与Thumb指令间的交互操作。此操作导致向量值的第0位在异常进入时加载至执行程序状态寄存器（EPSR）的T位。向量表中所有已填充的向量其第0位必须置位。若表项第0位清零，将在对应向量的处理程序首条指令处引发`INVSTATE`故障。

#### 3.7.4.7. 安全归属与内存保护

处理器中的安全归属与内存保护由安全归属单元（SAU）及内存保护单元（MPU）提供。

SAU是一种可编程单元，用于确定地址的安全属性。RP2350包含8个内存区域。

对于指令和数据，SAU返回与地址相关联的安全属性。

对于指令，该属性决定执行该指令时处理器允许的安全状态。

它还可以识别是否可以从非安全状态调用位于安全地址的代码。

对于数据，该属性决定内存地址是否可从非安全状态访问，以及外部存储访问请求是否标记为安全或非安全。

若非安全状态访问标记为安全的地址，则处理器将触发`SecureFault`异常。若安全状态访问标记为非安全的地址，则相关内存访问将被标记为非安全。

SAU返回的安全级别为内部SAU（如配置）定义的区域类型与相关实现定义属性单元（IDAU）返回类型的组合。若地址映射至由内部和外部归属单元共同定义的区域，则选择安全级别最高的区域。

寄存器字段`SAU_CTRL.EN`和`SAU_CTRL.ALLNS`控制SAU的启用状态及SAU禁用时的默认安全级别。当`SAU_CTRL.EN`和`SAU_CTRL.ALLNS`均复位为零时，SAU被禁用，且除PPB空间内某些特定区域外，所有内存均被设置为安全级别。若SAU未启用且`SAU_CTRL.ALLNS`为零，则IDAU无法将任何内存区域设置为低于安全级别的状态，例如`Secure NSC`或`NS`。若SAU启用，则`SAU_CTRL.ALLNS`不影响内存安全级别。

RP2350支持Armv8-M受保护内存系统架构（PMSA）。MPU全面支持以下功能：

- 保护区域
- 访问权限
- 向系统导出内存属性

MPU不匹配和权限违规将触发`MemManage`中断处理程序。更多信息，请参阅Armv8-M架构参考手册。

您可以使用MPU来：

- 强制执行权限规则
- 划分进程
- 管理内存属性

MPU支持16个内存区域：8个安全区和8个非安全区。MPU在安全与非安全状态之间进行分区。安全和非安全MPU中的区域数量可独立配置，且每个区域均可编程以保护对应安全状态的内存。

### 3.7.4.8. External coprocessors

The external coprocessor interface:

- Supports low-latency data transfer from the processor to and from the accelerator components.
- Has a sustained bandwidth up to twice of the processor memory interface.

The following instruction types are supported:

- Register transfer from the Cortex-M33 processor to the coprocessor [MCR](#), [MCRR](#), [MCR2](#), [MCRR2](#).
- Register transfer from the coprocessor to the Cortex-M33 processor [MRC](#), [MRRC](#), [MRC2](#), [MRRC2](#).
- Data processing instructions [CDP](#), [CDP2](#).

**NOTE**

The regular and extension forms of the coprocessor instructions for example, [MCR](#) and [MCRR2](#), have the same functionality but different encodings. The [MRC](#) and [MRC2](#) instructions support the transfer of [APSR.NZVC](#) flags when the processor register field is set to PC, for example  $Rt == 0xF$ .

#### 3.7.4.8.1. Restrictions

The following restrictions apply when to coprocessor instructions:

- The [LDC\(2\)](#) or [STC\(2\)](#) instructions are not supported. If these are included in software with the `<coproc>` field set to a value between 0-7 and the coprocessor is present and enabled in the appropriate fields in the [CPACR/NSACR](#) registers, the Cortex-M33 processor always attempts to take an *Undefined instruction* (UNDEFINSTR) UsageFault exception.
- The processor register fields for data transfer instructions must not include the stack pointer ( $Rt == 0xD$ ), this encoding is **UNPREDICTABLE** in the Armv8-M architecture and results in an *Undefined instruction* (UNDEFINSTR) UsageFault exception in the [CPACR/NSACR](#) registers.
- If any coprocessor instruction is executed when the corresponding coprocessor is disabled in the [CPACR/NSACR](#) register, the Cortex-M33 processor always attempts to take a *No coprocessor* (NOCP) UsageFault exception.

#### 3.7.4.8.2. Data transfer rates

The following table shows the ideal data transfer rates for the coprocessor interface. This means that the coprocessor responds immediately to an instruction. The ideal data transfer rates are sustainable if the corresponding coprocessor instructions are executed consecutively.

The following instructions have the following data transfer rates:

**MCR, MCR2 (Processor to coprocessor)**

32 bits per cycle

**MRC, MRC2 (Coprocessor to processor)**

32 bits per cycle

**MCRR, MCRR2 (Processor to coprocessor)**

64 bits per cycle

**MRRC, MRRC2 (Coprocessor to processor)**

64 bits per cycle

#### 3.7.4.9. Execution timing

This section describes the execution time of various Cortex-M33 instructions. The results are based on measurements

### 3.7.4.8. 外部协处理器

外部协处理器接口：

- 支持从处理器至加速器组件及反向的低延迟数据传输。
- 其持续带宽最高可达处理器内存接口的两倍。

支持以下指令类型：

- 从Cortex-M33处理器向协处理器传输寄存器 **MCR**, **MCRR**, **MCR2**, **MCRR2**。
- 从协处理器到Cortex-M33处理器的寄存器转移 **MRC**、 **MRRC**、 **MRC2**、 **MRRC2**。
- 数据处理指令 **CDP**、 **CDP2**。

#### **i 注意**

协处理器指令的常规形式和扩展形式，例如 **MCR** 和 **MCRR2**，功能相同，但编码不同。**MRC** 和 **MRC2** 指令在处理器寄存器字段设置为PC时支持传输APS.R.NZVC标志，例如 Rt == 0xF。

#### 3.7.4.8.1. 限制

协处理器指令适用以下限制：

- 不支持 **LDC(2)** 或 **STC(2)** 指令。若软件中包含 **<coproc>** 字段设置为0至7之间的值，且在 **CPACR/ NSACR** 寄存器相应字段启用协处理器，Cortex-M33处理器将始终尝试触发“未定义指令”(**UNDEFINSTR**)使用错误(**UsageFault**)异常。
- 数据传输指令的处理器寄存器字段不得包括堆栈指针(**Rt == 0xD**)，该编码在Armv8-M架构中为**不可预测**，并导致**CPACR/NSACR**寄存器中产生未定义指令(**UNDEFINSTR**) **UsageFault**异常。
- 如果在对应协处理器于 **CPACR/NSACR** 寄存器中被禁用时执行任何协处理器指令，Cortex-M33处理器将始终尝试产生一例无协处理器(**NOCP**) **UsageFault**异常。

#### 3.7.4.8.2. 数据传输速率

下表显示了协处理器接口的理想数据传输速率。这表明协处理器能够立即响应指令。若连续执行对应协处理器指令，则理想数据传输速率可持续保持。

以下指令的数据显示数据传输速率如下：

##### **MCR, MCR2 (处理器到协处理器)**

每周期32位

##### **MRC, MRC2 (协处理器至处理器)**

每周期32位

##### **MCRR, MCRR2 (处理器至协处理器)**

每周期64位

##### **MRRC, MRRC2 (协处理器至处理器)**

每周期64位

### 3.7.4.9. 执行时序

本节说明各类Cortex-M33指令的执行时间。该结果基于测量

of a limited and non-exceptional set of examples of the more common instructions and hence may not correctly cover some more unusual situations.

These measurements were taken with the following conditions:

- only one core is running
- there are no cache misses (in particular, no XIP cache misses)
- there is no active DMA

Any of the above conditions can affect the timing of instruction fetch as well as of load and store operations. See the description of the [bus fabric](#) elsewhere in this datasheet for information on possible contention for access to memory.

#### 3.7.4.9.1. Result delays

Some instructions generate results with a two-cycle latency. Using such a result as a source operand for a subsequent instruction incurs a one-cycle **result-use penalty**. Most of the input values of any instruction count as source operands, including:

- any source register in a data processing (ALU) instruction
- any registers used in address generation by an [LDR](#) or [LDM](#) (including [R13](#) in the case of [POP](#))
- any registers used in address generation (but not those to be stored) by a [STR](#) or [STM](#) (including [R13](#) in the case of [PUSH](#)).

The following example shows a load followed by a data-processing instruction, an instruction sequence which incurs this penalty:

```
LDR R0, [R1]
ADD R1, R0, R2
```

The following instructions generate results with a two-cycle latency:

- the destination register arising from some non-simple shifts in certain data-processing instructions (specified in more detail below)
- the destination register or registers of a multiply instruction
- the destination register of an [LDR](#)
- the *last* register in the register list of an [LDM](#) or [POP](#) unless that register is [R15](#)

Using results of the above instructions as a source operand for another instruction incurs a one-cycle penalty between the operations.

#### 3.7.4.9.2. Simple arithmetic and logical instructions

Most data processing instructions execute in a single cycle. Some **complex** operations (including those listed above and [SEL](#)) incur a result-use penalty.

Complex operations meet at least one of the following criteria:

- a shifted operand where the shift is not [LSL#0](#), [LSL#1](#), [LSL#2](#) or [LSL#3](#)
- an immediate operand which entails a shift (i.e., not of the form [0x000000XY](#), [0xXYXXXXXY](#), [0x00XY00XY](#) or [0xXY00XY00](#))

When a complex instruction has the [-S](#) suffix to set flags, the one-cycle penalty is always incurred, even if the next instruction does not depend on those flag values.

The following operations *do not* incur a penalty:

有限且非特殊的一组常见指令示例，因此可能无法覆盖某些较为特殊的情况。

测量条件如下：

- 仅有一个内核运行
- 无缓存未命中（尤其是无XIP缓存未命中）
- 无活动的DMA操作

上述任一条件均可能影响指令取指及加载和存储操作的时序。有关存储器访问总线竞争的情况，请参见本数据手册其他章节中总线结构的描述。

#### 3.7.4.9.1. 结果延时

某些指令会生成两周期延迟的结果。使用此类结果作为后续指令的源操作数，将导致一周期的**结果使用惩罚**。任何指令的大多数输入参数均视为源操作数，包括：

- 数据处理（ALU）指令中的任何源寄存器
- 由 **LDR** 或 **LDM** 用于地址生成的任何寄存器（包括 **POP** 指令中的 **R13**）
- 由 **STR** 或 **STM** 用于地址生成的任何寄存器（但不包括待存储寄存器）（包括 **PUSH** 指令中的 **R13**）。

下例展示了一个加载指令后紧跟一条数据处理指令的指令序列，该序列会导致此惩罚：

```
LDR R0, [R1]
ADD R1, R0, R2
```

以下指令生成两周期延迟的结果：

- 某些数据处理指令中非简单移位所产生的目标寄存器（详见下文说明）
- 乘法指令的一个或多个目标寄存器
- **LDR** 指令的目标寄存器
- 除非该寄存器为 **R15**，否则 **LDM** 或 **POP** 指令寄存器列表中的最后一个寄存器

将上述指令的结果用作另一指令的源操作数时，操作间会产生一个周期的惩罚延迟。

#### 3.7.4.9.2. 简单算术与逻辑指令

大多数数据处理指令均在单个周期内完成。某些复杂操作（包括上述列举的及 **SEL** 指令）会产生结果使用延迟惩罚。

复杂操作须满足以下至少一项条件：

- 移位操作数且移位方式非 **LSL#0**、**LSL#1**、**LSL#2** 或 **LSL#3**
- 包含移位的立即数操作数（即不符合 **0x000000XY**、**0xXYXYXYXY**、**0x00XY00XY** 或 **0xXY00XY00** 格式）

当复杂指令带有用于设置标志的 **-S** 后缀时，即使下一条指令不依赖该标志，也必然产生一个周期的惩罚延迟。

以下操作不产生惩罚：

```
AND R0, R1, R2, LSL#4
MOV R3, R4
```

However, the following operations *do* incur a penalty:

```
AND R0, R1, R2, LSL#4
MOV R3, R0
```

```
ANDS R0, R1, R2, LSL#4
MOV R3, R4
```

**ADD** and **SUB** are available in variants with a 12-bit plain immediate operand. These *do not* incur a penalty.

**MOV** and **MOVS** with an immediate operand, including **MOV** with a 16-bit plain immediate operand, *do not* incur a result-use penalty.

Despite their similarity to logical operations with a shifted operand, **UBFX**, **SBFX** and **BFI** *do not* incur a result-use penalty.

Simple shift instructions (**LSL**, **LSR**, **ASR**, and **ROR**, with the shift amount specified either as an immediate constant or in a register) take one cycle with no result-use penalty.

### 3.7.4.9.3. Multiply instructions

Multiply and multiply-accumulate instructions execute in a single cycle, but all have a result delay of one cycle.

However, the special case of using the result of a multiply instruction as the accumulate input to a following multiply-accumulate instruction *does not* incur a one-cycle penalty. As a result, repeated multiply-accumulate operations can run at one per cycle, assuming all of the following conditions hold:

- the operations accumulate into the same register or register pair
- the multiplier and multiplicand operands come from other registers

Sequences such as the following can execute one instruction per cycle:

```
MLA R0, R1, R2, R3
MLA R3, R1, R2, R0
MLA R0, R1, R2, R3
MLA R3, R1, R2, R0
...

```

```
UMLAL R0, R1, R4, R5
UMLAL R2, R3, R6, R7
UMLAL R0, R1, R4, R5
UMLAL R2, R3, R6, R7
...

```

The multiplier requires its multiply operands on cycle  $n$ , requires its accumulate operand (if any) on cycle  $n+1$ , and makes its result available on cycle  $n+2$ .

As a further example, the following sequence completes in 4 cycles:

```
AND R0, R1, R2, LSL#4
MOV R3, R4
```

然而，以下操作确实产生惩罚：

```
AND R0, R1, R2, LSL#4
MOV R3, R0
```

```
ANDS R0, R1, R2, LSL#4
MOV R3, R4
```

**ADD** 与 **SUB** 提供了带有12位纯立即数操作数的变体。这些不产生惩罚。

带立即数操作数的**MOV**与 **MVNS**（包括带16位纯立即数操作数的**MOV**）不产生结果使用惩罚。

尽管与带移位操作数的逻辑操作类似，**UBFX**、**SBFX**及**BFI**不产生结果使用惩罚。

简单移位指令（**LSL**、**LSR**、**ASR**及**ROR**，移位量可指定为立即数常量或寄存器）均为单周期执行，且不产生结果使用惩罚。

#### 3.7.4.9.3. 乘法指令

乘法和乘法-累加指令在单周期内执行，但其结果有一个周期的延迟。

然而，乘法指令的结果作为后续乘法-累加指令的累加输入这一特殊情况不会导致一个周期的延迟。因此，假定满足以下所有条件，重复的乘法-累加操作可实现每周期一次的执行：

- 操作累积于同一寄存器或寄存器对
- 乘数和被乘数操作数来源于其他寄存器

如以下序列可实现每周期执行一条指令：

```
MLA R0, R1, R2, R3
MLA R3, R1, R2, R0
MLA R0, R1, R2, R3
MLA R3, R1, R2, R0
...

```

```
UMLAL R0, R1, R4, R5
UMLAL R2, R3, R6, R7
UMLAL R0, R1, R4, R5
UMLAL R2, R3, R6, R7
...

```

乘法器要求其乘法操作数于周期  $n$  输入，累加操作数（如有）于周期  $n+1$  输入，结果在周期  $n+2$  可用。

作为进一步示例，以下序列可在4个周期内完成：

```

ADD R2, R0, R1, LSL#23
MLA R3, R4, R5, R2
MOV R6, R3

```

The `ADD` would normally incur a one-cycle result-use penalty, but in this case its result is not needed until the second cycle of the multiply-accumulate operation, eliminating the penalty.

#### 3.7.4.9.4. Divide instructions

Let  $n$  be the difference between the bit positions of the most significant ones in the absolute value of the dividend and the absolute value of the divisor. If  $n$  is negative (in which case the result will be zero), division takes 2 cycles. Otherwise, division takes  $4+n/4$  cycles, rounded down.

Using the result of division as input for the next instruction incurs a one-cycle result-use penalty.

#### 3.7.4.9.5. Register loads (LDR and LDM)

Loads execute in one cycle per register, plus a possible one-cycle result delay. Loads can slow down if the addressed memory is not able to accept the read request immediately, for example because of contention with instruction prefetch.

From the point of view of result delays, any register used in address generation counts as a source operand. For examples, see [Table 116](#).

*Table 116. Load instruction source operand examples*

| Instruction                   | Source Operand      | Not a Source Operand        |
|-------------------------------|---------------------|-----------------------------|
| <code>LDR R0,[R5,R6]</code>   | <code>R5, R6</code> | <code>R0</code>             |
| <code>LDMIA R7,{R0-R3}</code> | <code>R7</code>     | <code>R0, R1, R2, R3</code> |

There is one cycle of result delay associated with the destination register of an `LDR` and with the last register in the register list of an `LDM` or `POP`. For example, `R7` has one cycle of result delay both in `LDR R7,[R5,R6]` and in `LDMIA R0,{R1-R7}`. The latter case incurs no result delay associated with `R1` to `R6`.

Loading `R15` does not cause any result delay; however, extra cycles will be taken as described in [Section 3.7.4.9.7](#).

#### 3.7.4.9.6. Register stores (STR and STM)

Stores, including those which depend on the contents of three different registers such as `STR R0,[R1,R2,LSL#2]`, execute in one cycle. Like loads, stores can slow down if the addressed memory is not able to accept the request immediately.

The registers involved in address generation, but not the register or registers being stored, count as source operands from the point of view of result delays. For examples, see [Table 117](#).

*Table 117. Register stores source operand examples*

| Instruction                    | Source Operand      | Not a Source Operand        |
|--------------------------------|---------------------|-----------------------------|
| <code>STR R5,[R6,R7]</code>    | <code>R6, R7</code> | <code>R5</code>             |
| <code>STMFD R5!,{R0-R3}</code> | <code>R5</code>     | <code>R0, R1, R2, R3</code> |

#### 3.7.4.9.7. Branches

This section covers any instruction that can change `R15`, including the following:

- `MOV R15,Rx`

```

ADD R2, R0, R1, LSL#23
MLA R3, R4, R5, R2
MOV R6, R3

```

**ADD** 指令通常会导致一个周期的结果使用延迟惩罚，但在本例中，其结果直到乘累加操作的第二个周期才需要，因此消除了该惩罚。

#### 3.7.4.9.4. 除法指令

设  $n$  为被除数和除数绝对值中最高有效位1的位置差。如果  $n$  为负（此时结果为零），除法操作需耗费2个周期。

否则，除法操作需耗费  $4+n/4$  个周期，向下取整。

将除法结果用作下一条指令输入时会产生一个周期的结果使用延迟惩罚。

#### 3.7.4.9.5. 寄存器加载指令（LDR和LDM）

加载操作对每个寄存器执行一个周期，外加可能一周期的结果延迟。如果被寻址的内存无法立即响应读取请求，例如由于指令预取产生的冲突，加载速度可能会变慢。

从结果延迟的角度来看，任何用于地址生成的寄存器均视为源操作数。示例详见表116。

表116 加载  
指令源  
操作数示例

| 指令               | 源操作数   | 非源操作数          |
|------------------|--------|----------------|
| LDR R0,[R5,R6]   | R5, R6 | R0             |
| LDMIA R7,{R0-R3} | R7     | R0, R1, R2, R3 |

与 **LDR** 指令的目标寄存器相关联存在一个周期的结果延迟，且 **LDM** 或 **POP** 指令寄存器列表中的最后一个寄存器也存在一个周期的结果延迟。例如，**R7** 在 **LDR R7,[R5,R6]** 和 **LDMIA R0,{R1-R7}** 中均存在一个周期的结果延迟。

后者情况下，**R1** 至 **R6** 寄存器不产生结果延迟。

加载 **R15** 不会引起任何结果延迟；但如第3.7.4.9.7节所述，将需要额外的周期。

#### 3.7.4.9.6. 寄存器存储（STR 和 STM 指令）

存储，包括依赖三个不同寄存器内容的指令，如 **STR R0,[R1,R2,LSL#2]**，均在一个周期内执行完成。与加载类似，如果目标内存无法立即接受请求，存储操作将变慢。

从结果延迟角度看，参与地址生成但非存储目标的寄存器计为源操作数。示例详见表117。

表117。寄存器  
存储源操作数  
示例

| 指令                | 源操作数   | 非源操作数          |
|-------------------|--------|----------------|
| STR R5,[R6,R7]    | R6, R7 | R5             |
| STMFD R5!,{R0-R3} | R5     | R0, R1, R2, R3 |

#### 3.7.4.9.7. 分支

本节涵盖任何可能修改 **R15** 的指令，包括以下内容：

- **MOV R15,Rx**

- BNE
- BL
- BX
- LDR R15,...
- POP {...,R15}

When a branch arises from a load (LDR R15, ..., LDMxx Rx, {...,R15}, or POP {...,R15}), the basic time for the instruction is that taken by the load instruction itself, as described in Section 3.7.4.9.5.

For other instructions that can change R15 (MOV R15,Rx, B<cond>, BL, BX), the basic time for the instruction is zero.

The total time required for a branch that *does* occur is the basic time + 2 + L + U- (K & F) cycles, and the time required for a branch that *does not* occur is the basic time + 1 - F cycles, where L, U, F, K are each 0 or 1 as described below:

#### L

1 when the branch arises from a load (LDR R15,[R6], LDMIA R13,{R0-R3,R15}, and so on); 0 otherwise.

#### U

1 when the *all* of following conditions are true:

- the target address of the branch is not word-aligned
- the instruction at that address is 32 bits long
- the instruction executed immediately prior to the branch is not POP or PUSH

If any of the above conditions are not true, U is 0.

#### F

indicates when the branch can be dual issued (or "folded") with the previous instruction, PrevInst (the instruction executed immediately prior to the branch). F is 1 when *all* of the following conditions are true:

- the branch instruction is B, B<cond>, or BX R14 (but not BX to any other register or MOV R15,R14)
- PrevInst is 16 bits long
- PrevInst was executed sequentially (i.e., not itself branched to), or PrevInst is word-aligned
- PrevInst itself was not itself folded with a previous instruction

If any of the above conditions are not true, F is 0.

#### K

1 when it is known that the branch will execute prior to executing PrevInst; 0 otherwise. In other words, K is 1 unless the branch is conditional and PrevInst sets the flags.

For example, the following delay loop takes 299 cycles:

```
10000002: MOVS R5,#100
10000004: SUBS R5,R5,#1
10000006: BNE 0x10000004
```

Those cycles come from the following timings:

- 1 cycle for MOVS R5,#100
- 1 cycle for each SUBS R5,R5,#1
- 2 cycles each for the first 99 BNE instructions (L=U=0, F=1, K=0)
- 0 cycles for the last, non-taken, BNE (L=U=0, F=1, K=0, using the formula 1-F)

At a different alignment, the same delay loop takes 300 cycles:

- BNE
- BL
- BX
- LDR R15, …
- POP {…,R15}

当跳转由加载指令引起 (LDR R15, …, LDMxx Rx, {…,R15}, 或POP {…,R15}) 时, 指令的基本耗时即为加载指令本身所需时间, 详见第3.7.4.9.5节。

对于其他可修改 R15 的指令 (MOV R15,Rx, B<cond>, BL, BX) , 指令的基本耗时为零。

实际发生跳转所需的总时间为基本耗时 + 2 + L+U- (K&F) 个周期; 未发生跳转时所需时间为基本耗时 + 1 - F 个周期, 其中 L、U、F、K 的取值均为0或1, 具体如下:

#### L

当分支来源于加载指令时为1 (如LDR R15,[R6]、LDMIA R13,{R0-R3,R15}等) ; 否则为0。

#### U

当所有以下条件均满足时, 值为1:

- 分支的目标地址未对齐到字边界
- 该地址处的指令长度为32位
- 紧接分支前执行的指令既非 POP 也非 PUSH

若上述任一条件不满足, 则 U 为0。

#### F

指示该分支是否可与上一条指令 *PrevInst* (即紧接分支执行的指令) 实现双发射 (亦称“折叠”)。当所有以下条件均满足时, F 为1:

- 分支指令为 B、B<cond>或BX R14 (但不包括 BX 跳转到其他寄存器, 亦不包括MOV R15,R14)
- *PrevInst* 长度为16位
- *PrevInst* 按顺序执行 (即自身未发生分支跳转), 或 *PrevInst* 为字对齐
- *PrevInst* 自身未与先前指令合并

如上述任一条件不成立, F 即为0。

#### K

当已确认分支将在执行 *PrevInst* 之前执行时为1; 否则为0。换言之, K 为1, 除非该分支为条件分支且 *PrevInst* 设置了标志位。

例如, 以下延迟循环共耗时299个周期:

```
10000002: MOVS R5, #100
10000004: SUBS R5, R5, #1
10000006: BNE 0x10000004
```

这些周期基于如下时序:

- MOVS R5,#100 指令耗时1个周期
- 每条SUBS R5,R5,#1 指令耗时1个周期
- 前99条BNE 指令每条耗时2个周期 (L=U=0, F=1, K=0)
- 最后一次未执行的 BNE 指令耗时为0周期 (L=U=0, F=1, K=0, 使用公式1-F)

在不同对齐情况下, 相同的延时循环耗时300个周期:

```

10000000: MOVS R5,#100
10000002: SUBS R5,R5,#1
10000004: BNE 0x10000002

```

Those cycles come from the following timings:

- 1 cycle for `MOVS R5,#100`;
- 1 cycle for each `SUBS R5,R5,#1`;
- 2 cycles for the first `BNE (L=U=0, F=1, K=0)`;
- 2 cycles each for the next 98 `BNE` instructions ( $L=U=0, F=K=0$ );
- 1 cycle for the last, non-taken, `BNE (L=U=0, F=K=0, using the formula 1-F)`.

This longer delay loop also takes 300 cycles:

```

10000000: MOVS R5,#100
10000002: SUBS R5,R5,#1
10000004: MOV R1,R2
10000006: BNE 0x10000002

```

Those cycles come from the following timings:

- 1 cycle for `MOVS R5,#100`;
- 1 cycle for each `SUBS R5,R5,#1`;
- 1 cycle for each `MOV R1,R2`;
- 1 cycle each for the first 99 `BNE` instructions ( $L=U=0, F=K=1$ );
- 0 cycles for the last, non-taken, `BNE (L=U=0, F=K=1; using the formula 1-F)`.

This example illustrates that, if you can contrive to place an instruction between the loop-end test and the branch, it can potentially have zero net cost in execution time.

Another optimisation is to try to ensure that a branch target is either word-aligned or is a 16-bit instruction. Any instruction following a BL can be considered a branch target from this point of view as it is branched to by the return instruction from the subroutine.

If space and cache permit, unrolling loops and inlining subroutines avoids the branch cost altogether.

A sequence of branches not taken will alternately take 0 cycles and 1 cycle. That is the same as a sequence of `NOP` instructions, which can also be folded. However, this is *not* the same as sequence of instructions in an IT block that fail their condition.

### 3.7.4.9.8. IT (if-then) blocks

Instructions within an IT block whose condition fails execute in one cycle.

Most instructions within an IT block whose condition succeeds take the number of cycles they would have taken in their normal, unconditional state.

### 3.7.4.9.9. Dual issue

When a 16-bit instruction follows a `NOP` instruction (opcode `0xBF00`, not `0x46C0`), the instructions are **folded**, executing the `NOP` in zero cycles. In some situations, this can help align a branch target to a word-aligned address without an

```

10000000: MOVS R5, #100
10000002: SUBS R5, R5, #1
10000004: BNE 0x10000002

```

这些周期基于如下时序：

- 执行 `MOVS R5, #100` 指令耗时 1 周期；
- 每执行一次 `SUBS R5, R5, #1` 指令耗时 1 周期；
- 首次执行 `BNE` 指令耗时 2 周期 ( $L=U=0, F=1, K=0$ )；
- 之后的 98 次 `BNE` 指令每次耗时 2 周期 ( $L=U=0, F=K=0$ )；
- 最后一次未执行的 `BNE` 指令耗时 1 周期 ( $L=U=0, F=K=0$ ，使用公式  $1-F$ )。

此较长延迟循环同样消耗 300 个周期：

```

10000000: MOVS R5, #100
10000002: SUBS R5, R5, #1
10000004: MOV R1, R2
10000006: BNE 0x10000002

```

这些周期基于如下时序：

- 执行 `MOVS R5, #100` 指令耗时 1 周期；
- 每执行一次 `SUBS R5, R5, #1` 指令耗时 1 周期；
- 每条 `MOV R1, R2` 指令耗时 1 个周期；
- 前 99 条 `BNE` 指令各耗时 1 个周期 ( $L=U=0, F=K=1$ )；
- 最后一条未执行的 `BNE` 指令耗时 0 周期 ( $L=U=0, F=K=1$ ；采用公式  $1-F$ )。

本例说明，若能在循环结束测试与分支指令之间插入一条指令，执行时间有可能实现零净耗时。

另一种优化是确保分支目标地址为字对齐或为 16 位指令。从此角度看，`BL` 指令之后的任何指令均可视为分支目标，因为子程序返回指令会跳转至该处。

如果空间和缓存允许，展开循环并内联子程序可彻底避免分支开销。

未被执行的分支序列将在 0 周期和 1 周期之间交替。这相当于一系列 `NOP` 指令，这些指令同样可以被折叠。然而，这并不等同于 IT 块中条件失败的指令序列。

### 3.7.4.9.8. IT (if-then) 块

IT 块中条件失败的指令以单周期执行。

IT 块中条件成功的大多数指令，其周期数与其正常无条件状态下的周期数相同。

### 3.7.4.9.9. 双发射

当一条 16 位指令紧随 `NOP` 指令（操作码为 `0xBF00`，非 `0x46C0`）时，指令将被折叠，`NOP` 指令执行周期为零。在某些情况下，这有助于将分支目标地址对齐至字边界，而无需

execution-time penalty.

When a 16-bit opcode follows an **IT** instruction, the **IT** instruction executes in zero cycles.

The Cortex-M33 core folds a **NOP** with the previous instruction (**PrevInst**) if all of the following conditions are true:

- **PrevInst** is 16 bits long
- **PrevInst** was executed sequentially (not itself branched to) or **PrevInst** is word-aligned
- **PrevInst** was not itself folded with a previous instruction

Branches not taken are in this sense similar to **NOP** instructions: they can be folded according to the same rule. For further detail on when taken and not taken branches are folded, see [Section 3.7.4.9.7](#).

When two multi-cycle instructions are folded, at most one cycle can overlap between the instructions.

#### 3.7.4.9.10. Floating-point coprocessor operations

This section describes operations involving the single-precision floating-point coprocessor (FPU). For timings relating to the GPIO coprocessor, the double-precision coprocessor, and the redundancy coprocessor, see [Section 3.7.4.9.11](#) and the detailed descriptions of those coprocessors elsewhere in this document.

Issuing a floating-point instruction occupies the integer core for one cycle. After that, the integer core can proceed with other non-FPU operations without interruption.

Attempting to issue another FPU instruction stalls execution until the FPU is ready to accept the FPU instruction.

The following list details the timings of various FPU instructions:

- **VADD.F32**, **VSUB.F32** and **VMUL.F32** can execute in one cycle, but have an additional cycle of result delay. As a result, the following example sequence executes at two cycles per instruction:

```
VADD.F32 s0, s0, s2
VADD.F32 s0, s0, s3
VADD.F32 s0, s0, s4
VADD.F32 s0, s0, s5
...
```

The following interleaved example, however, executes at one cycle per instruction:

```
VADD.F32 s0, s0, s2
VADD.F32 s1, s1, s3
VADD.F32 s0, s0, s4
VADD.F32 s1, s1, s5
...
```

Furthermore, you can interleave **VADD.F32**, **VSUB.F32** and **VMUL.F32** instructions arbitrarily to execute in one cycle, as long as no instruction depends on the result of its predecessor.

- **VMLA.F32** and **VFMA.F32** occupy the FPU for 3 cycles, plus one cycle of result delay.

However, consecutive **VMLA.F32** or **VFMA.F32** instructions accumulating into the same register can run at one instruction every three cycles.

- When the work can be interleaved, separate **VMUL.F32** and **VADD.F32** instructions are faster than a single **VMLA.F32** instruction.
- **VDIV.F32** and **VSQRT.F32** occupy the FPU for 14 cycles, plus one cycle of result delay.
- **VMOV.F32 Sx,Ry** (move one word from integer register to coprocessor) takes one cycle.

执行时间惩罚。

当一条16位操作码紧随 **IT** 指令时， **IT** 指令以零周期执行。

当满足以下所有条件时，Cortex-M33核将 **NOP** 与前一条指令（**PrevInst**）合并：

- **PrevInst** 长度为16位
- **PrevInst** 为顺序执行（非跳转到的），或**PrevInst**为字对齐
- **PrevInst** 本身未与更早指令合并

未执行的分支在此意义上类似于 **NOP** 指令：可依据相同规则进行合并。有关采取与未采取的分支何时合并的详细内容，参见第3.7.4.9.7节。

当两条多周期指令合并时，相互之间最多重叠一个周期。

### 3.7.4.9.10. 浮点协处理器操作

本节描述涉及单精度浮点协处理器（FPU）的操作。有关GPIO协处理器、双精度协处理器及冗余协处理器的时序，详见第3.7.4.9.11节及本文件中相关协处理器的详细描述。

发出浮点指令会使整数核心占用一个周期。之后，整数核心可以继续执行其他非FPU操作而不受影响。

尝试发出另一条FPU指令时，将暂停执行，直至FPU准备好接收该指令。

下列表列出了各种FPU指令的执行时序：

- **VADD.F32**、**VSUB.F32**和**VMUL.F32**可在同一个周期内完成，但结果延迟一个周期。因此，以下示例序列以每条指令两个周期的速度执行：

```

VADD.F32 s0, s0, s2
VADD.F32 s0, s0, s3
VADD.F32 s0, s0, s4
VADD.F32 s0, s0, s5
...

```

然而，以下交错示例以每条指令一个周期的速度执行：

```

VADD.F32 s0, s0, s2
VADD.F32 s1, s1, s3
VADD.F32 s0, s0, s4
VADD.F32 s1, s1, s5
...

```

此外，只要无指令依赖其前驱指令结果，您可以任意交错 **VADD.F32**、**VSUB.F32**和**VMUL.F32**指令，以实现单周期执行。

- **VMLA.F32** 和 **VFMA.F32** 占用FPU 3个周期，外加一个周期的结果延迟。

然而，连续的**VMLA.F32**或**VFMA.F32**指令向同一寄存器累积时，可以实现每三周期执行一条指令。

- 当任务可以交叉执行时，分开的 **VMUL.F32**和 **VADD.F32**指令比单条 **VMLA.F32**指令更高效。
- **VDIV.F32** 和 **VSQRT.F32** 占用FPU 14个周期，外加一个周期的结果延迟。
- **VMOV.F32 Sx,Ry** （从整数寄存器向协处理器移动一个字）耗时一个周期。

- **VMOV.F32 Rx,Sy** (move one word from coprocessor to integer register) takes one cycle plus one cycle of result delay.
- **VMOV.F32 Sx,Sy** (move one word between coprocessor registers) takes one cycle.
- **VMOV.F64 Dx,Ry,Rz** (move two words from integer registers to coprocessor) occupies the FPU for two cycles and the integer core for one cycle.
- **VMOV.F64 Rx,Ry,Dz** (move two words from coprocessor to integer registers) occupies both the FPU and the integer core for two cycles.

### 3.7.4.9.11. Other coprocessor operations

A coprocessor can stall an operation if it is not ready. For more information, see the documentation for the specific coprocessor.

The following list details the timings of various coprocessor instructions:

- Assuming that no stalls occur, a **CDP** instruction takes one cycle.
- An **MCR** instruction (move one word from integer register to coprocessor) takes one cycle.
- An **MRC** instruction (move one word from coprocessor to integer register) takes one cycle, plus one cycle of result delay.
- An **MCRR** instruction (move two words from integer registers to coprocessor) takes one cycle.
- An **MRRC** instruction (move two words from coprocessor to integer registers) takes one cycle, plus one cycle of result delay.

### 3.7.4.9.12. Instruction fetch

Each Cortex-M33 core has separate instruction and data buses ("Harvard architecture"). Each core has a bandwidth to memory of 32 bits per cycle. Since each instruction is at most 32 bits long, for sequential code the instruction prefetcher has enough bandwidth to ensure that the processor core always has instructions.

In RP2350, contention can occur when the instruction and data buses attempt to access data stored in memory connected to the same downstream port of the AHB5 crossbar. For example, code running from the main SRAM might attempt to load a literal stored nearby. That load might conflict with an instruction prefetch to the same SRAM. To reduce the chance of this conflict, the main SRAM is striped into banks across groups of four words: words at addresses that are different modulo 16 are stored in different banks.

Since the prefetcher typically runs about two words (8 bytes) ahead of execution, that means that an instruction that reads 8 (modulo 16) bytes ahead of itself is liable to result in a conflict. For example, the following instruction, which reads 40 bytes ahead (because here **PC** means the address of the next instruction), can sometimes incur a penalty of one cycle:

```
LDR R8,[PC,#32] @ 32-bit instruction
```

### 3.7.4.10. Debug

Cortex-M33 debug functionality includes processor halt, single-step, processor core register access, Vector Catch, unlimited software breakpoints, and full system memory access.

The processor also includes support for hardware breakpoints and watchpoints configured during implementation:

- A breakpoint unit supporting eight instruction comparators
- A watchpoint unit supporting four data watchpoint comparators

The Cortex-M33 processor supports system level debug authentication to control access from a debugger to resources

- **VMOV.F32 Rx,Sy** （从协处理器向整数寄存器移动一个字）耗时一个周期，外加一个周期的结果延迟。
- **VMOV.F32 Sx,Sy** （协处理器寄存器间移动一个字）耗时一个周期。
- **VMOV.F64 Dx,Ry,Rz** （将两个字从整数寄存器移动至协处理器）占用浮点单元两周期，整数核心一周期。
- **VMOV.F64 Rx,Ry,Dz** （将两个字从协处理器移动至整数寄存器）占用浮点单元和整数核心两周期。

### 3.7.4.9.11. 其他协处理器操作

协处理器如果未准备好，可能会阻塞操作。欲了解更多信息，请参阅特定协处理器的文档。

下表详细说明了各类协处理器指令的执行时序：

- 假设无阻塞发生，**CDP**指令耗时一个周期。
- **MCR**指令（将一个字从整数寄存器移动至协处理器）耗时一个周期。
- **MRC**指令（将一个字从协处理器移动至整数寄存器）耗时一个周期，另加一个周期的结果延迟。
- **MCRR**指令（将两个字从整数寄存器移动至协处理器）耗时一个周期。
- 一条**MRRC**指令（将两个字从协处理器移动到整数寄存器）执行一个周期，外加一个周期的结果延迟。

### 3.7.4.9.12. 指令取指

每个Cortex-M33核心均具备独立的指令总线和数据总线（“哈佛架构”）。每个核心对内存的带宽为每周期32位。由于每条指令最长为32位，对于顺序执行的代码，指令预取器具备足够带宽，确保处理器核心始终拥有指令。

在RP2350中，当指令总线和数据总线尝试访问连接至AHB5交叉开关相同下游端口的内存时，可能发生争用。例如，从主SRAM执行的代码可能试图加载存储在附近的字面值。该加载可能与对同一SRAM的指令预取发生冲突。为降低此类冲突的可能性，主SRAM被划分为跨四字组的多个银行：地址模16不同的字被存储在不同的银行中。

由于预取器通常比执行提前约两个字（8字节）运行，这意味着一条指令如果读取自己前方8（模16）字节，可能会导致冲突。例如，以下指令读取前方40字节（因为此处**PC**表示下一条指令的地址），有时可能会导致一个周期的惩罚：

```
LDR R8, [PC, #32] @ 32位指令
```

### 3.7.4.10. 调试

Cortex-M33调试功能包括处理器暂停、单步执行、处理器核心寄存器访问、向量捕获、无限软件断点及完整系统内存访问。

处理器还支持在实现阶段配置的硬件断点和监视点：

- 支持八个指令比较器的断点单元
- 支持四个数据监视点比较器的监视单元

Cortex-M33处理器支持系统级调试认证，用以控制调试器对资源

and memory. Authentication via the Armv8-M Security Extension can be used to allow a debugger full access to Non-secure code and data without exposing any Secure information.

The processor implementation can be partitioned to place the debug components in a separate power domain from the processor core and NVIC.

All debug registers are accessible by the D-AHB interface.

For more information, see the [Armv8-M Architecture Reference Manual](#).

### 3.7.4.11. Data Watchpoint and Trace unit (DWT)

The DWT is a full configuration, containing four comparators ([DWT\\_COMP0](#) to [DWT\\_COMP3](#)). These comparators support the following features:

- Hardware watchpoint support
- Hardware trace packet support
- CMPMATCH support for ETM/MTB/CTI triggers
- Cycle counter matching support ([DWT\\_COMP0](#) only)
- Instruction address matching support
- Data address matching support
- Data value matching support ([DWT\\_COMP1](#) only in a reduced DWT, [DWT\\_COMP3](#) only in a Full DWT)
- Linked/limit matching support ([DWT\\_COMP1](#) and [DWT\\_COMP3](#) only)

The DWT contains counters for:

- Cycles ([DWT\\_CYCCNT.CYCCNT](#))
- Folded Instructions (FOLDCNT)
- Additional cycles required to execute all load/store instructions (LSUCNT)
- Processor sleep cycles (SLEEPCNT)
- Additional cycles required to execute multi-cycle instructions and instruction fetch stalls (CPICNT)
- Cycles spent in exception processing (EXCCNT)

Before using DWT, set the [DEMCR.TRCENA](#) bit to 1.

The DWT provides periodic requests for protocol synchronization to the ITM and the TPIU.

### 3.7.4.12. Cross Trigger Interface (CTI)

The CTI enables the debug logic, MTB, and ETM to interact with each other and with other CoreSight components. This is called cross triggering. For example, you can configure the CTI to generate an interrupt when the ETM trigger event occurs or to start tracing when a DWT comparator match is detected.

The following figure shows the debug system components and the available trigger inputs and trigger outputs:

[Figure 15](#) shows the components of the debug system.

及内存的访问。通过Armv8-M安全扩展进行的认证，可允许调试器完全访问非安全代码和数据，而不会泄露任何安全信息。

处理器实现可被划分为多个区域，以将调试组件置于独立于处理器核及NVIC的电源域中。

所有调试寄存器均可通过D-AHB接口访问。

更多信息，请参阅Armv8-M架构参考手册。

### 3.7.4.11. 数据观察点与跟踪单元（DWT）

DWT为全功能配置，包含四个比较器（[DWT\\_COMP0](#)至[DWT\\_COMP3](#)）。这些比较器支持以下功能：

- 硬件观察点支持
- 硬件跟踪数据包支持
- 支持ETM/MTB/CTI触发的CMPMATCH
- 支持周期计数匹配（仅限DWT\_COMP0）
- 支持指令地址匹配
- 支持数据地址匹配
- 支持数据值匹配（仅限简化DWT中的DWT\_COMP1，以及完整DWT中的DWT\_COMP3）
- 支持关联/限制匹配（仅限DWT\_COMP1和DWT\_COMP3）。DWT包

含以下计数器：

- 周期计数（[DWT\\_CYCCNT.CYCCNT](#)）
- 折叠指令计数（FOLDCNT）
- 执行所有加载/存储指令所需的额外周期（LSUCNT）
- 处理器休眠周期（SLEEP\_CNT）
- 执行多周期指令及指令取指阻塞所需的额外周期（CPICNT）
- 异常处理所用周期（EXCCNT）

使用DWT之前，请将[DEMCR.TRCENA](#)位设置为1。

DWT向ITM和TPIU周期性发送协议同步请求。

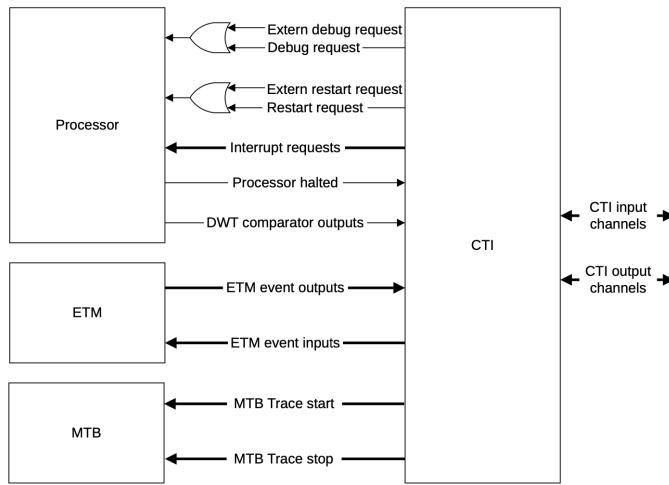

### 3.7.4.12. 交叉触发接口（CTI）

CTI使调试逻辑、MTB和ETM能够相互通信，并与其他CoreSight组件协作。这称为交叉触发。例如，您可以配置CTI，在ETM触发事件发生时生成中断，或在检测到DWT比较器匹配时启动跟踪。

下图展示了调试系统组件及可用的触发输入和输出：

[图15显示了调试系统的组成部分。](#)

Figure 15. Debug system components

The following table shows how the CTI trigger inputs are connected to the Cortex-M33 processor:

Table 118. Trigger signals to the CTI

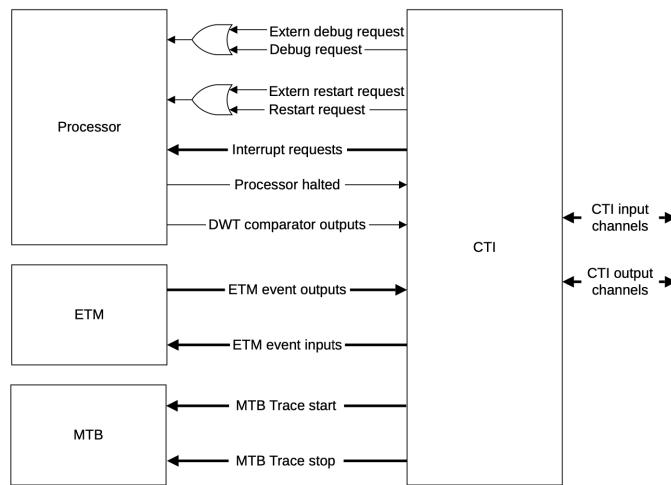

| Signal       | Description                               | Connection           | Acknowledge, handshake |
|--------------|-------------------------------------------|----------------------|------------------------|
| CTITRIGIN[7] |                                           | ETM to CTI           | Pulsed                 |
| CTITRIGIN[6] |                                           | ETM to CTI           | Pulsed                 |
| CTITRIGIN[5] | ETM Event Output 1                        | ETM to CTI           | Pulsed                 |
| CTITRIGIN[4] | ETM Event Output 0 or Comparator Output 3 | ETM/Processor to CTI | Pulsed                 |
| CTITRIGIN[3] | DWT Comparator Output 2                   | Processor to CTI     | Pulsed                 |
| CTITRIGIN[2] | DWT Comparator Output 1                   | Processor to CTI     | Pulsed                 |
| CTITRIGIN[1] | DWT Comparator Output 0                   | Processor to CTI     | Pulsed                 |
| CTITRIGIN[0] | Processor Halted                          | Processor to CTI     | Pulsed                 |

The following table shows how the CTI trigger outputs are connected to the processor and ETM:

Table 119. Trigger signals from the CTI

| Signal        | Description                          | Connection        | Acknowledge, handshake                                                   |
|---------------|--------------------------------------|-------------------|--------------------------------------------------------------------------|
| CTITRIGOUT[7] | ETM Event Input 3                    | CTI to ETM        | Pulsed                                                                   |
| CTITRIGOUT[6] | ETM Event Input 2                    | CTI to ETM        | Pulsed                                                                   |
| CTITRIGOUT[5] | ETM Event Input 1 or MTB Trace stop  | CTI to ETM or MTB | Pulsed                                                                   |
| CTITRIGOUT[4] | ETM Event Input 1 or MTB Trace start | CTI to ETM or MTB | Pulsed                                                                   |
| CTITRIGOUT[3] | Interrupt request 1                  | CTI to system     | Acknowledged by writing to the <a href="#">CTIINTACK</a> register in ISR |
| CTITRIGOUT[2] | Interrupt request 0                  | CTI to system     | Acknowledged by writing to the <a href="#">CTIINTACK</a> register in ISR |
| CTITRIGOUT[1] | Processor Restart                    | CTI to Processor  | Processor Restarted                                                      |

图 15. 调试  
系统组件

下表显示了 CTI 触发输入如何连接至 Cortex-M33 处理器：

表 118. 触发  
信号至 CTI

| 信号           | 描述                   | 连接           | 确认，握手 |
|--------------|----------------------|--------------|-------|
| CTITRIGIN[7] |                      | ETM 至 CTI    | 脉冲型   |
| CTITRIGIN[6] |                      | ETM 至 CTI    | 脉冲型   |
| CTITRIGIN[5] | ETM 事件输出 1           | ETM 至 CTI    | 脉冲型   |
| CTITRIGIN[4] | ETM 事件输出 0 或 比较器输出 3 | ETM/处理器至 CTI | 脉冲型   |
| CTITRIGIN[3] | DWT 比较器输出 2          | 处理器至 CTI     | 脉冲型   |
| CTITRIGIN[2] | DWT 比较器输出 1          | 处理器至 CTI     | 脉冲型   |
| CTITRIGIN[1] | DWT 比较器输出 0          | 处理器至 CTI     | 脉冲型   |
| CTITRIGIN[0] | 处理器已停止               | 处理器至 CTI     | 脉冲型   |

下表显示了 CTI 触发输出与处理器及 ETM 的连接方式：

表 119 来自 CTI  
的触发信号

| 信号            | 描述                    | 连接              | 确认，握手                                         |
|---------------|-----------------------|-----------------|-----------------------------------------------|
| CTITRIGOUT[7] | ETM 事件输入 3            | CTI 至 ETM       | 脉冲型                                           |
| CTITRIGOUT[6] | ETM 事件输入 2            | CTI 至 ETM       | 脉冲型                                           |
| CTITRIGOUT[5] | ETM 事件输入 1 或 MTB 跟踪停止 | CTI 至 ETM 或 MTB | 脉冲型                                           |
| CTITRIGOUT[4] | ETM 事件输入 1 或 MTB 跟踪启动 | CTI 至 ETM 或 MTB | 脉冲型                                           |
| CTITRIGOUT[3] | 中断请求 1                | CTI 至系统         | 通过在 ISR 中写入 <a href="#">CTIINTACK</a> 寄存器予以确认 |
| CTITRIGOUT[2] | 中断请求 0                | CTI 至系统         | 通过在 ISR 中写入 <a href="#">CTIINTACK</a> 寄存器予以确认 |
| CTITRIGOUT[1] | 处理器重启                 | CTI 至处理器        | 处理器已重启                                        |

| Signal        | Description             | Connection       | Acknowledge, handshake                                                         |
|---------------|-------------------------|------------------|--------------------------------------------------------------------------------|
| CTITRIGOUT[0] | Processor debug request | CTI to Processor | Acknowledged by the debugger writing to the <a href="#">CTIINTACK</a> register |

After the processor is halted using CTI Trigger Output 0, the Processor Debug Request signal remains asserted. The debugger must write to [CTIINTACK](#) to clear the halting request before restarting the processor.

After asserting an interrupt using the CTI Trigger Output 1 or 2, the Interrupt Service Routine (ISR) must clear the interrupt request by writing to the CTI Interrupt Acknowledge, [CTIINTACK](#).

Interrupt requests from the CTI to the system are only asserted when invasive debug is enabled in the processor.

### 3.7.4.12.1. CTI programmers model

The following table shows the CTI programmable registers, with address offset, type, and reset value for each register. See the Arm [CoreSight™ SoC-400 Technical Reference Manual](#) for register descriptions.

Table 120. Cortex-M33  
CTI register summary

| Address offset        | Name             | Type | Reset value | Description                              |
|-----------------------|------------------|------|-------------|------------------------------------------|
| 0xE0042000            | CTICONTROL       | RW   | 0x00000000  | CTI Control Register                     |

| 0xE0042EE8            | ITTRIGOUT        | WO   | UNKNOWN     | Integration Test Trigger Output Register |
| 0xE0042EF4            | ITCHIN           | RO   | 0x00000000  | Integration Test Channel Input Register  |
| 0xE0042F00            | ITCTRL           | RW   | 0x00000000  | Integration Mode Control Register        |
| 0xE0042FC8            | DEVID            | RO   | 0x00040800  | Device Configuration Register            |
| 0xE0042FBC            | DEVARCH          | RO   | 0x47701A14  | Device Architecture Register             |

| 信号            | 描述      | 连接      | 确认，握手                                     |
|---------------|---------|---------|-------------------------------------------|
| CTITRIGOUT[0] | 处理器调试请求 | CTI至处理器 | 通过调试器写入 <a href="#">CTIINTACK</a> 寄存器予以确认 |

在使用CTI触发输出0使处理器停止后，处理器调试请求信号仍保持有效。调试器必须先写入[CTIINTACK](#)以清除停止请求，随后方可重新启动处理器。

在通过CTI触发输出1或2发起中断后，中断服务例程（ISR）必须通过写入CTI中断确认寄存器[CTIINTACK](#)以清除中断请求。

仅当处理器启用了侵入式调试时，来自CTI到系统的中断请求才会被断言。

### 3.7.4.12.1. CTI编程模型

下表列出了CTI可编程寄存器，包括每个寄存器的地址偏移、类型及复位值。

有关寄存器说明，请参阅Arm CoreSight™ SoC-400技术参考手册。

表120. Cortex-M33  
CTI寄存器概要

| 地址偏移                  | 名称               | 类型 | 复位值        | 描述             |
|-----------------------|------------------|----|------------|----------------|
| 0xE0042000            | CTICONTROL       | 读写 | 0x00000000 | CTI控制寄存器       |

### 3.7.5. List of registers

The Arm Cortex-M33 registers start at a base address of `0xe0000000`, defined as `PPB_BASE` in the SDK.

Table 121. List of M33 registers

| Offset  | Name       | Info                          |
|---------|------------|-------------------------------|
| 0x00000 | ITM_STIM0  | ITM Stimulus Port Register 0  |
| 0x00004 | ITM_STIM1  | ITM Stimulus Port Register 1  |
| 0x00008 | ITM_STIM2  | ITM Stimulus Port Register 2  |
| 0x0000c | ITM_STIM3  | ITM Stimulus Port Register 3  |
| 0x00010 | ITM_STIM4  | ITM Stimulus Port Register 4  |
| 0x00014 | ITM_STIM5  | ITM Stimulus Port Register 5  |
| 0x00018 | ITM_STIM6  | ITM Stimulus Port Register 6  |
| 0x0001c | ITM_STIM7  | ITM Stimulus Port Register 7  |
| 0x00020 | ITM_STIM8  | ITM Stimulus Port Register 8  |
| 0x00024 | ITM_STIM9  | ITM Stimulus Port Register 9  |
| 0x00028 | ITM_STIM10 | ITM Stimulus Port Register 10 |
| 0x0002c | ITM_STIM11 | ITM Stimulus Port Register 11 |
| 0x00030 | ITM_STIM12 | ITM Stimulus Port Register 12 |
| 0x00034 | ITM_STIM13 | ITM Stimulus Port Register 13 |
| 0x00038 | ITM_STIM14 | ITM Stimulus Port Register 14 |
| 0x0003c | ITM_STIM15 | ITM Stimulus Port Register 15 |
| 0x00040 | ITM_STIM16 | ITM Stimulus Port Register 16 |
| 0x00044 | ITM_STIM17 | ITM Stimulus Port Register 17 |

| 地址偏移       | 名称      | 类型 | 复位值        | 描述        |
|------------|---------|----|------------|-----------|
| 0xE0042FCC | DEVTYPE | 只读 | 0x00000014 | 设备类型标识寄存器 |
| 0xE0042FD0 | PIDR4   | 只读 | 0x00000004 | 外设ID4寄存器  |
| 0xE0042FD4 | PIDR5   | 只读 | 0x00000000 | 外设ID5寄存器  |
| 0xE0042FD8 | PIDR6   | 只读 | 0x00000000 | 外设ID6寄存器  |
| 0xE0042FDC | PIDR7   | 只读 | 0x00000000 | 外设ID7寄存器  |
| 0xE0042FE0 | PIDR0   | 只读 | 0x00000021 | 外设ID0寄存器  |
| 0xE0042FE4 | PIDR1   | 只读 | 0x000000BD | 外设ID1寄存器  |
| 0xE0042FE8 | PIDR2   | 只读 | 0x0000000B | 外设ID2寄存器  |
| 0xE0042FEC | PIDR3   | 只读 | 0x00000001 | 外设ID3寄存器  |
| 0xE0042FF0 | CIDR0   | 只读 | 0x0000000D | 组件ID0寄存器  |
| 0xE0042FF4 | CIDR1   | 只读 | 0x00000090 | 组件ID1寄存器  |
| 0xE0042FF8 | CIDR2   | 只读 | 0x00000005 | 组件ID2寄存器  |
| 0xE0042FFC | CIDR3   | 只读 | 0x000000B1 | 组件ID3寄存器  |

### 3.7.5. 寄存器列表

Arm Cortex-M33 寄存器起始于基地址 `0xe0000000`, 在 SDK 中定义为 `PPB_BASE`。

表121 M33寄存器列表

| 偏移量     | 名称         | 说明             |
|---------|------------|----------------|
| 0x00000 | ITM_STIM0  | ITM 刺激端口寄存器 0  |
| 0x00004 | ITM_STIM1  | ITM 刺激端口寄存器 1  |
| 0x00008 | ITM_STIM2  | ITM 刺激端口寄存器 2  |
| 0x0000c | ITM_STIM3  | ITM 刺激端口寄存器 3  |
| 0x00010 | ITM_STIM4  | ITM 刺激端口寄存器 4  |
| 0x00014 | ITM_STIM5  | ITM 刺激端口寄存器 5  |
| 0x00018 | ITM_STIM6  | ITM 刺激端口寄存器 6  |
| 0x0001c | ITM_STIM7  | ITM 刺激端口寄存器 7  |
| 0x00020 | ITM_STIM8  | ITM 刺激端口寄存器 8  |
| 0x00024 | ITM_STIM9  | ITM 刺激端口寄存器 9  |
| 0x00028 | ITM_STIM10 | ITM 刺激端口寄存器 10 |
| 0x0002c | ITM_STIM11 | ITM 刺激端口寄存器 11 |
| 0x00030 | ITM_STIM12 | ITM 刺激端口寄存器 12 |

| 0x4100c | TRCSTATR      | The TRCSTATR indicates the ETM-Teal status                                                                                                                                                                     |
| 0x41010 | TRCCONFIGR    | The TRCCONFIGR sets the basic tracing options for the trace unit                                                                                                                                               |
| 0x41020 | TRCEVENTCTL0R | The TRCEVENTCTL0R controls the tracing of events in the trace stream. The events also drive the ETM-Teal external outputs.                                                                                     |
| 0x41024 | TRCEVENTCTL1R | The TRCEVENTCTL1R controls how the events selected by TRCEVENTCTL0R behave                                                                                                                                     |
| 0x4102c | TRCSTALLCTRLR | The TRCSTALLCTRLR enables ETM-Teal to stall the processor if the ETM-Teal FIFO goes over the programmed level to minimize risk of overflow                                                                     |
| 0x41030 | TRCTSCTRLR    | The TRCTSCTRLR controls the insertion of global timestamps into the trace stream. A timestamp is always inserted into the instruction trace stream                                                             |
| 0x41034 | TRCSYNCPR     | The TRCSYNCPR specifies the period of trace synchronization of the trace streams. TRCSYNCPR defines a number of bytes of trace between requests for trace synchronization. This value is always a power of two |
| 0x41038 | TRCCCCTRLR    | The TRCCCCTRLR sets the threshold value for instruction trace cycle counting. The threshold represents the minimum interval between cycle count trace packets                                                  |
| 0x41080 | TRCVICTLR     | The TRCVICTLR controls instruction trace filtering                                                                                                                                                             |
| 0x41140 | TRCCNTRLDVR   | The TRCCNTRLDVR defines the reload value for the reduced function counter                                                                                                                                      |
| 0x41180 | TRCIDR8       | TRCIDR8                                                                                                                                                                                                        |
| 0x41184 | TRCIDR9       | TRCIDR9                                                                                                                                                                                                        |
| 0x41188 | TRCIDR10      | TRCIDR10                                                                                                                                                                                                       |

## M33: ITM\_STIM0, ITM\_STIM1, ..., ITM\_STIM30, ITM\_STIM31 Registers

**Offsets:** 0x00000, 0x00004, ..., 0x00078, 0x0007c

### Description

Provides the interface for generating Instrumentation packets

Table 122.  
ITM\_STIM0,  
ITM\_STIM1, ...  
ITM\_STIM30,  
ITM\_STIM31 Registers

| Bits | Description                                                                                                                                                                              | Type | Reset      |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>STIMULUS:</b> Data to write to the Stimulus Port FIFO, for forwarding as an Instrumentation packet. The size of write access determines the type of Instrumentation packet generated. | RW   | 0x00000000 |

## M33: ITM\_TER0 Register

**Offset:** 0x00e00

### Description

Provide an individual enable bit for each ITM\_STIM register

Table 123. ITM\_TER0 Register

| Bits | Description                                                                                 | Type | Reset      |
|------|---------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>STIMENA:</b> For STIMENA[m] in ITM_TER*n, controls whether ITM_STIM(32*n + m) is enabled | RW   | 0x00000000 |

## M33: ITM\_TPR Register

**Offset:** 0x00e40

### Description

Controls which stimulus ports can be accessed by unprivileged code

Table 124. ITM\_TPR Register

| Bits | Description | Type | Reset |
|------|-------------|------|-------|
| 31:4 | Reserved.   | -    | -     |

| 偏移量     | 名称      | 说明               |
|---------|---------|------------------|
| 0x42fc8 | DEVID   | 设备配置寄存器          |

| 0x42ffc | CIDR3   | CoreSight 组件 ID3 |

## M33: ITM\_STIM0、ITM\_STIM1、...、ITM\_STIM30、ITM\_STIM31 寄存器

偏移: 0x00000、0x00004、...、0x00078、0x0007c

### 描述

提供生成仪表包的接口

表 122.  
ITM\_STIM0,  
ITM\_STIM1, ...  
ITM\_STIM30,  
ITM\_STIM31 寄存器

| 位    | 描述                                                           | 类型 | 复位         |
|------|--------------------------------------------------------------|----|------------|
| 31:0 | <b>STIMULUS:</b> 写入刺激端口 FIFO 的数据，用于转发为仪表包。写入访问的大小决定生成的仪表包类型。 | 读写 | 0x00000000 |

## M33: ITM\_TER0 寄存器

偏移: 0x00e00

### 说明

为每个 ITM\_STIM 寄存器配置独立的使能位

表 123. ITM\_TER0  
寄存器

| 位    | 描述                                                                   | 类型 | 复位         |
|------|----------------------------------------------------------------------|----|------------|
| 31:0 | <b>STIMENA:</b> 控制 ITM_TER*n 中的 STIMENA[m]，决定是否启用 ITM_STIM(32*n + m) | 读写 | 0x00000000 |

## M33: ITM\_TPR 寄存器

偏移: 0x00e40

### 描述

控制非特权代码可访问的刺激端口

表 124. ITM\_TPR  
寄存器

| 位    | 描述  | 类型 | 复位 |
|------|-----|----|----|
| 31:4 | 保留。 | -  | -  |

| Bits | Description                                                       | Type | Reset |
|------|-------------------------------------------------------------------|------|-------|
| 3:0  | <b>PRIVMASK:</b> Bit mask to enable tracing on ITM stimulus ports | RW   | 0x0   |

## M33: ITM\_TCR Register

Offset: 0x00e80

### Description

Configures and controls transfers through the ITM interface

Table 125. ITM\_TCR Register

| Bits  | Description                                                                                                                                                                     | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:24 | Reserved.                                                                                                                                                                       | -    | -     |
| 23    | <b>BUSY:</b> Indicates whether the ITM is currently processing events                                                                                                           | RO   | 0x0   |
| 22:16 | <b>TRACEBUSID:</b> Identifier for multi-source trace stream formatting. If multi-source trace is in use, the debugger must write a unique non-zero trace ID value to this field | RW   | 0x00  |
| 15:12 | Reserved.                                                                                                                                                                       | -    | -     |
| 11:10 | <b>GTSFREQ:</b> Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps              | RW   | 0x0   |
| 9:8   | <b>TSPRESCALE:</b> Local timestamp prescaler, used with the trace packet reference clock                                                                                        | RW   | 0x0   |
| 7:6   | Reserved.                                                                                                                                                                       | -    | -     |
| 5     | <b>STALLENA:</b> Stall the PE to guarantee delivery of Data Trace packets.                                                                                                      | RW   | 0x0   |
| 4     | <b>SWOENA:</b> Enables asynchronous clocking of the timestamp counter                                                                                                           | RW   | 0x0   |
| 3     | <b>TXENA:</b> Enables forwarding of hardware event packet from the DWT unit to the ITM for output to the TPIU                                                                   | RW   | 0x0   |
| 2     | <b>SYNCENA:</b> Enables Synchronization packet transmission for a synchronous TPIU                                                                                              | RW   | 0x0   |
| 1     | <b>TSENA:</b> Enables Local timestamp generation                                                                                                                                | RW   | 0x0   |
| 0     | <b>ITMENA:</b> Enables the ITM                                                                                                                                                  | RW   | 0x0   |

## M33: INT\_ATREADY Register

Offset: 0x00ef0

### Description

Integration Mode: Read ATB Ready

Table 126. INT\_ATREADY Register

| Bits | Description                                                     | Type | Reset |
|------|-----------------------------------------------------------------|------|-------|
| 31:2 | Reserved.                                                       | -    | -     |
| 1    | <b>AFVALID:</b> A read of this bit returns the value of AFVALID | RO   | 0x0   |
| 0    | <b>ATREADY:</b> A read of this bit returns the value of ATREADY | RO   | 0x0   |

## M33: INT\_ATVALID Register

Offset: 0x00ef8

| 位   | 描述                                  | 类型 | 复位  |
|-----|-------------------------------------|----|-----|
| 3:0 | <b>PRIVMASK</b> : 启用 ITM 刺激端口跟踪的位掩码 | 读写 | 0x0 |

## M33: ITM\_TCR 寄存器

偏移: 0x00e80

### 描述

配置并控制通过ITM接口的传输

表 125. *ITM\_TCR* 寄存器

| 位     | 描述                                                           | 类型 | 复位   |
|-------|--------------------------------------------------------------|----|------|
| 31:24 | 保留。                                                          | -  | -    |
| 23    | <b>BUSY</b> : 指示 ITM 当前是否正在处理事件                              | 只读 | 0x0  |
| 22:16 | <b>TRACEBUSID</b> : 多源跟踪流格式标识符若启用多源跟踪，调试器必须向此字段写入唯一且非零的跟踪 ID | 读写 | 0x00 |
| 15:12 | 保留。                                                          | -  | -    |
| 11:10 | <b>GTSFREQ</b> : 定义 ITM 生成全局时间戳的频率，基于全局时间戳时钟频率，或禁用全局时间戳生成    | 读写 | 0x0  |
| 9:8   | <b>TSPRESCALE</b> : 本地时间戳预分频器，用于配合跟踪数据包参考时钟                  | 读写 | 0x0  |
| 7:6   | 保留。                                                          | -  | -    |
| 5     | <b>STALLENA</b> : 暂停处理引擎，以保证数据跟踪数据包的传输                       | 读写 | 0x0  |
| 4     | <b>SWOENA</b> : 启用时间戳计数器的异步时钟                                | 读写 | 0x0  |
| 3     | <b>TXENA</b> : 启用将硬件事件数据包从DWT单元转发至ITM，以供TPIU输出               | 读写 | 0x0  |
| 2     | <b>SYNCENA</b> : 启用同步TPIU的同步数据包传输                            | 读写 | 0x0  |
| 1     | <b>TSENA</b> : 启用本地时间戳生成                                     | 读写 | 0x0  |
| 0     | <b>ITMENA</b> : 启用ITM                                        | 读写 | 0x0  |

## M33: INT\_ATREADY寄存器

偏移量: 0x00ef0

### 说明

集成模式：读取ATB就绪信号

表 126.  
*INT\_ATREADY* 寄存器

| 位    | 描述                               | 类型 | 复位  |
|------|----------------------------------|----|-----|
| 31:2 | 保留。                              | -  | -   |
| 1    | <b>AFVALID</b> : 读取此位返回AFVALID的值 | 只读 | 0x0 |
| 0    | <b>ATREADY</b> : 读取此位返回ATREADY的值 | 只读 | 0x0 |

## M33: INT\_ATVALID寄存器

偏移量: 0x00ef8

**Description**

Integration Mode: Write ATB Valid

*Table 127.*  
*INT\_ATVALID Register*

| Bits | Description                                                    | Type | Reset |
|------|----------------------------------------------------------------|------|-------|
| 31:2 | Reserved.                                                      | -    | -     |
| 1    | <b>AFREADY:</b> A write to this bit gives the value of AFREADY | RW   | 0x0   |
| 0    | <b>ATREADY:</b> A write to this bit gives the value of ATVALID | RW   | 0x0   |

**M33: ITM\_ITCTRL Register**

**Offset:** 0x00f00

**Description**

Integration Mode Control Register

*Table 128.*  
*ITM\_ITCTRL Register*

| Bits | Description                                                                                                                                                                                                                                                                    | Type | Reset |

| 18    | <b>EXCEVTENA</b> : Enables DWT_EXCCNT counter                                                                                                          | RW   | 0x1   |
| 17    | <b>CPIEVTEVA</b> : Enables DWT_CPICNT counter                                                                                                          | RW   | 0x0   |
| 16    | <b>EXTTRCENA</b> : Enables generation of Exception Trace packets                                                                                       | RW   | 0x0   |
| 15:13 | Reserved.                                                                                                                                              | -    | -     |
| 12    | <b>PCSAMPLENA</b> : Enables use of POSTCNT counter as a timer for Periodic PC Sample packet generation                                                 | RW   | 0x1   |
| 11:10 | <b>SYNCTAP</b> : Selects the position of the synchronization packet counter tap on the CYCCNT counter. This determines the Synchronization packet rate | RW   | 0x2   |
| 9     | <b>CYCTAP</b> : Selects the position of the POSTCNT tap on the CYCCNT counter                                                                          | RW   | 0x0   |
| 8:5   | <b>POSTINIT</b> : Initial value for the POSTCNT counter                                                                                                | RW   | 0x1   |
| 4:1   | <b>POSTPRESET</b> : Reload value for the POSTCNT counter                                                                                               | RW   | 0x2   |
| 0     | <b>CYCCNTENA</b> : Enables CYCCNT                                                                                                                      | RW   | 0x0   |

## M33: DWT\_CYCCNT Register

Offset: 0x01004

### Description

Shows or sets the value of the processor cycle counter, CYCCNT

Table 144.  
DWT\_CYCCNT  
Register

| Bits | Description                                                                                                                                        | Type | Reset      |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>CYCCNT</b> : Increments one on each processor clock cycle when DWT_CTRL.CYCCNTENA == 1 and DEMCR.TRCENA == 1. On overflow, CYCCNT wraps to zero | RW   | 0x00000000 |

## M33: DWT\_EXCCNT Register

Offset: 0x0100c

### Description

Counts the total cycles spent in exception processing

Table 145.  
DWT\_EXCCNT  
Register

| Bits | Description | Type | Reset |
|------|-------------|------|-------|
| 31:8 | Reserved.   | -    | -     |

| 位     | 描述                                                   | 类型 | 复位  |
|-------|------------------------------------------------------|----|-----|
| 24    | <b>NOPRFCNT</b> : 表示该实现不包含性能分析计数器                    | 只读 | 0x1 |
| 23    | <b>CYCDISS</b> : 控制在安全状态下是否禁用周期计数器                   | 读写 | 0x0 |
| 22    | <b>CYCEVTENA</b> : 使能POSTCNT下溢时事件计数包的生成              | 读写 | 0x1 |
| 21    | <b>FOLDEVTEA</b> : 使能DWT_FOLDCNT计数器                  | 读写 | 0x1 |
| 20    | <b>LSUEVTENA</b> : 使能DWT_LSU_CNT计数器                  | 读写 | 0x1 |
| 19    | <b>SLEEPEVTENA</b> : 使能DWT_SLEEP_CNT计数器              | 读写 | 0x0 |
| 18    | <b>EXCEVTENA</b> : 使能DWT_EXCCNT计数器                   | 读写 | 0x1 |
| 17    | <b>CPIEVTEA</b> : 使能DWT_CPI_CNT计数器                   | 读写 | 0x0 |
| 16    | <b>EXTTRCENA</b> : 使能异常跟踪包的生成                        | 读写 | 0x0 |
| 15:13 | 保留。                                                  | -  | -   |
| 12    | <b>PCSAMPLENA</b> : 使能使用POSTCNT计数器作为周期性PC采样包生成的定时器   | 读写 | 0x1 |
| 11:10 | <b>SYNCTAP</b> : 选择CYCCNT计数器上同步包计数器抽头的位置。该参数决定同步包的速率 | 读写 | 0x2 |
| 9     | <b>CYCTAP</b> : 选择CYCCNT计数器上POSTCNT抽头的位置。            | 读写 | 0x0 |
| 8:5   | <b>POSTINIT</b> : POSTCNT计数器的初始值。                    | 读写 | 0x1 |
| 4:1   | <b>POSTPRESET</b> : POSTCNT计数器的重装载值。                 | 读写 | 0x2 |
| 0     | <b>CYCCNTENA</b> : 启用CYCCNT。                         | 读写 | 0x0 |

## M33: DWT\_CYCCNT寄存器

偏移: 0x01004

### 描述

显示或设置处理器周期计数器CYCCNT的数值

表144。  
DWT\_CYCCNT  
寄存器

| 位    | 描述                                                                                            | 类型 | 复位         |
|------|-----------------------------------------------------------------------------------------------|----|------------|
| 31:0 | <b>CYCCNT</b> : 当DWT_CTRL.CYCCNTENA == 1且DEMCR.TRCENA == 1时, 每个处理器时钟周期递增1。溢出时, CYCCNT计数器回绕至零。 | 读写 | 0x00000000 |

## M33: DWT\_EXCCNT寄存器

偏移: 0x0100c

### 描述

统计异常处理期间消耗的总周期数

| 1     | <b>KEY:</b> 除非同时写入KEY，否则对FP_CTRL的写操作将被忽略。                                        | 读写 | 0x0 |
| 0     | <b>ENABLE:</b> 启用FPB。                                                            | 读写 | 0x0 |

## M33: FP\_REMAP 寄存器

偏移: 0x02004

### 描述

指示实现是否支持Flash Patch重映射，若支持，则保存重映射目标地址

表 171 FP\_REMAP 寄存器

| 位     | 描述  | 类型 | 复位 |
|-------|-----|----|----|
| 31:30 | 保留。 | -  | -  |

| Bits | Description                                                                           | Type | Reset    |
|------|---------------------------------------------------------------------------------------|------|----------|
| 29   | <b>RMPSP</b> : Indicates whether the FPB unit supports the Flash Patch remap function | RO   | 0x0      |
| 28:5 | <b>REMAP</b> : Holds the bits[28:5] of the Flash Patch remap address                  | RO   | 0x000000 |
| 4:0  | Reserved.                                                                             | -    | -        |

## M33: FP\_COMP0, FP\_COMP1, ..., FP\_COMP6, FP\_COMP7 Registers

**Offsets:** 0x02008, 0x0200c, ..., 0x02020, 0x02024

### Description

Holds an address for comparison. The effect of the match depends on the configuration of the FPB and whether the comparator is an instruction address comparator or a literal address comparator

Table 172. FP\_COMP0, FP\_COMP1, ..., FP\_COMP6, FP\_COMP7 Registers

| Bits | Description                                                         | Type | Reset |
|------|---------------------------------------------------------------------|------|-------|
| 31:1 | Reserved.                                                           | -    | -     |
| 0    | <b>BE</b> : Selects between flashpatch and breakpoint functionality | RW   | 0x0   |

## M33: FP\_DEVARCH Register

**Offset:** 0x02fbc

### Description

Provides CoreSight discovery information for the FPB

Table 173. FP\_DEVARCH Register

| Bits  | Description                                                                                                                                                                 | Type | Reset |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:21 | <b>ARCHITECT</b> : Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code. | RO   | 0x23b |
| 20    | <b>PRESENT</b> : Defines that the DEVARCH register is present                                                                                                               | RO   | 0x1   |
| 19:16 | <b>REVISION</b> : Defines the architecture revision of the component                                                                                                        | RO   | 0x0   |
| 15:12 | <b>ARCHVER</b> : Defines the architecture version of the component                                                                                                          | RO   | 0x1   |
| 11:0  | <b>ARCHPART</b> : Defines the architecture of the component                                                                                                                 | RO   | 0xa03 |

## M33: FP\_DEVTYP Register

**Offset:** 0x02fcc

### Description

Provides CoreSight discovery information for the FPB

Table 174. FP\_DEVTYP Register

| Bits | Description                         | Type | Reset |
|------|-------------------------------------|------|-------|
| 31:8 | Reserved.                           | -    | -     |
| 7:4  | <b>SUB</b> : Component sub-type     | RO   | 0x0   |
| 3:0  | <b>MAJOR</b> : Component major type | RO   | 0x0   |

## M33: FP\_PIDR4 Register

**Offset:** 0x02fd0

| 位    | 描述                                           | 类型 | 复位       |
|------|----------------------------------------------|----|----------|
| 29   | <b>RMPSPt</b> : 指示FPB单元是否支持Flash Patch重映射功能。 | 只读 | 0x0      |
| 28:5 | <b>REMAP</b> : 保存 Flash Patch 重映射地址的位[28:5]  | 只读 | 0x000000 |
| 4:0  | 保留。                                          | -  | -        |

## M33: FP\_COMP0、FP\_COMP1、...、FP\_COMP6、FP\_COMP7 寄存器

偏移量: 0x02008、0x0200c、...、0x02020、0x02024

### 描述

保存用于比较的地址。匹配结果取决于FPB配置及比较器为指令地址比较器或字面地址比较器

表172。FP\_COMP0、FP\_COMP1、...、FP\_COMP6、FP\_COMP7 寄存器

| 位    | 描述                               | 类型 | 复位  |
|------|----------------------------------|----|-----|
| 31:1 | 保留。                              | -  | -   |
| 0    | <b>BE</b> : 选择 Flash Patch 与断点功能 | 读写 | 0x0 |

## M33: FP\_DEVARCH 寄存器

偏移量: 0x02fbc

### 描述

提供FPB的CoreSight发现信息

表173。FP\_DEVARCH 寄存器

| 位     | 描述                                                                                 | 类型 | 复位    |
|-------|------------------------------------------------------------------------------------|----|-------|
| 31:21 | <b>ARCHITECT</b> : 定义组件的架构商。位[31:28]为JEP106连续码 (JEP106银行ID减1)，位[27:21]为JEP106 ID码。 | 只读 | 0x23b |
| 20    | <b>PRESENT</b> : 定义DEVARC寄存器的存在                                                    | 只读 | 0x1   |
| 19:16 | <b>REVISION</b> : 定义组件的架构修订版                                                       | 只读 | 0x0   |
| 15:12 | <b>ARCHVER</b> : 定义组件的架构版本                                                         | 只读 | 0x1   |
| 11:0  | <b>ARCHPART</b> : 定义组件的架构                                                          | 只读 | 0xa03 |

## M33: FP\_DEVTYPED 寄存器

偏移量: 0x02fcc

### 描述

提供FPB的CoreSight发现信息

表174。FP\_DEVTYPED 寄存器

| 位    | 描述                   | 类型 | 复位  |
|------|----------------------|----|-----|
| 31:8 | 保留。                  | -  | -   |
| 7:4  | <b>SUB</b> : 组件子类型   | 只读 | 0x0 |
| 3:0  | <b>MAJOR</b> : 组件主类型 | 只读 | 0x0 |

## M33: FP\_PIDR4 寄存器

偏移量: 0x02fd0

**Description**

Provides CoreSight discovery information for the FP

*Table 175. FP\_PIDR4 Register*

| Bits | Description                                             | Type | Reset |

| 1     | <b>TICKINT</b> : 启用SysTick异常请求：<br>0 = 计数到零时不产生SysTick异常请求。<br>1 = 计数到零时产生SysTick异常请求。                    | 读写 | 0x0 |

| Bits | Description                                                                             | Type | Reset |
|------|-----------------------------------------------------------------------------------------|------|-------|
| 0    | <b>ENABLE:</b> Enable SysTick counter:<br>0 = Counter disabled.<br>1 = Counter enabled. | RW   | 0x0   |

## M33: SYST\_RVR Register

Offset: 0x0e014

### Description

Use the SysTick Reload Value Register to specify the start value to load into the current value register when the counter reaches 0. It can be any value between 0 and 0x00FFFFFF. A start value of 0 is possible, but has no effect because the SysTick interrupt and COUNTFLAG are activated when counting from 1 to 0. The reset value of this register is UNKNOWN.

To generate a multi-shot timer with a period of N processor clock cycles, use a RELOAD value of N-1. For example, if the SysTick interrupt is required every 100 clock pulses, set RELOAD to 99.

Table 190. SYST\_RVR Register

| Bits  | Description                                                                                      | Type | Reset    |
|-------|--------------------------------------------------------------------------------------------------|------|----------|
| 31:24 | Reserved.                                                                                        | -    | -        |
| 23:0  | <b>RELOAD:</b> Value to load into the SysTick Current Value Register when the counter reaches 0. | RW   | 0x000000 |

## M33: SYST\_CVR Register

Offset: 0x0e018

### Description

Use the SysTick Current Value Register to find the current value in the register. The reset value of this register is UNKNOWN.

Table 191. SYST\_CVR Register

| Bits  | Description                                                                                                                                                                                                                                                  | Type | Reset    |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|----------|
| 31:24 | Reserved.                                                                                                                                                                                                                                                    | -    | -        |
| 23:0  | <b>CURRENT:</b> Reads return the current value of the SysTick counter. This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register. | RW   | 0x000000 |

## M33: SYST\_CALIB Register

Offset: 0x0e01c

### Description

Use the SysTick Calibration Value Register to enable software to scale to any required speed using divide and multiply.

Table 192. SYST\_CALIB Register

| Bits  | Description                                                                                                                                                                     | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31    | <b>NOREF:</b> If reads as 1, the Reference clock is not provided - the CLKSOURCE bit of the SysTick Control and Status register will be forced to 1 and cannot be cleared to 0. | RO   | 0x0   |
| 30    | <b>SKEW:</b> If reads as 1, the calibration value for 10ms is inexact (due to clock frequency).                                                                                 | RO   | 0x0   |
| 29:24 | Reserved.                                                                                                                                                                       | -    | -     |

| 位 | 描述                                                       | 类型 | 复位  |
|---|----------------------------------------------------------|----|-----|
| 0 | <b>ENABLE:</b> 启用SysTick计数器：<br>0 = 禁用计数器。<br>1 = 启用计数器。 | 读写 | 0x0 |

## M33: SYST\_RVR寄存器

偏移量: 0x0e014

### 说明

使用SysTick重载值寄存器指定计数器计数至0时加载入当前值寄存器的初始值。该初始值可为0至0xFFFFFFFF之间的任意值。起始值为0虽可行，但无效，因为SysTick中断和COUNTFLAG仅在从1计数至0时激活。该寄存器的复位值未知。

要生成一个周期为N个处理器时钟周期的多次定时器，应将RELOAD设为N-1。例如，若需每100个时钟脉冲触发一次SysTick中断，则将RELOAD设为99。

表190. SYST\_RVR  
寄存器

| 位     | 描述                                          | 类型 | 复位       |

NVIC\_ICER1 寄存器

| 位    | 描述                                                               | 类型 | 复位         |
|------|------------------------------------------------------------------|----|------------|
| 31:0 | <b>CLRENA:</b> 针对 NVIC_ICER*n 中的 CLRENA[m]，指示中断 $32*n + m$ 是否已启用 | 读写 | 0x00000000 |

## M33: NVIC\_ISPR0、NVIC\_ISPR1 寄存器

偏移量: 0x0e200、0x0e204

### 描述

启用或读取每组32个中断的挂起状态

表 195。  
NVIC\_ISPR0,  
NVIC\_ISPR1 寄存器

| 位    | 描述                                                                     | 类型 | 复位         |
|------|------------------------------------------------------------------------|----|------------|
| 31:0 | <b>SETPEND:</b> 针对 NVIC_ISPR*n 中的 SETPEND[m]，指示中断 $32*n + m$ 是否处于待处理状态 | 读写 | 0x00000000 |

## M33: NVIC\_ICPR0、NVIC\_ICPR1 寄存器

偏移量: 0x0e280、0x0e284

### 描述

清除或读取每组32个中断的挂起状态

表 196。  
NVIC\_ICPR0,  
NVIC\_ICPR1 寄存器

| 位    | 描述                                                              | 类型 | 复位         |
|------|-----------------------------------------------------------------|----|------------|
| 31:0 | <b>CLRPEND:</b> 在 NVIC_ICPR*n 中，CLRPEND[m] 表示中断 $32*n + m$ 是否挂起 | 读写 | 0x00000000 |

## M33: NVIC\_IABR0, NVIC\_IABR1 寄存器

偏移量: 0x0e300, 0x0e304

### 描述

针对每组32个中断，显示每个中断的活动状态

Table 197.  
NVIC\_IABR0,  
NVIC\_IABR1 Registers

| Bits | Description                                                                                  | Type | Reset      |
|------|----------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>ACTIVE:</b> For ACTIVE[m] in NVIC_IABR*n, indicates the active state for interrupt 32*n+m | RW   | 0x00000000 |

## M33: NVIC\_ITNS0, NVIC\_ITNS1 Registers

Offsets: 0x0e380, 0x0e384

### Description

For each group of 32 interrupts, determines whether each interrupt targets Non-secure or Secure state

Table 198.  
NVIC\_ITNS0,  
NVIC\_ITNS1 Registers

| Bits | Description                                                                                    | Type | Reset      |
|------|------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>ITNS:</b> For ITNS[m] in NVIC_ITNS*n, `IAAMO the target Security state for interrupt 32*n+m | RW   | 0x00000000 |

## M33: NVIC\_IPR0, NVIC\_IPR1, ..., NVIC\_IPR14, NVIC\_IPR15 Registers

Offsets: 0x0e400, 0x0e404, ..., 0x0e438, 0x0e43c

### Description

Sets or reads interrupt priorities

Table 199. NVIC\_IPR0,  
NVIC\_IPR1, ...,  
NVIC\_IPR14  
NVIC\_IPR15 Registers

| Bits  | Description                                                                                                                        | Type | Reset |
|-------|------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | <b>PRI_N3:</b> For register NVIC_IPRn, the priority of interrupt number 4*n+3, or RES0 if the PE does not implement this interrupt | RW   | 0x0   |
| 27:24 | Reserved.                                                                                                                          | -    | -     |
| 23:20 | <b>PRI_N2:</b> For register NVIC_IPRn, the priority of interrupt number 4*n+2, or RES0 if the PE does not implement this interrupt | RW   | 0x0   |
| 19:16 | Reserved.                                                                                                                          | -    | -     |
| 15:12 | <b>PRI_N1:</b> For register NVIC_IPRn, the priority of interrupt number 4*n+1, or RES0 if the PE does not implement this interrupt | RW   | 0x0   |
| 11:8  | Reserved.                                                                                                                          | -    | -     |
| 7:4   | <b>PRI_N0:</b> For register NVIC_IPRn, the priority of interrupt number 4*n+0, or RES0 if the PE does not implement this interrupt | RW   | 0x0   |
| 3:0   | Reserved.                                                                                                                          | -    | -     |

## M33: CPID Register

Offset: 0x0ed00

### Description

Provides identification information for the PE, including an implementer code for the device and a device ID number

Table 200. CPID Register

| Bits  | Description                                                                                                                                                             | Type | Reset |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:24 | <b>IMPLEMENTER:</b> This field must hold an implementer code that has been assigned by ARM                                                                              | RO   | 0x41  |
| 23:20 | <b>VARIANT:</b> IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product | RO   | 0x1   |
| 19:16 | <b>ARCHITECTURE:</b> Defines the Architecture implemented by the PE                                                                                                     | RO   | 0xf   |

表197。  
NVIC\_IABR0,  
NVIC\_IABR1 寄存器

| 位    | 描述                                                            | 类型 | 复位         |
|------|---------------------------------------------------------------|----|------------|
| 31:0 | <b>ACTIVE:</b> 在 NVIC_IABR*n 中, ACTIVE[m] 表示中断的激活状态<br>32*n+m | 读写 | 0x00000000 |

## M33: NVIC\_ITNS0, NVIC\_ITNS1 寄存器

偏移量: 0x0e380, 0x0e384

### 描述

针对每组32个中断, 确定每个中断的目标是非安全态还是安全态

表198。  
NVIC\_ITNS0,  
NVIC\_ITNS1 寄存器

| 位    | 描述                                                          | 类型 | 复位         |
|------|-------------------------------------------------------------|----|------------|
| 31:0 | <b>ITNS:</b> 在 NVIC_ITNS*n 中, ITNS[m] 表示中断 32*n+m 所属的目标安全状态 | 读写 | 0x00000000 |

## M33: NVIC\_IPR0, NVIC\_IPR1, ..., NVIC\_IPR14, NVIC\_IPR15 寄存器

偏移量: 0x0e400, 0x0e404, ..., 0x0e438, 0x0e43c

### 描述

设置或读取中断优先级

表199。NVIC\_IPR0、N  
VIC\_IPR1、...  
、NVIC\_IPR  
14、NVIC\_IPR15寄存器

| 位     | 描述                                                             | 类型 | 复位  |
|-------|----------------------------------------------------------------|----|-----|
| 31:28 | <b>PRI_N3:</b> 对寄存器NVIC_IPRn, 中断号4*n+3的优先级, 或若PE未实现该中断, 则为RES0 | 读写 | 0x0 |
| 27:24 | 保留。                                                            | -  | -   |
| 23:20 | <b>PRI_N2:</b> 对寄存器NVIC_IPRn, 中断号4*n+2的优先级, 或若PE未实现该中断, 则为RES0 | 读写 | 0x0 |
| 19:16 | 保留。                                                            | -  | -   |
| 15:12 | <b>PRI_N1:</b> 对寄存器NVIC_IPRn, 中断号4*n+1的优先级, 或若PE未实现该中断, 则为RES0 | 读写 | 0x0 |
| 11:8  | 保留。                                                            | -  | -   |
| 7:4   | <b>PRI_N0:</b> 对寄存器NVIC_IPRn, 中断号4*n+0的优先级, 或若PE未实现该中断, 则为RES0 | 读写 | 0x0 |
| 3:0   | 保留。                                                            | -  | -   |

## M33: CPUID寄存器

偏移量: 0x0ed00

### 描述

提供PE的识别信息, 包括设备的实现者代码及设备ID编号

表200。CPUID  
寄存器

| 位     | 描述                                                     | 类型 | 复位   |
|-------|--------------------------------------------------------|----|------|
| 31:24 | <b>IMPLEMENTER:</b> 该字段必须包含由ARM分配的实施者代码                | 只读 | 0x41 |
| 23:20 | <b>VARIANT:</b> 实现自定义的变体编号。通常, 此字段用于区分不同的产品变体或产品的主要版本。 | 只读 | 0x1  |
| 19:16 | <b>ARCHITECTURE:</b> 定义PE所实现的架构。                       | 只读 | 0xf  |

| Bits | Description                                                              | Type | Reset |
|------|--------------------------------------------------------------------------|------|-------|
| 15:4 | <b>PARTNO:</b> IMPLEMENTATION DEFINED primary part number for the device | RO   | 0xd21 |
| 3:0  | <b>REVISION:</b> IMPLEMENTATION DEFINED revision number for the device   | RO   | 0x0   |

## M33: ICSR Register

**Offset:** 0x0ed04

### Description

Controls and provides status information for NMI, PendSV, SysTick and interrupts

Table 201. ICSR Register

| Bits  | Description                                                                                             | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------|------|-------|
| 31    | <b>PENDNMISET:</b> Indicates whether the NMI exception is pending                                       | RO   | 0x0   |
| 30    | <b>PENDNMICLR:</b> Allows the NMI exception pend state to be cleared                                    | RW   | 0x0   |
| 29    | Reserved.                                                                                               | -    | -     |
| 28    | <b>PENDSVSET:</b> Indicates whether the PendSV `FTSSS exception is pending                              | RO   | 0x0   |
| 27    | <b>PENDSVCLR:</b> Allows the PendSV exception pend state to be cleared `FTSSS                           | RW   | 0x0   |
| 26    | <b>PENDSTSET:</b> Indicates whether the SysTick `FTSSS exception is pending                             | RO   | 0x0   |
| 25    | <b>PENDSTCLR:</b> Allows the SysTick exception pend state to be cleared `FTSSS                          | RW   | 0x0   |
| 24    | <b>STTNS:</b> Controls whether in a single SysTick implementation, the SysTick is Secure or Non-secure  | RW   | 0x0   |
| 23    | <b>ISRPREEMPT:</b> Indicates whether a pending exception will be serviced on exit from debug halt state | RO   | 0x0   |
| 22    | <b>ISR PENDING:</b> Indicates whether an external interrupt, generated by the NVIC, is pending          | RO   | 0x0   |
| 21    | Reserved.                                                                                               | -    | -     |
| 20:12 | <b>VECTPENDING:</b> The exception number of the highest priority pending and enabled interrupt          | RO   | 0x000 |
| 11    | <b>RETTOBASE:</b> In Handler mode, indicates whether there is more than one active exception            | RO   | 0x0   |
| 10:9  | Reserved.                                                                                               | -    | -     |
| 8:0   | <b>VECTACTIVE:</b> The exception number of the current executing exception                              | RO   | 0x000 |

## M33: VTOR Register

**Offset:** 0x0ed08

### Description

The VTOR indicates the offset of the vector table base address from memory address 0x00000000.

| 位    | 描述                             | 类型 | 复位    |
|------|--------------------------------|----|-------|
| 15:4 | <b>PARTNO</b> : 设备的实现自定义主零件编号。 | 只读 | 0xd21 |
| 3:0  | <b>REVISION</b> : 设备的实现自定义修订号。 | 只读 | 0x0   |

## M33: ICSR寄存器

偏移量: 0x0ed04

### 描述

控制并提供 NMI、PendSV、SysTick 及中断的状态信息

表201. ICSR  
寄存器

| 位     | 描述                                              | 类型 | 复位    |
|-------|-------------------------------------------------|----|-------|
| 31    | <b>PENDNMISET</b> : 指示NMI异常是否处于挂起状态。            | 只读 | 0x0   |
| 30    | <b>PENDNMICLR</b> : 允许清除NMI异常的挂起状态。             | 读写 | 0x0   |
| 29    | 保留。                                             | -  | -     |
| 28    | <b>PENDSVSET</b> : 指示PendSV `FTSSS异常是否处于挂起状态。   | 只读 | 0x0   |
| 27    | <b>PENDSVCLR</b> : 允许清除PendSV异常的挂起状态`FTSSS。     | 读写 | 0x0   |
| 26    | <b>PENDSTSET</b> : 指示SysTick的`FTSSS异常是否处于挂起状态   | 只读 | 0x0   |
| 25    | <b>PENDSTCLR</b> : 允许清除SysTick异常的挂起状态 `FTSSS    | 读写 | 0x0   |
| 24    | <b>STTNS</b> : 控制单个SysTick实现中, SysTick为安全或非安全状态 | 读写 | 0x0   |
| 23    | <b>ISRPREEMPT</b> : 指示是否在调试暂停状态退出时处理待处理异常       | 只读 | 0x0   |
| 22    | <b>ISR PENDING</b> : 指示由NVIC产生的外部中断是否处于挂起状态     | 只读 | 0x0   |
| 21    | 保留。                                             | -  | -     |
| 20:12 | <b>VECTPENDING</b> : 优先级最高且已启用的挂起中断的异常号         | 只读 | 0x000 |
| 11    | <b>RETTOBASE</b> : 在处理程序模式下, 指示是否存在多个活动异常       | 只读 | 0x0   |
| 10:9  | 保留。                                             | -  | -     |
| 8:0   | <b>VECTACTIVE</b> : 当前正在执行的异常号                  | 只读 | 0x000 |

## M33: VTOR寄存器

Offset: 0x0ed08

### 描述

VTOR指示向量表基地址相对于内存地址0x的偏移量00000000.

Table 202. VTOR Register

| Bits | Description                                                                                                                              | Type | Reset     |
|------|------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:7 | <b>TBLOFF:</b> Vector table base offset field. It contains bits[31:7] of the offset of the table base from the bottom of the memory map. | RW   | 0x0000000 |
| 6:0  | Reserved.                                                                                                                                | -    | -         |

## M33: AIRCR Register

Offset: 0x0ed0c

### Description

Use the Application Interrupt and Reset Control Register to: determine data endianness, clear all active state information from debug halt mode, request a system reset.

Table 203. AIRCR Register

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Type | Reset  |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | <b>VECTKEY:</b> Register key:<br>Reads as Unknown<br>On writes, write 0x05FA to VECTKEY, otherwise the write is ignored.                                                                                                                                                                                                                                                                                                                                               | RW   | 0x0000 |
| 15    | <b>ENDIANESS:</b> Data endianness implemented:<br>0 = Little-endian.                                                                                                                                                                                                                                                                                                                                                                                                   | RO   | 0x0    |
| 14    | <b>PRIS:</b> Prioritize Secure exceptions. The value of this bit defines whether Secure exception priority boosting is enabled.<br>0 Priority ranges of Secure and Non-secure exceptions are identical.<br>1 Non-secure exceptions are de-prioritized.                                                                                                                                                                                                                 | RW   | 0x0    |
| 13    | <b>BFHFNMIN:</b> BusFault, HardFault, and NMI Non-secure enable.<br>0 BusFault, HardFault, and NMI are Secure.<br>1 BusFault and NMI are Non-secure and exceptions can target Non-secure HardFault.                                                                                                                                                                                                                                                                    | RW   | 0x0    |
| 12:11 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                              | -    | -      |

| 3     | <b>SYSRESETREQS:</b> System reset request, Secure state only.<br>0 SYSRESETREQ functionality is available to both Security states.<br>1 SYSRESETREQ functionality is only available to Secure state.                                                                                                                                                                                                                                                                   | RW   | 0x0    |
| 2     | <b>SYSRESETREQ:</b> Writing 1 to this bit causes the SYSRESETREQ signal to the outer system to be asserted to request a reset. The intention is to force a large system reset of all major components except for debug. The C_HALT bit in the DCSR is cleared as a result of the system reset requested. The debugger does not lose contact with the device.                                                                                                           | RW   | 0x0    |
| 1     | <b>VECTCLRACTIVE:</b> Clears all active state information for fixed and configurable exceptions. This bit: is self-clearing, can only be set by the DAP when the core is halted. When set: clears all active exception status of the processor, forces a return to Thread mode, forces an IPSR of 0. A debugger must re-initialize the stack.                                                                                                                          | RW   | 0x0    |
| 0     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                              | -    | -      |

表202. VTOR  
寄存器

| 位    | 描述                                                        | 类型 | 复位        |
|------|-----------------------------------------------------------|----|-----------|
| 31:7 | <b>TBLOFF</b> : 向量表基偏移字段。它包含表基址相对于内存映射底部的偏移量的 bits[31:7]。 | 读写 | 0x0000000 |
| 6:0  | 保留。                                                       | -  | -         |

## M33：AIRCR 寄存器

偏移: 0x0ed0c

### 描述

使用应用程序中断和复位控制寄存器以：确定数据字节序，从调试停止模式清除所有活动状态信息，发起系统复位请求。

表 203。AIRCR  
寄存器

| 位     | 描述                                                                                                                                                                                                                                                                                                                                                                                             | 类型 | 复位     |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|--------|
| 31:16 | <b>VECTKEY</b> : 寄存器密钥：<br>读作未知<br>写入时，必须向 VECTKEY 写入 0x05FA，否则写入操作将被忽略。                                                                                                                                                                                                                                                                                                                       | 读写 | 0x0000 |
| 15    | <b>ENDIANESS</b> : 实现的数据字节序：<br>0 = 小端序。                                                                                                                                                                                                                                                                                                                                                       | 只读 | 0x0    |
| 14    | <b>PRIS</b> : 优先处理安全异常。该位值决定是否启用安全异常的优先级提升。<br>0 表示安全异常与非安全异常优先级范围相同。<br>1 表示非安全异常优先级被降低。                                                                                                                                                                                                                                                                                                      | 读写 | 0x0    |
| 13    | <b>BFHFNMIN</b> : 允许总线故障、硬故障和 NMI 的非安全访问。<br>0 表示总线故障、硬故障和 NMI 均为安全访问。<br>1 BusFault 和 NMI 为非安全态，异常可定位至非安全态硬故障。                                                                                                                                                                                                                                                                                | 读写 | 0x0    |
| 12:11 | 保留。                                                                                                                                                                                                                                                                                                                                                                                            | -  | -      |
| 10:8  | <b>PRIGROUP</b> : 中断优先级分组字段。该字段用于确定组优先级与子优先级的划分。<br><a href="https://developer.arm.com/documentation/100235/0004/the-cortex-m33-peripherals/system-control-block/application-interrupt-and-reset-control-register?lang=en">详见 https://developer.arm.com/documentation/100235/0004/the-cortex-m33-peripherals/system-control-block/application-interrupt-and-reset-control-register?lang=en</a> | 读写 | 0x0    |
| 7:4   | 保留。                                                                                                                                                                                                                                                                                                                                                                                            | -  | -      |
| 3     | <b>SYSRESETREQS</b> : 系统复位请求，仅限安全态。<br>0 表示 SYSRESETREQ 功能对两个安全态均可用。<br>1 表示 SYSRESETREQ 功能仅对安全态可用。                                                                                                                                                                                                                                                                                            | 读写 | 0x0    |
| 2     | <b>SYSRESETREQ</b> : 写1至该位将触发外部系统的 SYSRESETREQ 信号以请求复位。其目的是强制对除调试外所有主要组件执行大规模系统复位。系统复位请求将导致 DCSR 中的 C_HALT 位被清除。调试器不会与设备断开连接。                                                                                                                                                                                                                                                                  | 读写 | 0x0    |
| 1     | <b>VECTCLACTIVE</b> : 清除所有固定及可配置异常的活动状态信息。<br>该位为自清位，仅当核心处于暂停状态时由DAP设置。置位时：清除处理器所有活动异常状态，强制返回线程模式，强制将IPSR设为0。调试器必须重新初始化堆栈。                                                                                                                                                                                                                                                                     | 读写 | 0x0    |
| 0     | 保留。                                                                                                                                                                                                                                                                                                                                                                                            | -  | -      |

## M33: SCR Register

**Offset:** 0x0ed10

### Description

System Control Register. Use the System Control Register for power-management functions: signal to the system when the processor can enter a low power state, control how the processor enters and exits low power states.

Table 204. SCR Register

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Type | Reset |

## M33：SCR寄存器

偏移量：0x0ed10

### 描述

系统控制寄存器。该寄存器用于电源管理功能：向系统发出信号，指示处理器可进入低功耗状态，并控制处理器如何进入及退出低功耗状态。

表204. SCR  
寄存器

| 位    | 描述                                                                                                                                                                                                              | 类型 | 复位  |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31:5 | 保留。                                                                                                                                                                                                             | -  | -   |
| 4    | <b>SEVONPEND</b> : 挂起时发送事件位：<br>0 = 仅启用的中断或事件可唤醒处理器，禁用的中断除外。<br><br>1 = 启用的事件及所有中断（包含禁用中断）均可唤醒处理器。<br><br>当事件或中断变为挂起时，事件信号将唤醒处理器退出WFE。如果<br><br>处理器未处于等待事件状态，事件将被注册并影响下一次WFE。<br><br>处理器亦会在执行 SEV 指令或发生外部事件时唤醒。 | 读写 | 0x0 |
| 3    | <b>SLEEPDEEPS</b> : 0 表示 SLEEPDEEP 对两种安全状态均可用。<br>1 表示 SLEEPDEEP 仅对安全状态可用。                                                                                                                                      | 读写 | 0x0 |
| 2    | <b>SLEEPDEEP</b> : 控制处理器以睡眠还是深度睡眠作为低功耗模式：<br><br>0 = 睡眠。<br>1 = 深度睡眠。                                                                                                                                           | 读写 | 0x0 |
| 1    | <b>SLEEPONEXIT</b> : 指示从处理程序模式返回线程模式时是否进入睡眠状态：<br><br>0 = 返回线程模式时不进入睡眠。<br>1 = 从 ISR 返回线程模式时进入睡眠或深度睡眠。<br>将此位设为 1，可使中断驱动应用避免返回至空的主程序。                                                                           | 读写 | 0x0 |
| 0    | 保留。                                                                                                                                                                                                             | -  | -   |

## M33: CFSR 寄存器

偏移: 0x0ed28

### 描述

包含三个可配置故障状态寄存器

31:16 UFSR: 提供有关 UsageFault 异常的信息

15:8 BFRS: 提供有关 BusFault 异常的信息

7:0 MMFSR: 提供有关 MemManage 异常的信息

表 210. CFSR  
寄存器

| 位     | 描述                                                         | 类型 | 复位  |

| 31:5 | Reserved.                                                                                          | -    | -     |
| 4    | <b>EXTERNAL:</b> Sticky flag indicating whether an External debug request debug event has occurred | RW   | 0x0   |
| 3    | <b>VCATCH:</b> Sticky flag indicating whether a Vector catch debug event has occurred              | RW   | 0x0   |
| 2    | <b>DWTTRAP:</b> Sticky flag indicating whether a Watchpoint debug event has occurred               | RW   | 0x0   |
| 1    | <b>BKPT:</b> Sticky flag indicating whether a Breakpoint debug event has occurred                  | RW   | 0x0   |

| 位   | 描述                                             | 类型 | 复位   |
|-----|------------------------------------------------|----|------|
| 13  | <b>BFSR_LSPERR</b> : 记录是否在浮点延迟状态保存期间发生总线错误     | 读写 | 0x0  |
| 12  | <b>BFSR_STKERR</b> : 记录是否在异常进入堆栈操作期间发生派生总线错误   | 读写 | 0x0  |
| 11  | <b>BFSR_UNSTKERR</b> : 记录是否在异常返回出栈操作期间发生派生总线错误 | 读写 | 0x0  |
| 10  | <b>BFSR_IMPRECISERR</b> : 记录是否发生非精确数据访问错误      | 读写 | 0x0  |
| 9   | <b>BFSR_PRECISERR</b> : 记录是否发生精确数据访问错误         | 读写 | 0x0  |
| 8   | <b>BFSR_IBUSERR</b> : 记录是否发生指令预取时的总线错误         | 读写 | 0x0  |
| 7:0 | <b>MMFSR</b> : 提供内存管理异常信息                      | 读写 | 0x00 |

## M33: HFSR 寄存器

偏移: 0x0ed2c

### 描述

显示任何 HardFault 的原因

表211. HFSR  
寄存器

| 位    | 描述                                                                 | 类型 | 复位  |
|------|--------------------------------------------------------------------|----|-----|
| 31   | <b>DEBUGEV</b> : 指示调试事件发生时间                                        | 读写 | 0x0 |
| 30   | <b>FORCED</b> : 表示具有可配置优先级的故障已升级为 HardFault 异常，原因是该故障因优先级或被禁用而无法激活 | 读写 | 0x0 |
| 29:2 | 保留。                                                                | -  | -   |
| 1    | <b>VECTTBL</b> : 表示由于异常处理过程中向量表读取错误而发生故障                           | 读写 | 0x0 |
| 0    | 保留。                                                                | -  | -   |

## M33: DFSR 寄存器

偏移: 0x0ed30

### 描述

显示发生的调试事件类型

表212. DFSR寄  
存器

| 位    | 描述                                      | 类型 | 复位  |
|------|-----------------------------------------|----|-----|
| 31:5 | 保留。                                     | -  | -   |
| 4    | <b>EXTERNAL</b> : 粘滞标志，指示是否发生外部调试请求调试事件 | 读写 | 0x0 |
| 3    | <b>VCATCH</b> : 粘滞标志，指示是否发生向量捕获调试事件     | 读写 | 0x0 |
| 2    | <b>DWTTRAP</b> : 粘滞标志，指示是否发生观察点调试事件     | 读写 | 0x0 |
| 1    | <b>BKPT</b> : 粘滞标志，指示是否发生断点调试事件         | 读写 | 0x0 |

| Bits | Description                                                                                            | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------|------|-------|
| 0    | <b>HALTED:</b> Sticky flag indicating that a Halt request debug event or Step debug event has occurred | RW   | 0x0   |

## M33: MMFAR Register

**Offset:** 0x0ed34

### Description

Shows the address of the memory location that caused an MPU fault

Table 213. MMFAR Register

| Bits | Description                                                                                                                                                                                                                                                     | Type | Reset      |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>ADDRESS:</b> This register is updated with the address of a location that produced a MemManage fault. The MMFSR shows the cause of the fault, and whether this field is valid. This field is valid only when MMFSR.MMARVALID is set, otherwise it is UNKNOWN | RW   | 0x00000000 |

## M33: BFAR Register

**Offset:** 0x0ed38

### Description

Shows the address associated with a precise data access BusFault

Table 214. BFAR Register

| Bits | Description                                                                                                                                                                                                             | Type | Reset      |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>ADDRESS:</b> This register is updated with the address of a location that produced a BusFault. The BCSR shows the reason for the fault. This field is valid only when BCSR.BFARVALID is set, otherwise it is UNKNOWN | RW   | 0x00000000 |

## M33: ID\_PFR0 Register

**Offset:** 0x0ed40

### Description

Gives top-level information about the instruction set supported by the PE

Table 215. ID\_PFR0 Register

| Bits | Description                                | Type | Reset |
|------|--------------------------------------------|------|-------|
| 31:8 | Reserved.                                  | -    | -     |
| 7:4  | <b>STATE1:</b> T32 instruction set support | RO   | 0x3   |
| 3:0  | <b>STATE0:</b> A32 instruction set support | RO   | 0x0   |

## M33: ID\_PFR1 Register

**Offset:** 0x0ed44

### Description

Gives information about the programmers' model and Extensions support

Table 216. ID\_PFR1 Register

| Bits  | Description                                                                      | Type | Reset |
|-------|----------------------------------------------------------------------------------|------|-------|
| 31:12 | Reserved.                                                                        | -    | -     |
| 11:8  | <b>MPROGMOD:</b> Identifies support for the M-Profile programmers' model support | RO   | 0x5   |
| 7:4   | <b>SECURITY:</b> Identifies whether the Security Extension is implemented        | RO   | 0x2   |
| 3:0   | Reserved.                                                                        | -    | -     |

| 位 | 描述                                         | 类型 | 复位  |
|---|--------------------------------------------|----|-----|
| 0 | <b>HALTED</b> : 粘滞标志，指示是否发生挂起请求调试事件或单步调试事件 | 读写 | 0x0 |

## M33: MMFAR 寄存器

偏移：0x0ed34

### 描述

显示导致 MPU 故障的内存位置地址

表213. MMFAR 寄存器

| 位    | 描述                                                                                                 | 类型 | 复位         |
|------|----------------------------------------------------------------------------------------------------|----|------------|
| 31:0 | 地址：该寄存器会更新为引发 MemManage 错误的位置地址。MMFSR 显示错误原因及该字段的有效性。仅当 MMFSR.MMARVALID 被设置时，此字段有效，否则为未知（UNKNOWN）。 | 读写 | 0x00000000 |

## M33: BFAR 寄存器

偏移量：0x0ed38

### 说明

显示与精确数据访问总线错误（BusFault）相关联的地址。

表214. BFAR 寄存器

| 位    | 描述                                                                                    | 类型 | 复位         |
|------|---------------------------------------------------------------------------------------|----|------------|
| 31:0 | 地址：该寄存器会更新为引发 BusFault 的位置地址。BFSR 显示错误原因。仅当 BFSR.BFARVALID 被设置时，此字段有效，否则为未知（UNKNOWN）。 | 读写 | 0x00000000 |

## M33: ID\_PFR0 寄存器

偏移量：0x0ed40

### 说明

提供关于处理引擎（PE）支持的指令集的顶层信息。

表215. ID\_PFR0 寄存器

| 位    | 描述                       | 类型 | 复位  |
|------|--------------------------|----|-----|
| 31:8 | 保留。                      | -  | -   |
| 7:4  | <b>STATE1</b> : 支持T32指令集 | 只读 | 0x3 |
| 3:0  | <b>STATE0</b> : 支持A32指令集 | 只读 | 0x0 |

## M33: ID\_PFR1 寄存器

偏移：0x0ed44

### 描述

提供关于程序员模型及扩展支持的信息

表216. ID\_PFR1 寄存器

| 位     | 描述                                     | 类型 | 复位  |
|-------|----------------------------------------|----|-----|
| 31:12 | 保留。                                    | -  | -   |
| 11:8  | <b>MPROGMOD</b> : 标识对M-Profile程序员模型的支持 | 只读 | 0x5 |
| 7:4   | <b>SECURITY</b> : 标识是否实现安全扩展           | 只读 | 0x2 |
| 3:0   | 保留。                                    | -  | -   |

## M33: ID\_DFR0 Register

**Offset:** 0x0ed48

### Description

Provides top level information about the debug system

Table 217. ID\_DFR0 Register

| Bits  | Description                                                           | Type | Reset |
|-------|-----------------------------------------------------------------------|------|-------|
| 31:24 | Reserved.                                                             | -    | -     |
| 23:20 | <b>MPROFDBG:</b> Indicates the supported M-profile debug architecture | RO   | 0x2   |
| 19:0  | Reserved.                                                             | -    | -     |

## M33: ID\_AFR0 Register

**Offset:** 0x0ed4c

### Description

Provides information about the IMPLEMENTATION DEFINED features of the PE

Table 218. ID\_AFR0 Register

| Bits  | Description                                    | Type | Reset |
|-------|------------------------------------------------|------|-------|
| 31:16 | Reserved.                                      | -    | -     |
| 15:12 | <b>IMPDEF3:</b> IMPLEMENTATION DEFINED meaning | RO   | 0x0   |
| 11:8  | <b>IMPDEF2:</b> IMPLEMENTATION DEFINED meaning | RO   | 0x0   |
| 7:4   | <b>IMPDEF1:</b> IMPLEMENTATION DEFINED meaning | RO   | 0x0   |
| 3:0   | <b>IMPDEF0:</b> IMPLEMENTATION DEFINED meaning | RO   | 0x0   |

## M33: ID\_MMFR0 Register

**Offset:** 0x0ed50

### Description

Provides information about the implemented memory model and memory management support

Table 219. ID\_MMFR0 Register

| Bits  | Description                                                                        | Type | Reset |
|-------|------------------------------------------------------------------------------------|------|-------|
| 31:24 | Reserved.                                                                          | -    | -     |
| 23:20 | <b>AUXREG:</b> Indicates support for Auxiliary Control Registers                   | RO   | 0x1   |
| 19:16 | <b>TCM:</b> Indicates support for tightly coupled memories (TCMs)                  | RO   | 0x0   |
| 15:12 | <b>SHARELVL:</b> Indicates the number of shareability levels implemented           | RO   | 0x1   |
| 11:8  | <b>OUTERSHR:</b> Indicates the outermost shareability domain implemented           | RO   | 0xf   |
| 7:4   | <b>PMSA:</b> Indicates support for the protected memory system architecture (PMSA) | RO   | 0x4   |
| 3:0   | Reserved.                                                                          | -    | -     |

## M33: ID\_MMFR1 Register

**Offset:** 0x0ed54

## M33: ID\_DFR0寄存器

偏移: 0x0ed48

### 描述

提供关于调试系统的顶层信息

表217. ID\_DFR0  
寄存器

| 位     | 描述                                    | 类型 | 复位  |
|-------|---------------------------------------|----|-----|
| 31:24 | 保留。                                   | -  | -   |
| 23:20 | <b>MPROFDBG:</b> 指示所支持的M-Profile 调试架构 | 只读 | 0x2 |
| 19:0  | 保留。                                   | -  | -   |

## M33: ID\_AFR0寄存器

偏移: 0x0ed4c

### 描述

提供PE实现定义特性的信息

表218. ID\_AFR0  
寄存器

| 位     | 描述                     | 类型 | 复位  |
|-------|------------------------|----|-----|
| 31:16 | 保留。                    | -  | -   |
| 15:12 | <b>IMPDEF3:</b> 实现定义含义 | 只读 | 0x0 |
| 11:8  | <b>IMPDEF2:</b> 实现定义含义 | 只读 | 0x0 |
| 7:4   | <b>IMPDEF1:</b> 实现定义含义 | 只读 | 0x0 |
| 3:0   | <b>IMPDEF0:</b> 实现定义含义 | 只读 | 0x0 |

## M33: ID\_MMFR0 寄存器

偏移: 0x0ed50

### 描述

提供已实现的内存模型及内存管理支持的相关信息

表219. ID\_MMFR0寄  
存器

| 位     | 描述                                    | 类型 | 复位  |
|-------|---------------------------------------|----|-----|
| 31:24 | 保留。                                   | -  | -   |
| 23:20 | <b>AUXREG:</b> 指示辅助控制寄存器的支持情况         | 只读 | 0x1 |
| 19:16 | <b>TCM:</b> 指示紧耦合存储器 (TCMs) 的支持情况     | 只读 | 0x0 |
| 15:12 | <b>SHARELVL:</b> 指示所实现的共享级别数量         | 只读 | 0x1 |
| 11:8  | <b>OUTERSHR:</b> 指示所实现的最外层共享域         | 只读 | 0xf |
| 7:4   | <b>PMSA:</b> 指示受保护内存系统架构 (PMSA) 的支持情况 | 只读 | 0x4 |
| 3:0   | 保留。                                   | -  | -   |

## M33: ID\_MMFR1 寄存器

偏移: 0x0ed54

**Description**

Provides information about the implemented memory model and memory management support

Table 220. ID\_MMFR1 Register

| Bits | Description | Type | Reset |
|------|-------------|------|-------|
| 31:0 | Reserved.   | -    | -     |

**M33: ID\_MMFR2 Register**

**Offset:** 0x0ed58

**Description**

Provides information about the implemented memory model and memory management support

Table 221. ID\_MMFR2 Register

| Bits  | Description                                                                  | Type | Reset |
|-------|------------------------------------------------------------------------------|------|-------|
| 31:28 | Reserved.                                                                    | -    | -     |
| 27:24 | <b>WFISTALL:</b> Indicates the support for Wait For Interrupt (WFI) stalling | RO   | 0x1   |
| 23:0  | Reserved.                                                                    | -    | -     |

**M33: ID\_MMFR3 Register**

**Offset:** 0x0ed5c

**Description**

Provides information about the implemented memory model and memory management support

Table 222. ID\_MMFR3 Register

| Bits  | Description                                                                      | Type | Reset |
|-------|----------------------------------------------------------------------------------|------|-------|
| 31:12 | Reserved.                                                                        | -    | -     |
| 11:8  | <b>BPMINT:</b> Indicates the supported branch predictor maintenance              | RO   | 0x0   |
| 7:4   | <b>CMAINTSW:</b> Indicates the supported cache maintenance operations by set/way | RO   | 0x0   |
| 3:0   | <b>CMAINTVA:</b> Indicates the supported cache maintenance operations by address | RO   | 0x0   |

**M33: ID\_ISAR0 Register**

**Offset:** 0x0ed60

**Description**

Provides information about the instruction set implemented by the PE

Table 223. ID\_ISAR0 Register

| Bits  | Description                                                                        | Type | Reset |
|-------|------------------------------------------------------------------------------------|------|-------|
| 31:28 | Reserved.                                                                          | -    | -     |
| 27:24 | <b>DIVIDE:</b> Indicates the supported Divide instructions                         | RO   | 0x8   |
| 23:20 | <b>DEBUG:</b> Indicates the implemented Debug instructions                         | RO   | 0x0   |
| 19:16 | <b>COPROC:</b> Indicates the supported Coprocessor instructions                    | RO   | 0x9   |
| 15:12 | <b>CMPBRANCH:</b> Indicates the supported combined Compare and Branch instructions | RO   | 0x2   |
| 11:8  | <b>BITFIELD:</b> Indicates the supported bit field instructions                    | RO   | 0x3   |

**描述**

提供已实现的内存模型及内存管理支持的相关信息

表220. ID\_MMFR1寄存器

| 位    | 描述  | 类型 | 复位 |
|------|-----|----|----|
| 31:0 | 保留。 | -  | -  |

| 15:12 | <b>EXTEND:</b> Indicates the implemented Extend instructions                                      | RO   | 0x5   |
| 11:0  | Reserved.                                                                                         | -    | -     |

## M33: ID\_ISAR2 Register

Offset: 0x0ed68

### Description

Provides information about the instruction set implemented by the PE

Table 225. ID\_ISAR2 Register

| Bits  | Description                                                                              | Type | Reset |
|-------|------------------------------------------------------------------------------------------|------|-------|
| 31:28 | <b>REVERSAL:</b> Indicates the implemented Reversal instructions                         | RO   | 0x3   |
| 27:24 | Reserved.                                                                                | -    | -     |
| 23:20 | <b>MULTU:</b> Indicates the implemented advanced unsigned Multiply instructions          | RO   | 0x1   |
| 19:16 | <b>MULTS:</b> Indicates the implemented advanced signed Multiply instructions            | RO   | 0x7   |
| 15:12 | <b>MULT:</b> Indicates the implemented additional Multiply instructions                  | RO   | 0x3   |
| 11:8  | <b>MULTIACCESSINT:</b> Indicates the support for interruptible multi-access instructions | RO   | 0x4   |
| 7:4   | <b>MEMHINT:</b> Indicates the implemented Memory Hint instructions                       | RO   | 0x2   |
| 3:0   | <b>LOADSTORE:</b> Indicates the implemented additional load/store instructions           | RO   | 0x6   |

## M33: ID\_ISAR3 Register

Offset: 0x0ed6c

### Description

Provides information about the instruction set implemented by the PE

Table 226. ID\_ISAR3 Register

| Bits  | Description | Type | Reset |
|-------|-------------|------|-------|
| 31:28 | Reserved.   | -    | -     |

| 位   | 描述                           | 类型 | 复位  |
|-----|------------------------------|----|-----|
| 7:4 | <b>BITCOUNT</b> : 指示支持的位计数指令 | 只读 | 0x0 |
| 3:0 | 保留。                          | -  | -   |

## M33: ID\_ISAR1 寄存器

偏移量: 0x0ed64

### 描述

提供有关 PE 实现的指令集的信息

表224. ID\_ISAR1  
寄存器

| 位     | 描述                                   | 类型 | 复位  |
|-------|--------------------------------------|----|-----|
| 31:28 | 保留。                                  | -  | -   |
| 27:24 | <b>INTERWORK</b> : 表示已实现的交互指令        | 只读 | 0x5 |
| 23:20 | <b>IMMEDIATE</b> : 表示已实现的带长立即数数据处理指令 | 只读 | 0x7 |
| 19:16 | <b>IFTHEN</b> : 表示已实现的条件执行指令         | 只读 | 0x2 |
| 15:12 | <b>EXTEND</b> : 表示已实现的扩展指令           | 只读 | 0x5 |
| 11:0  | 保留。                                  | -  | -   |

## M33: ID\_ISAR2 寄存器

偏移: 0x0ed68

### 描述

提供有关 PE 实现的指令集的信息

表225. ID\_ISAR2  
寄存器

| 位     | 描述                                    | 类型 | 复位  |
|-------|---------------------------------------|----|-----|
| 31:28 | <b>REVERSAL</b> : 表示已实现的反转指令          | 只读 | 0x3 |
| 27:24 | 保留。                                   | -  | -   |
| 23:20 | <b>MULTU</b> : 表示已实现的高级无符号乘法指令        | 只读 | 0x1 |
| 19:16 | <b>MULTS</b> : 表示已实现的高级有符号乘法指令        | 只读 | 0x7 |
| 15:12 | <b>MULT</b> : 表示已实现的额外乘法指令            | 只读 | 0x3 |
| 11:8  | <b>MULTIACCESSINT</b> : 表示支持可中断多重访问指令 | 只读 | 0x4 |
| 7:4   | <b>MEMHINT</b> : 表示已实现的内存提示指令         | 只读 | 0x2 |
| 3:0   | <b>LOADSTORE</b> : 表示已实现的额外加载/存储指令    | 只读 | 0x6 |

## M33: ID\_ISAR3 寄存器

偏移: 0x0ed6c

### 描述

提供有关 PE 实现的指令集的信息

表226. ID\_ISAR3  
寄存器

| 位     | 描述  | 类型 | 复位 |
|-------|-----|----|----|
| 31:28 | 保留。 | -  | -  |

| Bits  | Description                                                                                                                            | Type | Reset |
|-------|----------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 27:24 | <b>TRUE NOP</b> : Indicates the implemented true NOP instructions                                                                      | RO   | 0x7   |
| 23:20 | <b>T32COPY</b> : Indicates the support for T32 non flag-setting MOV instructions                                                       | RO   | 0x8   |
| 19:16 | <b>TABBRANCH</b> : Indicates the implemented Table Branch instructions                                                                 | RO   | 0x9   |
| 15:12 | <b>SYNCHPRIM</b> : Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions | RO   | 0x5   |
| 11:8  | <b>SVC</b> : Indicates the implemented SVC instructions                                                                                | RO   | 0x7   |
| 7:4   | <b>SIMD</b> : Indicates the implemented SIMD instructions                                                                              | RO   | 0x2   |
| 3:0   | <b>SATURATE</b> : Indicates the implemented saturating instructions                                                                    | RO   | 0x9   |

## M33: ID\_ISAR4 Register

Offset: 0xed70

### Description

Provides information about the instruction set implemented by the PE

Table 227. ID\_ISAR4 Register

| Bits  | Description                                                                                                                           | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | Reserved.                                                                                                                             | -    | -     |
| 27:24 | <b>PSR_M</b> : Indicates the implemented M profile instructions to modify the PSRs                                                    | RO   | 0x1   |
| 23:20 | <b>SYNCPERM_FRAC</b> : Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions | RO   | 0x3   |
| 19:16 | <b>BARRIER</b> : Indicates the implemented Barrier instructions                                                                       | RO   | 0x1   |
| 15:12 | Reserved.                                                                                                                             | -    | -     |
| 11:8  | <b>WRITEBACK</b> : Indicates the support for writeback addressing modes                                                               | RO   | 0x1   |
| 7:4   | <b>WITHSHIFTS</b> : Indicates the support for writeback addressing modes                                                              | RO   | 0x3   |
| 3:0   | <b>UNPRIV</b> : Indicates the implemented unprivileged instructions                                                                   | RO   | 0x2   |

## M33: ID\_ISAR5 Register

Offset: 0xed74

### Description

Provides information about the instruction set implemented by the PE

Table 228. ID\_ISAR5 Register

| Bits | Description | Type | Reset |
|------|-------------|------|-------|
| 31:0 | Reserved.   | -    | -     |

## M33: CTR Register

Offset: 0xed7c

### Description

Provides information about the architecture of the caches. CTR is RES0 if CLIDR is zero.

Table 229. CTR Register

| Bits | Description                  | Type | Reset |
|------|------------------------------|------|-------|
| 31   | <b>RES1</b> : Reserved, RES1 | RO   | 0x1   |

| 位     | 描述                                                           | 类型 | 复位  |
|-------|--------------------------------------------------------------|----|-----|
| 27:24 | <b>TRUE NOP</b> : 表示已实现的真实NOP指令                              | 只读 | 0x7 |
| 23:20 | <b>T32COPY</b> : 表示支持T32非标志位设置的MOV指令                         | 只读 | 0x8 |
| 19:16 | <b>TABBRANCH</b> : 表示已实现的表分支指令                               | 只读 | 0x9 |
| 15:12 | <b>SYNCHPRIM</b> : 与ID_ISAR4.SynchPrim_frac配合使用，表示已实现的同步原语指令 | 只读 | 0x5 |
| 11:8  | <b>SVC</b> : 表示已实现的SVC指令                                     | 只读 | 0x7 |
| 7:4   | <b>SIMD</b> : 表示已实现的SIMD指令                                   | 只读 | 0x2 |
| 3:0   | <b>SATURATE</b> : 表示已实现的饱和指令                                 | 只读 | 0x9 |

## M33: ID\_ISAR4 寄存器

偏移: 0x0ed70

### 描述

提供有关 PE 实现的指令集的信息

表227. ID\_ISAR4 寄存器

| 位     | 描述                                                          | 类型 | 复位  |
|-------|-------------------------------------------------------------|----|-----|
| 31:28 | 保留。                                                         | -  | -   |
| 27:24 | <b>PSR_M</b> : 表示已实现用于修改PSRs的M配置文件指令                        | 只读 | 0x1 |
| 23:20 | <b>SYNCPROM_FRAC</b> : 与ID_ISAR3.SynchPrim配合使用，表示已实现的同步原语指令 | 只读 | 0x3 |
| 19:16 | <b>BARRIER</b> : 表示已实现的屏障指令                                 | 只读 | 0x1 |
| 15:12 | 保留。                                                         | -  | -   |
| 11:8  | <b>WRITEBACK</b> : 表示支持写回寻址模式                               | 只读 | 0x1 |
| 7:4   | <b>WITHSHIFTS</b> : 表示对回写寻址模式的支持                            | 只读 | 0x3 |
| 3:0   | <b>UNPRIV</b> : 表示已实现的非特权指令                                 | 只读 | 0x2 |

## M33: ID\_ISAR5 寄存器

偏移量: 0x0ed74

### 描述

提供有关 PE 实现的指令集的信息

表 228. ID\_ISAR5 寄存器

| 位    | 描述  | 类型 | 复位 |
|------|-----|----|----|
| 31:0 | 保留。 | -  | -  |

## M33: CTR 寄存器

偏移量: 0x0ed7c

### 描述

提供有关缓存架构的信息当CLIDR为零时，CTR为保留值0 (RES0)

表 229. CTR 寄存器

| 位  | 描述                     | 类型 | 复位  |

| 27:24 | <b>CWG</b> : 因驱逐包含已修改内存位置的缓存条目所能覆盖的最大内存大小（以字为单位）的对数（以2为底）                     | 只读 | 0x0 |
| 23:20 | <b>ERG</b> : 为 Load-Exclusive 与 Store-Exclusive 指令实现的最大保留粒度大小（以字为单位）的对数（以2为底） | 只读 | 0x0 |
| 19:16 | <b>DMINLINE</b> : PE 控制的所有数据缓存和统一缓存中最小缓存行大小（以字为单位）的对数（以2为底）                   | 只读 | 0x0 |
| 15:14 | <b>RES1_1</b> : 保留，RES1                                                       | 只读 | 0x3 |
| 13:4  | 保留。                                                                           | -  | -   |
| 3:0   | <b>IMINLINE</b> : PE 控制的所有指令缓存中最小缓存行大小（以字为单位）的对数（以2为底）                        | 只读 | 0x0 |

## M33: CPACR 寄存器

偏移: 0x0ed88

### 描述

指定协处理器及浮点扩展的访问权限

表230. CPACR寄存器

| 位     | 描述                                                                       | 类型 | 复位  |
|-------|--------------------------------------------------------------------------|----|-----|
| 31:24 | 保留。                                                                      | -  | -   |
| 23:22 | <b>CP11</b> : 此字段值将被忽略。若未实现浮点扩展，此字段为 RAZ/WI。若此位的值未设置为与 CP10 字段相同，则该值为未知。 | 读写 | 0x0 |
| 21:20 | <b>CP10</b> : 定义浮点功能的访问权限                                                | 读写 | 0x0 |
| 19:16 | 保留。                                                                      | -  | -   |
| 15:14 | <b>CP7</b> : 控制协处理器7的访问权限                                                | 读写 | 0x0 |
| 13:12 | <b>CP6</b> : 控制协处理器6的访问权限                                                | 读写 | 0x0 |
| 11:10 | <b>CP5</b> : 控制协处理器5的访问权限                                                | 读写 | 0x0 |
| 9:8   | <b>CP4</b> : 控制协处理器4的访问权限                                                | 读写 | 0x0 |
| 7:6   | <b>CP3</b> : 控制协处理器3的访问权限                                                | 读写 | 0x0 |
| 5:4   | <b>CP2</b> : 控制协处理器2的访问权限                                                | 读写 | 0x0 |
| 3:2   | <b>CP1</b> : 控制协处理器1的访问权限                                                | 读写 | 0x0 |
| 1:0   | <b>CP0</b> : 控制协处理器0的访问权限                                                | 读写 | 0x0 |

## M33: NSACR 寄存器

偏移: 0x0ed8c

### 描述

定义浮点扩展及协处理器 CP0 至 CP7 的非安全访问权限

Table 231. NSACR Register

| Bits  | Description                                                            | Type | Reset |
|-------|------------------------------------------------------------------------|------|-------|
| 31:12 | Reserved.                                                              | -    | -     |

## M33: MPU\_TYPE Register

Offset: 0x0ed90

### Description

The MPU Type Register indicates how many regions the MPU `FTSSS supports

Table 232. MPU\_TYPE Register

| Bits  | Description                                                                           | Type | Reset |
|-------|---------------------------------------------------------------------------------------|------|-------|
| 31:16 | Reserved.                                                                             | -    | -     |
| 15:8  | <b>DREGION:</b> Number of regions supported by the MPU                                | RO   | 0x08  |
| 7:1   | Reserved.                                                                             | -    | -     |
| 0     | <b>SEPARATE:</b> Indicates support for separate instructions and data address regions | RO   | 0x0   |

## M33: MPU\_CTRL Register

Offset: 0x0ed94

### Description

Enables the MPU and, when the MPU is enabled, controls whether the default memory map is enabled as a background region for privileged accesses, and whether the MPU is enabled for HardFaults, NMIs, and exception handlers when FAULTMASK is set to 1

Table 233. MPU\_CTRL Register

| Bits | Description                                                                                                                                                                                                        | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:3 | Reserved.                                                                                                                                                                                                          | -    | -     |
| 2    | <b>PRIVDEFENA:</b> Controls whether the default memory map is enabled for privileged software                                                                                                                      | RW   | 0x0   |
| 1    | <b>HFNMIENA:</b> Controls whether handlers executing with priority less than 0 access memory with the MPU enabled or disabled. This applies to HardFaults, NMIs, and exception handlers when FAULTMASK is set to 1 | RW   | 0x0   |
| 0    | <b>ENABLE:</b> Enables the MPU                                                                                                                                                                                     | RW   | 0x0   |

表231. NSACR 寄存器

| 5     | <b>CP5:</b> 启用非安全访问协处理器CP5 | 读写 | 0x0 |
| 4     | <b>CP4:</b> 启用非安全访问协处理器CP4 | 读写 | 0x0 |
| 3     | <b>CP3:</b> 启用非安全访问协处理器CP3 | 读写 | 0x0 |
| 2     | <b>CP2:</b> 启用非安全访问协处理器CP2 | 读写 | 0x0 |
| 1     | <b>CP1:</b> 启用非安全访问协处理器CP1 | 读写 | 0x0 |
| 0     | <b>CP0:</b> 启用非安全访问协处理器CP0 | 读写 | 0x0 |

## M33: MPU\_TYPE 寄存器

偏移: 0x0ed90

### 描述

MPU 类型寄存器指示 MPU `FTSSS 支持的区域数量

表232. MPU\_TYPE 寄存器

| 位     | 描述                                | 类型 | 复位   |
|-------|-----------------------------------|----|------|
| 31:16 | 保留。                               | -  | -    |
| 15:8  | <b>DREGION:</b> MPU 支持的区域数量       | 只读 | 0x08 |
| 7:1   | 保留。                               | -  | -    |
| 0     | <b>SEPARATE:</b> 表示支持独立的指令和数据地址区域 | 只读 | 0x0  |

## M33: MPU\_CTRL 寄存器

偏移: 0x0ed94

### 描述

使能 MPU；当 MPU 使能时，控制是否将默认内存映射作为特权访问的背景区域，以及在 FAULTMASK 置为 1 时，是否对 HardFault、NMI 及异常处理程序启用 MPU

表233. MPU\_CTRL 寄存器

| 位    | 描述                                                                                                  | 类型 | 复位  |
|------|-----------------------------------------------------------------------------------------------------|----|-----|
| 31:3 | 保留。                                                                                                 | -  | -   |
| 2    | <b>PRIVDEFENA:</b> 控制是否为特权软件启用默认内存映射                                                                | 读写 | 0x0 |
| 1    | <b>HFNMIENA:</b> 控制优先级低于 0 的处理程序在 MPU 启用或禁用时访问内存<br>此项适用于 HardFault、NMI 以及 FAULTMASK 设置为 1 时的异常处理程序 | 读写 | 0x0 |
| 0    | <b>ENABLE:</b> 启用 MPU                                                                               | 读写 | 0x0 |

## M33: MPU\_RNR Register

**Offset:** 0x0ed98

### Description

Selects the region currently accessed by MPU\_RBAR and MPU\_RLAR

Table 234. MPU\_RNR Register

| Bits | Description                                                                  | Type | Reset |
|------|------------------------------------------------------------------------------|------|-------|
| 31:3 | Reserved.                                                                    | -    | -     |
| 2:0  | <b>REGION:</b> Indicates the memory region accessed by MPU_RBAR and MPU_RLAR | RW   | 0x0   |

## M33: MPU\_RBAR Register

**Offset:** 0x0ed9c

### Description

Provides indirect read and write access to the base address of the currently selected MPU region `FTSSS

Table 235. MPU\_RBAR Register

| Bits | Description                                                                                                                                                                     | Type | Reset     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:5 | <b>BASE:</b> Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region. This value is zero extended to provide the base address to be checked against | RW   | 0x0000000 |
| 4:3  | <b>SH:</b> Defines the Shareability domain of this region for Normal memory                                                                                                     | RW   | 0x0       |
| 2:1  | <b>AP:</b> Defines the access permissions for this region                                                                                                                       | RW   | 0x0       |
| 0    | <b>XN:</b> Defines whether code can be executed from this region                                                                                                                | RW   | 0x0       |

## M33: MPU\_RLAR Register

**Offset:** 0x0eda0

### Description

Provides indirect read and write access to the limit address of the currently selected MPU region `FTSSS

Table 236. MPU\_RLAR Register

| Bits | Description                                                                                                                                                                             | Type | Reset     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:5 | <b>LIMIT:</b> Contains bits [31:5] of the upper inclusive limit of the selected MPU memory region. This value is postfixed with 0x1F to provide the limit address to be checked against | RW   | 0x0000000 |
| 4    | Reserved.                                                                                                                                                                               | -    | -         |
| 3:1  | <b>ATTRINDEX:</b> Associates a set of attributes in the MPU_MAIR0 and MPU_MAIR1 fields                                                                                                  | RW   | 0x0       |
| 0    | <b>EN:</b> Region enable                                                                                                                                                                | RW   | 0x0       |

## M33: MPU\_RBAR\_A1 Register

**Offset:** 0x0eda4

### Description

Provides indirect read and write access to the base address of the MPU region selected by MPU\_RNR[7:2]:(1[1:0]) `FTSSS

## M33: MPU\_RNR 寄存器

偏移: 0x0ed98

### 描述

选择当前由 MPU\_RBAR 和 MPU\_RLAR 访问的区域

表234. MPU\_RNR寄存器

| 位    | 描述                                            | 类型 | 复位  |
|------|-----------------------------------------------|----|-----|
| 31:3 | 保留。                                           | -  | -   |
| 2:0  | <b>REGION:</b> 指示 MPU_RBAR 与 MPU_RLAR 访问的内存区域 | 读写 | 0x0 |

## M33: MPU\_RBAR 寄存器

偏移: 0x0ed9c

### 描述

提供对当前选定 MPU 区域 `FTSSS 基地址的间接读写访问

表235. MPU\_RBAR寄存器

| 位    | 描述                                                            | 类型 | 复位         |
|------|---------------------------------------------------------------|----|------------|
| 31:5 | <b>BASE:</b> 包含所选 MPU 内存区域下限的[31:5]位（含端点）。该值通过零扩展以提供需匹配检测的基址。 | 读写 | 0x00000000 |
| 4:3  | <b>SH:</b> 定义该区域在普通内存中的共享域属性。                                 | 读写 | 0x0        |
| 2:1  | <b>AP:</b> 定义该区域的访问权限。                                        | 读写 | 0x0        |
| 0    | <b>XN:</b> 定义是否允许从该区域执行代码。                                    | 读写 | 0x0        |

## M33: MPU\_RLAR 寄存器

偏移: 0x0eda0

### 描述

提供对当前选定 MPU 区域 `FTSSS 限制地址的间接读写访问

表236. MPU\_RLAR寄存器

| 位    | 描述                                                                    | 类型 | 复位         |
|------|-----------------------------------------------------------------------|----|------------|
| 31:5 | <b>LIMIT:</b> 包含所选 MPU 内存区域上限的[31:5]位（含端点）。该值后缀附加 0x1F，以提供需匹配检测的限止地址。 | 读写 | 0x00000000 |
| 4    | 保留。                                                                   | -  | -          |
| 3:1  | <b>ATTRINDEX:</b> 关联 MPU_MAIR0 和 MPU_MAIR1 字段中的一组属性。                  | 读写 | 0x0        |
| 0    | <b>EN:</b> 区域使能                                                       | 读写 | 0x0        |

## M33: MPU\_RBAR\_A1 寄存器

偏移: 0x0eda4

### 描述

提供对由 MPU\_RNR[7:2] 选择的 MPU 区域地址的间接读写访问：(1[1:0])  
`FTSSS

Table 237.  
MPU\_RBAR\_A1  
Register

| Bits | Description                                                                                                                                                                     | Type | Reset     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:5 | <b>BASE:</b> Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region. This value is zero extended to provide the base address to be checked against | RW   | 0x0000000 |
| 4:3  | <b>SH:</b> Defines the Shareability domain of this region for Normal memory                                                                                                     | RW   | 0x0       |
| 2:1  | <b>AP:</b> Defines the access permissions for this region                                                                                                                       | RW   | 0x0       |
| 0    | <b>XN:</b> Defines whether code can be executed from this region                                                                                                                | RW   | 0x0       |

### M33: MPU\_RLAR\_A1 Register

Offset: 0x0eda8

#### Description

Provides indirect read and write access to the limit address of the currently selected MPU region selected by MPU\_RNR[7:2]:(1[1:0]) `FTSSS

Table 238.

### M33: MPU\_RBAR\_A2 Register

Offset: 0x0edac

#### Description

Provides indirect read and write access to the base address of the MPU region selected by MPU\_RNR[7:2]:(2[1:0]) `FTSSS

Table 239.  
MPU\_RBAR\_A2  
Register

| Bits | Description                                                                                                                                                                     | Type | Reset     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:5 | <b>BASE:</b> Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region. This value is zero extended to provide the base address to be checked against | RW   | 0x0000000 |
| 4:3  | <b>SH:</b> Defines the Shareability domain of this region for Normal memory                                                                                                     | RW   | 0x0       |
| 2:1  | <b>AP:</b> Defines the access permissions for this region                                                                                                                       | RW   | 0x0       |
| 0    | <b>XN:</b> Defines whether code can be executed from this region                                                                                                                | RW   | 0x0       |

### M33: MPU\_RLAR\_A2 Register

Offset: 0x0edb0

#### Description

Provides indirect read and write access to the limit address of the currently selected MPU region selected by MPU\_RNR[7:2]:(2[1:0]) `FTSSS

表 237。  
MPU\_RBAR\_A1  
寄存器

| 位    | 描述                                                              | 类型 | 复位        |
|------|-----------------------------------------------------------------|----|-----------|
| 31:5 | <b>BASE</b> : 包含所选 MPU 内存区域下限的[31:5]位（含端点）。该值通过零扩展以提供需匹配检测的基地址。 | 读写 | 0x0000000 |
| 4:3  | <b>SH</b> : 定义该区域在普通内存中的共享域属性。                                  | 读写 | 0x0       |
| 2:1  | <b>AP</b> : 定义该区域的访问权限。                                         | 读写 | 0x0       |
| 0    | <b>XN</b> : 定义是否允许从该区域执行代码。                                     | 读写 | 0x0       |

## M33: MPU\_RLAR\_A1 寄存器

偏移: 0x0eda8

### 描述

提供对由 MPU\_RNR[7:2](1[1:0]) 选择的当前 MPU 区域限制地址的间接读写访问 `FTSSS

表 238。  
MPU\_RLAR\_A1  
寄存器

| 位    | 描述                                                                     | 类型 | 复位        |
|------|------------------------------------------------------------------------|----|-----------|
| 31:5 | <b>LIMIT</b> : 包含所选 MPU 内存区域上限的[31:5]位（含端点）。该值后缀附加 0x1F，以提供需匹配检测的限止地址。 | 读写 | 0x0000000 |
| 4    | 保留。                                                                    | -  | -         |
| 3:1  | <b>ATTRINDEX</b> : 关联 MPU_MAIRO 和 MPU_MAIR1 字段中的一组属性。                  | 读写 | 0x0       |
| 0    | <b>EN</b> : 区域使能                                                       | 读写 | 0x0       |

## M33: MPU\_RBAR\_A2 寄存器

偏移: 0x0edac

### 描述

提供对由 MPU\_RNR[7:2] 选择的 MPU 区域地址的间接读写访问：(2[1:0])  
`FTSSS

| 3:1  | <b>ATTRINDEX</b> : 关联 MPU_MAIR0 和 MPU_MAIR1 字段中的一组属性。                  | 读写 | 0x0       |
| 0    | <b>EN</b> : 区域使能                                                       | 读写 | 0x0       |

## M33: MPU\_MAIR0寄存器

偏移: 0x0edc0

### 描述

与 MPU\_MAIR1 一起，提供对应于 AttrIndex 值的内存属性编码

表243。  
MPU\_MAIR0寄存器

| 位     | 描述                                      | 类型 | 复位   |
|-------|-----------------------------------------|----|------|
| 31:24 | <b>ATTR3</b> : AttrIndex为3的MPU区域的内存属性编码 | 读写 | 0x00 |

| Bits  | Description                                                                     | Type | Reset |
|-------|---------------------------------------------------------------------------------|------|-------|
| 23:16 | <b>ATTR2</b> : Memory attribute encoding for MPU regions with an AttrIndex of 2 | RW   | 0x00  |
| 15:8  | <b>ATTR1</b> : Memory attribute encoding for MPU regions with an AttrIndex of 1 | RW   | 0x00  |
| 7:0   | <b>ATTR0</b> : Memory attribute encoding for MPU regions with an AttrIndex of 0 | RW   | 0x00  |

## M33: MPU\_MAIR1 Register

**Offset:** 0x0edc4

### Description

Along with MPU\_MAIR0, provides the memory attribute encodings corresponding to the AttrIndex values

Table 244.  
MPU\_MAIR1 Register

| Bits  | Description                                                                     | Type | Reset |
|-------|---------------------------------------------------------------------------------|------|-------|
| 31:24 | <b>ATTR7</b> : Memory attribute encoding for MPU regions with an AttrIndex of 7 | RW   | 0x00  |
| 23:16 | <b>ATTR6</b> : Memory attribute encoding for MPU regions with an AttrIndex of 6 | RW   | 0x00  |
| 15:8  | <b>ATTR5</b> : Memory attribute encoding for MPU regions with an AttrIndex of 5 | RW   | 0x00  |
| 7:0   | <b>ATTR4</b> : Memory attribute encoding for MPU regions with an AttrIndex of 4 | RW   | 0x00  |

## M33: SAU\_CTRL Register

**Offset:** 0x0edd0

### Description

Allows enabling of the Security Attribution Unit

Table 245. SAU\_CTRL Register

| Bits | Description                                                                                                | Type | Reset |
|------|------------------------------------------------------------------------------------------------------------|------|-------|
| 31:2 | Reserved.                                                                                                  | -    | -     |
| 1    | <b>ALLNS</b> : When SAU_CTRL.ENABLE is 0 this bit controls if the memory is marked as Non-secure or Secure | RW   | 0x0   |
| 0    | <b>ENABLE</b> : Enables the SAU                                                                            | RW   | 0x0   |

## M33: SAU\_TYPE Register

**Offset:** 0x0edd4

### Description

Indicates the number of regions implemented by the Security Attribution Unit

Table 246. SAU\_TYPE Register

| Bits | Description                                            | Type | Reset |
|------|--------------------------------------------------------|------|-------|
| 31:8 | Reserved.                                              | -    | -     |
| 7:0  | <b>SREGION</b> : The number of implemented SAU regions | RO   | 0x08  |

## M33: SAU\_RNR Register

**Offset:** 0x0edd8

### Description

Selects the region currently accessed by SAU\_RBAR and SAU\_RLAR

Table 247. SAU\_RNR Register

| Bits | Description | Type | Reset |
|------|-------------|------|-------|
| 31:8 | Reserved.   | -    | -     |

| 位     | 描述                                        | 类型 | 复位   |
|-------|-------------------------------------------|----|------|
| 23:16 | <b>ATTR2</b> : AttrIndex为2的MPU区域的内存属性编码   | 读写 | 0x00 |
| 15:8  | <b>ATTR1</b> : AttrIndex为1的MPU区域的内存属性编码   | 读写 | 0x00 |
| 7:0   | <b>ATTR0</b> : 用于AttrIndex为0的MPU区域的内存属性编码 | 读写 | 0x00 |

## M33: MPU\_MAIR1 寄存器

偏移: 0x0edc4

### 描述

与 MPU\_MAIRO 一起, 提供对应于 AttrIndex 值的内存属性编码

表244。  
MPU\_MAIR1 寄存器

| 位     | 描述                                        | 类型 | 复位   |
|-------|-------------------------------------------|----|------|
| 31:24 | <b>ATTR7</b> : 用于AttrIndex为7的MPU区域的内存属性编码 | 读写 | 0x00 |
| 23:16 | <b>ATTR6</b> : 用于AttrIndex为6的MPU区域的内存属性编码 | 读写 | 0x00 |
| 15:8  | <b>ATTR5</b> : 用于AttrIndex为5的MPU区域的内存属性编码 | 读写 | 0x00 |
| 7:0   | <b>ATTR4</b> : 用于AttrIndex为4的MPU区域的内存属性编码 | 读写 | 0x00 |

## M33: SAU\_CTRL 寄存器

偏移: 0x0edd0

### 描述

允许启用安全属性单元

表245. SAU\_CTRL寄存器

| 位    | 描述                                                   | 类型 | 复位  |
|------|------------------------------------------------------|----|-----|
| 31:2 | 保留。                                                  | -  | -   |
| 1    | <b>ALLNS</b> : 当SAU_CTRL.ENABLE为0时, 该位控制内存的标记为非安全或安全 | 读写 | 0x0 |
| 0    | <b>ENABLE</b> : 启用SAU                                | 读写 | 0x0 |

## M33: SAU\_TYPE 寄存器

偏移: 0x0edd4

### 描述

指示安全归属单元 (SAU) 已实现的区域数

表246. SAU\_TYPE  
寄存器

| 位    | 描述                          | 类型 | 复位   |
|------|-----------------------------|----|------|
| 31:8 | 保留。                         | -  | -    |
| 7:0  | <b>SREGION</b> : 已实现的SAU区域数 | 只读 | 0x08 |

## M33: SAU\_RNR寄存器

偏移: 0x0edd8

### 描述

选择当前由 SAU\_RBAR 和 SAU\_RLAR 访问的区域

表247. SAU\_RNR  
寄存器

| 位    | 描述  | 类型 | 复位 |
|------|-----|----|----|
| 31:8 | 保留。 | -  | -  |

| Bits | Description                                                               | Type | Reset |
|------|---------------------------------------------------------------------------|------|-------|
| 7:0  | <b>REGION:</b> Indicates the SAU region accessed by SAU_RBAR and SAU_RLAR | RW   | 0x00  |

## M33: SAU\_RBAR Register

**Offset:** 0x0eddc

### Description

Provides indirect read and write access to the base address of the currently selected SAU region

Table 248. SAU\_RBAR Register

| Bits | Description                                                                     | Type | Reset      |
|------|---------------------------------------------------------------------------------|------|------------|
| 31:5 | <b>BADDR:</b> Holds bits [31:5] of the base address for the selected SAU region | RW   | 0x00000000 |
| 4:0  | Reserved.                                                                       | -    | -          |

## M33: SAU\_RLAR Register

**Offset:** 0x0ede0

### Description

Provides indirect read and write access to the limit address of the currently selected SAU region

Table 249. SAU\_RLAR Register

| Bits | Description                                                                                              | Type | Reset      |
|------|----------------------------------------------------------------------------------------------------------|------|------------|
| 31:5 | <b>LADDR:</b> Holds bits [31:5] of the limit address for the selected SAU region                         | RW   | 0x00000000 |
| 4:2  | Reserved.                                                                                                | -    | -          |
| 1    | <b>NSC:</b> Controls whether Non-secure state is permitted to execute an SG instruction from this region | RW   | 0x0        |
| 0    | <b>ENABLE:</b> SAU region enable                                                                         | RW   | 0x0        |

## M33: SFSR Register

**Offset:** 0x0ede4

### Description

Provides information about any security related faults

Table 250. SFSR Register

| Bits | Description                                                                                                                                                                                                        | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:8 | Reserved.                                                                                                                                                                                                          | -    | -     |
| 7    | <b>LSERR:</b> Sticky flag indicating that an error occurred during lazy state activation or deactivation                                                                                                           | RW   | 0x0   |
| 6    | <b>SFARVALID:</b> This bit is set when the SFAR register contains a valid value. As with similar fields, such as BFSR.BFARVALID and MMFSR.MMARVALID, this bit can be cleared by other exceptions, such as BusFault | RW   | 0x0   |
| 5    | <b>LSPERR:</b> Stick flag indicating that an SAU or IDAU violation occurred during the lazy preservation of floating-point state                                                                                   | RW   | 0x0   |
| 4    | <b>INVTRAN:</b> Sticky flag indicating that an exception was raised due to a branch that was not flagged as being domain crossing causing a transition from Secure to Non-secure memory                            | RW   | 0x0   |

| 位   | 描述                                         | 类型 | 复位   |
|-----|--------------------------------------------|----|------|
| 7:0 | <b>REGION:</b> 指示SAU_RBAR与SAU_RLAR访问的SAU区域 | 读写 | 0x00 |

## M33: SAU\_RBAR寄存器

偏移: 0x0eddc

### 描述

提供对当前选定 SAU 区域基址的间接读写访问

表248. SAU\_RBAR 寄存器

| 位    | 描述                                 | 类型 | 复位         |
|------|------------------------------------|----|------------|
| 31:5 | <b>BADDR:</b> 存储所选SAU区域基地址的位[31:5] | 读写 | 0x00000000 |
| 4:0  | 保留。                                | -  | -          |

## M33: SAU\_RLAR寄存器

偏移: 0x0ede0

### 描述

提供对当前选定 SAU 区域限制地址的间接读写访问

表249. SAU\_RLAR 寄存器

| 位    | 描述                                  | 类型 | 复位         |
|------|-------------------------------------|----|------------|
| 31:5 | <b>LADDR:</b> 存储所选SAU区域限制地址的位[31:5] | 读写 | 0x00000000 |
| 4:2  | 保留。                                 | -  | -          |
| 1    | <b>NSC:</b> 控制非安全状态是否允许从该区域执行SG指令   | 读写 | 0x0        |
| 0    | <b>ENABLE:</b> SAU区域使能              | 读写 | 0x0        |

## M33: SFSR寄存器

偏移: 0x0ede4

### 描述

提供有关任一安全相关故障的信息

表250. SFSR 寄存器

| 位    | 描述                                                                                                   | 类型 | 复位  |
|------|------------------------------------------------------------------------------------------------------|----|-----|
| 31:8 | 保留。                                                                                                  | -  | -   |
| 7    | <b>LSERR:</b> 粘滞标志，指示在延迟状态激活或停用期间发生错误                                                                | 读写 | 0x0 |
| 6    | <b>SFARVALID:</b> 当SFAR寄存器包含有效值时，此位被置位。与类似字段如BFSR.BFARVALID和MMFSR.MMARVALID相同，此位可被其他异常（如BusFault）清除。 | 读写 | 0x0 |
| 5    | <b>LSPERR:</b> 粘滞标志，指示在延迟保存浮点状态期间发生了SAU或IDAU违规。                                                      | 读写 | 0x0 |
| 4    | <b>INVTRAN:</b> 粘滞标志，指示由于分支未标记为跨域，导致从安全到非安全内存转换时引发异常。                                                | 读写 | 0x0 |

| Bits | Description                                                                                                                                                                                                                                                                | Type | Reset |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 3    | <b>AUVOIOL:</b> Sticky flag indicating that an attempt was made to access parts of the address space that are marked as Secure with NS-Req for the transaction set to Non-secure. This bit is not set if the violation occurred during lazy state preservation. See LSPERR | RW   | 0x0   |
| 2    | <b>INVER:</b> This can be caused by EXC_RETURN.DCRS being set to 0 when returning from an exception in the Non-secure state, or by EXC_RETURN.ES being set to 1 when returning from an exception in the Non-secure state                                                   | RW   | 0x0   |
| 1    | <b>INVIS:</b> This bit is set if the integrity signature in an exception stack frame is found to be invalid during the unstacking operation                                                                                                                                | RW   | 0x0   |
| 0    | <b>INVEP:</b> This bit is set if a function call from the Non-secure state or exception targets a non-SG instruction in the Secure state. This bit is also set if the target address is a SG instruction, but there is no matching SAU/IDAU region with the NSC flag set   | RW   | 0x0   |

## M33: SFAR Register

Offset: 0x0ede8

### Description

Shows the address of the memory location that caused a Security violation

Table 251. SFAR Register

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Type | Reset      |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>ADDRESS:</b> The address of an access that caused a attribution unit violation. This field is only valid when SFSR.SFARVALID is set. This allows the actual flip flops associated with this register to be shared with other fault address registers. If an implementation chooses to share the storage in this way, care must be taken to not leak Secure address information to the Non-secure state. One way of achieving this is to share the SFAR register with the MMFAR_S register, which is not accessible to the Non-secure state | RW   | 0x00000000 |

## M33: DHCSR Register

Offset: 0x0edf0

### Description

Controls halting debug

Table 252. DHCSR Register

| Bits  | Description                                                                                                                                                                                       | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:27 | Reserved.                                                                                                                                                                                         | -    | -     |
| 26    | <b>S_RESTART_ST:</b> Indicates the PE has processed a request to clear DHCSR.C_HALTI to 0. That is, either a write to DHCSR that clears DHCSR.C_HALTI from 1 to 0, or an External Restart Request | RO   | 0x0   |
| 25    | <b>S_RESET_ST:</b> Indicates whether the PE has been reset since the last read of the DHCSR                                                                                                       | RO   | 0x0   |
| 24    | <b>S_RETIRE_ST:</b> Set to 1 every time the PE retires one of more instructions                                                                                                                   | RO   | 0x0   |
| 23:21 | Reserved.                                                                                                                                                                                         | -    | -     |
| 20    | <b>S_SDE:</b> Indicates whether Secure invasive debug is allowed                                                                                                                                  | RO   | 0x0   |

## M33: DCRSR Register

Offset: 0x0edf4

### Description

With the DCRDR, provides debug access to the general-purpose registers, special-purpose registers, and the FP extension registers. A write to the DCRSR specifies the register to transfer, whether the transfer is a read or write, and starts the transfer

Table 253. DCRSR Register

| Bits  | Description                                                                                                 | Type | Reset |
|-------|-------------------------------------------------------------------------------------------------------------|------|-------|
| 31:17 | Reserved.                                                                                                   | -    | -     |
| 16    | <b>REGWR:</b> Specifies the access type for the transfer                                                    | RW   | 0x0   |
| 15:7  | Reserved.                                                                                                   | -    | -     |
| 6:0   | <b>REGSEL:</b> Specifies the general-purpose register, special-purpose register, or FP register to transfer | RW   | 0x00  |

## M33: DCRDR Register

Offset: 0x0edf8

### Description

With the DCRSR, provides debug access to the general-purpose registers, special-purpose registers, and the FP Extension registers. If the Main Extension is implemented, it can also be used for message passing between an external debugger and a debug agent running on the PE

Table 254. DCRDR Register

| Bits | Description                                                                                                                                                   | Type | Reset      |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | <b>DBGTMP:</b> Provides debug access for reading and writing the general-purpose registers, special-purpose registers, and Floating-point Extension registers | RW   | 0x00000000 |

## M33: DEMCR Register

Offset: 0x0edfc

### Description

Manages vector catch behavior and DebugMonitor handling when debugging

Table 255. DEMCR Register

| Bits  | Description | Type | Reset |

| 6     | <b>VC_CHKERR</b> : Enable halting debug trap on a UsageFault exception caused by a checking error, for example an alignment check error                     | RW   | 0x0   |
| 5     | <b>VC_NOCPERR</b> : Enable halting debug trap on a UsageFault caused by an access to a coprocessor                                                          | RW   | 0x0   |
| 4     | <b>VC_MMERR</b> : Enable halting debug trap on a MemManage exception                                                                                        | RW   | 0x0   |
| 3:1   | Reserved.                                                                                                                                                   | -    | -     |
| 0     | <b>VC_CORERESET</b> : Enable Reset Vector Catch. This causes a warm reset to halt a running system                                                          | RW   | 0x0   |

## M33: DCSR Register

Offset: 0xee08

### Description

Provides control and status information for Secure debug

Table 256. DCSR Register

| Bits  | Description                                                                                                                                                         | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:18 | Reserved.                                                                                                                                                           | -    | -     |
| 17    | <b>CDSKEY</b> : Writes to the CDS bit are ignored unless CDSKEY is concurrently written to zero                                                                     | RW   | 0x0   |
| 16    | <b>CDS</b> : This field indicates the current Security state of the processor                                                                                       | RW   | 0x0   |
| 15:2  | Reserved.                                                                                                                                                           | -    | -     |
| 1     | <b>SBRSEL</b> : If SBRSELEN is 1 this bit selects whether the Non-secure or the Secure version of the memory-mapped Banked registers are accessible to the debugger | RW   | 0x0   |

| 位     | 描述                                                              | 类型 | 复位  |
|-------|-----------------------------------------------------------------|----|-----|
| 24    | <b>TRCENA</b> : 启用所有DWT和ITM功能的全局开关                              | 读写 | 0x0 |
| 23:21 | 保留。                                                             | -  | -   |
| 20    | <b>SDME</b> : 指示调试监视器是否针对安全态或非安全态, 以及是否允许在安全态发生调试事件             | 只读 | 0x0 |
| 19    | <b>MON_REQ</b> : 调试监视器信号量位                                      | 读写 | 0x0 |
| 18    | <b>MON_STEP</b> : 启用调试监视器单步执行                                   | 读写 | 0x0 |
| 17    | <b>MON_PEND</b> : 设置或清除调试监视器异常的挂起状态                             | 读写 | 0x0 |
| 16    | <b>MON_EN</b> : 启用调试监视器异常                                       | 读写 | 0x0 |
| 15:12 | 保留。                                                             | -  | -   |
| 11    | <b>VC_SFERR</b> : 安全错误异常中止调试向量捕获的启用                             | 读写 | 0x0 |
| 10    | <b>VC_HARDERR</b> : 硬错误异常中止调试向量捕获的启用                            | 读写 | 0x0 |
| 9     | <b>VC_INTEERR</b> : 启用在异常入口和返回期间因故障而中止调试向量捕获                    | 读写 | 0x0 |
| 8     | <b>VC_BUSERR</b> : 启用总线错误异常的中止调试向量捕获                            | 读写 | 0x0 |
| 7     | <b>VC_STATERR</b> : 启用因状态信息错误 (例如未定义指令异常) 导致的UsageFault异常中止调试陷阱 | 读写 | 0x0 |
| 6     | <b>VC_CHKERR</b> : 启用因校验错误 (例如对齐校验错误) 导致的UsageFault异常中止调试陷阱     | 读写 | 0x0 |
| 5     | <b>VC_NOCPERR</b> : 启用因访问协处理器导致的UsageFault异常中止调试陷阱              | 读写 | 0x0 |
| 4     | <b>VC_MMERR</b> : 启用发生内存管理 (MemManage) 异常时的中止调试陷阱               | 读写 | 0x0 |
| 3:1   | 保留。                                                             | -  | -   |
| 0     | <b>VC_CORERESET</b> : 启用复位向量捕获。此功能会使暖复位中止正在运行的系统                | 读写 | 0x0 |

## M33: DCSR寄存器

偏移: 0x0ee08

### 描述

提供安全调试的控制与状态信息

表256. DCSR  
寄存器

| 位     | 描述                                                              | 类型 | 复位  |
|-------|-----------------------------------------------------------------|----|-----|
| 31:18 | 保留。                                                             | -  | -   |
| 17    | <b>CDSKEY</b> : 除非同时将CDSKEY写入零, 否则对CDS位的写入将被忽略                  | 读写 | 0x0 |
| 16    | <b>CDS</b> : 本字段指示处理器当前的安全状态                                    | 读写 | 0x0 |
| 15:2  | 保留。                                                             | -  | -   |
| 1     | <b>SBRSEL</b> : 当 SBRSELEN 为 1 时, 该位选择调试器访问非安全版本或安全版本的内存映射银行寄存器 | 读写 | 0x0 |

| Bits | Description                                                                                                                                                                                | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0    | <b>SBRSELEN:</b> Controls whether the SBRSEL field or the current Security state of the processor selects which version of the memory-mapped Banked registers are accessed to the debugger | RW   | 0x0   |

## M33: STIR Register

Offset: 0x0ef00

### Description

Provides a mechanism for software to generate an interrupt

Table 257. STIR Register

| Bits | Description                                                                                     | Type | Reset |
|------|-------------------------------------------------------------------------------------------------|------|-------|
| 31:9 | Reserved.                                                                                       | -    | -     |
| 8:0  | <b>INTID:</b> Indicates the interrupt to be pended. The value written is (ExceptionNumber - 16) | RW   | 0x000 |

## M33: FPCCR Register

Offset: 0x0ef34

### Description

Holds control data for the Floating-point extension

Table 258. FPCCR Register

| Bits  | Description                                                                                                                                                                                                                                                                                     | Type | Reset |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31    | <b>ASPEN:</b> When this bit is set to 1, execution of a floating-point instruction sets the CONTROL.FPCA bit to 1                                                                                                                                                                               | RW   | 0x0   |
| 30    | <b>LSPEN:</b> Enables lazy context save of floating-point state                                                                                                                                                                                                                                 | RW   | 0x0   |
| 29    | <b>LSPENS:</b> This bit controls whether the LSPEN bit is writeable from the Non-secure state                                                                                                                                                                                                   | RW   | 0x1   |
| 28    | <b>CLRONRET:</b> Clear floating-point caller saved registers on exception return                                                                                                                                                                                                                | RW   | 0x0   |
| 27    | <b>CLRONRETS:</b> This bit controls whether the CLRONRET bit is writeable from the Non-secure state                                                                                                                                                                                             | RW   | 0x0   |
| 26    | <b>TS:</b> Treat floating-point registers as Secure enable                                                                                                                                                                                                                                      | RW   | 0x0   |
| 25:11 | Reserved.                                                                                                                                                                                                                                                                                       | -    | -     |
| 10    | <b>UFRDY:</b> Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the UsageFault exception to pending                                                                                                                                 | RW   | 0x1   |
| 9     | <b>SPLIMVIOL:</b> This bit is banked between the Security states and indicates whether the floating-point context violates the stack pointer limit that was active when lazy state preservation was activated. SPLIMVIOL modifies the lazy floating-point state preservation behavior           | RW   | 0x0   |
| 8     | <b>MONRDY:</b> Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the DebugMonitor exception to pending                                                                                                                              | RW   | 0x0   |
| 7     | <b>SFRDY:</b> Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the SecureFault exception to pending. This bit is only present in the Secure version of the register, and behaves as RAZ/WI when accessed from the Non-secure state | RW   | 0x0   |

| 位 | 描述                                                            | 类型 | 复位  |
|---|---------------------------------------------------------------|----|-----|
| 0 | <b>SBRSELEN:</b> 控制由 SBRSEL 字段还是处理器当前的安全状态决定调试器访问的内存映射银行寄存器版本 | 读写 | 0x0 |

## M33: STIR 寄存器

偏移: 0x0ef00

### 描述

为软件生成中断提供机制

表 257. STIR 寄存器

| 位    | 描述                                                | 类型 | 复位    |
|------|---------------------------------------------------|----|-------|
| 31:9 | 保留。                                               | -  | -     |
| 8:0  | <b>INTID:</b> 指示要挂起的中断写入值为 (ExceptionNumber - 16) | 读写 | 0x000 |

## M33: FPCCR 寄存器

偏移: 0x0ef34

### 描述

存储浮点扩展的控制数据

表 258. FPCCR 寄存器

| 位     | 描述                                                                                      | 类型 | 复位  |
|-------|-----------------------------------------------------------------------------------------|----|-----|
| 31    | <b>ASPEN:</b> 该位置1时，执行浮点指令会将 CONTROL.FPCA 位置1                                           | 读写 | 0x0 |
| 30    | <b>LSPEN:</b> 启用浮点状态的延迟上下文保存                                                            | 读写 | 0x0 |
| 29    | <b>LSPENS:</b> 此位控制LSPEN位是否允许从非安全态写入                                                    | 读写 | 0x1 |
| 28    | <b>CLRONRET:</b> 在异常返回时清除浮点调用者保存寄存器                                                     | 读写 | 0x0 |
| 27    | <b>CLRONRETS:</b> 此位控制CLRONRET位是否允许从非安全态写入                                              | 读写 | 0x0 |
| 26    | <b>TS:</b> 将浮点寄存器视为启用安全状态                                                               | 读写 | 0x0 |
| 25:11 | 保留。                                                                                     | -  | -   |
| 10    | <b>UFRDY:</b> 指示分配浮点堆栈帧时执行的软件是否能够将UsageFault异常置为挂起                                      | 读写 | 0x1 |
| 9     | <b>SPLIMVIOL:</b> 此位为在安全状态间银行化，指示浮点上下文是否违反启用延迟状态保护时的堆栈指针限制SPLIMVIOL修改延迟浮点状态保护行为         | 读写 | 0x0 |
| 8     | <b>MONRDY:</b> 指示分配浮点堆栈帧时执行的软件是否能够将DebugMonitor异常置为挂起                                   | 读写 | 0x0 |
| 7     | <b>SFRDY:</b> 指示分配浮点堆栈帧时执行的软件是否能够将SecureFault异常置为挂起该位仅存在于寄存器的安全版本中，从非安全状态访问时表现为RA Z/WI。 | 读写 | 0x0 |

| Bits | Description                                                                                                                                                                                                                                                                                                 | Type | Reset |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 6    | <b>BFRDY:</b> Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the BusFault exception to pending                                                                                                                                               | RW   | 0x1   |
| 5    | <b>MMRDY:</b> Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the MemManage exception to pending                                                                                                                                              | RW   | 0x1   |
| 4    | <b>HFRDY:</b> Indicates whether the software executing when the PE allocated the floating-point stack frame was able to set the HardFault exception to pending                                                                                                                                              | RW   | 0x1   |
| 3    | <b>THREAD:</b> Indicates the PE mode when it allocated the floating-point stack frame                                                                                                                                                                                                                       | RW   | 0x0   |
| 2    | <b>S:</b> Security status of the floating-point context. This bit is only present in the Secure version of the register, and behaves as RAZ/WI when accessed from the Non-secure state. This bit is updated whenever lazy state preservation is activated, or when a floating-point instruction is executed | RW   | 0x0   |
| 1    | <b>USER:</b> Indicates the privilege level of the software executing when the PE allocated the floating-point stack frame                                                                                                                                                                                   | RW   | 0x1   |
| 0    | <b>LSPACT:</b> Indicates whether lazy preservation of the floating-point state is active                                                                                                                                                                                                                    | RW   | 0x0   |

## M33: FPCAR Register

**Offset:** 0x0ef38

### Description

Holds the location of the unpopulated floating-point register space allocated on an exception stack frame

Table 259. FPCAR Register

| Bits | Description                                                                                                         | Type | Reset      |
|------|---------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:3 | <b>ADDRESS:</b> The location of the unpopulated floating-point register space allocated on an exception stack frame | RW   | 0x00000000 |
| 2:0  | Reserved.                                                                                                           | -    | -          |

## M33: FPDSCR Register

**Offset:** 0x0ef3c

### Description

Holds the default values for the floating-point status control data that the PE assigns to the FPSCR when it creates a new floating-point context

Table 260. FPDSCR Register

| Bits  | Description                                 | Type | Reset |
|-------|---------------------------------------------|------|-------|
| 31:27 | Reserved.                                   | -    | -     |
| 26    | <b>AHP:</b> Default value for FPSCR.AHP     | RW   | 0x0   |
| 25    | <b>DN:</b> Default value for FPSCR.DN       | RW   | 0x0   |
| 24    | <b>FZ:</b> Default value for FPSCR.FZ       | RW   | 0x0   |
| 23:22 | <b>RMODE:</b> Default value for FPSCR.RMode | RW   | 0x0   |
| 21:0  | Reserved.                                   | -    | -     |

| 位 | 描述                                                                                   | 类型 | 复位  |
|---|--------------------------------------------------------------------------------------|----|-----|
| 6 | <b>BFRDY</b> : 指示在处理器分配浮点堆栈帧时，执行的软件是否能够将总线错误异常置为待处理状态。                               | 读写 | 0x1 |
| 5 | <b>MMRDY</b> : 指示在处理器分配浮点堆栈帧时，执行的软件是否能够将内存管理异常置为待处理状态。                               | 读写 | 0x1 |
| 4 | <b>HFRDY</b> : 指示在处理器分配浮点堆栈帧时，执行的软件是否能够将硬件故障异常置为待处理状态。                               | 读写 | 0x1 |
| 3 | <b>THREAD</b> : 指示处理器在分配浮点堆栈帧时的运行模式。                                                 | 读写 | 0x0 |
| 2 | <b>S</b> : 浮点上下文的安全状态。该位仅存在于寄存器的安全版本中，从非安全状态访问时表现为RAZ/WI。每当启用延迟状态保存或执行浮点指令时，该位都会被更新。 | 读写 | 0x0 |
| 1 | <b>USER</b> : 指示在处理器分配浮点堆栈帧时执行软件的特权级别。                                               | 读写 | 0x1 |
| 0 | <b>LSPACT</b> : 指示是否启用了浮点状态的惰性保存                                                     | 读写 | 0x0 |

## M33: FPCAR 寄存器

偏移: 0x0ef38

### 描述

存储异常堆栈帧上未使用的浮点寄存器空间位置

表 259. FPCAR 寄存器

| 位    | 描述                         | 类型 | 复位         |
|------|----------------------------|----|------------|
| 31:3 | 地址：异常堆栈帧上为未使用的浮点寄存器空间分配的位置 | 读写 | 0x00000000 |
| 2:0  | 保留。                        | -  | -          |

## M33: FPSCR 寄存器

偏移: 0x0ef3c

### 描述

保存处理器在创建新浮点上下文时赋予 FPSCR 的浮点状态控制数据的默认值

表 260. FPSCR 寄存器

| 位     | 描述                              | 类型 | 复位  |
|-------|---------------------------------|----|-----|
| 31:27 | 保留。                             | -  | -   |
| 26    | <b>AHP</b> : FPSCR.AHP 的默认值     | 读写 | 0x0 |
| 25    | <b>DN</b> : FPSCR.DN 的默认值       | 读写 | 0x0 |
| 24    | <b>FZ</b> : FPSCR.FZ 的默认值       | 读写 | 0x0 |
| 23:22 | <b>RMODE</b> : FPSCR.RMode 的默认值 | 读写 | 0x0 |
| 21:0  | 保留。                             | -  | -   |

## M33: MVFR0 Register

**Offset:** 0x0ef40

### Description

Describes the features provided by the Floating-point Extension

Table 261. MVFR0 Register

| Bits  | Description                                                                | Type | Reset |
|-------|----------------------------------------------------------------------------|------|-------|
| 31:28 | <b>FPROUND:</b> Indicates the rounding modes supported by the FP Extension | RO   | 0x6   |
| 27:24 | Reserved.                                                                  | -    | -     |
| 23:20 | <b>FPSQRT:</b> Indicates the support for FP square root operations         | RO   | 0x5   |
| 19:16 | <b>FPDIVIDE:</b> Indicates the support for FP divide operations            | RO   | 0x4   |
| 15:12 | Reserved.                                                                  | -    | -     |
| 11:8  | <b>FPDP:</b> Indicates support for FP double-precision operations          | RO   | 0x6   |
| 7:4   | <b>FPSP:</b> Indicates support for FP single-precision operations          | RO   | 0x0   |
| 3:0   | <b>SIMDREG:</b> Indicates size of FP register file                         | RO   | 0x1   |

## M33: MVFR1 Register

**Offset:** 0x0ef44

### Description

Describes the features provided by the Floating-point Extension

Table 262. MVFR1 Register

| Bits  | Description                                                                                           | Type | Reset |
|-------|-------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | <b>FMAC:</b> Indicates whether the FP Extension implements the fused multiply accumulate instructions | RO   | 0x8   |
| 27:24 | <b>FPHP:</b> Indicates whether the FP Extension implements half-precision FP conversion instructions  | RO   | 0x5   |
| 23:8  | Reserved.                                                                                             | -    | -     |
| 7:4   | <b>FPDNAN:</b> Indicates whether the FP hardware implementation supports NaN propagation              | RO   | 0x8   |
| 3:0   | <b>FPFTZ:</b> Indicates whether subnormals are always flushed-to-zero                                 | RO   | 0x9   |

## M33: MVFR2 Register

**Offset:** 0x0ef48

### Description

Describes the features provided by the Floating-point Extension

Table 263. MVFR2 Register

| Bits | Description                                                    | Type | Reset |
|------|----------------------------------------------------------------|------|-------|
| 31:8 | Reserved.                                                      | -    | -     |
| 7:4  | <b>FPMISC:</b> Indicates support for miscellaneous FP features | RO   | 0x6   |
| 3:0  | Reserved.                                                      | -    | -     |

## M33: DDEVARCH Register

**Offset:** 0x0efbc

## M33: MVFR0 寄存器

偏移: 0x0ef40

### 描述

描述浮点扩展所提供的特性

表 261. MVFR0 寄存器

| 位     | 描述                            | 类型 | 复位  |
|-------|-------------------------------|----|-----|

## M33: TRCSYNCPR Register

Offset: 0x41034

### Description

The TRCSYNCPR specifies the period of trace synchronization of the trace streams. TRCSYNCPR defines a number of bytes of trace between requests for trace synchronization. This value is always a power of two

Table 285.  
TRCSYNCPR Register

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Type | Reset |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:5 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | -    | -     |
| 4:0  | <b>PERIOD:</b> Defines the number of bytes of trace between trace synchronization requests as a total of the number of bytes generated by the instruction stream. The number of bytes is $2N$ where $N$ is the value of this field: - A value of zero disables these periodic trace synchronization requests, but does not disable other trace synchronization requests. - The minimum value that can be programmed, other than zero, is 8, providing a minimum trace synchronization period of 256 bytes. - The maximum value is 20, providing a maximum trace synchronization period of $2^{20}$ bytes | RO   | 0x0a  |

## M33: TRCCCCTRLR Register

Offset: 0x41038

### Description

The TRCCCCTRLR sets the threshold value for instruction trace cycle counting. The threshold represents the minimum interval between cycle count trace packets

Table 286.  
TRCCCCTRLR Register

| Bits  | Description | Type | Reset |
|-------|-------------|------|-------|
| 31:12 | Reserved.   | -    | -     |

偏移: 0x41034

### 描述

TRCSYNCPR 指定跟踪流的同步周期。TRCSYNCPR 定义请求跟踪同步之间的跟踪字节数。该值始终为二的幂。

表 285。  
TRCSYNCPR 寄存器

| 位    | 描述                                                                                                                                                                                      | 类型 | 复位   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|------|
| 31:5 | 保留。                                                                                                                                                                                     | -  | -    |
| 4:0  | <b>PERIOD:</b> 定义指令流生成的字节数中，用于跟踪同步请求的字节总数。字节数为 $2N$ ，其中 $N$ 为此字段的值：<br>- 该字段为零时禁用周期性跟踪同步请求，但不影响其他跟踪同步请求的启用。<br>- 除零以外，可编程的最小值为8，提供最小的跟踪同步周期为256字节。<br>- 最大值为20，提供最大跟踪同步周期为 $2^{20}$ 字节。 | 只读 | 0x0a |

## M33: TRCCCCTRLR 寄存器

偏移: 0x41038

### 描述

TRCCCCTRLR 设定指令跟踪周期计数的阈值。该阈值表示周期计数跟踪包之间的最小间隔。

表 286。

**3.7.5.1. Cortex-M33 EPPB 寄存器**

EPPB（扩展私有外设总线）包含由 Raspberry Pi 实现并集成于 Cortex-M33 PPB 中的寄存器，用于为特定 RP2350 功能提供每核控制。这些寄存器每个核心拥有一份

core (they are core-local), and they reset on a warm reset of the core.

These registers start at a base address of `0xe0080000`, defined as `EPPB_BASE` in the SDK.

*Table 362. List of M33\_EPPB registers*

| Offset | Name      | Info                                                                                                 |
|--------|-----------|------------------------------------------------------------------------------------------------------|
| 0x0    | NMI_MASK0 | NMI mask for IRQs 0 through 31. This register is core-local, and is reset by a processor warm reset. |
| 0x4    | NMI_MASK1 | NMI mask for IRQs 0 though 51. This register is core-local, and is reset by a processor warm reset.  |
| 0x8    | SLEEPCTRL | Nonstandard sleep control register                                                                   |

## 3.8. Hazard3 processor

Hazard3 is a low-area, high-performance RISC-V processor with a 3-stage in-order pipeline. RP2350 configures the following standard RISC-V extensions:

- **RV32I**: 32-bit base instruction set
- **M**: Integer multiply/divide/modulo instructions
- **A**: Atomic memory operations
- **C**: Compressed 16-bit instructions (equivalently spelled **Zca**)
- **Zba**: Address generation instructions
- **Zbb**: Basic bit manipulation instructions
- **Zbs**: Single-bit manipulation instructions
- **Zbkb**: Basic bit manipulation for scalar cryptography
- **Zcb**: Basic additional compressed instructions
- **Zcmp**: Push/pop and double-move compressed instructions
- **Zicsr**: CSR access instructions
- Debug, Machine and User execution modes
- Physical Memory Protection unit (PMP) with eight regions, 32-byte granule, NAPOT
- External debug support with four instruction address triggers

Additionally, RP2350 enables the following Hazard3 custom extensions:

- **Xh3power**: Power management instructions and CSRs
- **Xh3bextm**: Bit-extract-multiple instruction (used in bootrom)
- **Xh3irq**: Local interrupt controller with nested, prioritised IRQ support
- **Xh3ppm**: Unlocked M-mode PMP regions

### Hazard3 Source Code

All hardware source files for Hazard3 are available under Apache 2.0 licensing at:

[github.com/wren6991/hazard3](https://github.com/wren6991/hazard3)

### 3.8.1. Instruction set reference

This section is a programmer's reference guide for the instructions supported by Hazard3. It covers basic assembly syntax, instruction behaviour, ranges for immediate values, and conditions for instruction compression. [The index](#) lists instructions alphabetically, including pseudo-instructions.

The pseudocode in this guide is informative only, and is no replacement for the official RISC-V specifications in [Section 3.8.1.1](#). However, it should prove a useful mnemonic aid once you have read the specifications.

#### 3.8.1.1. Links to RISC-V specifications

This table links ratified versions of the base instruction set and extensions implemented by Hazard3. These are the authoritative reference for the instructions documented in this reference guide.

## 3.8. Hazard3 处理器

Hazard3是一款低面积、高性能的RISC-V处理器，采用3级有序流水线。RP2350配置了以下标准RISC-V扩展：

- **RV32I**: 32位基础指令集
- **M**: 整数乘除及取模指令
- **A**: 原子内存操作指令
- **C**: 压缩16位指令（同样记为 **Zca**）
- **Zba**: 地址生成指令
- **Zbb**: 基本位操作指令
- **Zbs**: 单个位操作指令
- **Zbkb**: 标量密码学的基本位操作
- **Zcb**: 基本附加压缩指令
- **Zcmp**: 压缩的压栈/出栈及双重移动指令
- **Zicsr**: CSR访问指令
- 调试、机器模式及用户执行模式
- 物理内存保护单元（PMP），包含八个区域，32字节粒度，采用NAPOT
- 支持四个指令地址触发器的外部调试功能

此外，RP2350 启用了以下 Hazard3 定制扩展：

- **Xh3power**: 电源管理指令与 CSR 寄存器
- **Xh3bextm**: 位提取多重指令（用于 bootrom）
- **Xh3irq**: 具嵌套和优先级支持的本地中断控制器
- **Xh3ppmp**: 解锁的 M 模式 PMP 区域

### Hazard3 源代码

Hazard3 所有硬件源文件均在 Apache 2.0 许可协议下开放，网址：

[github.com/wren6991/hazard3](https://github.com/wren6991/hazard3)

### 3.8.1. 指令集参考

本节为 Hazard3 支持指令的程序员参考指南，涵盖基本汇编语法、指令行为、立即数范围及指令压缩条件。索引按字母顺序列出指令，包括伪指令。

本指南中的伪代码仅供参考，不能替代第3.8.1.1节中官方RISC-V规范。然而，一旦您阅读了相关规范，它应成为有效的助记工具。

#### 3.8.1.1 RISC-V规范链接

本表提供了Hazard3实现的基本指令集及其扩展的正式批准版本链接，系本参考指南所载指令的权威依据。

| Extension                  | Specification                                  |
|----------------------------|------------------------------------------------|
| <code>RV32I</code> v2.1    | Unprivileged ISA 20191213                      |
| <code>M</code> v2.0        | Unprivileged ISA 20191213                      |
| <code>A</code> v2.1        | Unprivileged ISA 20191213                      |
| <code>C</code> v2.0        | Unprivileged ISA 20191213                      |
| <code>Zicsr</code> v2.0    | Unprivileged ISA 20191213                      |
| <code>Zifencei</code> v2.0 | Unprivileged ISA 20191213                      |
| <code>Zba</code> v1.0.0    | Bit Manipulation ISA extensions 20210628       |
| <code>Zbb</code> v1.0.0    | Bit Manipulation ISA extensions 20210628       |
| <code>Zbs</code> v1.0.0    | Bit Manipulation ISA extensions 20210628       |
| <code>Zbkb</code> v1.0.1   | Scalar Cryptography ISA extensions 20220218    |
| <code>Zcb</code> v1.0.3-1  | Code Size Reduction extensions frozen v1.0.3-1 |
| <code>Zcmp</code> v1.0.3-1 | Code Size Reduction extensions frozen v1.0.3-1 |
| Machine ISA v1.12          | Privileged Architecture 20211203               |
| Debug v0.13.2              | RISC-V External Debug Support 20190322         |

You may also refer to the [RISC-V Assembly Programmer's Manual](#) for information on assembly syntax.

Consult the [source code](#) for detailed questions about implementation-defined behaviour, which is not covered by the RISC-V specifications. RP2350 uses version `86fc4e3`, with metal ECOs for commits `2f6e983` and `af08c0b`.

### 3.8.1.2. Architecture strings

`-march` strings completely specify the set of available RISC-V instructions, so that a compiler can generate correct and optimal code for your device. Use the following in descending order of preference:

1. Use `rv32ima_zicsr_zifencei_zba_zbb_zbs_zbkb_zca_zcb_zcmp` for compilers which support the `Zcb` and `Zcmp` extensions, such as GCC 14.
2. Use `rv32ima_zicsr_zifencei_zba_zbb_zbs_zbkb_zca_zcb` for GCC 14 packaged with an older assembler which does not support `Zcmp`.
3. Use `rv32imac_zicsr_zifencei_zba_zbb_zbs_zbkb` for older compilers, such as GCC 13 and below.

### 3.8.1.3. RISC-V architectural state

The mutable state visible to the programmer consists of:

- The  $31 \times 32$ -bit integer general-purpose registers (GPRs), named `x1` through `x31`
- The program counter `pc`, which points to the beginning of the current instruction in memory
- The control and status registers (CSRs), which configure processor behaviour and are used in trap handling
- The local monitor bit, which helps maintain correctness of atomic read-modify-write sequences
- The current privilege level, which determines which memory locations the core can access, which CSRs it can access, and which instructions it can execute

Hazard3 supports two privilege levels: Machine and User. These are interchangeably referred to as **modes**, and are commonly abbreviated as M-mode and U-mode. Debug mode behaves as an additional privilege level above M-mode.

| 扩展                         | 规范                    |
|----------------------------|-----------------------|
| <code>RV32I</code> v2.1    | 非特权ISA 20191213       |
| <code>M</code> v2.0        | 非特权ISA 20191213       |
| <code>A</code> v2.1        | 非特权ISA 20191213       |
| <code>C</code> v2.0        | 非特权ISA 20191213       |
| <code>Zicsr</code> v2.0    | 非特权ISA 20191213       |
| <code>Zifencei</code> v2.0 | 非特权ISA 20191213       |
| <code>Zba</code> v1.0.0    | 位操作ISA扩展 20210628     |
| <code>Zbb</code> v1.0.0    | 位操作ISA扩展 20210628     |
| <code>Zbs</code> v1.0.0    | 位操作ISA扩展 20210628     |
| <code>Zbkb</code> v1.0.1   | 标量密码学ISA扩展 20220218   |
| <code>Zcb</code> v1.0.3-1  | 代码大小缩减扩展冻结版 v1.0.3-1  |
| <code>Zcmp</code> v1.0.3-1 | 代码大小缩减扩展冻结版 v1.0.3-1  |
| 机器ISA v1.12                | 特权架构 20211203         |
| 调试 v0.13.2                 | RISC-V外部调试支持 20190322 |

您也可以参考RISC-V汇编程序员手册以了解汇编语法信息。

有关实现定义行为的详细问题，请查阅源码，该部分不包含在RISC-V规范中。RP2350使用版本86fc4e3，针对提交2f6e983和af08c0b进行了金属ECO修订。

### 3.8.1.2 架构字符串

`-march`字符串完整指定了可用的RISC-V指令集，编译器可据此为您的设备生成正确且最优代码。请按以下优先顺序依次使用：

1. 使用`rv32ima_zicsr_zifencei_zba_zbb_zbs_zbkb_zca_zcb_zcmp`，适用于支持`Zcb`和`Zcmp`扩展的编译器，如GCC 14。
2. 使用`rv32ima_zicsr_zifencei_zba_zbb_zbs_zbkb_zca_zcb`，适用于配备较旧汇编器且不支持`Zcmp`的GCC 14。
3. 使用`rv32imac_zicsr_zifencei_zba_zbb_zbs_zbkb`，适用于较旧的编译器，如GCC 13及更早版本。

### 3.8.1.3. RISC-V 架构状态

程序员可见的可变状态包括：

- 31个32位整数通用寄存器(GPR)，命名为`x1`至`x31`
- 程序计数器`pc`，指向内存中当前指令的起始位置
- 控制和状态寄存器(CSR)，用于配置处理器行为并用于陷阱处理
- 本地监视位，有助于保持原子读-改-写序列的正确性
- 当前特权级，决定内核可访问的内存地址、可访问的CSR以及可执行的指令

Hazard3支持两个特权级：机器级和用户级。两者可交替称为模式，通常简称M模式和U模式。调试模式作为高于M模式的额外特权级存在。

The 0th general-purpose register, `x0`, is hardwired to zero and ignores writes.

There is no flags register; branch instructions perform GPR-to-GPR comparisons directly.

This state is duplicated per hardware thread, or `hart`. RP2350 implements two Hazard3 cores, each with one hart.

### 3.8.1.3.1. Register conventions

The following ABI names are synonymous with `x0` through `x31`:

| Register               | ABI Name              | Description                          |
|------------------------|-----------------------|--------------------------------------|
| <code>x0</code>        | <code>zero</code>     | Hardwired to zero; ignores writes    |
| <code>x1</code>        | <code>ra</code>       | Return address (link register)       |
| <code>x2</code>        | <code>sp</code>       | Stack pointer                        |
| <code>x3</code>        | <code>gp</code>       | Global pointer                       |
| <code>x4</code>        | <code>tp</code>       | Thread pointer                       |
| <code>x5 - x7</code>   | <code>t0 - t2</code>  | Temporaries                          |
| <code>x8</code>        | <code>s0 or fp</code> | Saved register or frame pointer      |
| <code>x9</code>        | <code>s1</code>       | Saved register                       |
| <code>x10 - x11</code> | <code>a0 - a1</code>  | Function arguments and return values |
| <code>x12 - x17</code> | <code>a2 - a7</code>  | Function arguments                   |
| <code>x18 - x27</code> | <code>s2 - s11</code> | Saved registers                      |
| <code>x28 - x31</code> | <code>t3 - t6</code>  | Temporaries                          |

Registers `x1` through `x31` are identical, and any 32-bit opcode can use any combination of these registers. However, compressed instructions give preferential treatment to commonly-used registers `sp`, `ra`, `s0`, `s1`, and `a0` through `a5` to improve code density. All compressed instructions implemented by Hazard3 are 16-bit aliases for existing 32-bit instructions, so you can still perform any operation on any register.

See the [RISC-V PSABI Specification](#) for more information on the ABI register assignment as well as the RISC-V procedure calling convention.

### 3.8.1.4. Compressed instructions

The RISC-V extensions which Hazard3 implements use a mixture of 32-bit and 16-bit opcodes, the latter being referred to as **compressed instructions**. With the exception of `Zcmp`, each compressed instruction maps to a subset of an existing 32-bit instruction. For example, `c.add` is a 16-bit alias of the `add` instruction, with restrictions on register allocation.

The assembler automatically uses compressed instructions when possible. For example, `add a0, a0, a1` is a compressible form of `add`. This assembles to the 16-bit opcode `c.add a0, a1` when compressed instructions are enabled in the assembler.

The following extensions use 16-bit opcodes:

- [C: compressed instructions](#) (the non-floating-point subset is equivalently spelled as `Zca`)
- [Zcb: additional basic compressed instructions](#)
- [Zcmp: compressed push, pop and double-move](#)

Disabling the above extensions for compilation (and assembly) aligns all instructions to 32-bit boundaries. This may have a minor performance advantage for branch-dense code sequences (see [Section 3.8.7](#)), at the cost of poorer code density.

第0号通用寄存器 `x0` 被硬连线为零，写入操作被忽略。

无标志寄存器；分支指令直接执行通用寄存器之间的比较。

该状态在每个硬件线程（`hart`）中复制。RP2350实现了两个Hazard3核心，每个核心含一个`hart`。

### 3.8.1.3.1. 寄存器约定

以下ABI名称与 `x0` 至 `x31` 同义：

| 寄存器                    | ABI名称                 | 描述           |
|------------------------|-----------------------|--------------|
| <code>x0</code>        | <code>zero</code>     | 硬连线为零；写入时被忽略 |
| <code>x1</code>        | <code>ra</code>       | 返回地址（链接寄存器）  |
| <code>x2</code>        | <code>sp</code>       | 栈指针          |
| <code>x3</code>        | <code>gp</code>       | 全局指针         |
| <code>x4</code>        | <code>tp</code>       | 线程指针         |
| <code>x5 - x7</code>   | <code>t0 - t2</code>  | 临时寄存器        |
| <code>x8</code>        | <code>s0 或 fp</code>  | 保存寄存器或帧指针    |
| <code>x9</code>        | <code>s1</code>       | 已保存寄存器       |
| <code>x10 - x11</code> | <code>a0 - a1</code>  | 函数参数和返回值     |
| <code>x12 - x17</code> | <code>a2 - a7</code>  | 函数参数         |
| <code>x18 - x27</code> | <code>s2 - s11</code> | 已保存寄存器       |
| <code>x28 - x31</code> | <code>t3 - t6</code>  | 临时寄存器        |

寄存器 `x1` 至 `x31` 均相同，任何32位操作码均可使用这些寄存器的任意组合。然而，压缩指令对常用寄存器 `sp`、`ra`、`s0`、`s1` 及 `a0` 至 `a5` 给予优先照顾，以提升代码密度。Hazard3实现的所有压缩指令都是现有32位指令的16位别名，因此仍可对任何寄存器执行任何操作。

有关ABI寄存器分配及RISC-V过程调用约定的详细信息，请参阅RISC-V PSABI规范。

### 3.8.1.4. 压缩指令

Hazard3 实现的 RISC-V 扩展使用了 32 位和 16 位操作码的混合，其中后者称为压缩指令。除 `Zcmp` 外，每条压缩指令均映射至现有 32 位指令的一个子集。例如，`c.add` 是 `add` 指令的 16 位别名，但对寄存器分配有特定限制。

汇编器在可能的情况下会自动使用压缩指令。例如，`add a0, a0, a1` 是可压缩形式的 `add` 指令。启用汇编器中的压缩指令时，该指令会被组装为 16 位操作码 `c.add a0, a1`。

以下扩展使用 16 位操作码：

- **C：压缩指令（非浮点子集等同表示为 Zca）**
- **Zcb：附加基础压缩指令**
- **Zcmp：压缩的入栈、出栈及双寄存器移动指令**

禁用上述扩展进行编译（及汇编）时，所有指令均对齐至 32 位边界。对于分支密集型代码序列（参见第3.8.7节），这可能带来轻微的性能优势，但代价是代码密度降低。

When an instruction has an optional 16-bit compressed form, the limitations of the compressed form are documented in the listing for the 32-bit form. It is useful to be aware of these restrictions when optimising for code size. If no such limitations are mentioned, it means the instruction is always a 32-bit opcode.

`Zcmp` is an outlier in that its instructions each expand to a sequence of 32-bit instructions from the RV32I base instruction set. They therefore have no direct 32-bit counterparts.

### 3.8.1.5. Conventions for pseudocode

Pseudocode in this section is in Verilog 2005 syntax (IEEE 1364-2005). These Verilog operators are used throughout:

- Infix operators `+`, `-`, `*`, `/`, `&`, `^`, `|`, `<<`, `==`, `!=`, `<` and `>=` can be considered the same as the corresponding C operator.
- `$signed()` bit-casts to a signed value; comparisons between two signed values are signed comparisons.
- `>>` is always a logical (zero-extending) right shift.
- `>>>` on a signed value is an arithmetic (sign-extending) right shift.
- `{a, b}` is the bit-concatenation of `a` and `b`, with `a` in the more-significant position of the result.
- `a[n]` on an array is a subscript array access. For example `mem[0]` is the first byte of memory.
- `x[m:l]` on a packed array (a bit vector) is a bit slice of `x`, where `m` is the (inclusive) MSB and `l` is the (inclusive) LSB. For example `rs1[7:0]` is the 8 least-significant bits of `rs1`.
- `{n{x}}`, where `n` is a constant and `x` is a packed array, replicates `x` `n` times. `n` copies of `x` are concatenated together. For example `{32{1'b1}}` is a 32-bit all-ones value.

The pseudocode uses `<=` non-blocking assignments to assign to outputs: all such assignments are applied in a batch after the block of pseudocode has executed. Local variables may be assigned with `=` blocking assignments, which update the assignee immediately, similar to `=` procedural assignments in e.g. C programs. This distinction is important in some cases where e.g. `rd` and `rs1` may alias the same register, but it's generally sufficient just to be aware that `a <= b` and `a = b` are both assignments into `a`.

#### 3.8.1.5.1. Variables used in pseudocode

Pseudocode in this guide uses the following conventions for variables:

- `rs1`, `rs2`, and `rd` are 32-bit unsigned packed arrays (bit vectors), representing the values of the two register operands and the destination register.
- `regnum_rs1`, `regnum_rs2`, and `regnum_rd` are the 5-bit register numbers which select a GPR for `rs1`, `rs2`, and `rd`
- `imm` is a 32-bit unsigned packed array referring to the instruction's immediate value.
- `pc` is a 32-bit unsigned packed array referring to the program counter, which is exactly the address of the current instruction.
- `mem` is an array of 8-bit unsigned packed arrays, each corresponding to a byte address in memory.
- `csr` is an array of 32-bit unsigned packed arrays, each corresponding to a CSR listed in [Section 3.8.9](#).
- `priv` is a 2-bit unsigned packed array which contains the value `0x3` when the core is in Debug or M-mode, and `0x0` when the core is in U-mode.
- `i` and `j` are pseudocode temporary variables of type `integer` which may be used for loop variables.

The following tasks are used throughout:

- `raise_exception(n)` raises an exception with a cause of `n` (see [Section 3.8.4.1](#)).
- `bus_error(addr)` returns `1` when the address `addr` returns a bus error, and `0` otherwise.

当指令具有可选的16位压缩形式时，压缩形式的限制会在32位形式的清单中作详细说明。在针对代码大小进行优化时，了解这些限制非常重要。若未提及此类限制，则表示该指令始终为32位操作码。

`Zcmp`是一个例外，其指令各自扩展为一系列来自RV32I基础指令集的32位指令，因此它们没有直接对应的32位指令。

### 3.8.1.5. 伪代码约定

本节的伪代码采用Verilog 2005语法（IEEE 1364-2005）。以下Verilog运算符贯穿全文使用：

- 中缀运算符`+`、`-`、`*`、`/`、`&`、`^`、`|`、`<<`、`==`、`!=`、`<及>`可视为与对应的C语言运算符相同。
- `$signed()`位转换为有符号值；两个有符号值之间的比较为有符号比较。
- `>>`始终表示逻辑（零扩展）右移。
- `>>>`对有符号值表示算术（符号扩展）右移。
- `{a, b}`是`a`和`b`的位连接，`a`位于结果的更高有效位。
- `a[n]`对数组的访问是下标访问。例如`mem[0]`表示内存的第一个字节。
- `x[m:l]`在打包数组（位向量）上是位切片，其中`m`为（包含）最高有效位，`l`为（包含）最低有效位。例如`rs1[7:0]`是`rs1`的最低8位。
- `{n{x}}`其中`n`为常数，`x`为打包数组，表示将`x`重复`n`次。`n`个`x`被连接在一起。例如`{32{1'b1}}`是一个32位的全一值。

伪代码使用`<=`非阻塞赋值来分配输出：所有此类赋值在伪代码块执行完成后统一应用。局部变量可以使用`=`阻塞赋值，立即更新被赋值对象，类似于如C语言程序中的`=`过程式赋值。该区别在某些情况下尤为重要，例如`rd`与`rs1`可能别名同一寄存器，但一般只需注意`a <= b`与`a = b`均为对`a`的赋值即可。

#### 3.8.1.5.1. 伪代码中使用的变量

本指南中的伪代码使用以下变量约定：

- `rs1`、`rs2`及`rd`为32位无符号打包数组（位向量），代表两个寄存器操作数及目标寄存器的值。
- `regnum_rs1`、`regnum_rs2`与`regnum_rd`是选择对应于`rs1`、`rs2`和`rd`通用寄存器的5位寄存器编号。
- `imm`是一个32位无符号打包数组，表示指令的立即数值。
- `pc`是一个32位无符号打包数组，表示程序计数器，即当前指令的精确地址。
- `mem`是一个8位无符号打包数组的数组，每个元素对应内存中的一个字节地址。
- `csr`是一个32位无符号打包数组的数组，每个元素对应第3.8.9节中列出的CSR。
- `priv`是一个2位无符号打包数组，当内核处于调试（Debug）或机器模式（M-mode）时，其值为`0x3`；处于用户模式（U-mode）时，其值为`0x0`。
- `i`和`j`为伪代码中的临时变量，类型为整数（integer），可用作循环变量。

以下任务在整个过程中广泛使用：

- `raise_exception(n)`引发一个原因是`n`的异常（参见第3.8.4.1节）。
- `bus_error(addr)`当地址`addr`返回总线错误时返回`1`，否则返回`0`。

### 3.8.1.6. Alphabetical list of instructions

This instruction reference covers all instructions from all extensions which Hazard3 implements on RP2350. The table below also includes common pseudo-instructions such as `not` and `ret`, which you may see in disassembly and be surprised not to see in the ISA manual. The links for pseudo-instructions go to the entry for the underlying hardware instruction aliased by that pseudo-instruction.

#### TIP

The instruction names at the left-hand margin of the instruction listings are links back to this index. Use them to quickly return here and look up another instruction.

| Alphabetical order: left-to-right, then top-to-bottom. |                          |                           |                            |                          |                           |
|--------------------------------------------------------|--------------------------|---------------------------|----------------------------|--------------------------|---------------------------|
| <a href="#">add</a>                                    | <a href="#">addi</a>     | <a href="#">amoadd.w</a>  | <a href="#">amoand.w</a>   | <a href="#">amomax.w</a> | <a href="#">amomaxu.w</a> |
| <a href="#">amomin.w</a>                               | <a href="#">amomin.w</a> | <a href="#">amoor.w</a>   | <a href="#">amoswap.w</a>  | <a href="#">amoxor.w</a> | <a href="#">and</a>       |

### 3.8.1.6. 指令字母顺序列表

本指令参考涵盖Hazard3在RP2350上实现的所有扩展指令。下表还包括常见伪指令，如 `not` 和 `ret`，您可能在反汇编中见到，但在ISA手册中未见收录。伪指令的链接指向其对应的底层硬件指令条目。

#### ● 提示

指令列表左侧边缘的指令名称为返回本索引的链接。使用这些链接可快速返回此处并查找其他指令。

| 字母顺序：先从左到右，后从上到下。        |                           |                           |                            |                          |                           |
|--------------------------|---------------------------|---------------------------|----------------------------|--------------------------|---------------------------|
| 加                        | <a href="#">addi</a>      | <a href="#">amoadd.w</a>  | <a href="#">amoand.w</a>   | <a href="#">amomax.w</a> | <a href="#">amomaxu.w</a> |

本参考指南其余部分根据扩展对指令进行分类：

- [RV32I：基础指令集架构（寄存器对寄存器）](#)
- [RV32I：基础指令集架构（寄存器对立即数）](#)
- [RV32I：基础指令集架构（大立即数）](#)
- [RV32I：基础指令集架构（控制转移）](#)
- [RV32I：基础指令集架构（加载/存储）](#)

- M: multiply and divide
- A: atomics
- C: compressed instructions
- Zba: bit manipulation for address generation
- Zbb: basic bit manipulation
- Zbs: single bit manipulation
- Zbkb: basic bit manipulation for scalar cryptography
- Zcb: additional basic compressed instructions
- Zcmp: compressed push, pop and double-move
- RV32I and Zifencei: memory ordering
- Zicsr: control and status register access
- Privileged instructions

### 3.8.1.7. RV32I: base ISA (register-register)

These instructions calculate a function of two register operands, `rs1` and `rs2`. They write the 32-bit result to a destination register, `rd`.

#### `add`

Add register to register.

Usage:

```
add rd, rs1, rs2
```

Operation:

```
rd <= rs1 + rs2;
```

Compressible if either:

- `rd` matches `rs1`, no operands are zero (aka `c.add`)
- `rs2` is zero and neither `rd` nor `rs1` is zero (aka `c.mv`)

#### `and`

Bitwise AND register with register.

Usage:

```
and rd, rs1, rs2
```

Operation:

- M：乘法与除法
- A：原子操作
- C：压缩指令
- Zba：用于地址生成的位操作扩展
- Zbb：基础位操作扩展
- Zbs：单个位操作扩展
- Zbkb：面向标量密码学的基础位操作扩展
- Zcb：附加基础压缩指令
- Zcmp：压缩的入栈、出栈及双寄存器移动指令
- RV32I 和 Zifencei：内存排序
- Zicsr：控制与状态寄存器访问
- 特权指令

### 3.8.1.7. RV32I：基础指令集架构（寄存器对寄存器）

这些指令计算两个寄存器操作数，`rs1`和`rs2`的函数值。并将32位结果写入目的寄存器`rd`。

#### 加

寄存器相加。

用法：

```
add rd, rs1, rs2
```

操作：

```
rd <= rs1 + rs2;
```

可压缩条件如下：

- 当`rd`等于`rs1`，且所有操作数均非零（即`c.add`）
- 当`rs2`为零，且`rd`和`rs1`均非零（即`c.mv`）

#### and

寄存器按位与操作。

用法：

```
and rd, rs1, rs2
```

操作：

```
rd <= rs1 & rs2;
```

Compressible if: **rd** matches **rs1**, registers are in **x8 - x15**.

**or**

Bitwise OR register with register.

Usage:

```
or rd, rs1, rs2
```

Operation:

```
rd <= rs1 | rs2;
```

Compressible if: **rd** matches **rs1**, registers are in **x8 - x15**.

**sll**

Shift left, logical. Shift amount is modulo 32.

Usage:

```
sll rd, rs1, rs2
```

Operation:

```
rd <= rs1 << rs2[4:0];
```

**slt**

Set if less than (signed). Result is **0** for false, **1** for true.

Usage:

```
slt rd, rs1, rs2
sltz rd, rs1 // pseudo: rs2 is zero
sgtz rd, rs2 // pseudo: rs1 is zero
```

Operation:

```
rd <= $signed(rs1) < $signed(rs2);
```

**sltu**

Set if less than (unsigned). Result is **0** for false, **1** for true.

Usage:

```
rd <= rs1 & rs2;
```

可压缩条件： **rd** 等于 **rs1**，且寄存器处于 x8至 x15范围内。

**or**

寄存器按位或操作。

用法：

```
or rd, rs1, rs2
```

操作：

```
rd <= rs1 | rs2;
```

可压缩条件： **rd** 等于 **rs1**，且寄存器处于 x8至 x15范围内。

**sll**

逻辑左移。移位量取模32。

用法：

```
sll rd, rs1, rs2
```

操作：

```
rd <= rs1 << rs2[4:0];
```

**slt**

若小于（有符号）则置位。结果为 0 表示假， 1 表示真。

用法：

```
slt rd, rs1, rs2
sltz rd, rs1 // 伪指令：rs2为零
sgtz rd, rs2 // 伪指令：rs1为零
```

操作：

```
rd <= $signed(rs1) < $signed(rs2);
```

**sltu**

若小于（无符号）则置位。结果为 0 表示假， 1 表示真。

用法：

```
sltu rd, rs1, rs
snez rd, rs2 // pseudo: rs1 is zero
```

Operation:

```
rd <= rs1 < rs2;
```

#### **sra**

Shift right, arithmetic. Shift amount is modulo 32.

Usage:

```
sra rd, rs1, rs2
```

Operation:

```
rd <= $signed(rs1) >>> rs2[4:0];
```

#### **srl**

Shift right, logical. Shift amount is modulo 32.

Usage:

```
srl rd, rs1, rs2
```

Operation:

```
rd <= rs1 >> rs2[4:0];
```

#### **sub**

Two's complement subtract register from register.

Usage:

```
sub rd, rs1, rs2
neg rd, rs2 // pseudo: rs1 is zero
```

Operation:

```
rd <= rs1 - rs2;
```

Compressible if: **rd** matches **rs1**, registers are in **x8 - x15**.

```
sltu rd, rs1, rs
snez rd, rs2 // 伪指令: rs1为零
```

操作:

```
rd <= rs1 < rs2;
```

#### sra

算术右移。移位量取模32。

用法:

```
sra rd, rs1, rs2
```

操作:

```
rd <= $signed(rs1) >>> rs2[4:0];
```

#### srl

逻辑右移。移位数取模32。

用法:

```
srl rd, rs1, rs2
```

操作:

```
rd <= rs1 >> rs2[4:0];
```

#### 减

寄存器间的二补数减法运算。

用法:

```
sub rd, rs1, rs2
neg rd, rs2 // 伪代码: rs1为零
```

操作:

```
rd <= rs1 - rs2;
```

可压缩条件: **rd**等于**rs1**, 且寄存器处于**x8**至**x15**范围内。

**xor**

Bitwise XOR register with register

Usage:

```
xor rd, rs1, rs2
```

Operation:

```
rd <= rs1 ^ rs2;
```

Compressible if: **rd** matches **rs1**, registers are in **x8 - x15**.

### 3.8.1.8. RV32I: base ISA (register-immediate)

These instructions calculate a function of one register **rs1** and one immediate operand **imm**. They write the 32-bit result to a destination register **rd**.

Immediate operands are constants encoded directly in the instruction, which avoids the cost of first materialising the constant value into a register.

**addi**

Add register to immediate.

Usage:

```
addi rd, rs1, imm
mv rd, rs1 // pseudo: imm is 0
nop // pseudo: rd, rs1 are zero, imm is 0
```

Operation:

```
rd <= rs1 + imm
```

Immediate range: **-0x800** through **0x7ff** for 32-bit, smaller for 16-bit.

Compressible if:

- **rd** matches **rs1**, and immediate is in the range **-0x20** through **0x1f** (aka **c.addi**)
- **rd** is not **zero**, **rs1** is **zero**, and immediate is in the range **-0x20** through **0x1f** (aka **c.li**)
- **rd** is in **x8 - x15**, **rs1** is **sp**, and immediate is a nonzero multiple of four in the range **0x000** through **0x3fc** (aka **c.addi4spn**)
- **rd** is **sp**, **rs1** is **sp**, and immediate is a nonzero multiple of 16 in the range **-0x200** through **0x1f0** (aka **c.addi16sp**)

Note compressed **c.mv** canonically expands to **add**, not **addi**.

**andi**

Bitwise AND register with immediate.

Usage:

**xor**

寄存器与寄存器的按位异或操作

用法：

```
xor rd, rs1, rs2
```

操作：

```
rd <= rs1 ^ rs2;
```

可压缩条件： **rd** 等于 **rs1**，且寄存器处于 **x8**至**x15**范围内。

### 3.8.1.8. RV32I：基础指令集（寄存器-立即数类型）

这些指令计算一个寄存器 **rs1**与一个立即数操作数 **imm**的函数。它们将32位结果写入目标寄存器 **rd**。

立即数操作数是直接编码于指令中的常量，避免了先将常量载入寄存器的开销。

**addi**

寄存器加立即数。

用法：

```
addi rd, rs1, imm
mv rd, rs1 // 伪代码: imm 为 0
nop // 伪代码: rd、rs1 为零, imm 为 0
```

操作：

```
rd <= rs1 + imm
```

立即数范围： **-0x800**至**0x7ff**（32位），16位则更小。

可压缩条件：

- **rd** 等于 **rs1**，且立即数范围为 **-0x20**至**0x1f**（即 **c.addi**）
- **rd**不为零，**rs1**为零，且立即数范围为-0x20至**0x1f**（即**c.li**）
- **rd**在 **x8**至 **x15**之间，**rs1**为 **sp**，且立即数为非零的四的倍数，范围为0x000至0x3fc（即**c.addi4spn**）

- **rd**为 **sp**，**rs1**为 **sp**，且立即数为非零的16的倍数，范围为-0x200至**0x1f0**（即**c.addi16sp**）

注意：压缩指令 **c.mv**在规范中扩展为add，而非 **addi**。

**andi**

按位与立即数寄存器操作。

用法：

```
andi rd, rs1, imm
zext.b rd, rs1 // pseudo: imm is 0xff
```

Operation:

```
rd <= rs1 & imm;
```

Immediate range: `-0x800` through `0x7ff` for 32-bit, `-0x20` through `0x1f` for 16-bit.

Compressible if: `rd` matches `rs1`, registers are in `x8 - x15`, and immediate is in the range `-0x20` through `0x1f`.

#### **ori**

Bitwise OR register with immediate.

Usage:

```
ori rd, rs1, imm
```

Operation:

```
rd <= rs1 | imm;
```

Immediate range: `-0x800` through `0x7ff`

#### **slli**

Shift left, logical, immediate.

Usage:

```
slli rd, rs1, imm
```

Operation:

```
rd <= rs1 << imm;
```

Immediate range: `0` through `31`.

Compressible if: `rd` matches `rs1`, registers are not `zero`.

#### **slti**

Set if less than immediate (signed). Result is `0` for false, `1` for true.

Usage:

```
slti rd, rs1, imm
```

Operation:

```
andi rd, rs1, imm
zext.b rd, rs1 // 伪指令: imm为0xff
```

操作:

```
rd <= rs1 & imm;
```

立即数范围: 32位为-0x800至0x7ff, 16位为-0x20至0x1f。

可压缩条件: rd与rs1相同, 寄存器位于x8至x15, 且立即数在-0x20至0x1f范围内。

**ori**

按位或立即数寄存器操作。

用法:

```
ori rd, rs1, imm
```

操作:

```
rd <= rs1 | imm;
```

立即数范围: -0x800至0x7ff

**slli**

立即数逻辑左移。

用法:

```
slli rd, rs1, imm
```

操作:

```
rd <= rs1 << imm;
```

立即数范围: 0至31。

可压缩条件: rd与rs1匹配, 且寄存器不为零。

**slti**

如果小于立即数(有符号), 则置位。结果为0表示假, 1表示真。

用法:

```
slti rd, rs1, imm
```

操作:

```
rd <= $signed(rs1) < $signed(imm);
```

Immediate range: -0x800 through 0x7ff

#### **sltiu**

Set if less than immediate (unsigned). Result is 0 for false, 1 for true.

Usage:

```
sltiu rd, rs1, imm
seqz rd, rs1 // pseudo: imm is 1
```

Operation:

```
rd <= rs1 < imm;
```

Immediate range: -0x800 through 0x7ff

Note the negative values indicated for the immediate range are two's complement: this instruction uses them in an unsigned context, so -0x800 through -0x001 can be thought of as +0xfffff800 through +0xffffffff for the comparison.

#### **srai**

Shift right, arithmetic, immediate.

Usage:

```
srai rd, rs1, imm
```

Operation:

```
rd <= $signed(rs1) >> imm;
```

Immediate range: 0 through 31.

Compressible if: rd matches rs1, registers are in x8 through x15.

#### **srlti**

Shift right, logical, immediate.

Usage:

```
srlti rd, rs1, imm
```

Operation:

```
rd <= rs1 >> imm;
```

Immediate range: 0 through 31.

```
rd <= $signed(rs1) < $signed(imm);
```

立即数范围： -0x800 至 0x7ff

#### **sltiu**

如果小于立即数（无符号），则置位。结果为 0 表示假， 1 表示真。

用法：

```
sltiu rd, rs1, imm
seqz rd, rs1 // 伪指令：imm 值为 1
```

操作：

```
rd <= rs1 < imm;
```

立即数范围： -0x800 至 0x7ff

注意立即数范围中标示的负值为二补数：该指令在无符号上下文中使用它们，因此 -0x800 至 -0x001 可视为 +0xfffffff800 至 +0xffffffff 用于比较。

#### **srai**

立即数算术右移。

用法：

```
srai rd, rs1, imm
```

操作：

```
rd <= $signed(rs1) >>> imm;
```

立即数范围： 0 至 31。

仅当满足以下条件时可压缩： rd 与 rs1 相同，且寄存器位于 x8 至 x15 范围内。

#### **srlti**

逻辑右移，立即数格式。

用法：

```
srlti rd, rs1, imm
```

操作：

```
rd <= rs1 >> imm;
```

立即数范围： 0 至 31。

Compressible if: `rd` matches `rs1`, registers are in `x8` through `x15`.

**xori**

Bitwise XOR register with immediate.

Usage:

```
xori rd, rs1, imm
not rd, rs1 // pseudo: imm is -1
```

Operation:

```
rd <= rs1 ^ imm;
```

Immediate range: `-0x800` through `0x7ff`

Compressible if: `rd` matches `rs1`, registers are in `x8` - `x15`, and immediate is `-1` (aka `c.not`)

**3.8.1.9. RV32I: base ISA (large immediate)**

These instructions are the first in a two-instruction sequence to materialise a 32-bit constant, or a 32-bit offset from `pc`.

**auipc**

Add upper immediate to program counter.

Usage:

```
auipc rd, imm
```

Operation:

```
rd <= pc + (imm << 12);
```

Immediate range: `-0x80000` through `0x7ffff`.

Note `-0x80000` through `-0x00001` are equivalent to `0x80000` through `0xfffff` after the left shift (**on RV32 only**) and the assembler may also accept these positive values.

**lui**

Load upper immediate.

Usage:

```
lui rd, imm
```

Operation:

仅当满足以下条件时可压缩： **rd**与 **rs1**相同，且寄存器位于 **x8**至 **x15**范围内。

**xori**

寄存器与立即数按位异或。

用法：

```
xori rd, rs1, imm
not rd, rs1 // 伪指令：imm 为 -1
```

操作：

```
rd <= rs1 ^ imm;
```

立即数范围： -0x800 至 0x7ff

仅当满足以下条件时可压缩： **rd**与 **rs1**相同，寄存器位于 **x8**至 **x15**范围，且立即数为 -1（亦称 **c.not**）

**3.8.1.9. RV32I：基础指令集（大立即数）**

这些指令为两条指令序列中的第一条，用于生成32位常数或基于 **pc**的32位偏移。

**auipc**

将高位立即数加至程序计数器。

用法：

```
auipc rd, imm
```

操作：

```
rd <= pc + (imm << 12);
```

立即数范围： -0x80000 至 0x7FFFF。

注意 -0x80000 至 -0x00001 等同于 0x80000 至 0xfffff（仅限**RV32**的左移操作后），汇编器亦可能接受这些正数值。

**lui**

加载高位立即数。

用法：

```
lui rd, imm
```

操作：

```
rd <= imm << 12;
```

Immediate range: `-0x80000` through `0x7ffff` if 32-bit, or `-0x20` through `0x1f` if 16-bit.

Compressible if: `rd` is neither `zero` nor `sp`, and `imm` is nonzero in the range `-0x20` through `0x1f`.

Note `-0x80000` through `-0x00001` are equivalent to `0x80000` through `0xfffff` after the left shift (**on RV32 only**) and the assembler may also accept these positive values.

### 3.8.1.10. RV32I: base ISA (control transfer)

These instructions modify the value of `pc`. When unmodified, `pc` increments by the size of the current instruction in bytes.

Conditional branches either modify or do not modify `pc`, based on a comparison between two registers. There is no flags register, however you can pass boolean conditions into branches by comparing a register with the `zero` register.

**beq**

Branch if equal.

Usage:

```
beq rs1, rs2, label
beqz rs1, label // pseudo: rs2 is zero
```

Operation:

```
if (rs1 == rs2)
 pc <= label;
```

Immediate range: even values in the range `-0x1000` through `0x0ffe` ( $\pm 4$  kB) if 32-bit, or `-0x100` through `0x0fe` ( $\pm 256$  B) if 16-bit.

Compressible if: `rs2` is `zero`, and immediate is in the range `-0x100` through `0x0fe` (aka `c.beqz`).

**bge**

Branch if greater than or equal (signed).

Usage:

```
bge rs1, rs2, label
bgez rs1, label // pseudo: rs2 is zero
ble rs2, rs1, label // pseudo: operands swapped by assembler
blez rs2, label // pseudo: rs1 is zero
```

Operation:

```
if ($signed(rs1) >= $signed(rs2))
 pc <= label;
```

Immediate range: even values in the range `-0x1000` through `0x0ffe` ( $\pm 4$  kB)

```
rd <= imm << 12;
```

立即数范围：如果为32位，则为 `-0x80000` 至 `0x7fffff`；如果为16位，则为 `-0x20` 至 `0x1f`。

可压缩条件为：`rd`既非 `zero` 也非 `sp`，且 `imm` 为范围-0x20至0x1f内的非零值。

注意 `-0x80000` 至 `-0x00001` 等同于 `0x80000` 至 `0xfffff`（仅限RV32的左移操作后），汇编器亦可能接受这些正数值。

### 3.8.1.10. RV32I：基础指令集（控制流转移）

这些指令会修改 `pc` 的值。未被修改时，`pc` 按当前指令的字节数递增。

条件分支根据两个寄存器的比较结果，选择性地修改或保持 `pc` 不变。没有标志寄存器，但您可以通过将寄存器与零寄存器比较，将布尔条件传递至分支。

**beq**

相等时分支。

用法：

```
beq rs1, rs2, label
beqz rs1, label // 伪指令：rs2 为零
```

操作：

```
if (rs1 == rs2)
 pc <= label;
```

立即数范围：对32位为 `-0x1000` 至 `0x0ffe` 之间的偶数 ( $\pm 4$  kB)；对16位为 `-0x100` 至 `0x0fe` 之间 ( $\pm 256$  B)。

可压缩条件：`rs2` 为零，且立即数位于 `-0x100` 至 `0x0fe` 范围内（即 `c.beqz` 指令）。

**bge**

有符号大于等于时分支。

用法：

```
bge rs1, rs2, label
bgez rs1, label // 伪指令：rs2 为零
ble rs2, rs1, label // 伪指令：操作数由汇编器交换
blez rs2, label // 伪指令：rs1 为零
```

操作：

```
if ($signed(rs1) >= $signed(rs2))
 pc <= label;
```

立即数范围：偶数值范围为 `-0x1000` 至 `0x0ffe` ( $\pm 4$  kB)

**bgeu**

Branch if less than or equal (unsigned).

Usage:

```
bgeu rs1, rs2, label
bleu rs2, rs1, label // pseudo: operands swapped by assembler
```

Operation:

```
if (rs1 >= rs2)
 pc <= label;
```

Immediate range: even values in the range **-0x1000** through **0x0ffe** ( $\pm 4$  kB)

**blt**

Branch if less than (signed).

Usage:

```
blt rs1, rs2, label
bltz rs1, label // pseudo: rs2 is zero
bgt rs2, rs1, label // pseudo: operands swapped by assembler
bgtz rs2, label // pseudo: rs1 is zero
```

Operation:

```
if ($signed(rs1) < $signed(rs2))
 pc <= label;
```

Immediate range: even values in the range **-0x1000** through **0x0ffe** ( $\pm 4$  kB)

**bltu**

Branch if less than (unsigned).

Usage:

```
bltu rs1, rs2, label
bgtu rs2, rs1, label // pseudo: operands swapped by assembler
```

Operation:

```
if (rs1 < rs2)
 pc <= label;
```

Immediate range: even values in the range **-0x1000** through **0x0ffe** ( $\pm 4$  kB)

**bne**

Branch if not equal.

**bgeu**

无符号小于等于条件分支。

用法：

```
bgeu rs1, rs2, label
bleu rs2, rs1, label // 伪指令：操作数由汇编器交换
```

操作：

```
if (rs1 >= rs2)
 pc <= label;
```

立即数范围：偶数值范围为 -**0x1000** 至 **0x0ffe** ( $\pm 4$  kB)

**blt**

有符号小于条件分支。

用法：

```
blt rs1, rs2, label
bltz rs1, label // 伪指令：rs2 为零
bgt rs2, rs1, label // 伪指令：操作数由汇编器交换
bgtz rs2, label // 伪代码：rs1 为零
```

操作：

```
if ($signed(rs1) < $signed(rs2))
 pc <= label;
```

立即数范围：偶数值范围为 -**0x1000** 至 **0x0ffe** ( $\pm 4$  kB)

**bltu**

无符号小于条件分支。

用法：

```
bltu rs1, rs2, label
bgtu rs2, rs1, label // 伪指令：操作数由汇编器交换
```

操作：

```
if (rs1 < rs2)
 pc <= label;
```

立即数范围：偶数值范围为 -**0x1000** 至 **0x0ffe** ( $\pm 4$  kB)

**bne**

不等则分支。

Usage:

```
bne rs1, rs2, label
bnez rs1, label // pseudo: rs2 is zero
```

Operation:

```
if (rs1 != rs2)
 pc <= label;
```

Immediate range: even values in the range `-0x1000` through `0x0ffe` ( $\pm 4$  kB) if 32-bit, or `-0x100` through `0x0fe` ( $\pm 256$  B) if 16-bit.

Compressible if: `rs2` is `zero`, and immediate is in the range `-0x100` through `0x0fe` (aka `c.bnez`).

**jal**

Jump and link, `pc`-relative.

Usage:

```
jal rd, label
jal label // pseudo: rd is ra
j label // pseudo: rd is zero
```

Operation:

```
rd <= pc + 4; // or +2 if opcode is 16-bit
pc <= label;
```

Immediate range: even values in the range `-0x100000` through `0x0ffffe` ( $\pm 1$  MB) if 32-bit, or `-0x800` through `0x7fe` ( $\pm 2$  kB) if 16-bit.

Compressible if: `rd` is `zero` or `ra`, and immediate is in the range `-0x800` through `0x7fe`.

**jalr**

Jump and link, register-offset.

Usage:

```
jalr rd, rs1, imm // (imm is implicitly 0 if omitted.)
jalr rd, imm(rs1) // alternate syntax. (imm is implicitly 0 if omitted.)
jalr rs1, imm // pseudo: rd is ra. (imm is implicitly 0 if omitted.)
jalr imm(rs1) // pseudo: rd is ra. (imm is implicitly 0 if omitted.)
jr rs1, imm // pseudo: rd is zero. (imm is implicitly 0 if omitted.)
jr imm(rs1) // pseudo: rd is zero. (imm is implicitly 0 if omitted.)
ret // pseudo for jr ra
```

Operation:

用法：

```
bne rs1, rs2, label
bnez rs1, label // 伪指令：rs2 为零
```

操作：

```
if (rs1 != rs2)
 pc <= label;
```

立即数范围：对32位为-0x1000至0x0ffe之间的偶数（±4 kB）；对16位为-0x100至0x0fe之间（±256 B）。

当且仅当 **rs2** 为零，且立即数位于-0x100至0x0fe之间时可压缩（即c.bnez）。

**jal**

跳转并链接，相对于 pc。

用法：

```
jal rd, label
jal label // 伪指令：rd 为 ra
j label // 伪指令：rd 为零
```

操作：

```
rd <= pc + 4; // 如果操作码为16位，则为 +2
pc <= label;
```

立即数范围：32位时，为 -0x100000 至 0x0ffffe 范围内的偶数值（±1 MB）；16位时，为 -0x800 至 0x7fe 范围内的偶数值（±2 kB）。

可压缩条件： **rd** 为零或 **ra**，且立即数范围为-0x800至0x7fe。

**jalr**

跳转并链接，寄存器偏移。

用法：

```
jalr rd, rs1, imm // (若省略, imm隐式为0。)
jalr rd, imm(rs1) // 替代语法。 (若省略, imm隐式为0。)
jalr rs1, imm // 伪指令：rd为ra。 (若省略, imm隐式为0。)
jalr imm(rs1) // 伪指令：rd为ra。 (若省略, imm隐式为0。)
jr rs1, imm // 伪指令：rd为零。 (若省略, imm隐式为0。)
jr imm(rs1) // 伪指令：rd为零。 (若省略, imm隐式为0。)
返回 // jr ra的伪指令
```

操作：

```

rd <= pc + 4; // or +2 if opcode is 16-bit
pc <= rs1 + imm;

```

Immediate range: `-0x800` through `0x7ff`.

Compressible if: `rd` is zero or `ra`, immediate is zero, and `rs1` is not zero.

### 3.8.1.11. RV32I: base ISA (load and store)

These instructions transfer data between memory and core registers. The register operand `rs1` and immediate `imm` are added to form the address. Stores write register operand `rs2` into memory, and loads read from memory into the destination register `rd`.

All load and store instructions to naturally aligned addresses on RISC-V are **single-copy atomic**. This means a naturally-aligned load does not observe byte tearing between the values that a memory location held before and after any naturally-aligned store to that location. Equivalently, all bytes covered by a single naturally-aligned load or store instruction transfer in a single transaction with the memory subsystem.

Hazard3 raises an exception on a load or store to a non-naturally-aligned address. See [Section 3.8.4.1](#) for an exhaustive list of exception causes.

#### `lb`

Load signed byte from memory.

Usage:

```

lb rd, imm(rs1)
lb rd, (rs1) // imm is implicitly 0 if omitted.

```

Operation:

```

reg [31:0] addr;
addr = rs1 + imm;
if (bus_fault(addr)) begin
 raise_exception(4'h5); // Cause = load fault
end else begin
 rd <= {
 {24{mem[addr][7]}}, // Sign-extend
 mem[addr]
 };
end

```

Immediate range: `-0x800` through `0x7ff` for 32-bit, or `0x0` through `0x3` for 16-bit.

#### `lbu`

Load unsigned byte from memory.

Usage:

```

lbu rd, imm(rs1)
lbu rd, (rs1) // imm is implicitly 0 if omitted.

```

Operation:

```
rd <= pc + 4; // 若指令码为16位，则为+2, pc <=
rs1 + imm;
```

立即数范围： -0x800 至 0x7ff。

可压缩条件： rd 为零或 ra， 立即数为零， 且 rs1 不为零。

### 3.8.1.11. RV32I：基础ISA（加载与存储）

这些指令在内存与核心寄存器之间传输数据。寄存器操作数 rs1 与立即数 imm 相加以生成地址。存储指令将寄存器操作数 rs2 写入内存，加载指令则从内存读取到目标寄存器 rd。

所有针对 RISC-V 自然对齐地址的加载和存储指令均为 **单复制原子操作**。这意味着，自然对齐的加载指令不会观察到该地址在任何自然对齐存储前后出现的字节断裂。等效地，单个自然对齐的加载或存储指令所覆盖的所有字节，均通过与内存子系统的一次事务传输完成。

Hazard3 在对非自然对齐地址执行加载或存储时触发异常。详见第 3.8.4.1 节，获取异常原因的全面列表。

#### lb

从内存加载带符号字节。

用法：

```
lb rd, imm(rs1)
lb rd, (rs1) // 若省略, imm默认为0。
```

操作：

```
reg [31:0] addr;
addr = rs1 + imm;
if (bus_fault(addr)) begin
 raise_exception(4'h5); // 原因 = 加载故障
end else begin
 rd <= {
 {24{mem[addr][7]}}, // 符号扩展
 mem[addr]
 };
end
```

立即数范围： -0x800 至 0x7ff (32位)， 或 0x0 至 0x3 (16位)。

#### lbu

从内存加载无符号字节。

用法：

```
lbu rd, imm(rs1)
lbu rd, (rs1) // 若省略, imm默认为0。
```

操作：

```

reg [31:0] addr;
addr = rs1 + imm;
if (bus_fault(addr)) begin
 raise_exception(4'h5); // Cause = load fault
end else begin
 rd <= {
 24'h000000,
 mem[addr]
 };
end

```

Immediate range: `-0x800` through `0x7ff` for 32-bit, or `0x0` through `0x3` for 16-bit.

Compressible if: `rd` and `rs1` are in `x8` through `x15`, and immediate is in the range `0x0` through `0x3`.

### `lh`

Load signed halfword from memory.

Usage:

```

lh rd, imm(rs1)
lh rd, (rs1) // imm is implicitly 0 if omitted.

```

Operation:

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[0]) begin
 raise_exception(4'h4); // Cause = unaligned load
end else if (bus_fault(addr)) begin
 raise_exception(4'h5); // Cause = load fault
end else begin
 rd <= {
 {16{mem[addr + 1][7]}}, // Sign-extend
 mem[addr + 1],
 mem[addr]
 };
end

```

Immediate range: `-0x800` through `0x7ff` for 32-bit, or even values in the range `0x0` through `0x2` for 16-bit.

Compressible if: `rd` and `rs1` are in `x8` through `x15`, and immediate is `0x0` or `0x2`.

### `lhu`

Load unsigned halfword from memory.

Usage:

```

lhu rd, imm(rs1)
lhu rd, (rs1) // imm is implicitly 0 if omitted.

```

Operation:

```

reg [31:0] addr;
addr = rs1 + imm;
if (bus_fault(addr)) begin
 raise_exception(4'h5); // 原因 = 加载故障
end else begin
 rd <= {
 24'h000000,
 mem[addr]
 };
end

```

立即数范围： -0x800 至 0x7ff （32位），或 0x0 至 0x3 （16位）。

可压缩条件：rd和rs1均为x8至x15，且立即数范围为0x0至0x3。

#### lh

从内存加载有符号半字。

用法：

```

lh rd, imm(rs1)
lh rd, (rs1) // 若省略, imm 隐含为0。

```

操作：

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[0]) begin
 raise_exception(4'h4); // 原因 = 非对齐加载
end else if (bus_fault(addr)) begin
 raise_exception(4'h5); // 原因 = 读取故障
end else begin
 rd <= {
 {16{mem[addr + 1][7]}},
 mem[addr + 1],
 mem[addr]
 };
end

```

立即数范围：32位为 -0x800 至 0x7ff，或16位偶数值为 0x0 至 0x2。

满足以下情况则可压缩：rd和rs1位于x8至x15，且立即数为0x0或0x2。

#### lhu

从内存加载无符号半字。

用法：

```

lhu rd, imm(rs1)
lhu rd, (rs1) // 若省略, imm 默认为0。

```

操作：

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[0]) begin
 raise_exception(4'h4); // Cause = unaligned load
end else if (bus_fault(addr)) begin
 raise_exception(4'h5); // Cause = load fault
end else begin
 rd <= {
 16'h0000, // Zero-extend
 mem[addr + 1],
 mem[addr]
 };
end

```

Immediate range: `-0x800` through `0x7ff` for 32-bit, or even values in the range `0x0` through `0x2` for 16-bit.

Compressible if: `rd` and `rs1` are in `x8` through `x15`, and immediate is `0x0` or `0x2`.

#### `lw`

Load word from memory.

Usage:

```

lw rd, imm(rs1)
lw rd, (rs1) // imm is implicitly 0 if omitted.

```

Operation:

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[1:0]) begin
 raise_exception(4'h4); // Cause = unaligned load
end else if (bus_fault(addr)) begin
 raise_exception(4'h5); // Cause = load fault
end else begin
 rd <= {
 mem[addr + 3], // Note little-endian;
 mem[addr + 2], // MSBs are highest address
 mem[addr + 1],
 mem[addr]
 };
end

```

Immediate range: `-0x800` through `0x7ff` for 32-bit, smaller for 16-bit.

Compressible if:

- `rd` and `rs1` are in `x8` - `x15`, and immediate is a multiple of four in the range `0x00` through `0x7c` (aka `c.lw`)
- `rd` is not zero, `rs1` is `sp`, and immediate is a multiple of four in the range `0x00` through `0xfc` (aka `c.lwsp`)

#### `sb`

Store byte to memory.

Usage:

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[0]) begin
 raise_exception(4'h4); // 原因 = 非对齐加载
end else if (bus_fault(addr)) begin
 raise_exception(4'h5); // 原因 = 读取故障
end else begin
 rd <= {
 16'h0000, // 零扩展
 mem[addr + 1],
 mem[addr]
 };
end

```

立即数范围：32位为 -0x800 至 0x7ff，或16位偶数值为 0x0 至 0x2。

满足以下情况则可压缩：rd和rs1位于x8至x15，且立即数为0x0或0x2。

#### lw

从内存加载字。

用法：

```

lw rd, imm(rs1)
lw rd, (rs1) // 若省略, imm 默认为 0。

```

操作：

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[1:0]) begin
 raise_exception(4'h4); // 原因 = 非对齐加载
end else if (bus_fault(addr)) begin
 raise_exception(4'h5); // 原因 = 读取故障
end else begin
 rd <= {
 mem[addr + 3], // 注意小端序;
 mem[addr + 2], // 最高有效位存于最高地址
 mem[addr + 1],
 mem[addr]
 };
end

```

立即数范围：-0x800 至 0x7ff（32位），16位则更小。

可压缩条件：

- rd 和 rs1 均处于 x8 至 x15，立即数为 0x00 至 0x7c 范围内的四的倍数（即 c.lw）
- rd 不为零，rs1 为 sp，且立即数为 0x00 至 0xfc 范围内的四的倍数（即 c.lwsp）

#### 设置位

将字节存储至内存。

用法：

```
sb rs2, imm(rs1)
sb rs2, (rs1) // imm is implicitly 0 if omitted.
```

Operation:

```
reg [31:0] addr;
addr = rs1 + imm;
if (bus_fault(addr)) begin
 raise_exception(4'h7); // Cause = store/AMO fault
end else begin
 mem[addr] <= rs2[7:0];
end
```

Immediate range: `-0x800` through `0x7ff` for 32-bit, or `0x0` through `0x3` for 16-bit.

Compressible if: `rd` and `rs1` are in `x8` through `x15`, and immediate is in the range `0x0` through `0x3`.

**sh**

Store halfword to memory.

Usage:

```
sh rs2, imm(rs1)
sh rs2, (rs1) // imm is implicitly 0 if omitted.
```

Operation:

```
reg [31:0] addr;
addr = rs1 + imm;
if (addr[0]) begin
 raise_exception(4'h6); // Cause = unaligned store/AMO
end else if (bus_fault(addr)) begin
 raise_exception(4'h7); // Cause = store/AMO fault
end else begin
 mem[addr] <= rs2[7:0];
 mem[addr + 1] <= rs2[15:8];
end
```

Immediate range: `-0x800` through `0x7ff` for 32-bit, or even values in the range `0x0` through `0x2` for 16-bit.

Compressible if: `rd` and `rs1` are in `x8` through `x15`, and immediate is `0x0` or `0x2`.

**sw**

Store word to memory.

Usage:

```
sw rs2, imm(rs1)
sw rs2, (rs1) // imm is implicitly 0 if omitted.
```

Operation:

```
sb rs2, imm(rs1)
sb rs2, (rs1) // 若省略, imm隐式为0。
```

操作：

```
reg [31:0] addr;
addr = rs1 + imm;
if (bus_fault(addr)) begin
 raise_exception(4'h7); // 原因 = 存储/AMO故障
end else begin
 mem[addr] <= rs2[7:0];
end
```

立即数范围： -0x800 至 0x7ff （32位），或 0x0 至 0x3 （16位）。

可压缩条件： rd和rs1均为x8至x15，且立即数范围为0x0至0x3。

#### 带符号右移

将半字存储至内存。

用法：

```
sh rs2, imm(rs1)
sh rs2, (rs1) // 若省略, imm隐式为0。
```

操作：

```
reg [31:0] addr;
addr = rs1 + imm;
if (addr[0]) begin
 raise_exception(4'h6); // 原因 = 非对齐存储/AMO
end else if (bus_fault(addr)) begin
 raise_exception(4'h7); // 原因 = 存储/AMO故障
end else begin
 mem[addr] <= rs2[7:0];
 mem[addr + 1] <= rs2[15:8];
end
```

立即数范围：32位为 -0x800 至 0x7ff，或 16位偶数值为 0x0 至 0x2。

满足以下情况则可压缩： rd和 rs1位于 x8至 x15，且立即数为 0x0 或 0x2。

#### SW

将字存储至内存。

用法：

```
sw rs2, imm(rs1)
sw rs2, (rs1) // 若省略, imm隐式为0。
```

操作：

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[1:0]) begin
 raise_exception(4'h6); // Cause = unaligned store/AMO
end else if (bus_fault(addr)) begin
 raise_exception(4'h7); // Cause = store/AMO fault
end else begin
 mem[addr] <= rs2[7:0];
 mem[addr + 1] <= rs2[15:8];
 mem[addr + 2] <= rs2[23:16];
 mem[addr + 3] <= rs2[31:24];
end

```

Immediate range: `-0x800` through `0x7ff` for 32-bit, smaller for 16-bit.

Compressible if:

- `rs1` and `rs2` are in `x8 - x15`, and immediate is a multiple of four in the range `0x00` through `0x7c` (aka `c.sw`)
- `rs2` is not `zero`, `rs1` is `sp`, and immediate is a multiple of four in the range `0x00` through `0xfc` (aka `c.swsp`)

### 3.8.1.12. M: Multiply and Divide

These instructions implement integer multiply, divide and modulo.

`div`

Divide (signed).

Usage:

```
div rd, rs1, rs2
```

Operation:

```

if (rs2 == 32'h0)
 rd <= 32'hffffffff; // Defined for division by zero
else if (rs1 == 32'h80000000 && rs2 == 32'hffffffffff)
 rd <= 32'h80000000; // Defined for signed overflow
else
 rd <= $signed(rs1) / $signed(rs2); // Sign of rd is XOR of signs

```

`divu`

Divide (unsigned).

Usage:

```
divu rd, rs1, rs2
```

Operation:

```

reg [31:0] addr;
addr = rs1 + imm;
if (addr[1:0]) begin
 raise_exception(4'h6); // 原因 = 非对齐存储/AMO
end else if (bus_fault(addr)) begin
 raise_exception(4'h7); // 原因 = 存储/AMO故障
end else begin
 mem[addr] <= rs2[7:0];
 mem[addr + 1] <= rs2[15:8];
 mem[addr + 2] <= rs2[23:16];
 mem[addr + 3] <= rs2[31:24];
end

```

立即数范围：-0x800至0x7ff（32位），16位则更小。

可压缩条件：

- **rs1** 和 **rs2**位于 x8至 x15，立即数为四的倍数，范围为 0x00至 0x7c（即 **c.sw**）
- **rs2**不为零，**rs1**为 sp，且立即数为四的倍数，范围为0x00至0xfc（即**c.swsp**）

### 3.8.1.12. M：乘法和除法

这些指令实现整数乘法、除法和取模运算。

**div**

除法（带符号）。

用法：

```
div rd, rs1, rs2
```

操作：

```

if (rs2 == 32'h0)
 rd <= 32'hffffffff; // 针对除零的定义
else if (rs1 == 32'h80000000 && rs2 == 32'hffffffff)
 rd <= 32'h80000000; // 定义有符号溢出
else
 rd <= $signed(rs1) / $signed(rs2); // rd的符号为符号的异或值

```

**divu**

无符号除法。

用法：

```
divu rd, rs1, rs2
```

操作：

```

if (rs2 == 32'h0)
 rd <= 32'ffffffff; // Defined for division by zero
else
 rd <= rs1 / rs2;

```

**mul**

Multiply  $32 \times 32 \rightarrow 32$ .

Usage:

```
mul rd, rs1, rs2
```

Operation:

```
rd <= rs1 * rs2;
```

Compressible if: **rd** matches **rs1**, registers are in **x8** through **x15**.

**mulh**

Multiply signed (32) by signed (32), return upper 32 bits of the 64-bit result.

Usage:

```
mulh rd, rs1, rs2
```

Operation:

```

// Both operands are sign-extended to 64 bits:
reg [63:0] result_full;
result_full = {{32{rs1[31]}}, rs1} * {{32{rs2[31]}}, rs2};
rd <= result_full[63:32];

```

**mulhsu**

Multiply signed (32) by unsigned (32), return upper 32 bits of the 64-bit result.

Usage:

```
mulhsu rd, rs1, rs2
```

Operation:

```

// rs1 is sign-extended, rs2 is zero-extended:
reg [63:0] result_full;
result_full = {{32{rs1[31]}}, rs1} * {32'h00000000, rs2};
rd <= result_full[63:32];

```

```

if (rs2 == 32'h0)
 rd <= 32'hffffffff; // 针对除零的定义
else
 rd <= rs1 / rs2;

```

**mul**

乘法  $32 \times 32 \rightarrow 32$ 。

用法：

```
mul rd, rs1, rs2
```

操作：

```
rd <= rs1 * rs2;
```

仅当满足以下条件时可压缩： **rd** 与 **rs1** 相同，且寄存器位于 **x8** 至 **x15** 范围内。

**mulh**

有符号（32位）乘以有符号（32位），返回64位结果的高32位。

用法：

```
mulh rd, rs1, rs2
```

操作：

```

// 两个操作数均符号扩展至64位：
reg [63:0] result_full;
result_full = {{32{rs1[31]}}, rs1} * {{32{rs2[31]}}, rs2};
rd <= result_full[63:32];

```

**mulhsu**

有符号（32位）乘以无符号（32位），返回64位结果的高32位。

用法：

```
mulhsu rd, rs1, rs2
```

操作：

```

// rs1 为符号扩展，rs2 为零扩展：
reg [63:0] result_full;
result_full = {{32{rs1[31]}}, rs1} * {32'h00000000, rs2};
rd <= result_full[63:32];

```

**mulhu**

Multiply unsigned (32) by unsigned (32), return upper 32 bits of the 64-bit result.

Usage:

```
mulhu rd, rs1, rs2
```

Operation:

```
// Both operands are zero-extended to 64 bits:
reg [63:0] result_full;
result_full = {32'h00000000, rs1} * {32'h00000000, rs2};
rd <= result_full[63:32];
```

**rem**

Remainder (signed).

Usage:

```
rem rd, rs1, rs2
```

Operation:

```
if (rs2 == 32'h0)
 rd <= rs1; // Defined for division by zero
else
 rd <= $signed(rs1) % $signed(rs2); // Sign of rd is sign of rs1
```

**remu**

Remainder (unsigned).

Usage:

```
remu rd, rs1, rs2
```

Operation:

```
if (rs2 == 32'h0)
 rd <= rs1;
else
 rd <= rs1 % rs2;
```

### 3.8.1.13. A: Atomics

These instructions help software to safely and concurrently modify shared variables. They fall into two groups:

**mulhu**

无符号乘法（32 位乘以 32 位），返回 64 位结果的高 32 位。

用法：

```
mulhu rd, rs1, rs2
```

操作：

```
// 两个操作数均零扩展至 64 位：
reg [63:0] result_full;
result_full = {32'h00000000, rs1} * {32'h00000000, rs2};
rd <= result_full[63:32];
```

**余数**

取余（带符号）。

用法：

```
rem rd, rs1, rs2
```

操作：

```
if (rs2 == 32'h0)
 rd <= rs1; // 针对除零的定义
else
 rd <= $signed(rs1) % $signed(rs2); // rd 的符号与 rs1 相同
```

**重新移动**

取余（无符号）。

用法：

```
remu rd, rs1, rs2
```

操作：

```
if (rs2 == 32'h0)
 rd <= rs1;
else
 rd <= rs1 % rs2;
```

**3.8.1.13. A: Atomics**

这些指令帮助软件安全且并发地修改共享变量。它们分为两类：

- **lr.w** and **sc.w**, load-reserved and store-conditional instructions, which allow software to safely perform read-modify-write operations on shared variables by looping until success
- **amo\*.w** instructions (atomic memory operations or AMOs), which atomically modify a memory location and return the value it held immediately prior to modification

The pseudocode in this section references the 1-bit global variable **local\_monitor\_valid**. It is true when the hart has:

- previously completed a successful AHB5 exclusive read
- not attempted an exclusive write since the read
- not been interrupted or taken an exception since the read (*implementation-defined behaviour*)

The pseudocode maintains this invariant over the **local\_monitor\_valid** flag. This flag helps the hart maintain atomicity of its read-modify-write sequences with respect to its own interrupts. Hardware refuses to perform exclusive writes when the local monitor flag is not set.

AMOs clear the local monitor state even when bailing out during the read phase, since even in this case you have attempted to execute an instruction which performs an exclusive write. In an **lr.w, sc.w** sequence with an AMO executed in between, the **sc.w** always fails.

Hazard3 builds its atomic shared memory implementation on top of AHB5 exclusive accesses. The following tasks, used throughout this section, represent AHB5 32-bit exclusive reads and writes:

```
// Read 32 bits from memory and return reservation success/fail according to
// global monitor. Set local monitor bit if the reservation succeeded.
task exclusive_read_32;
 input [31:0] addr;
 output [31:0] data;
 output exclusive_ok;
begin
 data = {
 mem[addr + 3],
 mem[addr + 2],
 mem[addr + 1],
 mem[addr]
 };
 local_monitor_valid = global_monitor_read(addr);
 exclusive_ok = local_monitor_valid;
end
endtask

// Attempt to write 32 bits to memory, and return write success/fail according
// to global monitor. Always clear the local monitor flag.
task exclusive_write_32;
 input [31:0] addr;
 input [31:0] data;
 output exclusive_ok;
begin
 if (!local_monitor_valid) begin
 exclusive_ok = 0; // Write refused by local monitor
 end else if (global_monitor_write(addr)) begin
 exclusive_ok = 1; // Write succeeds
 mem[addr + 3] <= data[31:24];
 mem[addr + 2] <= data[23:16];
 mem[addr + 1] <= data[15: 8];
 mem[addr + 0] <= data[7: 0];
 end else begin
 exclusive_ok = 0; // Write refused by global monitor
 end
 local_monitor_valid = 0; // Always clear local monitor
end
```

- **lr.w**和**sc.w**，即保留加载和条件存储指令，允许软件通过循环直到成功，安全地对共享变量执行读-改-写操作。
- **amo\*.w**指令（原子内存操作，简称AMO），原子性地修改内存位置并返回修改前该位置的值。

本节伪代码引用了一个位全局变量`local_monitor_valid`。当hart满足以下条件时，该变量为真：

- 先前已成功完成一次AHB5独占读取；
- 自该读取以来未尝试过独占写入；
- 自该读取以来未被中断或未发生异常（实现定义的行为）。

伪代码在`local_monitor_valid`标志上维护该不变量。该标志帮助hart在自身中断范围内维持读-改-写序列的原子性。当本地监视器标志未设置时，硬件拒绝执行独占写入。

即使在读取阶段中止时，AMO仍会清除本地监视器状态，因为即使在此情况下，您已尝试执行包含独占写入的指令。在包含介于lr.w和sc.w之间执行AMO的lr.w、sc.w序列中，sc.w始终失败。

Hazard3基于AHB5独占访问构建其原子共享内存实现。以下任务贯穿本节，用于表示AHB5 32位独占读写操作：

```
// 从内存读取32位，并根据 // 全局监视器返回预留成功或失败。如果预留成功，则设置本地监视器位
。
task exclusive_read_32;
 input [31:0] addr;
 output [31:0] data;
 output exclusive_ok;
begin
 data = {
 mem[addr + 3],
 mem[addr + 2],
 mem[addr + 1],
 mem[addr]
 };
 local_monitor_valid = global_monitor_read(addr);
 exclusive_ok = local_monitor_valid;
end
endtask

// 尝试向内存写入32位数据，并根据全局监视器返回写入成功或失败。始终清除本地监视器标志。

task exclusive_write_32;
 input [31:0] addr;
 input [31:0] data;
 output exclusive_ok;
begin
 if (!local_monitor_valid) begin
 exclusive_ok = 0; // 本地监视器拒绝写入，否则若(global_
 monitor_write(addr)) 成功，则 exclusive_ok = 1;
 // 写入成功
 mem[addr + 3] <= data[31:24];
 mem[addr + 2] <= data[23:16];
 mem[addr + 1] <= data[15: 8];
 mem[addr + 0] <= data[7: 0];
 end else begin
 exclusive_ok = 0; // 全局监视器拒绝写入
 end
 local_monitor_valid = 0; // 始终清除本地监视器标志
end
```

```
 endtask
```

The functions `global_monitor_read(addr)`; and `global_monitor_write(addr)`; in the above code return the global monitor response for an exclusive read or write to this address, following the rules laid out in [Section 2.1.6](#). The global monitor enforces atomicity of this hart's read-modify-write sequences with respect to other harts sharing the same memory.

Because Hazard3 implements an AMO as a hardware-sequenced read-modify-write retry loop using AHB5 exclusives, the hardware promotes a read reservation failure during an AMO to a store/AMO fault exception (`mcause = 7`). This behaviour avoids an infinite loop when accessing locations which do not support exclusive access.

The following local variables are common to all AMO pseudocode:

```
reg done = 0;
reg exclusive_success;
reg [31:0] tmp;
```

#### **amoadd.w**

Atomically add register to memory and return original memory value.

Usage:

```
amoadd.w rd, rs2, (rs1)
```

Operation:

```
if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = tmp + rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor
```

#### **amoand.w**

Atomically bitwise AND register into memory. Return original memory value.

Usage:

```
amoand.w rd, rs2, (rs1)
```

Operation:

```
endtask
```

函数`global_monitor_read(addr)`和`global_monitor_write(addr)`;上述代码中，这两个函数返回对该地址进行独占读取或写入的全局监视器响应，遵循第2.1.6节中规定的规则。全局监视器确保本hart针对共享相同内存的其他harts执行的读-改-写序列的原子性。

由于Hazard3以硬件顺序的读-改-写重试循环实现了基于AHB5独占的AMO，硬件会在AMO期间将读保留失败提升为存储/AMO故障异常（`mcause = 7`）。该行为避免了访问不支持独占访问的位置时出现无限循环。

以下局部变量适用于所有AMO伪代码：

```
reg done = 0;
reg exclusive_success;
reg [31:0] tmp;
```

#### amoadd.w

以原子方式将寄存器值加至内存，并返回原内存值。

用法：

```
amoadd.w rd, rs2, (rs1)
```

操作：

```
if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = tmp + rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志
```

#### amoand.w

以原子方式将寄存器按位与写入内存。返回原始内存值。

用法：

```
amoand.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = tmp & rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amomax.w**

Atomically: check if register is signed-greater-than memory value, and write to memory if true. Return original memory value.

Usage:

```
amomax.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = $signed(tmp) < $signed(rs2) ? rs2 : tmp;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amomaxu.w**

Atomically: check if register is unsigned-greater-than memory value, and write to memory if so. Return original memory value.

Usage:

```
amomaxu.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = tmp & rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amomax.w**

以原子方式：检查寄存器的有符号值是否大于内存值，若是则写入内存。返回原始内存值。

用法：

```
amomax.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = $signed(tmp) < $signed(rs2) ? rs2 : tmp;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amomaxu.w**

以原子方式：检查寄存器的无符号值是否大于内存值，若是则写入内存。返回原始内存值。

用法：

```
amomaxu.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = tmp < rs2 ? rs2 : tmp;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amomin.w**

Atomically: check if register is signed-less-than memory value, and write to memory if so. Return original memory value.

Usage:

```
amomin.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = $signed(tmp) < $signed(rs2) ? tmp : rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amominu.w**

Atomically: check if register is unsigned-less-than memory value, and write to memory if so. Return original memory value.

Usage:

```
amominu.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = tmp < rs2 ? rs2 : tmp;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amomin.w**

原子操作：检查寄存器是否小于内存中的有符号值，若是，则写入内存。返回原内存值。

用法：

```
amomin.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = $signed(tmp) < $signed(rs2) ? tmp : rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amominu.w**

原子操作：检查寄存器是否小于内存中的无符号值，若是，则写入内存。返回原内存值。

用法：

```
amominu.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = tmp < rs2 ? tmp : rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amoor.w**

Atomically bitwise OR register into memory. Return original memory value.

Usage:

```
amoor.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 tmp = tmp | rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amoswap.w**

Atomically: write a value to memory, and return the value the memory location held immediately prior to the write.

Usage:

```
amoswap.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = tmp < rs2 ? tmp : rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amoor.w**

原子操作：将寄存器的按位或结果写入内存。返回原始内存值。

用法：

```
amoor.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 tmp = tmp | rs2;
 exclusive_write_32(rs1, tmp, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amoswap.w**

原子操作：向内存写入值，并返回写入前内存中的原值。

用法：

```
amoswap.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 exclusive_write_32(rs1, rs2, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**amoxor.w**

Atomically bitwise OR register into memory. Return original memory value.

Usage:

```
amoxor.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
 done = 1;
 end else begin
 exclusive_write_32(rs1, rs2, done);
 end
end
local_monitor_valid = 0; // Always clear local monitor

```

**lr.w**

Load a value from memory and make a reservation with the global monitor. Set local monitor bit according to reservation success.

Usage:

```
lr.w rd, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 exclusive_write_32(rs1, rs2, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**amoxor.w**

原子操作：将寄存器的按位或结果写入内存。返回原始内存值。

用法：

```
amoxor.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因：存储/原子操作地址对齐错误
 done = 1;
end
while (!done) begin
 exclusive_read_32(rs1, tmp, exclusive_success);
 if (!exclusive_success || bus_fault(addr)) begin
 raise_exception(4'h7); // 原因：存储/原子操作访问错误
 done = 1;
 end else begin
 exclusive_write_32(rs1, rs2, done);
 end
end
local_monitor_valid = 0; // 始终清除本地监视器标志

```

**lr.w**

从内存加载值并通过全局监视器建立保留。根据保留是否成功设置本地监视器位。

用法：

```
lr.w rd, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h4); // Cause: load align
end else if (bus_fault(rs1)) begin
 raise_exception(4'h5); // Cause: load fault
end else begin
 read_exclusive_32(rs1, tmp, local_monitor_valid);
 rd <= tmp;
end

```

**sc.w**

Conditionally store a value to memory. Succeed if reservation is valid at both local and global monitor. Return 1 for failure, 0 for success.

Usage:

```
sc.w rd, rs2, (rs1)
```

Operation:

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // Cause: store/AMO align
end else if (bus_fault(addr)) begin
 raise_exception(4'h7); // Cause: store/AMO fault
end else if (!local_monitor_valid) begin
 rd <= 1; // Refused by local monitor
end else begin
 write_exclusive_32(rs1, rs2, exclusive_success);
 rd <= !exclusive_success;
end
local_monitor_valid = 0; // Always clear local monitor

```

### 3.8.1.14. C: Compressed instructions

All instructions in the **C** extension are 16-bit aliases of 32-bit instructions from other extensions. In the case of Hazard3, which lacks the **F** extension, these are all aliases of base **I** instructions. They behave identically to their 32-bit counterparts.

**C** adds compressed aliases for the following instructions from RV32I:

| Alphabetical order: left-to-right, then top-to-bottom. |      |      |      |     |     |
|--------------------------------------------------------|------|------|------|-----|-----|
| add                                                    | addi | and  | andi | beq | bne |
| ebreak                                                 | jal  | jalr | lui  | lw  | or  |
| slli                                                   | srai | srl  | sub  | sw  | xor |

See the per-instruction documentation for the compression limitations of each instruction. The assembler automatically uses compressed variants when the limitations are met, and when the relevant compressed instruction extension is enabled for the assembler, for example by passing **c** in the **-march** ISA string.

The above also applies to **Zca** and **Zcb**: the former is an alias for the non-floating-point subset of **C**, and the latter adds 16-bit aliases for additional common instructions from the **I**, **M** and **Zbb** extensions. Each **Zcmp** instruction expands to a sequence of multiple instructions from the **I** extension.

```

if (rs1[1:0]) begin
 raise_exception(4'h4); // 原因: 加载地址未对齐
end else if (bus_fault(rs1)) begin
 ise_exception(4'h5); // 原因: 加载故障 end else
begin
 read_exclusive_32(rs1, tmp, local_monitor_valid);
 rd <= tmp;
end

```

**sc.w**

有条件地向内存存储值。仅当本地和全局监视器的保留均有效时，存储操作才算成功。返回 1 表示失败，0 表示成功。

用法：

```
sc.w rd, rs2, (rs1)
```

操作：

```

if (rs1[1:0]) begin
 raise_exception(4'h6); // 原因: 存储/原子操作地址对齐错误
end else if (bus_fault(addr)) begin
 raise_exception(4'h7); // 原因: 存储/AMO故障 end else
 e if (!local_monitor_valid) begin
 rd <= 1; // 被本地监视器拒绝
 end else begin
 write_exclusive_32(rs1, rs2, exclusive_success);
 rd <= !exclusive_success;
 end
 local_monitor_valid = 0; // 始终清除本地监视器标志

```

### 3.8.1.14. C：压缩指令

C 扩展中的所有指令均为其他扩展中 32 位指令的 16 位别名。对于缺少 F 扩展的 Hazard3，这些均为基本 I 指令的别名。它们的行为与对应的 32 位指令完全一致。

C 为 RV32I 中的以下指令添加了压缩别名：

| 字母顺序：先从左到右，后从上到下。 |      |      |      |     |     |
|-------------------|------|------|------|-----|-----|
| 加                 | addi | and  | andi | beq | bne |
| ebreak            | jal  | jalr | lui  | lw  | or  |
| slli              | srai | srl  | 减    | sw  | xor |

关于每条指令的压缩限制，请参阅各指令的专门文档。当满足限制条件且为汇编器启用了相关压缩指令扩展时（例如通过在 `-marchISA` 字符串中加入 C），汇编器会自动使用压缩变体。

上述说明同样适用于 Zca 和 Zcb：前者是 C 非浮点子集的别名，后者为 I、M 和 Zbb 扩展中的若干常用指令添加了 16 位别名。每条 Zcmp 指令均扩展为来自 Iextension 的一系列多条指令。

[\(Return to index\)](#)

### 3.8.1.15. Zba: bit manipulation (address generation)

These instructions accelerate address generation for arrays of 2, 4 and 8-byte elements. They can also multiply by constant values 3, 5 and 9 if that is more your style.

#### sh1add

Add, with the first addend shifted left by 1.

Usage:

```
sh1add rd, rs1, rs2
```

Operation:

```
rd <= (rs1 << 1) + rs2;
```

#### sh2add

Add, with the first addend shifted left by 2.

Usage:

```
sh2add rd, rs1, rs2
```

Operation:

```
rd <= (rs1 << 2) + rs2;
```

#### sh3add

Add, with the first addend shifted left by 3.

Usage:

```
sh3add rd, rs1, rs2
```

Operation:

```
rd <= (rs1 << 3) + rs2;
```

### 3.8.1.16. Zbb: bit manipulation (basic)

These instructions are useful for bitfield manipulation, and complex integer arithmetic, such as in soft floating point routines. Many of them substitute directly for common pairs of RV32I instructions, like `zext.h → sll, srl`.

[\(返回索引\)](#)

### 3.8.1.15. Zba：位操作（地址生成）

这些指令用于加速2、4及8字节元素数组的地址生成。若更符合您的需求，也可通过常数3、5及9进行乘法运算。

#### 带1加法

加法操作，第一加数左移1位。

用法：

```
sh1add rd, rs1, rs2
```

操作：

```
rd <= (rs1 << 1) + rs2;
```

#### 带2加法

加法操作，第一加数左移2位。

用法：

```
sh2add rd, rs1, rs2
```

操作：

```
rd <= (rs1 << 2) + rs2;
```

#### 带3加法

加法操作，第一加数左移3位。

用法：

```
sh3add rd, rs1, rs2
```

操作：

```
rd <= (rs1 << 3) + rs2;
```

### 3.8.1.16. Zbb：位操作（基础）

这些指令适用于位域操作及复杂整数算术运算，如软浮点例程中的操作。其中许多指令直接替代常见的RV32I指令对，如 `ext.h → sll, srl`。

**andn**

Bitwise AND with inverted second operand.

Usage:

```
andn rd, rs1, rs2
```

Operation:

```
rd <= rs1 & ~rs2;
```

**clz**

Count leading zeroes (starting from MSB, searching LSB-ward).

Usage:

```
clz rd, rs1
```

Operation:

```
rd <= 32; // Default = 32 if no set bits
reg found = 1'b0; // Local variable

for (i = 0; i < 32; i = i + 1) begin
 if (rs1[31 - i] && !found) begin
 found = 1'b1;
 rd <= i;
 end
end
```

**cpop**

Population count.

Usage:

```
cpop rd, rs1
```

Operation:

```
reg [5:0] sum = 6'd0; // Local variable
for (i = 0; i < 32; i = i + 1)
 sum = sum + rs1[i];
rd <= sum;
```

**ctz**

Count trailing zeroes (starting from LSB, searching MSB-ward).

**andn**

与第二操作数取反后的按位与操作。

用法：

```
andn rd, rs1, rs2
```

操作：

```
rd <= rs1 & ~rs2;
```

**clz**

计算前导零（从最高有效位开始，向最低有效位方向搜索）。

用法：

```
clz rd, rs1
```

操作：

```
rd <= 32; // 默认值=32, 若无任何置位
reg found = 1'b0; // 局部变量

for (i = 0; i < 32; i = i + 1) begin
 if (rs1[31 - i] && !found) begin
 found = 1'b1;
 rd <= i;
 end
end
```

**cpop**

位计数。

用法：

```
cpop rd, rs1
```

操作：

```
reg [5:0] sum = 6'd0; // 局部变量
for (i = 0; i < 32; i = i + 1)
 sum = sum + rs1[i];
rd <= sum;
```

**ctz**

计算尾随零（从最低有效位开始，向最高有效位方向搜索）。

Usage:

```
ctz rd, rs1
```

Operation:

```
rd <= 32; // Default = 32 if no set bits
reg found = 1'b0; // Local variable

for (i = 0; i < 32; i = i + 1) begin
 if (rs1[i] && !found) begin
 found = 1'b1;
 rd <= i;
 end
end
```

**max**

Maximum of two values (signed).

Usage:

```
max rd, rs1, rs2
```

Operation:

```
if ($signed(rs1) < $signed(rs2))
 rd <= rs2;
else
 rd <= rs1;
```

**maxu**

Maximum of two values (unsigned).

Usage:

```
maxu rd, rs1, rs2
```

Operation:

```
if (rs1 < rs2)
 rd <= rs2;
else
 rd <= rs1;
```

**min**

Minimum of two values (signed).

用法：

```
ctz rd, rs1
```

操作：

```
rd <= 32; // 默认值=32, 若无任何置位
reg found = 1'b0; // 局部变量

for (i = 0; i < 32; i = i + 1) begin
 if (rs1[i] && !found) begin
 found = 1'b1;
 rd <= i;
 end
end
```

**max**

两个数的最大值（有符号）。

用法：

```
max rd, rs1, rs2
```

操作：

```
if ($signed(rs1) < $signed(rs2))
 rd <= rs2;
else
 rd <= rs1;
```

**maxu**

两个数的最大值（无符号）。

用法：

```
maxu rd, rs1, rs2
```

操作：

```
if (rs1 < rs2)
 rd <= rs2;
else
 rd <= rs1;
```

**min**

两个数的最小值（有符号）。

Usage:

```
min rd, rs1, rs2
```

Operation:

```
if ($signed(rs1) < $signed(rs2))
 rd <= rs1;
else
 rd <= rs2;
```

#### **minu**

Minimum of two values (unsigned).

Usage:

```
minu rd, rs1, rs2
```

Operation:

```
if (rs1 < rs2)
 rd <= rs1;
else
 rd <= rs2;
```

#### **orc.b**

OR-combine of bits within each byte. Generates a mask of nonzero bytes.

Usage:

```
orc.b rd, rs1
```

Operation:

```
rd <= {
 {8{|rs1[31:24]}},
 {8{|rs1[23:16]}},
 {8{|rs1[15:8]}},
 {8{|rs1[7:0]}}
};
```

#### **orn**

Bitwise OR with inverted second operand.

Usage:

用法：

```
min rd, rs1, rs2
```

操作：

```
if ($signed(rs1) < $signed(rs2))
 rd <= rs1;
else
 rd <= rs2;
```

#### **minu**

两个数的最小值（无符号）。

用法：

```
minu rd, rs1, rs2
```

操作：

```
if (rs1 < rs2)
 rd <= rs1;
else
 rd <= rs2;
```

#### **orc.b**

对每个字节内的位进行按位或组合。生成非零字节掩码。

用法：

```
orc.b rd, rs1
```

操作：

```
rd <= {
 {8{|rs1[31:24]}},
 {8{|rs1[23:16]}},
 {8{|rs1[15:8]}},
 {8{|rs1[7:0]}}
};
```

#### **orn**

与第二操作数取反后的按位或运算。

用法：

```
orn rd, rs1, rs2
```

Operation:

```
rd <= rs1 | ~rs2;
```

#### **rev8**

Reverse bytes within word.

Usage:

```
rev8 rd, rs1
```

Operation:

```
rd <= {
 rs1[7:0],
 rs1[15:8],
 rs1[23:16],
 rs1[31:24]
};
```

#### **rol**

Rotate left by register, modulo 32.

Usage:

```
rol rd, rs1, rs2
```

Operation:

```
rd <= ({rs1, rs1} << rs2[4:0]) >> 32;
```

#### **ror**

Rotate right by register, modulo 32.

Usage:

```
ror rd, rs1, rs2
```

Operation:

```
orn rd, rs1, rs2
```

操作：

```
rd <= rs1 | ~rs2;
```

#### **rev8**

字内字节逆序。

用法：

```
rev8 rd, rs1
```

操作：

```
rd <= {
 rs1[7:0],
 rs1[15:8],
 rs1[23:16],
 rs1[31:24]
};
```

#### **循环左移**

按寄存器值左循环移位，模32。

用法：

```
rol rd, rs1, rs2
```

操作：

```
rd <= ({rs1, rs1} << rs2[4:0]) >> 32;
```

#### **循环右移**

按寄存器右旋，模32。

用法：

```
ror rd, rs1, rs2
```

操作：

```
rd <= {rs1, rs1} >> rs2[4:0];
```

**rori**

Rotate right by immediate.

Usage:

```
rori rd, rs1, imm
```

Operation:

```
rd <= {rs1, rs1} >> imm;
```

Immediate range: 0 through 31.

**sext.b**

Sign-extend from byte.

Usage:

```
sext.b rd, rs1
```

Operation:

```
rd <= {
 {24{rs1[7]}},
 rs1[7:0]
};
```

Compressible if: **rd** matches **rs1**, and registers are in **x8 - x15**.

**sext.h**

Sign-extend from halfword.

Usage:

```
sext.h rd, rs1
```

Operation:

```
rd <= {
 {16{rs1[15]}},
 rs1[15:0]
};
```

Compressible if: **rd** matches **rs1**, and registers are in **x8 - x15**.

```
rd <= {rs1, rs1} >> rs2[4:0];
```

**循环右移带进位**

按立即数右旋。

用法：

```
rori rd, rs1, imm
```

操作：

```
rd <= {rs1, rs1} >> imm;
```

立即数范围： 0至 31。

**符号扩展字节**

从字节符号扩展。

用法：

```
sext.b rd, rs1
```

操作：

```
rd <= {
 {24{rs1[7]}},
 rs1[7:0]
};
```

满足以下条件时可压缩： rd与 rs1匹配，且寄存器位于 x8至 x15之间。

**符号扩展半字**

从半字符号扩展。

用法：

```
sext.h rd, rs1
```

操作：

```
rd <= {
 {16{rs1[15]}},
 rs1[15:0]
};
```

满足以下条件时可压缩： rd与 rs1匹配，且寄存器位于 x8至 x15之间。

**xnor**

Bitwise XOR with inverted operand. Equivalently, bitwise NOT of bitwise XOR.

Usage:

```
xnor rd, rs1, rs2
```

Operation:

```
rd <= rs1 ^ ~rs2;
```

**zext.b**

Zero-extend from byte.

Usage:

```
zext.b rd, rs1
```

Operation:

```
rd <= {
 24'h000000,
 rs1[7:0]
};
```

Compressible if: **rd** matches **rs1**, and registers are in **x8 - x15**.

The 32-bit opcode for **zext.b** is a pseudo-instruction for **andi**. However, the compressed variant is a dedicated instruction from **Zcb**. It is not actually a part of **Zbb**, but is documented here for grouping with the other **sext./zext** instructions.

**zext.h**

Zero-extend from halfword.

Usage:

```
zext.h rd, rs1
```

Operation:

```
rd <= {
 16'h0000,
 rs1[15:0]
};
```

Compressible if: **rd** matches **rs1**, and registers are in **x8 - x15**.

**xnor**

与取反操作数的按位异或。等价于按位异或的按位取反。

用法：

```
xnor rd, rs1, rs2
```

操作：

```
rd <= rs1 ^ ~rs2;
```

**zext.b**

从字节零扩展。

用法：

```
zext.b rd, rs1
```

操作：

```
rd <= {
 24'h000000,
 rs1[7:0]
};
```

满足以下条件时可压缩： **rd** 与 **rs1** 匹配，且寄存器位于 **x8** 至 **x15** 之间。

32位操作码 **zext.b** 为andi的伪指令。然而，压缩变体是 **Zcb** 专用指令。它实际上不属于 **Zbb**，但为便于与其他 **sext./ze xt** 指令归类，故此处予以说明。

**zext.h**

从半字节零扩展。

用法：

```
zext.h rd, rs1
```

操作：

```
rd <= {
 16'h0000,
 rs1[15:0]
};
```

满足以下条件时可压缩： **rd** 与 **rs1** 匹配，且寄存器位于 **x8** 至 **x15** 之间。

### 3.8.1.17. Zbs: Bit manipulation (single-bit)

These instructions invert, set and extract single bits in a register.

#### bclr

Clear single bit.

Usage:

```
bclr rd, rs1, rs2
```

Operation:

```
rd <= rs1 & ~(32'h1 << rs2[4:0]);
```

#### bclri

Clear single bit (immediate).

Usage:

```
bclri rd, rs1, imm
```

Operation:

```
rd <= rs1 & ~(32'h1 << imm);
```

Immediate range: 0 through 31.

#### bext

Extract single bit.

Usage:

```
bext rd, rs1, rs2
```

Operation:

```
rd <= (rs1 >> rs2[4:0]) & 32'h1;
```

#### bexti

Extract single bit (immediate).

Usage:

```
bexti rd, rs1, imm
```

### 3.8.1.17. Zbs: 位操作（单个位）

这些指令用于反转、设置、清除及提取寄存器中的单个位。

#### bclr

清除单个位。

用法：

```
bclr rd, rs1, rs2
```

操作：

```
rd <= rs1 & ~(32'h1 << rs2[4:0]);
```

#### bclri

清除单个位（立即数）。

用法：

```
bclri rd, rs1, imm
```

操作：

```
rd <= rs1 & ~(32'h1 << imm);
```

立即数范围： 0至 31。

#### bext

提取单个位。

用法：

```
bext rd, rs1, rs2
```

操作：

```
rd <= (rs1 >> rs2[4:0]) & 32'h1;
```

#### bexti

提取单个位（立即数）。

用法：

```
bexti rd, rs1, imm
```

Operation:

```
rd <= (rs1 >> imm) & 32'h1;
```

Immediate range: 0 through 31.

**binv**

Invert single bit.

Usage:

```
binv rd, rs1, rs2
```

Operation:

```
rd <= rs1 ^ (32'h1 << rs2[4:0]);
```

**binvi**

Invert single bit (immediate).

Usage:

```
binvi rd, rs1, imm
```

Operation:

```
rd <= rs1 ^ (32'h1 << imm);
```

Immediate range: 0 through 31.

**bset**

Set single bit.

Usage:

```
bset rd, rs1, rs2
```

Operation:

```
rd <= rs1 | (32'h1 << rs2[4:0])
```

**bseti**

Set single bit (immediate).

Usage:

操作:

```
rd <= (rs1 >> imm) & 32'h1;
```

立即数范围: 0至 31。

**binv**

反转单个位。

用法:

```
binv rd, rs1, rs2
```

操作:

```
rd <= rs1 ^ (32'h1 << rs2[4:0]);
```

**binvi**

反转单个位 (立即数)。

用法:

```
binvi rd, rs1, imm
```

操作:

```
rd <= rs1 ^ (32'h1 << imm);
```

立即数范围: 0至 31。

**bset**

设置单个位。

用法:

```
bset rd, rs1, rs2
```

操作:

```
rd <= rs1 | (32'h1 << rs2[4:0])
```

**bseti**

设置单个位 (立即数)。

用法:

```
bseti rd, rs1, imm
```

Operation:

```
rd <= rs1 | (32'h1 << imm);
```

Immediate range: 0 through 31.

### 3.8.1.18. Zbkb: basic bit manipulation for cryptography

Zbkb has a large overlap with Zbb (basic bit manipulation). This section covers instructions in Zbkb but not in Zbb.

**brev8**

Bit-reverse within each byte.

Usage:

```
brev8 rd, rs1
```

Operation:

```
for (i = 0; i < 32; i = i + 8) begin
 for (j = 0; j < 8; j = j + 1) begin
 rd[i + j] <= rs1[i + (7 - j)];
 end
end
```

**pack**

Pack two halfwords into one word.

Usage:

```
pack rd, rs1, rs2
```

Operation:

```
rd <= {
 rs2[15:0],
 rs1[15:0]
};
```

**packh**

Pack two bytes into one halfword.

Usage:

```
bseti rd, rs1, imm
```

操作：

```
rd <= rs1 | (32'h1 << imm);
```

立即数范围： 0 至 31。

### 3.8.1.18. Zbkb：用于密码学的基本位操作

Zbkb 与 Zbb（基本位操作）有较大重叠。本节涵盖 Zbkb 中的指令，但不包括 Zbb 中的指令。

**brev8**

在每个字节内进行位反转操作。

用法：

```
brev8 rd, rs1
```

操作：

```
for (i = 0; i < 32; i = i + 8) begin
 for (j = 0; j < 8; j = j + 1) begin
 rd[i + j] <= rs1[i + (7 - j)];
 end
end
```

**pack**

将两个半字合并为一个字。

用法：

```
pack rd, rs1, rs2
```

操作：

```
rd <= {
 rs2[15:0],
 rs1[15:0]
};
```

**打包高**

将两个字节合并为一个半字。

用法：

```
packh rd, rs1, rs2
```

Operation:

```
rd <= {
 16'h0000,
 rs2[7:0],
 rs1[7:0]
};
```

#### **unzip**

Deinterleave odd/even bits of register into upper/lower half of result.

Usage:

```
unzip rd, rs1
```

Operation:

```
for (i = 0; i < 32; i = i + 2) begin
 rd[i / 2] <= rs1[i];
 rd[i / 2 + 16] <= rs1[i + 1];
end
```

#### **zip**

Interleave upper/lower half of register into odd/even bits of result.

Usage:

```
zip rd, rs1
```

Operation:

```
for (i = 0; i < 32; i = i + 2) begin
 rd[i] <= rs1[i / 2];
 rd[i + 1] <= rs1[i / 2 + 16];
end
```

### 3.8.1.19. Zcb: Additional basic compressed instructions

Zcb adds 16-bit compressed aliases for the following instructions from the I, M and Zbb extensions:

| Alphabetical order: left-to-right, then top-to-bottom. |    |     |     |     |    |
|--------------------------------------------------------|----|-----|-----|-----|----|
| lbu                                                    | lh | lhu | mul | not | sb |

```
packh rd, rs1, rs2
```

操作：

```
rd <= {
 16'h0000,
 rs2[7:0],
 rs1[7:0]
};
```

### 解压

将寄存器中的奇偶位解交织至结果的上下半部分。

用法：

```
unzip rd, rs1
```

操作：

```
for (i = 0; i < 32; i = i + 2) begin
 rd[i / 2] <= rs1[i];
 rd[i / 2 + 16] <= rs1[i + 1];
end
```

### zip

将寄存器的上下半部分交织为结果的奇偶位。

用法：

```
zip rd, rs1
```

操作：

```
for (i = 0; i < 32; i = i + 2) begin
 rd[i] <= rs1[i / 2];
 rd[i + 1] <= rs1[i / 2 + 16];
end
```

### 3.8.1.19. Zcb：新增基础压缩指令

Zcb为来自 I、M 和 Zbb 扩展的以下指令新增了16位压缩别名：

| 字母顺序：先从左到右，后从上到下。 |    |     |     |     |     |
|-------------------|----|-----|-----|-----|-----|
| lbu               | lh | lhu | mul | not | 设置位 |

|                                                        |        |    |        |        |
|--------------------------------------------------------|--------|----|--------|--------|
| Alphabetical order: left-to-right, then top-to-bottom. |        |    |        |        |
| sext.b                                                 | sext.h | sh | zext.b | zext.h |
|                                                        |        |    |        |        |

See per-instruction documentation for the compressibility limitations for each instruction.

[\(Return to index\)](#)

### 3.8.1.20. Zcmp: Compressed push, pop, and double move

**Zcmp** adds 16-bit instructions which expand to common sequences of 32-bit RV32I instructions used in function prologues and epilogues. The following is a rough description of the available instructions:

- **cm.push**: allocates a stack frame and saves registers.
  - Push **ra** onto the stack.
  - Optionally push a number of the **s0** through **s11** saved registers, consecutively up from **s0**.
  - Round the total stack decrement to a multiple of 16 bytes, to maintain stack alignment if already aligned.
  - Decrement the stack pointer by up to 48 additional bytes, in multiples of 16 bytes, to allocate additional frame space.
  - There are twelve **s\*** registers, and you can push any number of them except for eleven. If you need to push more than ten **s\*** registers, push twelve.
- **cm.pop**: reverse of **cm.push**. Deallocation a stack frame and restores **ra**, optionally **s0** through **s11**.
- **cm.popret**: equivalent to **cm.pop** followed by **ret**. Deallocation a stack frame, restores saved registers, and returns.
- **cm.popretz**: equivalent to **cm.pop; li a0, 0; ret**. It is common for functions to return a constant **0**.
- **cm.mvsa01**: move **a0** and **a1** into any two registers in the range **s0** through **s7**. Used to save arguments over embedded calls.
- **cm.mva01s**: move into **a0** and **a1**, from any two registers in **s0** through **s7**. Used to restore saved arguments.

See [Section 3.8.1.1](#) for a link to the **Zcmp** specification which covers key details such as stack layout and atomicity with respect to interrupts. See [Section 3.8.7](#) for cycle counts for these instructions on Hazard3.

[\(Return to index\)](#)

### 3.8.1.21. RV32I and Zifencei: Memory ordering instructions

These instructions control observed memory ordering of loads and stores in multi-hart systems. They also enforce when a hart's instruction fetch observes its own stores.

#### fence

Constrain the position of this hart's accesses in the total memory order, according to this hart's program order.

Usage:

```
// <set> is a nonempty string which matches the regex i?o?r?w?
fence <set>, <set> // predecessor, successor
fence // pseudo: fence iorw, iorw
fence.tso // variant of fence rw, rw; see below
```

Operation: Hazard3 has no store buffer, and assumes the memory subsystem is sequentially consistent. Therefore no additional book-keeping is required to enforce ordering on shared memory, and this instruction executes as a no-op. (The SDK still uses **fence** instructions, and the ordered variants of **amo\*.w**, for portability across platforms which

**字母顺序：先从左到右，后从上到下。**

请参阅各指令文档，了解每条指令的可压缩性限制。

(返回索引)

### 3.8.1.20. Zcmp: 压缩的推送、弹出和双重移动

Zcmp增加了16位指令，这些指令可扩展为用于函数序言和尾声的常见32位RV32I指令序列。以下是可用指令的简要描述：

- `cm.push`: 分配栈帧并保存寄存器。
    - 将 `ra` 推入栈中。
    - 可选择依次从 `s0` 到 `s11` 推入多个保存寄存器，顺序从 `s0` 开始。
    - 将栈指针的总减少量四舍五入至16字节的整数倍，以在已对齐时保持栈对齐。
    - 将栈指针额外递减最多48字节，按16字节倍数递减，以分配附加的栈帧空间。
  - 共有十二个 `s*` 寄存器，您可以推入任意数量，唯独不能推入寄存器11。若需推入超过十个`s*`寄存器，则必须推入十二个。
  - `cm.pop`: `cm.push`的逆操作。释放栈帧并恢复 `ra`，可选地恢复 `s0` 到 `s11` 寄存器。
  - `cm.popret`: 等同于先执行 `cm.pop`，然后执行 `ret`。释放栈帧，恢复被保存的寄存器，并返回。
  - `cm.popretz`: 等同于执行`cm.pop; li a0, 0; ret`。函数通常返回常量 `0`。
  - `cm.mvsa01`: 将 `a0` 和 `a1` 移动到 `s0` 到 `s7` 范围内的任意两个寄存器。用于在嵌入式调用过程中保存参数。
  - `cm.mva01s`: 将 `s0` 到 `s7` 范围内任意两个寄存器的值移动到 `a0` 和 `a1`。用于恢复已保存的参数。

有关堆栈布局以及中断相关的原子性等关键细节，请参见第3.8.1.1节中有关 [Zcmp](#) 规范的链接。有关 Hazard3 处理器中这些指令的周期计数，请参见第3.8.7节。

(返回索引)

### 3.8.1.21. RV32I 与 Zifencei：内存排序指令

这些指令控制多核系统中负载与存储操作的可观测内存顺序。它们还强制保证某核的指令取指能够观察到其自身的存储。

fence

根据该核的程序顺序，限制该核访问在整个内存顺序中的位置。

用法：

```
// <set> 为匹配正则表达式 i?o?r?w? 的非空字符串
fence <set>, <set> // 前驱, 后继
fence // 伪代码: fence iorw, iorw
fence.tso // fence rw, rw 的变体; 详见下文
```

操作：Hazard3 无存储缓冲区，并假定内存子系统为顺序一致。因此，无需额外记录管理以保证共享内存的顺序，该指令作为无操作执行。（SDK 仍使用 fence 指令及其有序变体 amo\*<sub>w</sub>，以保证跨平台的兼容性）

take advantage of relaxed memory ordering.)

Nominally a `fence` enforces that the **predecessor** set appears before the **successor** set in the total memory order. These sets respectively contain the hart's memory accesses before and after the `fence` instruction in program order, and are further filtered by a 4-bit mask each:

- Device input (I)
- Device output (O)
- Read (R)
- Write (W)

The `fence.tso` (total store order) variant is equivalent to `fence rw, rw` except that it does not enforce write-before-read ordering.

#### `fence.i`

Instruction fence. Ensure subsequent instruction fetches on this hart observe this hart's previous stores.

Usage:

```
fence.i
```

Operation:

1. Clear the branch target buffer ([Section 3.8.7.10](#))
2. Jump to the instruction at the sequentially-next address (`pc + 4`), to clear the prefetch buffer.

The prefetch buffer can reorder instruction fetch against stores which are earlier in program order. For example:

```
la a0, label // get address for store instruction
li a1, 0x9002 // get immediate value of c.ebreak
div t1, t1, t1 // long-running instruction, fills prefetch buffer
sh a1, (a0) // write to next address. (16-bit opcode)
label:
nop // (16-bit opcode)
```

If you execute the above code on Hazard3, you may or may not get a breakpoint exception at `label`. The outcome depends on how many cycles the bus accesses take. This is permitted by the RISC-V memory model.

This case is generally only reachable on fall-through, because Hazard3 does not prefetch through control flow instructions except for the taken backward conditional branch currently allocated in the branch target buffer. In particular it does not prefetch through indirect branches like `ret`. You are unlikely to hit this issue in practice; however, be aware `fence.i` is the standard mechanism for solving this class of problem.

Hazard3 behaves unpredictably if you write to the address of a conditional branch instruction that is currently tagged in the branch target buffer, and then execute that conditional branch instruction without first executing a `fence.i`. Avoid this by always executing a `fence.i` between writing to memory and executing that same memory.

### 3.8.1.22. Zicsr: Control and status register access

These instructions access the control and status registers (CSRs) listed in [Section 3.8.9](#). A CSR instruction may read a CSR, modify a CSR, or simultaneously read and modify the same CSR. A modification consists of a normal write, an atomic bit-clear, or an atomic bit-set.

CSR addresses are in the range `0x000` through `0xffff` (12 bits, 4096 possible CSRs). The CSR address is an immediate constant in the instruction, so you cannot index CSRs with runtime values. The assembler accepts numeric constants or

利用放宽的内存排序。

名义上，`fence`屏障强制要求前驱集合在整体内存顺序中出现在后继集合之前。这些集合分别包含该hart在程序顺序中`fence`指令之前和之后的内存访问，并各自通过4位掩码进一步过滤：

- 设备输入 (I)
- 设备输出 (O)
- 读取 (R)
- 写入 (W)

`fence.tso`（总存储顺序）变体等同于`fence rw, rw`，只是不强制写前于读的顺序。

#### `fence.i`

指令屏障。确保该hart上随后的指令取指能观察到该hart先前的存储操作。

用法：

```
fence.i
```

操作：

1. 清除分支目标缓冲区（第3.8.7.10节）
2. 跳转至顺序下一条指令地址（`pc + 4`），以清除预取缓冲区。

预取缓冲区可能会使指令取指操作与程序顺序更早的存储操作重排序。例如：

```
la a0, label // 获取存储指令的地址
li a1, 0x9002 // 获取 c.ebreak 的立即数值
div t1, t1, t1 // 长时间执行的指令，填充预取缓冲区
sh a1, (a0) // 写入下一个地址。（16位操作码）
label:
nop // （16位操作码）
```

如果您在 Hazard3 上执行上述代码，可能会在 `label` 处产生断点异常，也可能不会。结果取决于总线访问所需的周期数。此行为符合 RISC-V 内存模型的规定。

此情况通常仅在顺序执行时才会发生，因为 Hazard3 不会通过控制流指令进行预取，除非是分支目标缓冲区中当前分配的向后条件分支。特别是，它不会通过类似 `ret` 的间接分支进行预取。您在实际中不大可能遇到此问题；

但请注意，`fence.i` 是解决此类问题的标准方法。

如果您写入当前在分支目标缓冲区标记的条件分支指令地址，并且未先执行`fence.i`便执行该条件分支指令，Hazard3 的行为将无法预测。请通过始终在写入内存与执行该内存之间执行`fence.i`指令以避免此类问题。

### 3.8.1.22. Zicsr：控制及状态寄存器访问

这些指令访问第3.8.9节所列控制与状态寄存器（CSR）。CSR指令可用于读取CSR、修改CSR，或同时读取并修改同一CSR。修改包括普通写入、原子位清除或原子位设置。

CSR地址范围为 `0x000` 至 `0xffff`（12位，共4096个可能的CSR）。CSR地址为指令中的立即数，故无法使用运行时值进行索引。汇编器接受数字常量或

CSR names such as `mstatus` as CSR addresses.

#### `csrrc`

Simultaneously read and clear bits in a CSR.

Usage:

```
csrrc rd, <addr>, rs1
csrc <addr>, rs1 // pseudo: rd is zero
```

Operation:

```
rd <= csr[addr];
if (regnum_rs1 != 5'h00)
 csr[addr] <= csr[addr] & ~rs1;
```

#### `csrrci`

Simultaneously read and clear bits in a CSR, with an immediate value for the clear.

Usage:

```
csrrci rd, <addr>, imm
csrci <addr>, imm // pseudo: rd is zero
```

Operation:

```
rd <= csr[addr];
if (imm != 32'h0)
 csr[addr] <= csr[addr] & ~imm;
```

Immediate range: `0` through `31`.

#### `csrrs`

Simultaneously read and set bits in a CSR.

Usage:

```
csrrs rd, <addr>, rs1
csrs <addr>, rs1 // pseudo: rd is zero
csrr rd, <addr> // pseudo: rs1 is zero
```

Operation:

```
rd <= csr[addr];
if (regnum_rs1 != 5'h00)
 csr[addr] <= csr[addr] | rs1;
```

诸如 `mstatus` 的CSR名称作为CSR地址。

#### `csrrc`

同时读取并清除CSR中的位。

用法：

```
csrrc rd, <addr>, rs1
csrc <addr>, rs1 // 伪指令：rd 为零
```

操作：

```
rd <= csr[addr];
if (regnum_rs1 != 5'h00)
 csr[addr] <= csr[addr] & ~rs1;
```

#### `csrrci`

同时读取并清除CSR中的位，清除操作使用立即数。

用法：

```
csrrci rd, <addr>, imm
csrci <addr>, imm // 伪指令：rd 为零
```

操作：

```
rd <= csr[addr];
if (imm != 32'h0)
 csr[addr] <= csr[addr] & ~imm;
```

立即数范围： 0 至 31。

#### `csrrs`

同时读取并设置CSR中的位。

用法：

```
csrrs rd, <addr>, rs1
csrs <addr>, rs1 // 伪指令：rd 为零
csrr rd, <addr> // 伪代码：rs1为零
```

操作：

```
rd <= csr[addr];
if (regnum_rs1 != 5'h00)
 csr[addr] <= csr[addr] | rs1;
```

**csrrsi**

Simultaneously read and set bits in a CSR, with an immediate value for the set.

Usage:

```
csrrsi rd, <addr>, imm
csrsi <addr>, imm // pseudo: rd is zero
```

Operation:

```
rd <= csr[addr];
if (imm != 32'h0)
 csr[addr] <= csr[addr] | imm;
```

Immediate range: 0 through 31.

**csrrw**

Simultaneously read and write a CSR.

Usage:

```
csrrw rd, <addr>, rs1
csrw <addr>, rs1 // pseudo: rd is zero
```

Operation:

```
if (regnum_rd != 5'h00)
 rd <= csr[addr];
 csr[addr] <= rs1;
```

**csrrwi**

Simultaneously read and write a CSR, with an immediate value for the write.

Usage:

```
csrrwi rd, <addr>, imm
csrwi <addr>, imm // pseudo: rd is zero
```

Operation:

```
if (regnum_rd != 5'h00)
 rd <= csr[addr];
 csr[addr] <= imm;
```

Immediate range: 0 through 31.

**csrrsi**

同时读取并设置CSR中的位，设置操作使用立即数。

用法：

```
csrrsi rd, <addr>, imm
csrsi <addr>, imm // 伪指令：rd 为零
```

操作：

```
rd <= csr[addr];
if (imm != 32'h0)
 csr[addr] <= csr[addr] | imm;
```

立即数范围： 0 至 31。

**csrrw**

同时读取并写入CSR。

用法：

```
csrrw rd, <addr>, rs1
csrw <addr>, rs1 // 伪指令：rd 为零
```

操作：

```
if (regnum_rd != 5'h00)
 rd <= csr[addr];
csr[addr] <= rs1;
```

**csrrwi**

同时读取并写入CSR，写入时使用立即数。

用法：

```
csrrwi rd, <addr>, imm
csrwi <addr>, imm // 伪指令：rd 为零
```

操作：

```
if (regnum_rd != 5'h00)
 rd <= csr[addr];
csr[addr] <= imm;
```

立即数范围： 0 至 31。

### 3.8.1.23. Privileged instructions

These instructions are part of the trap and interrupt control support defined in the privileged ISA manual. The other part of this support is the CSRs ([Section 3.8.9](#)).

#### **ebreak**

Raise a breakpoint exception.

Usage:

```
ebreak
```

Operation:

```
raise_exception(4'h3); // Cause = ebreak
```

Compressible if: always.

Privilege requirements: any privilege level.

See [Section 3.8.4](#) for details of the RISC-V trap entry sequence. All exceptions trap into M-mode on Hazard3. The exception program counter `mepc` points to the start of the `ebreak` instruction.

An external debug host can catch the execution of breakpoint instructions. If the core is in M-mode, and `DCSR.EBREAKM` is set, the core enters Debug mode instead of taking the exception. In U-mode, `DCSR.EBREAKU` enables the same behaviour.

#### **ecall**

Environment call. Raise an exception to access a handler at a higher privilege level.

Usage:

```
ecall
```

Operation:

```
if (priv == 2'h3)
 raise_exception(4'hb); // Cause: Environment call from M-mode
else
 raise_exception(4'h8); // Cause: Environment call from U-mode
```

Privilege requirements: any privilege level.

See [Section 3.8.4](#) for details of the RISC-V trap entry sequence. All exceptions trap into M-mode on Hazard3. The exception program counter `mepc` points to the start of the `ecall` instruction.

#### **mret**

Return from M-mode trap.

Usage:

```
mret
```

### 3.8.1.23. 特权指令

这些指令属于特权ISA手册中定义的陷阱与中断控制支持。该支持的另一部分为CSR（参见第3.8.9节）。

#### **ebreak**

引发断点异常。

用法：

```
ebreak
```

操作：

```
raise_exception(4'h3); // Cause = ebreak
```

可压缩条件：始终可压缩。

特权级别要求：任意等级。

有关RISC-V陷阱入口序列的详细说明，参见第3.8.4节。所有异常均在Hazard3的M态下陷阱处理。异常程序计数器 **me\_pc** 指向 **ebreak** 指令的起始地址。

外部调试主机可以捕获断点指令的执行。如果内核处于M模式且DCSR.EBREAKM已设置，内核将进入调试模式，而非触发异常。在U模式下，DCSR.EBREAKU启用相同的行为。

#### **ecall**

环境调用。引发异常以访问更高特权级的处理程序。

用法：

```
ecall
```

操作：

```
if (priv == 2'h3)
 raise_exception(4'hb); // 原因：来自M模式的环境调用，否则

 raise_exception(4'h8); // 原因：来自U模式的环境调用
```

特权级别要求：任意等级。

有关RISC-V陷阱入口序列的详细说明，参见第3.8.4节。所有异常均在Hazard3中陷入M模式。异常程序计数器 **me\_pc** 指向 **ecall** 指令的起始位置。

#### **mret**

从M模式陷阱返回。

用法：

```
mret
```

Operation: execute the trap return sequence described in [Section 3.8.4](#).

Privilege requirements: M-mode only.

**wfi**

Wait for interrupt.

Usage:

```
wfi
```

Operation: pause execution until the processor is interrupted, or enters Debug mode.

Privilege requirements: M-mode is always permitted. U-mode is permitted if [MSTATUS.TW](#) is clear.

**wfi** ignores the global interrupt enable, [MSTATUS.MIE](#). It respects all other interrupt controls. For example:

- If [MIP.MEIP](#) is 1, [MIE.MEIE](#) is 1, and [MSTATUS.MIE](#) is 0, a **wfi** instruction falls through immediately without pausing.
- In this example, setting [MSTATUS.MIE](#) to 1 would cause the core to immediately take the interrupt.
- If no bit is set in both [MIP](#) and [MIE](#), the **wfi** stalls until there is at least one such bit.

When a **wfi** is interrupted, the exception return address [MEPC](#) points to the instruction following the **wfi**.

When the debugger halts the core during a **wfi**, [DPC](#) points to the instruction immediately following the **wfi** instruction. **wfi** executes as a no-op under instruction single-stepping (it does not stall), and under Debug-mode execution in the Program Buffer.

Hazard3's [MSLEEP](#) CSR controls additional power-saving measures the core can implement during a **wfi** sleep state.

### 3.8.2. Memory access

Hazard3 accesses memory within a 4 GB ( $2^{32}$  bytes) physical address space. There is no address translation. Each possible value of an integer register uniquely identifies a single byte in the physical address space. Multi-byte values occupy consecutive byte addresses.

#### 3.8.2.1. Endianness

Hazard3 is always little-endian for all load and store accesses. RISC-V instruction fetch is always little-endian.

This means in a multi-byte access such as a **sw** instruction (four bytes are transferred), data stored at higher byte addresses has greater numerical significance. For example:

```
li a0, 0x0d0c0b0a // materialise constant in register
la a4, some_global_variable // materialise address (assume addr % 4 == 0)
sw a0, (a4) // 4-byte write to memory
lbu a0, 0(a4) // load byte from addr + 0: 0xa
lbu a1, 1(a4) // load byte from addr + 1: 0xb
lbu a2, 2(a4) // load byte from addr + 2: 0xc
lbu a3, 3(a4) // load byte from addr + 3: 0xd
```

操作：执行第3.8.4节中描述的陷阱返回序列。

特权要求：仅限M模式。

wfi

等待中断。

用法：

```
wfi
```

操作：暂停执行，直到处理器被中断或进入调试模式。

特权要求：始终允许M模式。当 MSTATUS.TW 清零时，允许进入用户模式。

wfi 指令会忽略全局中断使能标志 MSTATUS.MIE，但会遵循所有其他中断控制。例如：

- 若 MIP.MEIP 为 1，MIE.MEIE 为 1，且 MSTATUS.MIE 为 0，则 wfi 指令会立即执行下去，无需暂停。
- 在此示例中，将 MSTATUS.MIE 设为 1 将使核心立即响应中断。
- 当 MIP 和 MIE 中均无置位标志时，wfi 指令会等待，直到至少有一个置位标志出现。

当 wfi 指令被中断时，异常返回地址 MEPC 指向紧跟该 wfi 指令之后的下一条指令。

当调试器在 wfi 指令执行期间暂停核心时，DPC 指向紧跟该 wfi 指令之后的下一条指令。wfi 在单步指令执行模式下作为空操作执行（不会引起暂停），且在程序缓冲区的调试模式下亦是如此。

Hazard3 的 MSLEEP CSR 控制核心在 wfi 睡眠状态下可执行的额外省电措施。

### 3.8.2. 内存访问

Hazard3 访问位于 4 GB (2<sup>32</sup>字节) 物理地址空间内的内存。不存在地址转换。整型寄存器的每个可能值唯一标识物理地址空间中的一个字节。多字节数据占据连续的字节地址。

#### 3.8.2.1. 字节序

Hazard3 对所有加载与存储访问始终采用小端字节序。RISC-V 指令获取始终采用小端字节序。

这意味着在如 sw 指令（传输四个字节）等多字节访问中，存储于较高字节地址的数据具有更大数值权重。例如：

```
li a0, 0x0d0c0b0a // 在寄存器中生成常数
la a4, some_global_variable // 生成地址（假设地址 % 4 == 0）
sw a0, (a4) // 对内存进行4字节写入
lbu a0, 0(a4) // 从地址偏移0加载字节: 0x0a
lbu a1, 1(a4) // 从地址偏移1加载字节: 0x0b
lbu a2, 2(a4) // 从地址偏移2加载字节: 0x0c
lbu a3, 3(a4) // 从地址偏移3加载字节: 0x0d
```

### 3.8.2.2. Physical memory attributes

The RP2350 address space has the following physical memory attributes:

Table 366. List of physical memory attributes for the RP2350 address space. Main SRAM supports all atomics, other addresses support none. Peripherals are non-idempotent, all other addresses are idempotent.

| Start      | End        | Description                  | Access                        | Atomicity                      | Idempotency    |
|------------|------------|------------------------------|-------------------------------|--------------------------------|----------------|
| 0x00000000 | 0x00007fff | Boot ROM                     | No AMOs                       | RsrvNone, AMONone              | Idempotent     |
| 0x10000000 | 0x13fffff  | XIP, Cached                  | No AMOs                       | RsrvNone, AMONone              | Idempotent     |
| 0x14000000 | 0x17fffff  | XIP, Uncached                | No AMOs                       | RsrvNone, AMONone              | Idempotent     |
| 0x18000000 | 0x1bfffff  | XIP, Cache Maintenance       | Write-only                    | RsrvNone, AMONone              | Idempotent     |
| 0x1c000000 | 0x1fffffff | XIP, Uncached + Untranslated | No AMOs                       | RsrvNone, AMONone              | Idempotent     |
| 0x20000000 | 0x20081fff | Main SRAM                    | Any                           | RsrvNonEventual, AMOArithmetic | Idempotent     |
| 0x40000000 | 0x4fffffff | APB Peripherals              | No AMOs, no instruction fetch | RsrvNone, AMONone              | Non-idempotent |
| 0x50000000 | 0x5fffffff | AHB Peripherals              | No AMOs, no instruction fetch | RsrvNone, AMONone              | Non-idempotent |
| 0xd0000000 | 0xdfffffff | SIO Peripherals              | No AMOs, no instruction fetch | RsrvNone, AMONone              | Non-idempotent |

All addresses have Strong ordering. Any address not listed in [Table 366](#) is a Vacant address. Accessing these addresses has no effect other than returning a bus fault.

Hazard3's PMP implementation requires that non-read-idempotent PMAs are also non-executable, because it enforces execute permissions at the point an instruction is executed, rather than the point an instruction is fetched. Therefore all non-idempotent locations in [Table 366](#) are also non-executable. This is enforced at a lower level than the PMP, and executing these addresses at any privilege level will always fault.

Cached XIP regions are not cacheable from a PMA point of view, because the cache is private to the memory controller. Each system address is served by either a single cache controller or none, so coherence between harts is irrelevant. You might have to perform manual cache maintenance following some operations like flash programming, but this is a detail of the XIP subsystem, not the system-level memory model.

For definitions of these attributes, see section 3.6 of the RISC-V privileged ISA manual linked in [Section 3.8.1.1](#).

### 3.8.3. Memory protection

Hazard3 implements Physical Memory Protection (PMP). It does not implement the Sv32 virtual memory extension or its associated protections.

The PMP defines permissions for physical addresses. It mostly protects M-mode memory from S-mode and U-mode access. Hazard3 only implements M-mode and U-mode.

A PMP **region** applies read, write and execute permissions to a span of byte addresses. For each region there is one address register, [PMPADDR0](#) through [PMPADDR15](#), and an 8-bit configuration field packed into [PMPCFG0](#) through [PMPCFG3](#). The read, write and execute permissions are always enforced for U-mode. They may also be enforced for M-mode, depending on the [PMPCFG L](#) bit for that region, and the [PMPCFGM0](#) register.

RP2350 configures Hazard3's PMP hardware with the following features:

### 3.8.2.2 物理存储器属性

RP2350地址空间具有以下物理存储器属性：

表366 RP2350地址空间物理存储器属性列表  
主SRAM支持所有原子操作，其他地址不支持。

外设为非幂等，其他所有地址均为幂等。

| 起始         | 结束         | 描述           | 访问权限        | 原子性                            | 幂等性 |
|------------|------------|--------------|-------------|--------------------------------|-----|
| 0x00000000 | 0x00007fff | 启动只读存储器      | 无AMO        | RsrvNone, AMONone              | 幂等  |
| 0x10000000 | 0x13fffff  | XIP, 缓存      | 无AMO        | RsrvNone, AMONone              | 幂等  |
| 0x14000000 | 0x17fffff  | XIP, 非缓存     | 无AMO        | RsrvNone, AMONone              | 幂等  |
| 0x18000000 | 0x1bfffff  | XIP, 缓存维护    | 仅写          | RsrvNone, AMONone              | 幂等  |
| 0x1c000000 | 0x1fffffff | XIP, 非缓存+未翻译 | 无AMO        | RsrvNone, AMONone              | 幂等  |
| 0x20000000 | 0x20081fff | 主SRAM        | 任意          | RsrvNonEventual, AMOArithmetic | 幂等  |
| 0x40000000 | 0x4fffffff | APB 外设       | 无AMO, 无指令获取 | RsrvNone, AMONone              | 非幂等 |
| 0x50000000 | 0x5fffffff | AHB 外设       | 无AMO, 无指令获取 | RsrvNone, AMONone              | 非幂等 |
| 0xd0000000 | 0xdfffffff | SIO 外设       | 无AMO, 无指令获取 | RsrvNone, AMONone              | 非幂等 |

所有地址均具有强序性。表 366 中未列出的任何地址均为空闲地址。访问这些地址除返回总线错误外，不产生任何其他效果。

Hazard3 的 PMP 实现要求非只读幂等的 PMA 也必须为不可执行，因为其执行权限在指令执行点而非指令获取点强制执行。因此，表 366 中所有非幂等的位置均为不可执行。此要求在低于 PMP 级别实现，任何特权级别执行这些地址均必然产生异常。

从 PMA 角度看，缓存的 XIP 区域不可缓存，因为该缓存为内存控制器私有。

每个系统地址由单一缓存控制器服务或无服务，因此各核间一致性无关紧要。在执行诸如闪存编程之类的操作后，您可能需要进行手动缓存维护，但这是 XIP 子系统的细节，而非系统级内存模型的内容。

有关这些属性的定义，请参见第3.8.1.1节所链接的RISC-V特权ISA手册第3.6节。

### 3.8.3. 内存保护

Hazard3实现了物理内存保护（PMP）。它未实现Sv32虚拟内存扩展及其相关保护机制。

PMP定义了物理地址的权限。它主要保护M模式内存免受S模式和U模式的访问。Hazard3仅实现了M模式和U模式。

PMP区域适用于一段字节地址范围的读、写和执行权限。每个区域设有一个地址寄存器，分别为PMPADDR0至PMPADD R15，以及一个封装于PMPCFG0至PMPCFG3中的8位配置字段。对U模式的读、写和执行权限始终被强制执行。根据各区域的PMPCFG L位及PMPCFGM0寄存器的设置，该权限也可能被强制应用于M模式。

RP2350 配置 Hazard3 的 PMP 硬件，具备以下特点：

- 8x dynamically configurable regions, 0 through 7
- 3x statically configured (hardwired) regions, 8 through 10
- (Remaining regions 11 through 15 are hardwired to OFF)
- A granule of 32 bytes
- Support for naturally aligned power of two (NAPOT) region shapes only
- The custom PMPCFGM0 CSR can apply M-mode permissions to individual regions without locking them

Section 3.8.8.1 defines the configuration of the hardwired regions 8 through 10. These regions apply default U-mode permissions to RP2350 ROM and peripherals, to avoid having to spend dynamic regions to cover these addresses. The system-level ACCESSCTRL registers (Section 10.6) can assign each peripheral individually to M-mode or U-mode.

When multiple PMP regions match the same byte address, the lowest-numbered of these regions takes effect. The other regions are ignored.

### 3.8.3.1. PMP address registers

Addresses in PMP address registers PMPADDR0 through PMPADDR15 are stored with a right-shift of two, so that they can cover a 16 GB physical address space when Sv32 address translation is in effect. Hazard3 does not implement address translation, so the physical address space is 4 GB (32-bit byte-addressed) and the two MSBs of each address register are hardwired to zero.

The RP2350 configuration of Hazard3 supports only the OFF and NAPOT values for the PMPCFG A fields (e.g. PMPCFG0.R0\_A). Setting A to OFF means the region matches no bytes, and is effectively disabled. Setting A to NAPOT means the region matches on a naturally aligned span of bytes (the base address modulo the size is zero) whose size is a power of two.

The number of trailing 1s in the PMP address value encodes the size of an NAPOT region. This is the number of consecutive 1s counted from the LSB without reaching a 0. A PMP address value with no trailing ones (ending in a 0) matches a region eight bytes in size, and the region size is doubled with each additional 1 bit.

The PMP region matches on the address bits to the left of the least-significant 0 bit. Because the PMP address registers are right-shifted by two, you must apply the same shift to the addresses being compared. The following examples demonstrate how to match addresses based on PMPADDRx values:

- The 30-bit all-ones bit pattern `0xffffffff` has the maximum possible size, and matches all addresses.
- The all-zeroes bit pattern `0x00000000` has the minimum possible size.
  - Since there are no trailing 1s, this matches starting from bit 1 of the PMP address register.
  - Due to addresses being right-shifted by two, this is a region of eight bytes starting from address `0x0`.
- The bit pattern `0x???????` (where ? is any digit) matches any 64-byte region.
  - Shift the base address of this 64-byte region by two to get bits 29:4 of the PMPADDRx value.
- The bit pattern `0x0800000f` matches byte addresses between `0x20000000` and `0x20000007f`, the first 128 bytes of SRAM.
  - Right-shift the base address (`0x20000000`) by two to get `0x08000000`.
  - Add trailing ones to increase the region size and get the final value of `0x0800000f`.
  - The size of the region is eight bytes times two to the power of the number of trailing 1 bits, which in this case (four 1s) works out to  $8 \times 2^4 = 128$  bytes.

For more examples of PMP address match patterns, see the hardwired PMP region values in Section 3.8.8.1.

RP2350 configures Hazard3 with a **granule** of 32 bytes. This means the two least-significant bits of each PMP address register are hardwired to all-ones when the region is enabled. The hardware does not decode address regions smaller than 32 bytes.

- 8×动态可配置区域，**0**至**7**
- 3×静态配置（硬连线）区域，**8**至**10**
- （剩余区域**11**至**15**被硬连线设置为关闭）
- 粒度为32字节
- 仅支持自然对齐的2的幂次方区域形状（**NAPOT**）
- 自定义PMPCFGM0 CSR可对单个区域施加M模式权限，且不会锁定

第3.8.8.1节定义了硬连线区域**8**至**10**的配置。这些区域对RP2350只读存储器和外设应用默认的U模式权限，以避免使用动态区域覆盖这些地址。系统级ACCESSCTRL寄存器（第10.6节）可分别将每个外设分配为M模式或U模式。

当多个PMP区域匹配同一字节地址时，以编号最低的区域优先生效。其他区域将被忽略。

### 3.8.3.1. PMP地址寄存器

PMP地址寄存器PMPADDR0至PMPADDR15中的地址经过右移两位存储，因此在启用Sv32地址转换时，可覆盖16GB的物理地址空间。Hazard3不实现地址转换，故物理地址空间为4GB（32位字节寻址），且每个地址寄存器的两个最高有效位硬连线为零。

Hazard3的RP2350配置仅支持**OFF**和**NAPOT**两种PMPCFGA字段值（例如PMPCFG0.R0\_A）。将A设置为**OFF**表示该区域不匹配任何字节，实质被禁用。将A设置为**NAPOT**表示该区域匹配自然对齐的一段字节（基址模该大小为零），且大小为二的幂。

PMP地址值中尾随的1的数量编码了一个NAPOT区域的大小。这是从最低有效位开始连续计数的1的数量，直到遇到0为止。没有尾随1（以0结尾）的PMP地址值对应一个大小为八字节的区域，且每增加一个1位时区域大小翻倍。

PMP区域匹配最低有效0位左侧的地址位。由于PMP地址寄存器右移两位，比较时地址也必须进行相同的右移。以下示例演示如何基于PMPADDRx值匹配地址：

- 30位全为一的位模式**0xffffffff**具有最大可能的大小，并能匹配所有地址。
- 全为零的位模式**0x00000000**具有最小可能的大小。
  - 由于没有尾随的1，此匹配从PMP地址寄存器的第1位开始。
  - 由于地址右移两位，此地址范围为从地址**0x0**开始的八字节区域。
- 位模式**0x????????**（其中？为任意数字）匹配任意64字节区域。
  - 将此64字节区域的基址右移两位，即可获得PMPADDRx值的29:4位。
- 位模式**0x0800000f**匹配字节地址范围在**0x20000000**至**0x2000007f**之间，即SRAM的前128字节。
  - 将基地址（**0x20000000**）右移两位，得到**0x08000000**。
  - 通过添加尾随的1位以增大区域大小，最终得到值**0x0800000f**。
  - 该区域大小等于八字节乘以尾随1位数的2的幂，此处四个尾随1位，计算结果为 $8 \times 2^4 = 128$ 字节。

有关更多PMP地址匹配模式的示例，请参见第3.8.8.1节中硬连线的PMP区域值。

RP2350将Hazard3配置为32字节的粒度。这表示当该区域启用时，每个PMP地址寄存器的最低两位被硬连线为全1。硬件不会解码小于32字节的地址区域。

### 3.8.3.2. PMP permissions

Each 8-bit PMP configuration field contains three permission flags:

- **R** permits non-instruction-fetch reads:
  - load instructions
  - the read phase of AMOs
- **W** permits writes:
  - store instructions
  - the write phase of AMOs
- **X** permits instruction execution

A **1** value for each permission means it is granted, and a **0** means it is revoked. These permissions apply to U-mode access to the region. They also apply to M-mode accesses when any of the following is true:

- The **L** (lock) configuration bit is **1**
- The Hazard3 custom **PMPCFGM0** register bit for this region is **1**

The **L** (lock) bit also locks the associated PMP address register and 8-bit PMP configuration field, so that it ignores future writes. You should always lock PMP regions consecutively from region **0**, so that locked regions cannot be bypassed by unlocked regions.

U-mode accesses that match no PMP regions have no permissions: all memory accesses fail. M-mode accesses that match no PMP regions have *all* permissions. The hardwired PMP regions in [Section 3.8.8.1](#) define additional U-mode permissions for the ROM and peripheral address ranges: these can be overridden by enabling any of the dynamically configured regions.

#### **NOTE**

Due to [RP2350-E6](#) the field order in the PMP configuration fields is **R, W, X** (MSB-first) rather than the standard **X, W, R**. The SDK register headers match the as-implemented order.

### 3.8.3.3. Accesses spanning multiple PMP regions

Hazard3 does not support non-naturally-aligned loads or stores, other than to generate standard exceptions when they are attempted. Since **NAPOT** PMP regions are always naturally aligned, it is impossible for a load or store to span two PMP regions. Therefore, all bytes covered by a load or store instruction are determined by at most a single active PMP region that matches the lowest byte address accessed by that instruction.

Instructions are up to 32 bits in size with as little as 16-bit alignment. Therefore it is possible for an instruction to match multiple PMP regions. When this happens, the instruction generates an instruction fault exception, (**mcause = 0x1**), unless there is a lower-numbered PMP region that fully covers the instruction. Lower-numbered PMP regions take precedence.

The exact quote from the privileged ISA specification is: *"The lowest-numbered PMP entry that matches any byte of an access determines whether that access succeeds or fails. The matching PMP entry must match all bytes of an access, or the access fails, irrespective of the L, R, W, and X bits."* (page 60 of RISC-V privileged ISA manual version 20211203).

The RISC-V specification is flexible in what is considered a single access for the purposes of memory protection checking. Hazard3 considers the fetch of one instruction to be a single access. It therefore forbids instruction fetches that straddle two PMP regions, even if both regions grant execute permission. Due to this architecture rule, portable RISC-V software *must not* assume it can execute instructions that span multiple PMP regions.

Avoid this issue by using *hole-punching* region configurations in preference to *glueing* configurations. Suppose you want to cover the first 12 kB of SRAM (**0x20000000 → 0x20002fff**), this can be achieved in two ways:

- One region adding permissions to **0x20000000 → 0x200001fff**, and another region adding permissions to **0x20002000 → 0x20002fff**

### 3.8.3.2. PMP权限

每个8位PMP配置字段包含三个权限标志：

- **R** 允许非指令取指的读取操作：
  - 加载指令
  - AMO的读取阶段
- **W** 允许写入操作：
  - 存储指令
  - AMO的写入阶段
- **X** 允许指令执行

每个权限值为**1**表示授予，值为**0**表示撤销。这些权限适用于U模式对该区域的访问。当满足下列任一条件时，亦适用于M模式访问：

- **L**（锁定）配置位为**1**
- 该区域的Hazard3自定义PMPCFGM0寄存器位为**1**

**L**（锁定）位还会锁定关联的PMP地址寄存器和8位PMP配置字段，从而忽略后续的写入操作。您应始终从区域0开始连续锁定PMP区域，以防止锁定区域被未锁定区域绕过。

不匹配任何PMP区域的U态访问无权限：所有内存访问均将失败。不匹配任何PMP区域的M态访问具有全部权限。第3.8.8.1节中硬连线的PMP区域定义了只读存储器和外设地址范围的额外U态权限：启用任一动态配置区域后，该权限可被覆盖。

#### ① 注意

由于RP2350-E6，PMP配置字段中的字段顺序为 **R、W、X**（最高有效位优先），而非标准的 **X、W、R**。SDK寄存器头文件与实际实现顺序一致。

### 3.8.3.3 跨越多个PMP区域的访问

Hazard3不支持非自然对齐的加载或存储，尝试时仅产生标准异常。由于 **NAPOT**PMP区域始终自然对齐，加载或存储操作不可能跨越两个PMP区域。因此，一条加载或存储指令所覆盖的所有字节，最多由一个与该指令访问的最低字节地址匹配的活动PMP区域确定。

指令最大长度为32位，对齐要求最低16位。因此，指令有可能匹配多个PMP区域。发生这种情况时，指令会产生指令异常（**mcause = 0x1**），除非存在编号更低且完全覆盖该指令的PMP区域。编号较低的PMP区域优先。

特权ISA规范中相关表述为：“匹配访问任一字节的编号最低的PMP条目，决定该访问是否成功。” 匹配的PMP条目必须匹配访问的所有字节，否则访问将失败，无论L、R、W和X位的状态如何。”（摘自RISC-V特权ISA手册，版本20211203，第60页）

RISC-V规范对内存保护检查中认定的单次访问范围具有一定灵活性。Hazard3视单条指令的取指为一次完整访问。因此，即便两个PMP区域均授予执行权限，也禁止跨越两个PMP区域的指令取指。基于该架构规则，便携式RISC-V软件不得假定可执行跨越多个PMP区域的指令。

建议通过采用*hole-punching*区域配置，而非*glueing*配置，以避免此类问题。假设您要覆盖SRAM的前12 kB（**0x20000000 → 0x20002fff**），可通过以下两种方式实现：

- 一个区域向 **0x2**添加权限 **0000000 → 0x20001fff**，另一个区域向 **0x20002000 → 0x20002fff**

- One region adding permissions to `0x20000000 → 0x20003fff`, and a lower-numbered region *subtracting* permissions from `0x20003000 → 0x20003fff`

The former option has a crack between the two regions, which has potentially unwanted effects on some platforms. The latter avoids this issue entirely.

### 3.8.4. Interrupts and exceptions

In the RISC-V privileged ISA manual, a **trap** refers to either an interrupt or an exception:

#### Interrupt

A signal from outside the processor requests that it temporarily abandons its current task to deal with some system-level event. The processor responds by transferring control to an interrupt handler function.

#### Exception

An instruction encounters a condition that prevents that instruction from completing normally. The processor transfers control to an exception handler function to deal with the exceptional condition before it can resume execution.

The two are closely related, and they are collectively referred to as traps to avoid stating everything twice.

Hardware performs the following steps automatically and atomically when entering a trap:

1. Save the address of the interrupted or excepting instruction to **MEPC**
2. Set the MSB of **MCAUSE** to indicate the cause is an interrupt, or clear it to indicate an exception
3. Write the detailed trap cause to the LSBs of the **MCAUSE** register
4. Save the current privilege level to **MSTATUS.MPP**
5. Set the privilege to M-mode (note Hazard3 does not implement S-mode)
6. Save the current value of **MSTATUS.MIE** to **MSTATUS.MPIE**
7. Disable interrupts by clearing **MSTATUS.MIE**
8. Jump to the correct offset from **MTVEC** depending on the trap cause

#### NOTE

The above sequence of events is standard and is also described in the RISC-V Privileged ISA Manual. See [Section 3.8.1.1](#) for a list of links to RISC-V specifications.

All earlier instructions than the one pointed to by **MEPC** execute normally, and their effects are visible to the trap handler. These earlier instructions are not affected by the exception or interrupt. On the other hand the instruction pointed to by **MEPC**, and all later instructions, does not execute before entering the trap handler. These instructions have no visible side effects, with the possible exception of load/store fault exceptions, where the bus fault itself may have observable effects on the bus or peripheral.

Expanding on the **MEPC** behaviour in architectural terms, all traps are **precise**, meaning there exists some point in program order where the trap handler observes all earlier instructions to have retired and all later instructions to have not. The **MEPC** register indicates this point. All exceptions are also **synchronous**, meaning there is a particular instruction that originated the trap, and the trap architecturally takes place in between that instruction and its predecessors in program order.

M-mode software executes an `mret` instruction to return to the interrupted or excepting instruction at the end of a handler. This largely reverses the process of entering the trap:

1. Restore core privilege level to the value of **MSTATUS.MPP**
2. Write `0` (U-mode) to **MSTATUS.MPP**

- 一个区域向 `0x2`添加权限 `0000000 → 0x20003fff`, 且编号较低的区域从 `0x20003000 → 0x20003ffff` 移除权限

前者在两个区域之间存在缝隙, 可能对某些平台产生不良影响。后者则完全避免了该问题。

### 3.8.4. 中断与异常

在RISC-V特权ISA手册中, `trap`指中断或异常:

#### 中断

处理器外部发送的信号, 要求处理器暂时中止当前任务以处理某些系统级事件。处理器通过转移控制至中断处理函数来响应该信号。

#### 异常

指令遇到某种条件, 导致该指令无法正常完成。处理器将控制权转移至异常处理函数, 以处理异常情况, 之后方可恢复执行。

这两者密切相关, 统称为陷阱, 以避免重复陈述所有内容。

硬件在进入陷阱时自动且以原子方式执行以下步骤:

1. 将被中断或发生异常的指令地址保存至 MEPC
2. 设置 MCAUSE 的最高有效位以指示原因为中断, 或清除该位以表示异常
3. 将详细的陷阱原因写入 MCAUSE 寄存器的最低有效位
4. 将当前特权级保存到 MSTATUS.MPP
5. 将特权级设置为 M 模式 (注意 Hazard3 不支持 S 模式)
6. 将 MSTATUS.MIE 的当前值保存至 MSTATUS.MPIE
7. 通过清除 MSTATUS.MIE 禁用中断
8. 根据陷阱原因跳转至 MTVEC 的正确偏移地址

#### 注意

上述事件序列为标准流程, 亦记载于 RISC-V 特权 ISA 手册。RISC-V 规范的链接列表详见第 3.8.1.1 节。

MEPC 指向的指令之前的所有指令均正常执行, 其效果对陷阱处理程序可见。早期指令不受异常或中断的影响。另一方面, 由MEPC指向的指令及其之后的所有指令, 在进入陷阱处理程序之前不会执行。这些指令没有可见的副作用, 但在加载/存储故障异常情况下, 总线故障本身可能对总线或外围设备产生可感知的影响。

从体系结构角度进一步说明MEPC的行为, 所有陷阱均为精确陷阱, 即存在程序顺序中的节点, 陷阱处理程序观察到所有之前指令均已完成退役, 而所有之后指令尚未执行。MEPC寄存器指示该节点。所有异常亦为同步异常, 意味着存在特定指令引发陷阱, 陷阱在该指令与其前序指令之间的程序顺序处发生。

M态软件通过执行 `mret` 指令, 在处理程序结束时返回到被中断或引发异常的指令。此过程在很大程度上逆转了进入陷阱的步骤:

1. 将核心特权级恢复到 MSTATUS.MPP 的值
2. 向 MSTATUS.MPP 写入 `0` (用户模式)

3. Restore **MSTATUS.MIE** from **MSTATUS.MPIE**
4. Write **1** to **MSTATUS.MPIE**
5. Jump to the address in **MEPC**.

Often, the values restored on exit are exactly those values saved on entry. However this need not be the case, as all CSRs mentioned above are read/writable by M-mode software at any time. Hand-manipulating the trap handling CSRs is useful for low-level OS operations such as context switching, or to make exception handlers return to the instruction *after* the trap point by incrementing **MEPC** before return. You can execute an **mret** without any prior trap, for example when entering U-mode code from M-mode for the first time.

Hardware does not save or restore any other registers. In particular, it does not save the core GPRs, and software is responsible for ensuring the execution of the handler does not perturb the foreground context. For an interrupt, this may mean saving the core registers on the interruptee's stack, or using the **MSCRATCH** CSR to swap the stack pointer before saving registers on a dedicated interrupt stack. For a fatal exception this may be unimportant, as there is no requirement for the handler to return.

### 3.8.4.1. Exceptions

Exceptions occur for a variety of reasons. **MCAUSE** indicates the specific reason for the latest exception:

| Cause      | Meaning                                                                                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0x0</b> | Instruction alignment: Does not occur on RP2350, because 16-bit compressed instructions are implemented, and it is impossible to jump to a byte-aligned address.                                                                                                      |
| <b>0x1</b> | Instruction fetch fault: Attempted to fetch from an address that does not support instruction fetch (like APB/AHB peripherals on RP2350), or lacks PMP execute permission, or is forbidden by ACCESSCTRL, or returned a fault from the memory device itself.          |
| <b>0x2</b> | Illegal instruction: Encountered an instruction that was not a valid RISC-V opcode implemented by this processor, or attempted to access a nonexistent CSR, or attempted to execute a privileged instruction or access a privileged CSR without sufficient privilege. |
| <b>0x3</b> | Breakpoint: An <b>ebreak</b> or <b>c.ebreak</b> instruction was executed, and no external debug host caught it ( <b>DCSR.EBREAKM</b> or <b>DCSR.EBREAKU</b> was not set).                                                                                             |
| <b>0x4</b> | Load alignment: Attempted to load from an address that was not a multiple of access size.                                                                                                                                                                             |
| <b>0x5</b> | Load fault: Attempted to load from an address that does not exist, or lacks PMP read permissions, or is forbidden by ACCESSCTRL, or returned a fault from a peripheral.                                                                                               |
| <b>0x6</b> | Store/AMO alignment: Attempted to write to an address that was not a multiple of access size.                                                                                                                                                                         |
| <b>0x7</b> | Store/AMO fault: Attempted to write to an address that does not exist, or lacks PMP write permissions, or is forbidden by ACCESSCTRL, or returned a fault from a peripheral. Also raised when attempting an AMO on an address that does not support AHB5 exclusives.  |
| <b>0x8</b> | An <b>ecall</b> instruction was executed in U-mode.                                                                                                                                                                                                                   |
| <b>0xb</b> | An <b>ecall</b> instruction was executed in M-mode.                                                                                                                                                                                                                   |

Exceptions jump to exactly the address of **MTVEC**, no matter the cause and no matter whether vectoring is enabled.

The **MSTATUS.MIE** global interrupt enable does not affect exception entry. You can still take an exception and trap into the exception handler when exceptions are disabled.

Returning from an exception will jump to **MEPC**, which hardware sets to the address of the excepting instruction before entering the exception handler. This means by default you will return to the exact same instruction that caused the exception. When emulating illegal instructions, you should increment **mepc** before returning, so that execution resumes after the problematic instruction.

Hazard3 hardwires **mtval** to zero. To emulate a misaligned load/store instruction you must decode the instruction and

### 3. 从 MSTATUS.MPIE 恢复 MSTATUS.MIE

4. 向 MSTATUS.MPIE 写入 1

5. 跳转至 MEPC 中的地址。

通常，退出时恢复的值与进入时保存的值完全相同。但情况不一定如此，因为上述所有 CSR 均可由机器模式软件随时读写。手动操作陷阱处理 CSR 对于上下文切换等低级操作系统功能非常有用，或者通过在返回前递增 MEPC，使异常处理程序返回至陷阱点之后的指令。例如，当首次从机器模式进入用户模式代码时，可执行 mret 而无需事先发生陷阱。

硬件不会保存或恢复任何其他寄存器。特别是硬件不会保存核心通用寄存器，软件必须确保处理程序的执行不会干扰前台上下文。对于中断，这可能意味着在被中断者的堆栈上保存核心寄存器，或使用 MSCRATCH CSR 交换堆栈指针，然后在专用的中断堆栈上保存寄存器。对于致命异常来说，这可能无关紧要，因为处理程序不要求返回。

#### 3.8.4.1. 异常

异常发生的原因多种多样。MCAUSE 指示最近异常的具体原因：

| 原因  | 含义                                                                                               |
|-----|--------------------------------------------------------------------------------------------------|
| 0x0 | 指令对齐错误：RP2350 不会发生此异常，因为实现了 16 位压缩指令，且不可跳转到非字节对齐地址。                                              |
| 0x1 | 指令取指错误：尝试从不支持指令取指的地址（如 RP2350 上的 APB/AHB 外设）、缺乏 PMP 执行权限、被 ACCESSCTRL 禁止，或内存设备本身返回错误。            |
| 0x2 | 非法指令：遇到未被该处理器实现的有效 RISC-V 操作码指令，或尝试访问不存在的 CSR，或尝试执行特权指令或访问特权 CSR 时权限不足。                          |
| 0x3 | 断点：执行了 ebreak 或 c.ebreak 指令，但未被任何外部调试主机捕获（DCSR.EBREAKM 或 DCSR.EBREAKU 未设置）。                      |
| 0x4 | 加载对齐错误：尝试从非访问大小倍数的地址进行加载。                                                                        |
| 0x5 | 加载错误：尝试从不存在的地址加载数据，或缺乏 PMP 读取权限，或被 ACCESSCTRL 禁止，或外设返回错误。                                        |
| 0x6 | 存储/AMO 对齐错误：尝试写入非访问大小倍数的地址。                                                                      |
| 0x7 | 存储/AMO 错误：尝试写入不存在的地址，或缺乏 PMP 写入权限，或被 ACCESSCTRL 禁止，或外设返回错误。尝试对不支持 AHB5 排他访问的地址执行 AMO 操作时亦会触发此错误。 |
| 0x8 | 执行了 U 模式下的 ecall 指令。                                                                             |
| 0xb | 执行了 M 模式下的 ecall 指令。                                                                             |

异常无论原因如何，无论是否启用了中断向量，都精确跳转至 MTVEC 的地址。

MSTATUS.MIE 全局中断使能不影响异常的进入。即使异常被禁用，仍然可以捕获异常并陷入异常处理程序。

从异常返回将跳转至 MEPC，硬件在进入异常处理程序前会将其设置为引发异常的指令地址。这意味着默认情况下，你将返回到导致该异常的完全相同指令处。仿真非法指令时，应在返回前递增 mepc，以使执行从出错指令之后继续。

Hazard3 将 mtval 固定硬接为零。要仿真未对齐的加载/存储指令，必须解码该指令并

read the spilled register state to calculate the address, and to emulate an illegal instruction you must read the instruction bits from memory yourself by dereferencing `mepc`.

### 3.8.4.2. Interrupts

Hazard3 implements the standard RISC-V interrupt scheme with a single external interrupt routed to `MIP.MEIP`, and the standard timer and soft interrupts routed to `MTIP` and `MSIP`. An interrupt controller such as a standard RISC-V PLIC can be integrated externally to route multiple interrupts through to the single external interrupt line. Alternatively, the Hazard3 interrupt controller (see Xh3irq extension, [Section 3.8.6.1](#)) multiplexes multiple external interrupts onto `MIP.MEIP` in such a way that interrupts can efficiently pre-empt one another, with configurable dynamic priority per interrupt.

RP2350 configures Hazard3 with the Xh3irq interrupt controller, with 52 external interrupt lines and 16 levels of pre-emption priority. The IRQ numbers for the system-level interrupts, documented in [Section 3.2](#), are the same on both Arm and RISC-V.

The core enters an interrupt when all of the following are true:

- `MSTATUS.MIE` is set
- An interrupt pending bit in the standard `MIP` CSR is set
- The matching interrupt enable in the standard `MIE` CSR is also set

When vectoring is disabled (LSB of `MTVEC` is clear), interrupts transfer control directly to the address indicated by `mtvec`. Setting the LSB enables vectoring: interrupts transfer control to the address `mtvec + 4 * cause`, where the interrupt cause is one of:

- `meip: cause = 11`
- `mtip: cause = 7`
- `msip: cause = 3`

The pointer written to `mtvec` must be word-aligned (4 bytes). Additionally, when vectoring is enabled, it must be aligned to the size of the table, rounded up to a power of two. This works out to 64-byte alignment. On RP2350, `mtvec` is fully writable except for bit 1, which is hardwired to zero as it is only used for additional vectoring modes not supported by Hazard3.

When multiple interrupts are active, hardware picks one to enter, in the order `meip > msip > mtip`. (This is not quite the same order as the cause values.)

#### 3.8.4.2.1. RISC-V interrupt signals

The standard timer interrupt `MIP.MTIP` connects to the RISC-V platform timer in the SIO subsystem ([Section 3.1.8](#)). This is a 64-bit timer with a per-core 64-bit comparison value. The interrupt is asserted whenever the timer is greater than or equal to the comparison value, and de-asserts automatically when less than. The same interrupt signal also appears in the system-level IRQs, as `SIO_IRQ_MTIMECMP` (IRQ 29). The timer is a standard RISC-V peripheral, often used by operating systems to generate context switch interrupts.

The standard software interrupt `MIP.MSIP` connects to the `RISCV_SOFTIRQ` register in the SIO subsystem. The register has a single bit per hart, which asserts the soft IRQ interrupt to that hart. This can be used to interrupt the other hart, or to interrupt yourself as though the other hart had interrupted you, which can help to make handler code more symmetric. On RP2350 there is a one-to-one correspondence between harts and cores, so you could equivalently say there is one soft IRQ per core.

Hazard3's internal interrupt controller drives the `MIP.MEIP` external interrupt pending bit based on its internal state and the system-level interrupt signals, to transfer control to the interrupt vector when it is both safe and necessary. [Section 3.8.6.1](#) describes the Xh3irq interrupt controller in depth.

读取溢出的寄存器状态以计算地址；要仿真非法指令，必须通过解引用 `mepc` 自行从内存读取指令位。

### 3.8.4.2. 中断

Hazard3实现了标准RISC-V中断方案，包含一个外部中断路由至MIP.MEIP，标准计时器和软件中断分别路由至MTIP和MSIP。可在外部集成标准RISC-V PLIC等中断控制器，通过单个外部中断线路由多个中断。或者，Hazard3中断控制器（参见Xh3irq扩展，3.8.6.1节）将多个外部中断复用至MIP.MEIP，使中断能够高效相互抢占，并可针对各中断配置动态优先级。

RP2350配置了配备Xh3irq中断控制器的Hazard3，具备52条外部中断线及16级抢占优先级。系统级中断的IRQ编号（详见3.2节）在Arm与RISC-V架构中保持一致。

仅当以下所有条件均成立时，核心才进入中断状态：

- MSTATUS.MIE位被置位
- 标准MIP CSR中的某个待处理中断位被置位
- 标准MIE CSR中对应的中断使能位亦被置位

向量化禁用时（MTVEC最低有效位清零），中断控制直接转移至 `mtvec` 指定的地址。

将最低有效位设为1则启用向量化：中断控制转移至地址`mtvec + 4 * cause`，其中中断原因包括：

- `meip`: 原因 = 11
- `mtip`: 原因 = 7
- `msip`: 原因 = 3

写入 `mtvec` 的指针必须是字对齐（4字节）。此外，启用矢量模式时，指针必须对齐到表大小，并向上取整为2的幂次方，即64字节对齐。在RP2350上，`mtvec`除第1位外完全可写，第1位为硬连线0，仅用于Hazard3不支持的额外矢量模式。

当多个中断同时激活时，硬件将按顺序 `meip` > `msip` > `mtip` 选择一个进入。（该顺序与cause值的顺序不完全相同。）

#### 3.8.4.2.1. RISC-V中断信号

标准定时器中断MIP.MTIP连接至SIO子系统中的RISC-V平台定时器（第3.1.8节）。该定时器为64位，且每核带有64位比较值。当定时器值大于或等于比较值时，中断被触发；当值小于比较值时，中断自动取消。同一中断信号同时出现在系统级IRQ中，标识为 `SIO_IRQ_MTIMECMP`(IRQ 29)。该定时器为标准RISC-V外设，操作系统常用其生成上下文切换中断。

标准软件中断MIP.MSIP连接至SIO子系统中的RISCV\_SOFTIRQ寄存器。该寄存器每个hart对应一个位，用于向该hart触发软IRQ中断。此功能可用于中断其他hart，或模拟其他hart中断自身，从而使中断处理代码更加对称。在RP2350中，hart与核心一一对应，因此等同于每个核心拥有一个软IRQ。

Hazard3的内部中断控制器依据其内部状态和系统级中断信号驱动MIP.MEIP外部中断待处理位，在安全且必要时切换到中断向量。第3.8.6.1节详细描述了Xh3irq中断控制器。

### 3.8.4.2.2. Interrupt calling convention

The default SDK `hardware_irq` library expects function pointers registered for system-level IRQs to be normal C functions. There must be no `__attribute__((interrupt))` on an interrupt handler passed into functions such as `set_exclusive_irq_handler()`. This is an API detail that is consistent across all architectures supported by the SDK. Using regular C calling convention is also efficient under heavy interrupt load, because the cost of saving/restoring all caller save and temporary registers can be amortised over multiple interrupt handlers due to tail sharing, and a save triggered by a low-priority IRQ can be taken over by a high-priority IRQ that asserted during the save.

Conversely, handlers registered for the standard RISC-V `mtip` and `msip` interrupts via the SDK `irq_set_riscv_vector_handler()` function must be `__attribute__((interrupt))`. In terms of the generated code, this means they should use save-as-you-go calling convention, and end with an `mret`. These interrupts are entered directly by the hardware without any intermediate dispatch code.

As software is responsible for the dispatch to individual system interrupt handlers from the `meip` vector, it is possible to support other interrupt calling conventions by supplying a different implementation for the dispatch.

## 3.8.5. Debug

### RISC-V debug specification

Hazard3 implements version 0.13.2 of the RISC-V External Debug Support specification, available at:

[riscv.org/wp-content/uploads/2019/03/riscv-debug-release.pdf](https://riscv.org/wp-content/uploads/2019/03/riscv-debug-release.pdf)

RP2350 implements a single RISC-V Debug Module, which enables debug access to the two Hazard3 processor instances. Hazard3 should be supported by any debug translator implementing version 0.13.2 of the RISC-V External Debug Support specification, but some details of its implementation-defined behaviour are described here for completeness. The Debug Module source code, available in the Hazard3 repository, can be consulted to answer more detailed questions about the debug implementation.

As configured on RP2350, Hazard3 supports the following standard RISC-V debug features:

- Run/halt/reset control of each processor
- Halt-on-reset support for all processors
- Hart array mask register, for halting/resuming multiple processors simultaneously
- Abstract access to GPRs
- Program Buffer: 2 words with an implicit `ebreak` (`impebreak`)
- Automatic trigger of abstract commands (`abstractauto`)
- System Bus Access, arbitrated with core 1's load/store port
- An instruction address trigger unit with four hardware breakpoints

### 3.8.5.1. Accessing the Debug Module

The Debug Module is accessed through a CoreSight APB-AP, which can be accessed in one of two ways:

- Externally, through the system's SW-DP (see [Section 3.5](#))
- Internally, via self-hosted debug (see [Section 3.5.6](#))

The APB-AP for the Debug Module is located at offset `0xa000` in the debug address space. The Debug Module starts at address 0 in the APB-AP's downstream address space. The Debug Module addresses registers in increments of four bytes, as APB is byte-addressed rather than word-addressed. This means the Debug Module register addresses listed in the RISC-V debug specification must be multiplied by four.

### 3.8.4.2.2. 中断调用约定

默认的SDK `hardware_irq` 库要求系统级IRQ注册的函数指针必须为普通C函数。

传入诸如 `set_exclusive_irq_handler()` 等函数的中断处理程序不得带有 `__attribute__((interrupt))` 属性。这一API细节在SDK支持的所有架构中保持一致。使用常规C调用约定在高中断负载下同样高效，因为保存和恢复所有调用者保存寄存器及临时寄存器的开销可通过多个中断处理程序间的尾部共享加以摊销，且由低优先级IRQ触发的保存操作可被在保存过程中断的高优先级IRQ接管。

相反，通过SDK的 `irq_set_riscv_vector_handler()` 函数为标准RISC-V `mtip` 和 `msip` 中断注册的处理程序必须标注 `__attribute__((interrupt))` 属性。就生成的代码而言，应采用边调试边保存（`save-as-you-go`）调用约定，并以 `mret` 指令结束。这些中断由硬件直接触发，无需任何中间调度代码。

由于软件负责从 `meip` 向量调度至各系统中断处理程序，因此可以通过提供不同的调度实现，支持其他中断调用约定。

### 3.8.5. 调试

#### RISC-V 调试规范

Hazard3 实现了 RISC-V 外部调试支持规范 0.13.2 版本，详见：

[riscv.org/wp-content/uploads/2019/03/riscv-debug-release.pdf](https://riscv.org/wp-content/uploads/2019/03/riscv-debug-release.pdf)

RP2350 实现了单一 RISC-V 调试模块，支持对两个 Hazard3 处理器实例进行调试访问。任何实现了 RISC-V 外部调试支持规范 0.13.2 版本的调试转换器均应支持 Hazard3，本文为完整性目的描述了其中一些实现定义的行为细节。调试模块源代码可在 Hazard3 仓库中查阅，以便解答有关调试实现的更详细问题。

如在 RP2350 上配置，Hazard3 支持以下标准 RISC-V 调试功能：

- 每个处理器的运行／停止／复位控制
- 所有处理器的复位停止支持
- Hart 阵列掩码寄存器，用于同时停止／恢复多个处理器
- 对通用寄存器（GPR）的抽象访问
- 程序缓冲区：2字，带有隐式的 `ebreak`（`impebreak`）
- 抽象命令的自动触发（`abstractauto`）
- 系统总线访问，与核心1的加载／存储端口仲裁
- 具有4个硬件断点的指令地址触发单元

#### 3.8.5.1. 访问调试模块

调试模块通过 CoreSight APB-AP 访问，访问方式有两种：

- 外部访问，通过系统的 SW-DP（见第 3.5 节）
- 内部访问，通过自托管调试（见第 3.5.6 节）

调试模块的 APB-AP 位于调试地址空间偏移 `0xa000` 处。调试模块起始于 APB-AP 下游地址空间的地址 0。调试模块以四字节为单位访问寄存器，因为 APB 是按字节寻址而非按字寻址。这意味着 RISC-V 调试规范中列出的调试模块寄存器地址必须乘以 4。

### 3.8.5.2. Harts

Each Hazard3 core possesses exactly one hardware thread, or **hart**. This means each processor executes only a single stream of instructions at a time. The two Hazard3 processor cores on RP2350, core 0 and 1, have hart IDs of 0 and 1 respectively. These values can be read from the [MHARTID](#) register on each processor, and match the values read from the [CPUID](#) register in SIO.

The [dmcontrol.hartsel](#) field in RP2350's Debug Module supports writing the values 0 and 1 only (it implements only a single writable bit), and these correspond to hart IDs 0 and 1, which execute on core 0 and core 1 respectively.

### 3.8.5.3. Resets

The [dmcontrol.hartreset](#) field resets the selected cores only. This can be a single core selected by [dmcontrol.hartsel](#), or multiple cores selected by the hart array mask. It does not reset cores that are not selected, nor does it reset any other system hardware. There is a one-to-one correspondence between harts and cores on this system.

The [dmcontrol.ndmreset](#) field resets both cores. It does not reset any other hardware. As per the specification: *"Exactly what is affected by this reset is implementation dependent, as long as it is possible to debug programs from the first instruction executed."*

### 3.8.5.4. Implementation-defined behaviour

The following are not implemented:

- Abstract access memory
- Abstract access CSR
- Post-incrementing abstract access GPR

The core behaves as follows:

- Branch, [jal](#), [jalr](#) and [auipc](#) are illegal in Debug mode, because they observe PC: attempting to execute will halt Program Buffer execution and report an exception in [abstractes.cmderr](#)
- The [dret](#) instruction is not implemented (a special purpose DM-to-core signal is used to signal resume)
- The [dscratch](#) CSRs are not implemented
- The Debug Module's [data0](#) register is mapped into the core as a CSR, [DMDATA0](#)
- [dcsr.stepie](#) is hardwired to 0 (no interrupts during single stepping)
- [dcsr.stopcount](#) and [dcsr.stoptime](#) are hardwired to 1 (no counter or internal timer increment in Debug mode)
- [dcsr.mprven](#) is hardwired to 0
- [dcsr.prv](#) accepts only the values 3 (M-mode) and 0 (U-mode), rounding to nearest on write

For more details on the core-side Debug mode registers, see [DCSR](#) and [DPC](#).

The trigger unit implements four exact instruction address match triggers. Triggers can be configured to trap to M-mode as well as Debug-mode, meaning M-mode can use triggers for self-hosted hardware breakpoint support. The [tcontrol.mte](#) and [tcontrol.mpte](#) fields are implemented to avoid infinite exception loops when an M-mode trigger is set on the M-mode exception handler.

## 3.8.6. Custom extensions

Hazard3 implements a small number of custom extensions. All are optional: custom extensions are only included if the relevant feature flags are set to 1 when instantiating the processor ([Section 3.8.8](#)). Hazard3 is always a **conforming** RISC-V implementation; when these extensions are disabled, it is also a **standard** RISC-V implementation.

### 3.8.5.2 硬线程

每个Hazard3核心恰好拥有一个硬件线程，亦称为 **hart**。这表示每个处理器一次仅执行单个指令流。RP2350上的两个Hazard3处理器核心，编号为0和1的核心，分别对应hart ID 0和1。这些值可从每个处理器的MHARTID寄存器读取，且与SI0中CPUID寄存器的读取值一致。

RP2350调试模块中的`dmcontrol.hartsel`字段仅支持写入0和1（该字段仅实现一个可写位），对应于hart ID 0和1，分别在核心0和核心1上执行。

### 3.8.5.3. 复位

`dmcontrol.hartreset`字段仅复位所选核心。这可以是由`dmcontrol.hartsel`选择的单个核心，也可以是由`hart`数组掩码选择的多个核心。它不会复位未选择的核心，也不会复位其他任何系统硬件。该系统中，`hart`与核心之间存在一一对应关系。

`dmcontrol.ndmreset`字段复位两个核心。它不会复位任何其他硬件。根据规范：“该复位具体影响的内容由实现决定，只要能够从执行的第一条指令开始调试程序即可。”

### 3.8.5.4. 实现定义的行为

以下内容未被实现：

- 抽象访问内存
- 抽象访问控制状态寄存器（CSR）
- 递增型抽象访问通用寄存器（GPR）

核心行为如下：

- 在调试模式下，`branch`、`jal`、`jalr`和`auipc`均为非法指令，因为它们需观察程序计数器（PC）；执行时将导致暂停。程序缓冲区执行并在`abstractes.cmderr`报告异常
- `dret`指令未实现（使用专用的DM到核心信号来指示恢复）
- `dscratchCSR`未实现
- 调试模块的`data0`寄存器映射为核心中的CSR，称为DMDATA0
- `dcsr.stepie`硬连线为0（单步执行期间无中断）
- `dcsr.stopcount`和`dcsr.stoptime`硬连线为1（调试模式下无计数器或内部定时器增量）
- `dcsr.mprven`硬连线为0
- `dcsr.prv`仅接受值3（M模式）和0（U模式），写入时采用四舍五入

有关核心侧调试模式寄存器的详细信息，请参见DCSR和DPC。

触发单元实现了四个精确指令地址匹配触发器。触发器可配置为陷入M模式及调试模式，这意味着M模式可利用触发器支持自托管硬件断点。`tcontrol.mte`和`tcontrol.mpte`字段的实现目的是防止当M模式触发器设定于M模式异常处理器时发生无限异常循环。

### 3.8.6. 自定义扩展

Hazard3实现了少量自定义扩展。所有扩展均为可选：仅当实例化处理器时相关功能标志置为1（参见第3.8.8节）时，才会包含自定义扩展。Hazard3始终是一个符合规范的RISC-V实现；当这些扩展禁用时，它同样是一个标准的RISC-V实现。

If any one of these extensions is enabled, the `x` bit in [MISA](#) is set to indicate the presence of a non-standard extension.

### 3.8.6.1. Xh3irq: Hazard3 interrupt controller

Xh3irq controls up to 512 external interrupts, with up to 16 levels of pre-emption. It is architected as a layer on top of the standard `mip.meip` external interrupt line, and all standard RISC-V interrupt behaviour still applies. This extension adds no new instructions, but does add several CSRs:

- [MEIEA](#): external interrupt enable array
- [MEIPA](#): external interrupt pending array
- [MEIFA](#): external interrupt force array
- [MEIPRA](#): external interrupt priority array
- [MEINEXT](#): get next external interrupt
- [MEICONTEXT](#): external interrupt context register

Xh3irq is geared towards supporting interrupt handlers as bare C functions, with dispatch implemented in software and pre-emption priority logic implemented in hardware. However, the exact interrupt ABI is up to the implementation of the soft dispatch routine installed as the `mip.meip` external interrupt handler.

#### 3.8.6.1.1. Array CSRs

RISC-V CSRs are ideal for interrupt controls because they are closely coupled to the processor, offer native atomic set/clear accesses, and can be accessed in a single instruction without first having to materialise an address. However there are issues with using CSRs for large bit arrays, such as interrupt enables:

- The CSR address space is limited
- CSRs can not be addressed indirectly, so are difficult to iterate over
- Using a CSR to index other CSRs is problematic for interrupt handlers due to additional mutable state

Xh3irq uses the **array CSR** idiom to expose a large bit vector at a single CSR address, such as [MEIEA](#). The upper half of the CSR is a 16-bit window into the array, and the window is indexed by the LSBs of the write data for the same CSR instruction.

For example, the following assembly code writes `0xa5a5` to bits `47:32` of the interrupt enable array, since the window index is `0x2` and the window is 16 bits in size:

```
li a0, 0xa5a50002
csrw RVCSR_MEIEA_OFFSET, a0
```

The following reads bits 63:48 of the interrupt pending array into register `a0`, since the index is `0x3`, and a CSR set of `0x0000` does not modify the window contents:

```
csrrsi a0, RVCSR_MEIPA_OFFSET, 0x3
```

Setting an arbitrary IRQ enable from C works as follows:

```
void enable_irq(uint irq) {
 uint index = irq / 16;
 uint32_t mask = 1u << (irq % 16);
 asm (
```

若启用任一扩展，则 MISA 寄存器中的 **x** 位将被置位，以指示存在非标准扩展。

### 3.8.6.1. Xh3irq: Hazard3 中断控制器

Xh3irq 最多支持 512 个外部中断，并提供多达 16 级的抢占优先级。其架构设计为建立于标准的 **mip.meip** 外部中断线之上，所有标准 RISC-V 中断行为依然适用。该扩展未新增指令，但添加了若干 CSR：

- **MEIEA**: 外部中断使能数组
- **MEIPA**: 外部中断挂起数组
- **MEIFA**: 外部中断强制数组
- **MEIPRA**: 外部中断优先级数组
- **MEINEXT**: 获取下一个外部中断
- **MEICONTEXT**: 外部中断上下文寄存器

Xh3irq 旨在支持以裸 C 函数形式实现的中断处理程序，调度由软件实现，抢占优先级逻辑由硬件实现。然而，具体的中断 ABI 由作为 **mip.meip** 外部中断处理程序安装的软件调度例程的实现决定。

#### 3.8.6.1.1. 数组CSR

RISC-V CSR 非常适合中断控制，因为它们与处理器紧密耦合，支持原子性的设置/清除访问，且可通过单条指令访问，无需先物化地址。然而，使用 CSR 处理大型位数组（例如中断使能）存在若干问题：

- CSR 地址空间有限
- CSR 无法通过间接寻址，因此难以迭代
- 由于附加的可变状态，使用 CSR 来索引其他 CSR 对中断处理程序而言存在问题

Xh3irq 采用 **array CSR** 惯用法，在单一 CSR 地址（如 MEIEA）处暴露大型位向量。该 CSR 的高 16 位作为数组的一个窗口，窗口通过相同 CSR 指令写入数据的最低有效位进行索引。

例如，以下汇编代码将 **0xa5a5** 写入中断使能数组的第 **47:32** 位，因窗口索引为 **0x2** 且窗口大小为 16 位：

```
li a0, 0xa5a50002
csrw RVCSR_MEIEA_OFFSET, a0
```

以下代码将中断挂起数组的第 **63:48** 位读取至寄存器 **a0**，因索引为 **0x3**，且一个 CSR set **0x0000** 不修改窗口内容：

```
csrrsi a0, RVCSR_MEIPA_OFFSET, 0x3
```

在 C 语言中设置任意 IRQ 使能的操作如下：

```
void enable_irq(uint irq) {
 uint index = irq / 16;
 uint32_t mask = 1u << (irq % 16);
 asm (
```

```

 "csrs 0xbe0, %0\n"
 : : "r" (index | (mask << 16))
);
}

```

Getting an arbitrary IRQ pending flag from C is as follows:

```

bool check_irq_pending(uint irq) {
 uint index = irq / 16;
 uint32_t csr_rdata;
 asm (
 "csrrs %0, 0xbe1, %1\n"
 : "=r" (csr_rdata)
 : "r" (index)
);
 csr_rdata >>= 16;
 return csr_rdata & (1u << (irq % 16));
}

```

The SDK implements similar operations in the [hardware\\_irq](#) API.

Hazard3 supports up to 512 interrupts, which is one 16-bit window for each of the possible values of a 5-bit CSR immediate.

### 3.8.6.1.2. Enable, pending, and force arrays

The [MEIEA](#), [MEIPA](#) and [MEIFA](#) CSRs expose the interrupt enable, pending and force arrays respectively. Each array contains one bit per system-level interrupt line, of which there are 52 lines in total. (See [Section 3.2](#) for the assignment of system IRQ numbers to peripherals.)

The interrupt enable array gates the entry of interrupt signals into the core. When a bit is clear in [MEIEA](#), the corresponding interrupt signal is ignored. When a bit is set, assertion of the corresponding interrupt signal will send the core to the [meip](#) vector as soon as it is safe and appropriate to do so. From there, the [meip](#) handler vectors to the correct handler, after saving the interruptee's context.

The SDK [irq\\_set\\_enabled\(\)](#) function in the [hardware\\_irq](#) library is a convenient way to manipulate the interrupt enable array.

The interrupt pending array displays the current status of the system-level interrupt signals. Interrupts are visible in [MEIPA](#) even if the corresponding bit is clear in [MEIEA](#), and even if the interrupt has insufficient priority to interrupt the core at this time. This register is read-only: bits in [MEIPA](#) clear automatically when the corresponding interrupt source de-asserts. For example, a UART RX FIFO interrupt should clear on its own after data has been read from the FIFO.

The interrupt force array causes interrupts to appear pending, even when the corresponding system-level interrupt signal is de-asserted. When a bit is set in [MEIFA](#), the corresponding bit in [MEIPA](#) reads as 1, and will interrupt the core if it meets the usual prerequisites.

[MEIFA](#) bits clear automatically when the corresponding interrupt is sampled from [MEINEXT](#). It is not necessary to write a 1 bit to [MEINEXT.UPDATE](#) for the interrupt force bit to clear. This means setting an [MEIFA](#) bit should cause the interrupt to be taken once. Normal [csrw](#) and [csrc](#) instructions will also clear [MEIFA](#).

Six spare interrupt lines 46 through 51, referred to as [SPAREIRQ\\_IRQ\\_0](#) through [SPAREIRQ\\_IRQ\\_5](#) in the SDK, deliberately do not connect to system-level hardware. However they are still fully implemented in the interrupt controller, and fire when set pending in [MEIFA](#). For example, a fast interrupt top-half handler can schedule its longer-running bottom half to run at a lower priority, or a high-priority context switch interrupt might schedule a context switch to take place at a lower priority in order to clear interrupt frames off the stack.

```

 "csrs 0xbe0, %0\n"
 : : "r" (index | (mask << 16))
);
}

```

在C语言中获取任意IRQ挂起标志的操作如下：

```

bool check_irq_pending(uint irq) {
 uint index = irq / 16;
 uint32_t csr_rdata;
 asm (
 "csrrs %0, 0xbe1, %1\n"
 : "=r" (csr_rdata)
 : "r" (index)
);
 csr_rdata >>= 16;
 return csr_rdata & (1u << (irq % 16));
}

```

SDK在[hardware\\_irq](#) API中实现了类似操作。

Hazard3 支持最多 512 个中断，即针对 5 位 CSR 立即数所有可能值的每个值分配一个 16 位窗口。

### 3.8.6.1.2. 使能、挂起与强制数组

MEIEA、MEIPA 和 MEIFA CSR 分别表示中断使能、挂起和强制数组。每个数组中包含对应每条系统级中断线的一位，系统总计有 52 条中断线。（有关系统 IRQ 号分配给外设的详情，请参见第 3.2 节。）

中断使能数组用于控制中断信号进入核心的权限。当 MEIEA 中某位被清零时，相关的中断信号将被忽略。当某位被置位时，断言的对应中断信号将会在安全且适当的时机引导核心进入 [meip](#) 向量。从该向量处，[meip](#) 处理程序保存被中断者上下文后跳转至正确的处理程序。

SDK 中[hardware\\_irq](#)库的[irq\\_set\\_enabled\(\)](#)函数提供了操作中断使能数组的便捷方法。

中断挂起数组显示系统级中断信号的当前状态。即使在 MEIEA 中相应位被清除，中断仍可在 MEIPA 中被检测到，即使该中断优先级不足以立即中断核心。此寄存器为只读：当相应中断源解除断言时，MEIPA 中的位会自动清除。例如，UART RX FIFO 中断在从 FIFO 读取数据后应自动清除。

中断强制数组使中断即使在相应系统级中断信号被解除断言时，仍显示为挂起状态。当 MEIFA 中的某一位被设置时，MEIPA 中对应位读为 1，如满足通常前提条件，将中断核心。

MEIFA 位在从 MEINEXT 采样相应中断时自动清除，无需向 MEINEXT.UPDATE 写入 1 位以清除中断强制位。这意味着设置 MEIFA 位应使中断被捕获 once。普通的 [csrw](#) 和 [csrw](#) 指令同样会清除 MEIFA。

六条备用中断线，编号为 46 至 51，在 SDK 中称为 SPAREIRQ\_IRQ\_0 至 SPAREIRQ\_IRQ\_5，故意未连接至系统级硬件。但它们仍然在中断控制器中完整实现，并在 MEIFA 中被设置为挂起时触发。例如，快速中断的上半部处理程序可以安排其较耗时的下半部以较低优先级执行，或者高优先级的上下文切换中断可能调度低优先级上下文切换，以清理堆栈上的中断帧。

### 3.8.6.1.3. Next interrupt register

**MEINEXT** always displays the next interrupt that should be handled, taking priority order into account. Interrupts appear in **MEINEXT** when they meet all of the following criteria:

1. Pending in **MEIPA**
2. Enabled in **MEIEA**
3. Of priority greater than or equal to **MEICONTEXT.PPREEMPT**

The value returned is the IRQ number of the highest-priority interrupt that meets these three criteria, left-shifted by two. When multiple interrupts have the highest priority, the lowest-numbered of those interrupts is chosen, as a tie-break.

The MSB of **MEINEXT** is set to indicate there were no eligible interrupts, and the remaining bits are undefined in this case. Software should repeatedly read **MEINEXT** until all available interrupts are exhausted. The **bltz** and **bgez** instructions are a convenient way to test the MSB of a register.

The purpose of rule 3 above is to ensure that any interrupt that may already be in progress in a pre-empted interrupt frame is not re-entered in the current frame. Without this rule, multiple executions of the same interrupt handler could be interleaved due to pre-emption by other handlers. Programmers are usually surprised when this happens.

**MEINEXT.UPDATE** is a write-only field which instructs hardware to update **MEICONTEXT** with information about the interrupt displayed in **MEINEXT** on that cycle. [Section 3.8.6.1.5](#) goes into more detail about context register updates.

#### ⚠️ IMPORTANT

**MEINEXT** is constantly changing as interrupt signals come and go. The write to **MEINEXT.UPDATE** must be the *same instruction* that reads the interrupt index from **MEINEXT** to avoid a data race. This can be achieved with a **csrrw** or **csrrwi** instruction.

### 3.8.6.1.4. Interrupt priority

The interrupt priority array **MEIPRA** implements a four-bit field per interrupt. In hardware, numerically higher (unsigned) **MEIPRA** values have higher priority, taking precedence over lower-priority interrupts. The **irq\_set\_priority()** SDK function uses the opposite convention, with lower numeric values indicating greater precedence. This section uses the hardware numbering.

The interrupt priority in **MEIPRA** determines three things:

1. Whether the interrupt source is permitted to interrupt the core at this moment: must be greater than or equal **MEICONTEXT.PREEMPT**
2. Whether the interrupt source can appear in **MEINEXT**: must be greater than or equal to **MEICONTEXT.PPREEMPT**
3. What order this interrupt will appear in when there are multiple candidates for **MEINEXT**

When **MEICONTEXT** is correctly saved and restored, PREEMPT and PPREEMPT are both zero outside of interrupt handlers, and PREEMPT is strictly greater than PPREEMPT when inside an interrupt handler. Together they define the band of interrupt priorities which may be processed without any pushing or popping of interrupt stack frames.

Manipulating interrupt priority outside of interrupts is safe. There is no need to disable interrupts when writing to the priority array. Manipulating interrupt priority *inside* of an interrupt handler requires care: hardware operation is well-defined, but the results can be surprising. Be wary of the following cases:

1. Increasing the priority of the current handler: if still enabled and pending, you will instantly pre-empt yourself.
2. Increasing the priority of a different interrupt, with priority lower than **MEICONTEXT.PPREEMPT**: this interrupt may already be in progress in a frame that was pre-empted in order to run your handler. Increasing the priority may cause it to execute in a higher frame before returning to the original frame where it is still in progress, thereby interleaving with its own execution.

PPREEMPT is guaranteed to be no greater than the current handler priority if **MEICONTEXT** is correctly saved/restored, since it contains the previous value of PREEMPT at the time a pre-emption took place, and interrupts lower than

### 3.8.6.1.3. 下一个中断寄存器

MEINEXT始终显示应处理的下一个中断，且考虑优先级顺序。仅当中断满足以下全部条件时，才会显示于MEINEXT：

1. 在MEIPA中处于挂起状态
2. 在MEIEA中被使能
3. 其优先级大于或等于MEICONTEXT.PPREEMPT

返回值为满足这三个条件的最高优先级中断的IRQ编号，左移两位。

当多个中断具有最高优先级时，将选择其中编号最低的中断作为决胜。

MEINEXT的最高有效位（MSB）被设置，表明没有符合条件的中断，且其余位在此情况下未定义。软件应反复读取MEINEXT，直至所有可用中断被处理完毕。`bltz`和`bgez`指令为测试寄存器最高有效位提供了方便手段。

上述规则3的目的是确保任何可能在被抢占中断帧中已执行的中断不会在当前帧中重新进入。若无此规则，同一中断处理程序多次执行可能因其他处理程序的抢占而交叉进行。程序员通常会对该情况感到惊讶。

`MEINEXT.UPDATE`为只写字段，用以指示硬件在该周期内将MEICONTEXT更新为关于MEINEXT中所示中断的信息。第3.8.6.1.5节详细说明了上下文寄存器的更新。

#### ！重要

随着中断信号的出现和消失，MEINEXT持续变化。对`MEINEXT.UPDATE`的写操作必须与读取MEINEXT中断索引的指令相同，以避免数据竞争。这可以通过`csrrw`或`csrrwi`指令实现。

### 3.8.6.1.4 中断优先级

中断优先级数组MEIPRA为每个中断实现了四位字段。在硬件中，数值更高（无符号）的MEIPRA值对应更高优先级，优先于低优先级中断。`irq_set_priority()` SDK函数采用相反约定，数值越低表示优先级越高。本节采用硬件编号。

MEIPRA中的中断优先级决定以下三项内容：

1. 中断源是否允许此时中断核心：其优先级必须大于或等于MEICONTEXT.PREEMPT
2. 中断源是否可以出现在MEINEXT：必须大于或等于MEICONTEXT.PPREEMPT。
3. 当MEINEXT存在多个候选时，该中断出现的顺序。

当MEICONTEXT被正确保存和恢复后，在中断处理程序之外，PREEMPT和PPREEMPT均为零；在中断处理程序内部，PREEMPT严格大于PPREEMPT。它们共同定义了可在无需推入或弹出中断堆栈帧的情况下处理的中断优先级范围。

在中断外操作中断优先级是安全的。写入优先级数组时无需禁用中断。在中断处理程序内部操作中断优先级须谨慎：硬件操作定义明确，但结果可能出乎意料。请注意以下情况：

1. 提升当前处理程序的优先级：若仍启用且待处理，将立即发生自我抢占。
2. 提升优先级低于MEICONTEXT.PPREEMPT的其他中断的优先级：该中断可能已在另一个因抢占您的处理程序而被中断的帧中处理中。提升优先级可能导致该处理程序在返回到仍处于执行中的原始帧之前于更高帧中执行，从而与自身执行交织。

如果正确保存和恢复MEICONTEXT，则PPREEMPT保证不会高于当前处理中断的优先级，因为它包含了抢占发生时PREEMPT的前一个值，而优先级低于

`PREEMPT` can not interrupt the core. Therefore a safe approximation for case 2 above is: do not increase (by any amount) the priority of a handler with lower priority than the currently running handler.

If an interrupt *must* increase the priority of a lower-priority interrupt, one solution is to queue up interrupt priority updates, and pend a lowest-priority handler assigned to one of the spare IRQs, which processes the enqueued updates. You can pend this handler manually by setting its bit in `MEIFA`. The handler will run last thing before returning to foreground code. This is safe because an interrupt of the lowest priority by definition can not have pre-empted any other interrupts.

### 3.8.6.1.5. Interrupt context management

The `MEICONTEXT` register has two functions: manage the core pre-emption priority across multiple pre-empting interrupt stack frames, and help software track which interrupt handler it is currently executing, if any.

`MEICONTEXT.PREEMPT`, `MEICONTEXT.PPREEMPT` and `MEICONTEXT.PPPREEMPT` form a three-level stack of pre-emption priorities:

- `PREEMPT` sets the minimum interrupt priority which interrupts the core
- `PPREEMPT` sets the minimum interrupt priority which appears in `MEINEXT`: this avoids redundant execution of interrupt handlers which may have been pre-empted
- `PPPREEMPT` has no hardware function other than save/restore of `PPREEMPT`

When entering the `MIP.MEIP` vector, hardware atomically performs the following updates to `MEICONTEXT` simultaneous to the standard trap entry sequence described in [Section 3.8.4](#):

1. Save the current value of `MEICONTEXT.PPREEMPT` to `PPREEMPT`
2. Save the current value of `MEICONTEXT.PREEMPT` to `PPREEMPT`
3. Write one plus the priority of the IRQ which caused this interrupt to `MEICONTEXT.PREEMPT`
4. Write 1 to `MEICONTEXT.MRETEIRQ`, to enable priority restore on next `mret`

The standard trap entry sequence includes clearing `MSTATUS.MIE`, so interrupts are disabled at the start of the handler. To implement pre-emption, the `MIP.MEIP` handler must re-enable interrupts after its context save critical section. This should include saving `MEICONTEXT`, `MSTATUS`, `MEPC`, and the caller-saved general-purpose registers.

Any trap entry not caused by `MIP.MEIP` clears `MRETEIRQ`. Trap exit (`mret`) also clears `MRETEIRQ`.

A trap exit where `MEICONTEXT.MRETEIRQ` is set atomically performs the following updates to `MEICONTEXT` simultaneous to the standard trap exit sequence:

1. Restore `MEICONTEXT.PREEMPT` from `MEICONTEXT.PPREEMPT`
2. Restore `MEICONTEXT.PPREEMPT` from `MEICONTEXT.PPPREEMPT`
3. Write 0 to `MEICONTEXT.PPPREEMPT`

The `MRETEIRQ` flag allows hardware to match each `MIP.MEIP` vector entry with its associated `mret`. This balances pushes and pops of the `PREEMPT` priority stack. When there is no pre-emption, and no exceptions raised within interrupt handlers, `MRETEIRQ` can be left in place in the `MEICONTEXT.MRETEIRQ` register. Otherwise, you must save `MEICONTEXT` upon entering the external interrupt vector and restore it before the `mret` at the end of the handler. Interrupts must be disabled during save/restore.

Writing 1 to `MEINEXT.UPDATE` updates `MEICONTEXT` as follows:

1. Write `MEINEXT.NOIRQ` to `MEICONTEXT.NOIRQ`
2. Write `MEINEXT.IRQ` (the IRQ number) to `MEICONTEXT.IRQ`
3. If `MEINEXT.NOIRQ` is...
  - Clear: Write one plus the priority of `MEINEXT.IRQ` to `MEICONTEXT.PREEMPT`

的中断无法中断内核。因此，对于上述情况 2，安全的近似处理方式为：切勿（以任何幅度）提升优先级低于当前运行处理程序的优先级。

如果必须提升优先级较低的中断的优先级，一种解决方案是将中断优先级的更新排队，并挂起分配给备用 IRQ 之一的最低优先级处理程序，以处理这些排队更新。

您可以通过在 MEIFA 中设置对应位来手动挂起该处理程序。该处理程序将在返回前台代码之前最后执行。这是安全的，因为最低优先级的中断按定义不能抢占任何其他中断。

### 3.8.6.1.5. 中断上下文管理

MEICONTEXT 寄存器具有两个功能：管理多个抢占中断堆栈帧间的核心抢占优先级，以及帮助软件跟踪当前正在执行的中断处理程序（如果存在）。

[MEICONTEXT.PREEMPT](#)、[MEICONTEXT.PPREEMPT](#)和[MEICONTEXT.PPPREEMPT](#)构成了三级抢占优先级堆栈：

- [PREEMPT](#) 设置中断核心的最低中断优先级
- [PPREEMPT](#)设置MEINEXT中出现的最低中断优先级：避免了可能已被抢占的中断处理程序的重复执行
- [PPPREEMPT](#)除保存/恢复PPREEMPT之外无其他硬件功能

在进入 [MIP.MEIP](#)向量时，硬件会与第3.8.4节所述的标准陷阱入口序列同步，原子性地对 [MEICONTEXT](#)进行以下更新：

1. 将当前 [MEICONTEXT.PPREEMPT](#) 的值保存至 [PPPREEMPT](#)
2. 将当前 [MEICONTEXT.PREEMPT](#) 的值保存至 [PPREEMPT](#)
3. 将引发该中断的 IRQ 优先级加一写入 [MEICONTEXT.PREEMPT](#)
4. 向 [MEICONTEXT.MRETEIRQ](#) 写入 1，以启用下一次 [mret](#) 的优先级恢复功能

标准陷阱入口序列包括清除 MSTATUS.MIE，故处理中断处理程序开始时中断处于禁用状态。

为实现抢占，[MIP.MEIP](#) 处理程序必须在上下文保存关键区段后重新启用中断。应保存 [MEICONTEXT](#)、[MSTATUS](#)、[MEPC](#) 以及调用者保存的通用寄存器。

任何非由 [MIP.MEIP](#) 触发的陷阱入口会清除 MRETEIRQ。陷阱退出 ([mret](#)) 亦会清除 MRETEIRQ。

当陷阱退出且 [MEICONTEXT.MRETEIRQ](#) 被设置时，会在标准陷阱退出序列同时，原子性地对 [MEICONTEXT](#) 进行以下更新：

1. 从 [MEICONTEXT.PPREEMPT](#) 恢复 [MEICONTEXT.PREEMPT](#)
2. 从 [MEICONTEXT.PPPREEMPT](#) 恢复 [MEICONTEXT.PPREEMPT](#)
3. 写入 0 至 [MEICONTEXT.PPPREEMPT](#)

MRETEIRQ 标志允许硬件将每个 [MIP.MEIP](#) 向量项与其对应的 [mret](#) 匹配。此操作平衡了 PREEMPT 优先级栈的入栈与出栈。当无抢占且中断处理程序中未引发异常时，可将 MRETEIRQ 保留在 [MEICONTEXT.MRETEIRQ](#) 寄存器中。否则，必须在进入外部中断向量时保存 [MEICONTEXT](#)，并在处理程序末尾的 [mret](#) 指令之前恢复。

保存和恢复期间必须禁用中断。

向 [MEINEXT.UPDATE](#) 写入 1 将按以下规则更新 [MEICONTEXT](#)：

1. 将 [MEINEXT.NOIRQ](#) 写入 [MEICONTEXT.NOIRQ](#)
2. 将 [MEINEXT.IRQ](#) (IRQ 号) 写入 [MEICONTEXT.IRQ](#)
3. 如果 [MEINEXT.NOIRQ](#) 是……
  - 清除：向 [MEICONTEXT.PREEMPT](#) 写入 [MEINEXT.IRQ](#) 的优先级加一

- o Set: Write **0x10** to **MEICONTEXT.PREEMPT** (greater than any interrupt priority in **MEIPRA**)

**MEICONTEXT.IRQ** and **NOIRQ** help code determine in which interrupt handler it is running. **MEICONTEXT** should be saved/restored by interrupts which pre-empt the current one, so is safe to check these fields *during* the handler.

The update to **MEICONTEXT.PREEMPT** upon writing **MEINEXT.UPDATE** ensures the core will be pre-empted by interrupts higher-priority than the one it is about to enter. Equally important, it ensures the core is *not* pre-empted by lower or equal priority interrupts, including the one whose handler it is about to enter.

To avoid awkward interactions between the **MIP.MEIP** handler, which should be aware of the Xh3irq extension, and the MTIP/MSIP handlers, which may not be, it's best to avoid pre-emption of the former by the latter. **MEICONTEXT.CLEARSTS**, **MTIESAVE** and **MSIESAVE** support disabling and restoring the timer/software interrupt enables as part of the **MEICONTEXT** CSR accesses that take place during context save/restore in the MEIP handler.

### 3.8.6.1.6. Minimal handler example

This example demonstrates a minimal **meip** handler which dispatches to an array of C-function interrupt handlers, without enabling pre-emption. In this case the priorities configured in **MEIPRA** still determine the order in which interrupts are entered when multiple are asserted, but when an interrupt handler starts running, no other interrupts are serviced until that handler completes.

```
#include "hardware/regs/rvcsr.h"

isr_riscv_machine_external_irq:
 // Save all caller saves and temporaries before entering a C ABI function.
 // Note mstatus.mie is cleared by hardware on interrupt entry, and
 // we're going to leave it clear.
 addi sp, sp, -64
 sw ra, 0(sp)
 sw t0, 4(sp)
 sw t1, 8(sp)
 sw t2, 12(sp)
 sw a0, 16(sp)
 sw a1, 20(sp)
 sw a2, 24(sp)
 sw a3, 28(sp)
 sw a4, 32(sp)
 sw a5, 36(sp)
 sw a6, 40(sp)
 sw a7, 44(sp)

 sw t4, 52(sp)
 sw t5, 56(sp)
 sw t6, 60(sp)

get_first_irq:
 // Sample the current highest-priority active IRQ (left-shifted by 2) from
 // meinext. Don't set the `update` bit as we aren't saving/restoring meicontext --
 // this is fine, just means you can't check meicontext to see whether you are in an IRQ.
 csrr a0, RVCSR_MEINEXT_OFFSET

 // MSB will be set if there is no active IRQ at the current priority level
 bltz a0, no_more_irqs
dispatch_irq:
 // Load indexed table entry and jump through it. No bounds checking is necessary
 // because the hardware will not return a nonexistent IRQ.
 lui a1, %hi(__soft_vector_table)
 add a1, a1, a0
 lw a1, %lo(__soft_vector_table)(a1)
 jalr ra, a1
get_next_irq:
```

- 设置：向 MEICONTEXT.PREEMPT 写入 **0x10**（大于 MEIPRA 中任何中断优先级）

**MEICONTEXT.IRQ 和 NOIRQ 协助代码确定当前运行的是哪个中断处理程序。抢占当前中断的中断必须保存/恢复 MEICONTEXT，因此在处理程序期间检查这些字段是安全的。**

写入 MEINEXT.UPDATE 时对 MEICONTEXT.PREEMPT 的更新确保核心将被优先级高于即将进入中断的中断抢占。同样重要的是，它确保核心不会被优先级低或相等的中断抢占，包括即将进入处理程序的中断。

为避免应关注 Xh3irq 扩展的 MIP.MEIP 处理程序与可能不关注该扩展的 MTIP/MSIP 处理程序之间产生不当相互作用，最好避免后者抢占前者。

**MEICONTEXT.CLEARCS、MTIESAVE 和 MSIESAVE 支持在 MEIP 处理中断保存与恢复上下文期间，作为 MEICONTEXT CSR 访问的一部分，禁用并恢复定时器/软件中断使能。**

### 3.8.6.1.6. 最简处理程序示例

本示例演示一个最简的 **meip** 处理程序，该程序调度至由 C 函数组成的中断处理数组，且不启用抢占。在该情况下，MEIP RA 中配置的优先级仍决定多个中断同时断言时的中断进入顺序，但处理中断处理程序运行期间，直至其完成前，不处理其他中断。

```
#include "hardware/regs/rvcsr.h"

isr_riscv_machine_external_irq:
 // 进入 C ABI 函数前保存所有调用者保存寄存器和临时寄存器。
 // 注意，mstatus.mie 在中断入口时由硬件清除，且
 // 我们将保持该清除状态。

 mret

// Array of function pointers for interrupt handlers
.section ".bss"
.p2align 2
.global __soft_vector_table
__soft_vector_table:
.space 52 * 4

```

Since the handler loops on `meinext` until no more interrupts are pending, multiple interrupts are processed with a single save/restore of the caller saves and temporaries.

The pending status of each IRQ in `MEIPA` clears when the corresponding peripheral de-asserts its interrupt output. A correctly programmed interrupt handler should cause the peripheral interrupt to de-assert, so each successive read from `meinext` will return a new interrupt. Because `meinext` always returns the highest-priority active interrupt, this loop iterates over active interrupts in descending priority order.

The overhead of performing the register save/restore in software is minimal because the save/restore routine is limited by bus bandwidth, not by instruction execution overhead. This also makes the hardware more flexible because the same hardware can support multiple interrupt ABIs.

### 3.8.6.2. Xh3pppm: M-mode PMP regions

This extension adds a new M-mode CSR, `PMPCFGM0`, which allows a PMP region to be enforced in M-mode without locking the region.

This is useful when the PMP is used for non-security-related purposes such as stack guarding, or trapping and emulation of peripheral accesses.

### 3.8.6.3. Xh3power: Hazard3 power management

This extension adds a new M-mode CSR (`MSLEEP`), and two new hint instructions, `h3.block` and `h3.unblock`, in the `slt` nop-compatible custom hint space.

The `msleep` CSR controls how deeply the processor sleeps in the WFI sleep state. By default, a WFI is implemented as a

```

// 获取下一个最高优先级的中断请求
csrr a0, RVCCSR_MEINEXT_OFFSET
// 若当前优先级等级无活动中断请求，则最高有效位将被置位
bgez a0, dispatch_irq

no_more_irqs:
 // 恢复保存的上下文并从中断请求返回 lw ra, 0(sp)

 lw t0, 4(sp)
 lw t1, 8(sp)
 lw t2, 12(sp)
 lw a0, 16(sp)
 lw a1, 20(sp)
 lw a2, 24(sp)
 lw a3, 28(sp)
 lw a4, 32(sp)
 lw a5, 36(sp)
 lw a6, 40(sp)
 lw a7, 44(sp)
 lw t3, 48(sp)
 lw t4, 52(sp)
 lw t5, 56(sp)
 lw t6, 60(sp)
 addi sp, sp, 64
 mret

 // 中断处理函数指针数组
.section ".bss"
.p2align 2
.global __soft_vector_table
__soft_vector_table:
.space 52 * 4

```

由于处理程序在 `meinext` 上循环，直到没有更多中断待处理，因此多个中断可通过一次保存和恢复调用者保存寄存器及临时寄存器完成处理。

MEIPA 中每个 IRQ 的挂起状态在对应外设取消中断输出信号时清除。正确编写的中断处理程序应促使外设中断取消断言，因此每次从 `meinext` 读取均将返回新的中断。因为 `meinext` 始终返回优先级最高的有效中断，该循环按照优先级降序遍历有效中断。

执行软件寄存器保存/恢复的开销极小，因为保存/恢复例程受限于总线带宽，而非指令执行开销。这也使硬件更具灵活性，因为相同硬件能够支持多种中断 ABI。

### 3.8.6.2. Xh3pppm：M 模式 PMP 区域

该扩展新增了一个 M 模式 CSR，PMPCFGM0，允许在 M 模式下对 PMP 区域强制执行而无需锁定该区域。

当 PMP 用于非安全相关目的，如栈保护或外设访问的捕获与仿真时，该功能尤为实用。

### 3.8.6.3. Xh3power：Hazard3 电源管理

该扩展新增了一项 M 模式 CSR (MSLEEP) 及两条新的提示指令，`h3.block` 和 `h3.unblock`，位于 `slt` nop 兼容的自定义提示空间。

`msleepCSR` 控制处理器在 WFI 睡眠状态下的睡眠深度。默认情况下，WFI 被实现为

normal pipeline stall. By configuring `msleep` appropriately, the processor can gate its own clock when asleep or, with a simple 4-phase req/ack handshake, negotiate power up/down of external hardware with an external power controller. These options can improve the sleep current at the cost of greater wakeup latency.

The hints allow processors to sleep until woken by other processors in a multiprocessor environment. They are implemented on top of the standard WFI state, which means they interact in the same way with external debug, and benefit from the same deep sleep states in `msleep`.

### 3.8.6.3.1. h3.block

Enter a WFI sleep state until either an unblock signal is received, or an interrupt is asserted that would cause a WFI to exit.

If `mstatus.tw` is set, attempting to execute this instruction in privilege modes lower than M-mode will generate an illegal instruction exception.

If an unblock signal has been received in the time since the last `h3.block`, this instruction executes as a `nop`, and the processor does not enter the sleep state. Conceptually, the sleep state falls through immediately because the corresponding unblock signal has already been received.

An unblock signal is received when a neighbouring processor (the exact definition of "neighbouring" being left to the implementer) executes an `h3.unblock` instruction, or for some other platform-defined reason.

This instruction is encoded as `slt x0, x0, x0`, which is part of the custom nop-compatible hint encoding space.

Example C macro:

```
#define __h3_block() asm ("slt x0, x0, x0")
```

Example assembly macro:

```
.macro h3.block
 slt x0, x0, x0
.endm
```

### 3.8.6.3.2. h3.unblock

Post an unblock signal to other processors in the system. For example, to notify another processor that a work queue is now non-empty.

If `mstatus.tw` is set, attempting to execute this instruction in privilege modes lower than M-mode will generate an illegal instruction exception.

This instruction is encoded as `slt x0, x0, x1`, which is part of the custom nop-compatible hint encoding space.

Example C macro:

```
#define __h3_unblock() asm ("slt x0, x0, x1")
```

Example assembly macro:

正常流水线停顿。通过适当配置msleep，处理器在睡眠时可关闭自身时钟，或通过简单的四阶段请求/确认握手，协商外部电源控制器以实现外部硬件的电源开启/关闭。  
这些选项可降低睡眠电流，但会增加唤醒延迟。

这些提示允许处理器在多处理器环境中进入睡眠状态，直到被其他处理器唤醒。它们基于标准 WFI 状态实现，因此与外部调试的交互方式相同，并且可利用 msleep 中的相同深度睡眠状态。

### 3.8.6.3.1. h3.block

进入 WFI 睡眠状态，直到收到解除阻塞信号或触发会导致 WFI 退出的中断。

若 mstatus.tw 被设置，则在低于 M 模式的特权级执行该指令将引发非法指令异常。

如果自上次 h3.block 以来已接收到解除阻塞信号，则该指令作为 nop 执行，处理器不会进入睡眠状态。从概念上讲，睡眠状态会立即跳过，因为对应的解除阻塞信号已被接收。

当邻近处理器（“邻近”的确切定义由实现者决定）执行 h3.unblock 指令，或因其他平台定义的其他原因时，将接收到解除阻塞信号。

该指令编码为 slt x0, x0, x0，属于自定义的兼容 nop 的提示编码空间。

示例 C 宏：

```
#define __h3_block() asm ("slt x0, x0, x0")
```

示例汇编宏：

```
.macro h3.block
 slt x0, x0, x0
.endm
```

### 3.8.6.3.2. h3.unblock

向系统中的其他处理器发出解除阻塞信号。例如，用于通知另一处理器工作队列目前非空。

若 mstatus.tw 被设置，则在低于 M 模式的特权级执行该指令将引发非法指令异常。

该指令编码为 slt x0, x0, x1，属于自定义的nop兼容提示编码空间。

示例 C 宏：

```
#define __h3_unblock() asm ("slt x0, x0, x1")
```

示例汇编宏：

```
.macro h3.unblock
 slt x0, x0, x1
.endm
```

### 3.8.6.4. Xh3bextm: Hazard3 bit extract multiple

This is a small extension with multi-bit versions of the "bit extract" instructions from Zbs, used for extracting small, contiguous bit fields.

#### 3.8.6.4.1. h3.bextm

"Bit extract multiple", a multi-bit version of the `bext` instruction from Zbs. Perform a right-shift followed by a mask of 1-8 LSBs.

Encoding (R-type):

| Bits  | Name                     | Value                | Description                                                                                         |
|-------|--------------------------|----------------------|-----------------------------------------------------------------------------------------------------|
| 31:29 | <code>funct7[6:4]</code> | <code>0b000</code>   | RES0                                                                                                |
| 28:26 | <code>size</code>        | -                    | Number of ones in mask, values 0→7 encode 1→8 bits.                                                 |
| 25    | <code>funct7[0]</code>   | <code>0b0</code>     | RES0, because aligns with <code>shamt[5]</code> of potential RV64 version of <code>h3.bextmi</code> |
| 24:20 | <code>rs2</code>         | -                    | Source register 2 (shift amount)                                                                    |
| 19:15 | <code>rs1</code>         | -                    | Source register 1                                                                                   |
| 14:12 | <code>funct3</code>      | <code>0b000</code>   | <code>h3.bextm</code>                                                                               |
| 11:7  | <code>rd</code>          | -                    | Destination register                                                                                |
| 6:2   | <code>opc</code>         | <code>0b01011</code> | custom0 opcode                                                                                      |
| 1:0   | <code>size</code>        | <code>0b11</code>    | 32-bit instruction                                                                                  |

Example C macro (using GCC statement expressions):

```
// nbits must be a constant expression
#define __h3_bextm(nbites, rs1, rs2) ({\
 uint32_t __h3_bextm_rd; \
 asm ("insn r 0x0b, 0, %3, %0, %1, %2" \
 : "=r" (__h3_bextm_rd) \
 : "r" (rs1), "r" (rs2), "i" (((nbites) - 1) & 0x7) << 1) \
); \
 __h3_bextm_rd; \
})
```

Example assembly macro:

```
// rd = (rs1 >> rs2[4:0]) & ~(-1 << nbites)
.macro h3.bextm rd rs1 rs2 nbites
.if (\nbites < 1) || (\nbites > 8)
.err
.endif
#if NO_HAZARD3_CUSTOM
```

```
.macro h3.unblock
 slt x0, x0, x1
.endm
```

### 3.8.6.4. Xh3.bextm: Hazard3 多位位提取指令

该扩展包含Zbs中“位提取”指令的多位版本，用于提取小范围连续位字段。

#### 3.8.6.4.1. h3.bextm

“位多提取”，为Zbs中 `bext` 指令的多位版本。先执行右移操作，随后对1至8位最低有效位进行掩码处理。

编码（R型）：

| 位     | 名称                       | 值       | 描述                                                                  |
|-------|--------------------------|---------|---------------------------------------------------------------------|
| 31:29 | <code>funct7[6:4]</code> | 0b000   | RES0                                                                |
| 28:26 | 大小                       | -       | 掩码中1的个数，值0→7表示1→8位。                                                 |
| 25    | <code>funct7[0]</code>   | 0b0     | RES0，因为与潜在的RV64版本中 <code>h3.bextm</code> 的 <code>shamt[5]</code> 对齐 |
| 24:20 | <code>rs2</code>         | -       | 源寄存器2（移位量）                                                          |
| 19:15 | <code>rs1</code>         | -       | 源寄存器1                                                               |
| 14:12 | <code>funct3</code>      | 0b000   | <code>h3.bextm</code>                                               |
| 11:7  | <code>rd</code>          | -       | 目标寄存器                                                               |
| 6:2   | <code>opc</code>         | 0b01011 | custom0 操作码                                                         |
| 1:0   | 大小                       | 0b11    | 32位指令                                                               |

示例C宏（使用GCC语句表达式）：

```
// nbits 必须为常量表达式
#define __h3_bextm(nbts, rs1, rs2) ({\
 uint32_t __h3_bextm_rd; \
 asm (" .insn r 0x0b, 0, %3, %0, %1, %2" \
 : "=r" (__h3_bextm_rd) \
 : "r" (rs1), "r" (rs2), "i" (((nbts) - 1) & 0x7) << 1) \
); \
 __h3_bextm_rd; \
})
```

示例汇编宏：

```
// rd = (rs1 >> rs2[4:0]) & ~(-1 << nbts)
.macro h3.bextm rd rs1 rs2 nbts
.if (\nbts < 1) || (\nbts > 8)
.err
.endif
#if NO_HAZARD3_CUSTOM
```

```

 srl \rd, \rs1, \rs2
 andi \rd, \rd, ((1 << \nbits) - 1)
#else
.insn r 0x0b, 0x0, (((\nbits - 1) & 0x7) << 1), \rd, \rs1, \rs2
#endif
.endm

```

### 3.8.6.4.2. h3.bextmi

Immediate variant of [h3.bextm](#).

Encoding (I-type):

| Bits  | Name      | Value   | Description                                         |
|-------|-----------|---------|-----------------------------------------------------|
| 31:29 | imm[11:9] | 0b000   | RES0                                                |
| 28:26 | size      | -       | Number of ones in mask, values 0→7 encode 1→8 bits. |
| 25    | imm[5]    | 0b0     | RES0, for potential future RV64 version             |
| 24:20 | shamt     | -       | Shift amount, 0 through 31                          |
| 19:15 | rs1       | -       | Source register 1                                   |
| 14:12 | funct3    | 0b100   | h3.bextmi                                           |
| 11:7  | rd        | -       | Destination register                                |
| 6:2   | opc       | 0b01011 | custom0 opcode                                      |
| 1:0   | size      | 0b11    | 32-bit instruction                                  |

Example C macro (using GCC statement expressions):

```

// nbits and shamt must be constant expressions
#define __h3_bextmi(nbts, rs1, shamt) ({\
 uint32_t __h3_bextmi_rd; \
 asm (.insn i 0x0b, 0x4, %0, %1, %2" \
 : "=r" (__h3_bextmi_rd) \
 : "r" (rs1), "i" (((nbts) - 1) & 0x7) << 6 | ((shamt) & 0x1f)) \
); \
 __h3_bextmi_rd; \
})

```

Example assembly macro:

```

// rd = (rs1 >> shamt) & ~(-1 << nbts)
.macro h3.bextmi rd rs1 shamt nbts
.if (\nbts < 1) || (\nbts > 8)
.err
.endif
.if (\shamt < 0) || (\shamt > 31)
.err
.endif
#if NO_HAZARD3_CUSTOM
 srli \rd, \rs1, \shamt
 andi \rd, \rd, ((1 << \nbts) - 1)
#else
 .insn i 0x0b, 0x4, \rd, \rs1, (\shamt & 0x1f) | (((\nbts - 1) & 0x7) << 6)

```

```

 srl \rd, \rs1, \rs2
 andi \rd, \rd, ((1 << \nbits) - 1)
#else
.insn r 0x0b, 0x0, (((\nbits - 1) & 0x7) << 1), \rd, \rs1, \rs2
#endif
.endm

```

### 3.8.6.4.2. h3.bextmi

**h3.bextm** 的立即数变体。

编码 (I型) :

| 位     | 名称        | 值       | 描述                     |
|-------|-----------|---------|------------------------|
| 31:29 | imm[11:9] | 0b000   | RES0                   |
| 28:26 | 大小        | -       | 掩码中1的个数，值0→7表示1→8位。    |
| 25    | imm[5]    | 0b0     | RES0，预留用于未来可能的 RV64 版本 |
| 24:20 | shamt     | -       | 移位量，范围 0 至 31          |
| 19:15 | rs1       | -       | 源寄存器1                  |
| 14:12 | funct3    | 0b100   | h3.bextmi              |
| 11:7  | rd        | -       | 目标寄存器                  |
| 6:2   | opc       | 0b01011 | custom0 操作码            |
| 1:0   | 大小        | 0b11    | 32位指令                  |

示例C宏（使用GCC语句表达式）：

```

// nbits 和 shamt 必须为常量表达式
#define __h3_bextmi(nbits, rs1, shamt) ({\
 uint32_t __h3_bextmi_rd; \
 asm (" .insn i 0x0b, 0x4, %0, %1, %2" \
 : "=r" (__h3_bextmi_rd) \
 : "r" (rs1), "i" (((nbits) - 1) & 0x7) << 6 | ((shamt) & 0x1f)) \
); \
 __h3_bextmi_rd; \
})

```

示例汇编宏：

```

// rd = (rs1 >> shamt) & ~(-1 << nbits)
.macro h3.bextmi rd rs1 shamt nbits
.if (\nbits < 1) || (\nbits > 8)
.err
.endif
.if (\shamt < 0) || (\shamt > 31)
.err
.endif
#if NO_HAZARD3_CUSTOM
 srli \rd, \rs1, \shamt
 andi \rd, \rd, ((1 << \nbits) - 1)
#else
 .insn i 0x0b, 0x4, \rd, \rs1, (\shamt & 0x1f) | (((\nbits - 1) & 0x7) << 6)

```

```
#endif
.endm
```

### 3.8.7. Instruction cycle counts

All timings are given assuming perfect bus behaviour (no downstream bus stalls).

See [Section 3.8.1.6](#) for a synopsis of instruction behaviour.

#### 3.8.7.1. RV32I

| Instruction                | Cycles    | Note                                  |
|----------------------------|-----------|---------------------------------------|
| Integer Register-register  |           |                                       |
| add rd, rs1, rs2           | 1         |                                       |
| sub rd, rs1, rs2           | 1         |                                       |
| slt rd, rs1, rs2           | 1         |                                       |
| sltu rd, rs1, rs2          | 1         |                                       |
| and rd, rs1, rs2           | 1         |                                       |
| or rd, rs1, rs2            | 1         |                                       |
| xor rd, rs1, rs2           | 1         |                                       |
| sll rd, rs1, rs2           | 1         |                                       |
| srl rd, rs1, rs2           | 1         |                                       |
| sra rd, rs1, rs2           | 1         |                                       |

| amoxor.w rd, rs2, (rs1)  | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |
| amoand.w rd, rs2, (rs1)  | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |
| amoor.w rd, rs2, (rs1)   | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |
| amomin.w rd, rs2, (rs1)  | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |
| amamax.w rd, rs2, (rs1)  | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |
| amominu.w rd, rs2, (rs1) | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |
| amamaxu.w rd, rs2, (rs1) | 4+     | 4 per attempt. Multiple attempts if reservation is lost. <sup>[4]</sup> |

### 3.8.7.4. C extension

All C extension 16-bit instructions are aliases of base RV32I instructions. On Hazard3, they perform identically to their 32-bit counterparts.

A consequence of the C extension is that 32-bit instructions can be non-naturally-aligned. This has no penalty during sequential execution, but branching to a 32-bit instruction that is not 32-bit-aligned carries a 1 cycle penalty, because the instruction fetch is cracked into two naturally-aligned bus accesses.

### 3.8.7.5. Privileged instructions (including Zicsr)

| Instruction          | Cycles           | Note                                            |
|----------------------|------------------|-------------------------------------------------|
| CSR Access           |                  |                                                 |
| csrrw rd, csr, rs1   | 1                |                                                 |
| csrrc rd, csr, rs1   | 1                |                                                 |
| csrrs rd, csr, rs1   | 1                |                                                 |
| csrrwi rd, csr, imm  | 1                |                                                 |
| csrrci rd, csr, imm  | 1                |                                                 |
| csrrsi rd, csr, imm  | 1                |                                                 |
| Traps and Interrupts |                  |                                                 |
| ecall                | 3                | Time given is for jumping to <code>mtvec</code> |
| ebreak               | 3                | Time given is for jumping to <code>mtvec</code> |
| mret                 | 2 <sup>[1]</sup> |                                                 |
| wfi                  | 2+               | Always stalls for one cycle, no upper limit     |

### 3.8.7.6. Bit manipulation

| 指令                                    | 周期 | 注意                                           |
|---------------------------------------|----|----------------------------------------------|
| 原子内存操作                                |    |                                              |
| <code>amoswap.w rd, rs2, (rs1)</code> | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |
| <code>amoadd.w rd, rs2, (rs1)</code>  | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |
| <code>amoxor.w rd, rs2, (rs1)</code>  | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |
| <code>amoand.w rd, rs2, (rs1)</code>  | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |
| <code>amoor.w rd, rs2, (rs1)</code>   | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |

| <code>amamax.w rd, rs2, (rs1)</code>  | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |
| <code>amominu.w rd, rs2, (rs1)</code> | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |
| <code>amamaxu.w rd, rs2, (rs1)</code> | 4+ | 每次尝试 4 次。如果保留失效，可进行多次尝试。 <a href="#">[4]</a> |

### 3.8.7.4. C 扩展

所有 C 扩展的 16 位指令均为基础 RV32I 指令的别名。在 Hazard3 上，它们的执行效果与对应的 32 位指令完全一致。

C 扩展的一个结果是 32 位指令可以非自然对齐。这在顺序执行时无惩罚，但跳转到非 32 位自然对齐的指令时，会产生 1 个周期的惩罚，因为指令抓取被拆分为两个自然对齐的总线访问。

### 3.8.7.5. 特权指令（包括 Zicsr）

| 指令                               | 周期       | 注意                           |
|----------------------------------|----------|------------------------------|
| CSR 访问                           |          |                              |
| <code>csrrw rd, csr, rs1</code>  | 1        |                              |
| <code>csrrc rd, csr, rs1</code>  | 1        |                              |
| <code>csrrs rd, csr, rs1</code>  | 1        |                              |
| <code>csrrwi rd, csr, imm</code> | 1        |                              |
| <code>csrrci rd, csr, imm</code> | 1        |                              |
| <code>csrrsi rd, csr, imm</code> | 1        |                              |
| 陷阱与中断                            |          |                              |
| <code>ecall</code>               | 3        | 给定时间用于跳转至 <code>mtvec</code> |
| <code>ebreak</code>              | 3        | 给定时间用于跳转至 <code>mtvec</code> |
| <code>mret</code>                | $2^{11}$ |                              |
| <code>wfi</code>                 | 2+       | 始终停顿一个周期，无上限                 |

### 3.8.7.6. 位操作

| Instruction                                           | Cycles | Note                                                       |

### 3.8.7.7. Zcb extension

Similarly to the C extension, this extension contains 16-bit variants of common 32-bit instructions:

- RV32I base ISA: `lbu`, `lh`, `lhu`, `sb`, `sh`, `zext.b` (alias of `andi`), `not` (alias of `xori`)
- Zbb extension: `sext.b`, `zext.h`, `sext.h`
- M extension: `mul`

They perform identically to their 32-bit counterparts.

### 3.8.7.8. Zcmp extension

| Instruction                        | Cycles                                               | Note                                             |
|------------------------------------|------------------------------------------------------|--------------------------------------------------|
| <code>cm.push rlist, -imm</code>   | $1 + n$                                              | $n$ is number of registers in <code>rlist</code> |
| <code>cm.pop rlist, imm</code>     | $1 + n$                                              | $n$ is number of registers in <code>rlist</code> |
| <code>cm.popret rlist, imm</code>  | $4 (n = 1)^{[5]} \text{ or } 2 + n (n \geq 2)^{[1]}$ | $n$ is number of registers in <code>rlist</code> |
| <code>cm.popretz rlist, imm</code> | $5 (n = 1)^{[5]} \text{ or } 3 + n (n \geq 2)^{[1]}$ | $n$ is number of registers in <code>rlist</code> |
| <code>cm.mva01s r1s', r2s'</code>  | 2                                                    |                                                  |
| <code>cm.mvsa01 r1s', r2s'</code>  | 2                                                    |                                                  |

### 3.8.7.9. Table footnotes

- [1] A jump or branch to a 32-bit instruction that isn't 32-bit-aligned requires one additional cycle because two naturally aligned bus cycles are required to fetch the target instruction.
- [2] If an instruction in stage 2 (e.g. an `add`) uses data from stage 3 (e.g. a `lw` result), a 1-cycle bubble is inserted between the pair. A load data → store data dependency is *not* an example of this, because data is produced and consumed in stage 3. However, load data → load address *would* qualify, as would e.g. `sc.w` → `beqz`.
- [3] AMOs are issued as a paired exclusive read and exclusive write on the bus, at the maximum speed of 2 cycles per access, since the bus does not permit pipelining of exclusive reads/writes. If the write phase fails due to the global monitor reporting a lost reservation, the instruction loops at a rate of 4 cycles per loop, until success. If the read reservation is refused by the global monitor, the instruction generates a Store/AMO Fault exception, to avoid an infinite loop.
- [4] A pipeline bubble is inserted between `lr.w/sc.w` and an immediately-following `lr.w/sc.w/amo*`, because the AHB5 bus standard does not permit pipelined exclusive accesses. A stall would be inserted between `lr.w` and `sc.w` anyhow, so the local monitor can be updated based on the `lr.w` data phase in time to suppress the `sc.w` address phase.
- [5] The single-register variants of `cm.popret` and `cm.popretz` take the same number of cycles as the two-register variants, because of an internal load-use dependency on the loaded return address.

| 指令            | 周期 | 注意 |
|---------------|----|----|
| brev8 rd, rs1 | 1  |    |
| zip rd, rs1   | 1  |    |
| unzip rd, rs1 | 1  |    |

### 3.8.7.7. Zcb 扩展

与C扩展类似，本扩展包含常见32位指令的16位变体：

- RV32I基准ISA：`lbu`, `lh`, `luh`, `sb`, `sh`, `zext.b` (`andi`别名), `not` (`xori`别名)
- Zbb扩展：`sext.b`, `zext.h`, `sext.h`
- M扩展：`mul`

其性能与对应的32位指令完全一致。

### 3.8.7.8. Zcmp扩展

| 指令                                 | 周期                                                   | 注意                              |
|------------------------------------|------------------------------------------------------|---------------------------------|
| <code>cm.push rlist, -imm</code>   | $1 + n$                                              | $n$ 为 <code>rlist</code> 中寄存器数量 |
| <code>cm.pop rlist, imm</code>     | $1 + n$                                              | $n$ 为 <code>rlist</code> 中寄存器数量 |
| <code>cm.popret rlist, imm</code>  | $4 (n = 1)^{[5]} \text{ or } 2 + n (n \geq 2)^{[1]}$ | $n$ 为 <code>rlist</code> 中寄存器数量 |
| <code>cm.popretz rlist, imm</code> | $5 (n = 1)^{[5]} \text{ or } 3 + n (n \geq 2)^{[1]}$ | $n$ 为 <code>rlist</code> 中寄存器数量 |
| <code>cm.mva01s r1s', r2s'</code>  | 2                                                    |                                 |
| <code>cm.mvsa01 r1s', r2s'</code>  | 2                                                    |                                 |

### 3.8.7.9. 表格脚注

- [1] 对非32位对齐的32位指令进行跳转或分支需要额外一个周期，因为需要两个自然对齐的总线周期来获取目标指令。
- [2] 如果第2阶段的指令（例如 `add`）使用了第3阶段的数据（例如 `lw` 指令结果），则在这两者之间会插入一个1周期的气泡。加载数据 → 存储数据的依赖关系并非此类情况，因为数据在第3阶段被产生和使用。然而，加载数据 → 加载地址的情况则符合该例子，如同 `sc.w`。  
→ `beqz`.
- [3] AMO操作以总线上成对的独占读和独占写方式发出，最大访问速度为每次2周期，因总线不允许独占读/写的流水线化。如果写入阶段因全局监视器报告保留丢失而失败，指令会以每循环4个周期的速率循环，直到成功。如果全局监视器拒绝读取保留，指令将触发存储/原子操作异常（Store/AMO Fault exception），以防止无限循环。
- [4] 在 `lr.w/sc.w` 和紧随其后的 `lr.w/sc.w/amo*` 之间插入流水线气泡，因AHB5总线标准不允许流水线独占访问。无论如何，在 `lr.w` 和 `sc.w` 之间会插入停顿，以便根据 `lr.w` 的数据阶段及时更新本地监视器，从而抑制 `sc.w` 的地址阶段。
- [5] `cm.popret` 和 `cm.popretz` 的单寄存器版本所需周期与双寄存器版本相同，因内部存在对加载返回地址的加载-使用依赖。

### 3.8.7.10. Branch predictor

Hazard3 includes a minimal branch predictor, to accelerate tight loops:

- The instruction frontend remembers the last taken, backward branch in a single-entry **branch target buffer** (BTB)
- If the same branch is seen again, it is predicted taken
- All other branches are predicted non-taken
- If the core executes but does not take a predicted-taken branch:
  - The core clears the BTB
  - The branch is predicted non-taken on its next execution

Correctly predicted branches execute in one cycle: the frontend is able to stitch together the two nonsequential fetch paths so that they appear sequential. Mispredicted branches incur a penalty cycle, since a nonsequential fetch address must be issued when the branch is executed. Consider the following copy routine:

```
// a0 is dst pointer
// a1 is src pointer
// a2 is len
copy_data:
 beqz a2, 2f
 add a2, a2, a1
1:
 lbu a3, (a0)
 sb a3, (a1)
 addi a0, a0, 1
 addi a1, a1, 1
 bltu a1, a2, 1b
2:
 ret
```

In the steady state this executes at 5 cycles per loop:

- One cycle for the load
- One cycle for the store: though it depends on the load, the dependency is within stage 3 so there is no stall
- One cycle for each `add`
- One cycle for the repeatedly-taken backward branch

Without the branch predictor the throughput is 6 cycles per loop. The branch predictor increases the throughput by 20%, and also reduces energy dissipation due to wasted instruction fetch (memory access is a large fraction of the instruction energy cost for an embedded processor).

For the above example code, a copy of 10 bytes would take 52 cycles:

- The base cost is 5 cycles per iteration, and there are 10 iterations
- The mispredicted, taken branch at the end of the first iteration costs one cycle
- The mispredicted, non-taken branch at the end of the last iteration costs one cycle

#### 3.8.7.10.1. Caveat: delay loops

The branch predictor does not engage when all of the following are true:

- The loop body consists of a single 16-bit instruction (followed by a repeatedly taken backward branch)
- The loop body is 32-bit-aligned

### 3.8.7.10. 分支预测器

Hazard3 包含一个最简化分支预测器，用以加速紧密循环：

- 指令前端在单入口分支目标缓冲区（BTB）中记录最后一次采取的后向分支
- 如果再次遇到相同的分支，则预测其被采取
- 所有其他分支均预测为不采取
- 若核心执行但未采取预测为已采取的分支：
  - 核心将清除BTB
  - 该分支在下一次执行时预测为不采取

正确预测的分支以单周期执行：前端能够将两个非顺序的取指路径拼接，以使其表现为顺序执行。错误预测的分支会产生一个周期的惩罚，因为在分支执行时必须发出非顺序取指地址。请参见如下复制例程：

```
// a0 为目标指针
// a1 为源指针
// a2 为长度
copy_data:
 beqz a2, 2f
 add a2, a2, a1
1:
 lbu a3, (a0)
 sb a3, (a1)
 addi a0, a0, 1
 addi a1, a1, 1
 bltu a1, a2, 1b
2:
 返回
```

在稳态情况下，该操作每个循环执行5个周期：

- 加载操作占用一个周期。
- 存储操作占用一个周期：虽然依赖加载，但该依赖发生在第3阶段内，因此不会产生停顿。
- 每个 `add` 操作占用一个周期。
- 重复执行的后跳分支占用一个周期。

无分支预测时，吞吐率为每个循环6个周期。分支预测器提升吞吐率20%，并减少了因无效指令获取导致的能耗（对于嵌入式处理器，内存访问占指令能耗的最大比例）。

对于上述示例代码，拷贝10字节需要52个周期：

- 基本代价为每次迭代5个周期，迭代次数共计10次。
- 第一轮迭代末尾误预测且跳转的分支耗时一个周期。
- 最后一轮迭代末尾误预测且未跳转的分支耗时一个周期。

#### 3.8.7.10.1. 注意：延迟循环

当以下所有条件均满足时，分支预测器不会启动：

- 循环体仅包含单条16位指令（后接一条反复执行的后向分支）
- 循环体地址为32位对齐

- There are no bus stalls on the instruction fetch port

This is because the branch predictor looks up functions by comparing bits 31:2 of the sequential-fetch counter to the BTB tag. In this case the BTB tag points to the same word as the loop entry. In the aforementioned case the sequential-fetch counter never actually contains the address of the loop entry, because the loop entry address goes straight to the bus, and the sequential-fetch counter pre-increments to the next address. This manifests in delay loops like the following:

```
.p2align 2
delay_loop_bad_dont_copy_paste_this:
 addi a0, a0, -1
 bgez a0, delay_loop_bad_dont_copy_paste_this
```

Given the description in [Section 3.8.7.10](#), you might expect this loop to execute at two cycles per iteration in the steady state. The actual behaviour is it executes at *three* cycles per iteration until instruction fetch encounters a stall, whereupon it accelerates to two cycles per instruction until the loop ends.

Avoid this by using a 32-bit instruction in the loop body. Force 32-bit alignment of the loop body to avoid an alignment penalty. The following code executes at the expected two cycles per iteration in the steady state:

```
.p2align 2 // Force 4-byte alignment
delay_cycles:
.option push
.option norvc // Force 32-bit opcode
 addi a0, a0, -1
.option pop
 bgez a0, delay_cycles
```

### 3.8.8. Configuration

Hazard3 uses the parameters given in the [hazard3\\_config.vh](#) header to customise the core. These values are set before taping out a Hazard3 instance on silicon, so they are *fixed* from a user point of view. They determine which instructions the processor supports, the area-performance trade-off for certain instructions, and static configuration for core peripherals like the PMP. RP2350 uses the following values for these parameters:

| Parameter          | Value |
|--------------------|-------|
| EXTENSION_A        | 1     |
| EXTENSION_C        | 1     |
| EXTENSION_M        | 1     |
| EXTENSION_ZBA      | 1     |
| EXTENSION_ZBB      | 1     |
| EXTENSION_ZBC      | 0     |
| EXTENSION_ZBS      | 1     |
| EXTENSION_ZCB      | 1     |
| EXTENSION_ZCMP     | 1     |
| EXTENSION_ZBKB     | 1     |
| EXTENSION_ZIFENCEI | 1     |
| EXTENSION_XH3BEXTM | 1     |
| EXTENSION_XH3IRQ   | 1     |

- 指令取指端口无总线阻塞

这是因为分支预测器通过比较顺序取指计数器的位 31:2与 BTB 标签，实现查找。在此情况下，BTB 标签指向与循环入口相同的指令字。在上述情况下，顺序取指计数器从不实际包含循环入口地址，因为循环入口地址直接送往总线，顺序取指计数器提前递增至下一个地址。这在如下延迟循环中体现：

```
.p2align 2
delay_loop_bad_dont_copy_paste_this:
 addi a0, a0, -1
 bgez a0, delay_loop_bad_dont_copy_paste_this
```

根据第3.8.7.10节的描述，您可能预期该循环在稳定状态下每次迭代执行两个周期。实际情况是它在每次迭代执行三个周期，直到指令取指遇到阻塞，随后加速至每条指令两个周期，直到循环结束。

请通过在循环体中使用32位指令来避免此情况。强制循环体32位对齐以避免对齐惩罚。以下代码在稳定状态下如预期每次迭代执行两个周期：

```
.p2align 2 // 强制4字节对齐
delay_cycles:
.option push
.option norvc // 强制32位操作码
 addi a0, a0, -1
.option pop
 bgez a0, delay_cycles
```

### 3.8.8. 配置

Hazard3 使用 hazard3\_config.vh 头文件中给定的参数定制核心。这些数值在硅片流片前已设定，因此从用户角度来看它们是固定的。它们决定了处理器支持的指令、某些指令的面积与性能权衡，以及诸如PMP等核心外设的静态配置。RP2350对这些参数采用以下数值：

| 参数                 | 值 |
|--------------------|---|
| EXTENSION_A        | 1 |
| EXTENSION_C        | 1 |
| EXTENSION_M        | 1 |
| EXTENSION_ZBA      | 1 |
| EXTENSION_ZBB      | 1 |
| EXTENSION_ZBC      | 0 |
| EXTENSION_ZBS      | 1 |
| EXTENSION_ZCB      | 1 |
| EXTENSION_ZCMP     | 1 |
| EXTENSION_ZBKB     | 1 |
| EXTENSION_ZIFENCEI | 1 |
| EXTENSION_XH3BEXTM | 1 |
| EXTENSION_XH3IRQ   | 1 |

| Parameter            | Value                               |
|----------------------|-------------------------------------|
| EXTENSION_XH3PPM     | 1                                   |
| EXTENSION_XH3POWER   | 1                                   |
| CSR_M_MANDATORY      | 1                                   |
| CSR_M_TRAP           | 1                                   |
| CSR_COUNTER          | 1                                   |
| U_MODE               | 1                                   |
| PMP_REGIONS          | 11                                  |
| PMP_GRAIN            | 3                                   |

| MULH_FAST            | 1                                   |
| FAST_BRANCHCMP       | 1                                   |
| RESET_REGFILE        | 1                                   |
| BRANCH_PREDICTOR     | 1                                   |
| MTVEC_WMASK          | 32'hfffffffffd                      |

### 3.8.8.1. Hardwired PMP regions

RP2350 configures Hazard3 with eight dynamically configured PMP regions, and three static ones. The static regions provide default U-mode RWX permissions on the following ranges:

- ROM: `0x00000000` through `0xffffffff`
- Peripherals: `0x40000000` through `0x5fffffff`
- SIO: `0xd0000000` through `0xdfffffff`

These addresses appear in [PMPADDR8](#), [PMPADDR9](#) and [PMPADDR10](#). The hardwired PMP address registers behave the same as dynamic registers, except that they ignore writes (exercising the WARL rule). The permissions for these

| 参数                   | 值                |
|----------------------|------------------|
| EXTENSION_XH3PPM     | 1                |
| EXTENSION_XH3POWER   | 1                |
| CSR_M_MANDATORY      | 1                |
| CSR_M_TRAP           | 1                |
| CSR_COUNTER          | 1                |
| U_MODE               | 1                |
| PMP_REGIONS          | 11               |
| PMP_GRAIN            | 3                |

| PMP_HARDWIRED_ADDR   | 参见第3.8.8.1节      |
| PMP_HARDWIRED_CFG    | 参见第3.8.8.1节      |
| DEBUG_SUPPORT        | 1                |
| BREAKPOINT_TRIGGERES | 4                |
| NUM_IRQS             | 52               |
| IRQ_PRIORITY_BITS    | 4                |
| IRQ_INPUT_BYPASS     | {NUM_IRQS{1'b1}} |
| MVENDORID_VAL        | 32'h00000493     |
| MIMPID_VAL           | 32'h86fc4e3f     |
| MCONFIGPTR_VAL       | 32'h0            |
| REDUCED_BYPASS       | 0                |
| MULDIV_UNROLL        | 2                |
| MUL_FAST             | 1                |
| MUL_FASTER           | 1                |
| MULH_FAST            | 1                |
| FAST_BRANCHCMP       | 1                |
| RESET_REGFILE        | 1                |
| BRANCH_PREDICTOR     | 1                |
| MTVEC_WMASK          | 32'hfffffffffd   |

### 3.8.8.1 硬连线PMP区域

RP2350在Hazard3中配置了八个动态PMP区域及三个静态PMP区域。静态区域为以下范围提供默认的用户态读写执行权限：

- 只读存储器： 0x00000000至 0xffffffff
- 外设： 0x40000000至 0x5fffffff
- SIO: 0xd0000000 至 0xffffffff

这些地址出现在 PMPADDR8、PMPADDR9 和 PMPADDR10 寄存器中。硬连线 PMP 地址寄存器的行为与动态寄存器相同，但它们忽略写入操作（遵循 WARL 规则）。这些权限

regions are in [PMPCFG2](#).

The hardwired regions have a similar role to the Exempt regions added to the Cortex-M33 IDAU address map specified in [Section 10.2.2](#).

RP2350 puts default U-mode permissions on AHB/APB peripherals because these are expected to be assigned using ACCESSCTRL ([Section 10.6](#)). ACCESSCTRL can assign each peripheral individually, using the existing address decoders in the bus fabric, whereas PMP regions are in limited supply so are less useful for peripheral assignment.

Similarly, SIO has internal banking over Secure/Non-secure bus attribution, which is mapped onto Machine and User modes as described in [Section 10.6.2](#).

The dynamic regions 0 through 7 take priority over the hardwired regions, because the PMP prioritises lower-numbered regions.

### 3.8.9. Control and status registers

Control and status registers (CSRs) are registers internal to the processor that affect its behaviour. They are hart-local: every hart has a copy of the CSRs. On RP2350 hart-local is a synonym for core-local.

Use dedicated CSR instructions to access the CSRs, as described in [Section 3.8.1.22](#). You cannot access CSRs with load or store instructions.

The RISC-V privileged specification is flexible on which CSRs are implemented, and how they behave. This section documents the as-implemented behaviour of CSRs on Hazard3 specifically, and does not enumerate all possible behaviour of all platforms.

#### **IMPORTANT**

The [RISC-V Privileged Specification](#) should be your primary reference for writing software to run on Hazard3. Portable RISC-V software should not rely on any implementation-defined behaviour described in this section.

All CSRs are 32-bit, and MXLEN is fixed at 32 bits. CSR addresses not listed in this section are unimplemented. Accessing an unimplemented CSR raises an illegal instruction exception (`mcause = 2`). This includes all S-mode CSRs.

Table 367. List of RVCSR registers

| Offset | Name                          | Info                                                                                           |
|--------|-------------------------------|------------------------------------------------------------------------------------------------|
| 0x300  | <a href="#">MSTATUS</a>       | Machine status register                                                                        |
| 0x301  | <a href="#">MISA</a>          | Summary of ISA extension support                                                               |
| 0x302  | <a href="#">MEDELEG</a>       | Machine exception delegation register. Not implemented, as no S-mode support.                  |
| 0x303  | <a href="#">MIDELEG</a>       | Machine interrupt delegation register. Not implemented, as no S-mode support.                  |
| 0x304  | <a href="#">MIE</a>           | Machine interrupt enable register                                                              |
| 0x305  | <a href="#">MTVEC</a>         | Machine trap handler base address.                                                             |
| 0x306  | <a href="#">MCOUNTEREN</a>    | Counter enable. Control access to counters from U-mode. Not to be confused with mcountinhibit. |
| 0x30a  | <a href="#">MENVCFG</a>       | Machine environment configuration register, low half                                           |
| 0x310  | <a href="#">MSTATUSH</a>      | High half of mstatus, hardwired to 0.                                                          |
| 0x31a  | <a href="#">MENVCFGH</a>      | Machine environment configuration register, high half                                          |
| 0x320  | <a href="#">MCOUNTINHIBIT</a> | Count inhibit register for <code>mcycle/minstret</code>                                        |
| 0x323  | <a href="#">MHPMEVENT3</a>    | Extended performance event selector, hardwired to 0.                                           |

区域位于 PMPCFG2 中。

硬连线区域的功能类似于第 10.2.2 节中指定的 Cortex-M33 IDAU 地址映射中新增的豁免区域。

RP2350 对 AHB/APB 外设设置了默认的用户模式 (U-mode) 权限，因为这些外设预期通过 ACCESSCTRL (第 10.6 节) 进行分配。ACCESSCTRL 可利用总线结构中的现有地址解码器，逐个分配各外设，而 PMP 区域数量有限，因此在外设分配中作用有限。

同样，SIO 在安全/非安全总线归属内实施内部分区，映射至第 10.6.2 节所述的机器模式和用户模式。

动态区域 0 至 7 的优先级高于硬连线区域，因为 PMP 优先级按区域编号由低至高排序。

### 3.8.9. 控制与状态寄存器

控制和状态寄存器 (CSR) 是影响处理器行为的内部寄存器。它们是 hart本地的：

每个 hart拥有一份 CSR 的副本。在 RP2350 中，hart本地是 core本地的同义词。

应使用专用的 CSR 指令访问 CSR，如第 3.8.1.22 节所述。无法通过 load 或 store 指令访问 CSR。

RISC-V 特权规范对实施哪些 CSR 及其行为具有灵活性。本节专门记录了 Hazard3 上 CSR 的实际实现行为，未详尽列举所有平台的全部可能行为。

#### 重要

RISC-V 特权规范应作为编写运行于 Hazard3 软件的主要参考依据。

可移植的 RISC-V 软件不应依赖本节中描述的任何实现定义行为。

所有 CSR 均为 32 位，且 MXLEN 固定为 32 位。本节未列出的 CSR 地址未被实现。

访问未实现的 CSR 将引发非法指令异常 (`mcause = 2`)。此处包含所有 S 模式控制状态寄存器 (CSRs)。

表367。  
RVCSR 寄存器列表

| 偏移量   | 名称            | 说明                                                |
|-------|---------------|---------------------------------------------------|
| 0x300 | MSTATUS       | 机器状态寄存器                                           |
| 0x301 | MISA          | ISA 扩展支持摘要                                        |
| 0x302 | MEDELEG       | 机器异常委托寄存器。未实现，因为不支持 S 状态。                         |
| 0x303 | MIDELEG       | 机器中断委托寄存器。未实现，因不支持 S 模式。                          |
| 0x304 | MIE           | 机器中断使能寄存器                                         |
| 0x305 | MTVEC         | 机器陷阱处理程序基址。                                       |
| 0x306 | MCOUNTEREN    | 计数器使能。控制来自用户态 (U 状态) 对计数器的访问。不可与 mcountinhibit混淆。 |
| 0x30a | MENVCFG       | 机器环境配置寄存器，低半字节                                    |
| 0x310 | MSTATUSH      | mstatus 的高半字节，硬连线为 0。                             |

## RVCSR: MISA Register

Offset: 0x301

### Description

Summary of ISA extension support

On RP2350, Hazard3's full **-march** string is: **rv32ima\_zicsr\_zifencei\_zba\_zbb\_zbs\_zbkb\_zca\_zcb\_zcmp**

Note Zca is equivalent to the C extension in this case; all instructions from the RISC-V C extension relevant to a 32-bit non-floating-point processor are supported. On older toolchains which do not support the Zc extensions, the appropriate **-march** string is: **rv32imac\_zicsr\_zifencei\_zba\_zbb\_zbs\_zbkb**

In addition the following custom extensions are configured: Xh3bm, Xh3power, Xh3irq, Xh3pppm

Table 369. MISA Register

| Bits  | Description                                                     | Type | Reset |
|-------|-----------------------------------------------------------------|------|-------|
| 31:30 | <b>MXL</b> : Value of 0x1 indicates this is a 32-bit processor. | RO   | 0x1   |
| 29:24 | Reserved.                                                       | -    | -     |

| 偏移量   | 名称         | 说明                |
|-------|------------|-------------------|
| 0xf14 | MHARTID    | 硬件线程标识符           |
| 0xf15 | MCONFIGPTR | 指向配置数据结构的指针（固定为0） |

## RVCSR: MSTATUS寄存器

偏移: 0x300

### 描述

机器状态寄存器

表368。MSTATUS 寄存器

| 位     | 描述                                                                           | 类型 | 复位  |
|-------|------------------------------------------------------------------------------|----|-----|
| 31:22 | 保留。                                                                          | -  | -   |
| 21    | <b>TW:</b> 超时等待。当该位为1时，尝试在用户模式执行WFI指令将立即导致非法指令异常。                            | 读写 | 0x0 |
| 20:18 | 保留。                                                                          | -  | -   |
| 17    | <b>MPRV:</b> 修改权限。若为1，加载和存储操作将视当前权限级别为 mpp。这包括物理内存保护检查，以及系统总线上的特权级别和加载/存储地址。 | 读写 | 0x0 |
| 16:13 | 保留。                                                                          | -  | -   |
| 12:11 | <b>MPP:</b> 先前的特权级别。可存储值3（M模式）或0（U模式）。如果写入其他值，硬件将舍入到最近的支持模式。                 | 读写 | 0x3 |
| 10:8  | 保留。                                                                          | -  | -   |
| 7     | <b>MPIE:</b> 先前的中断使能。可读写。在陷阱进入时设置为mstatus.mie的当前值。在陷阱返回时设置为1。                | 读写 | 0x0 |
| 6:4   | 保留。                                                                          | -  | -   |
| 3     | <b>MIE:</b> 中断使能。可读写。在陷阱进入时设置为0。在陷阱返回时设置为mstatus.mie的当前值。                    | 读写 | 0x0 |
| 2:0   | 保留。                                                                          | -  | -   |

## RVCSR: MISA寄存器

偏移: 0x301

### 描述

ISA扩展支持摘要

在RP2350上，Hazard3 的完整 -march字符串为：rv32imac\_zicsr\_zifencei\_zba\_zbb\_zbs\_zbkb\_zca\_zcb\_zcmp

注意Zca在此情况下等同于C扩展；支持所有与32位非浮点处理器相关的RISC-V C扩展指令。在不支持Zc扩展的旧工具链中，适用的-march字符串为：rv32imac\_zicsr\_zifencei\_zba\_zbb\_zbs\_zbkb

此外，配置了以下自定义扩展：Xh3bm、Xh3power、Xh3irq、Xh3pppm。

表369. MISA 寄存器

| 位     | 描述                             | 类型 | 复位  |
|-------|--------------------------------|----|-----|
| 31:30 | <b>MXL:</b> 值为0x1表示这是一个32位处理器。 | 只读 | 0x1 |
| 29:24 | 保留。                            | -  | -   |

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                  | Type | Reset |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 23    | <b>X</b> : Value of 1 indicates nonstandard extensions are present. (Xh3b bit manipulation, and custom sleep and interrupt control CSRs)                                                                                                                                                                                                                     | RO   | 0x1   |

| 0    | <b>FIOM:</b> When set, fence instructions in modes less privileged than M-mode which specify that IO memory accesses are ordered will also cause ordering of main memory accesses.<br><br>FIOM is hardwired to zero on Hazard3, because S-mode is not supported, and because fence instructions execute as NOPs (with the exception of <code>fence.i</code> ) | RO   | 0x0   |

## RVCSR: MSTATUSH Register

**Offset:** 0x310

Table 376. MSTATUSH  
Register

| Bits | Description                           | Type | Reset      |
|------|---------------------------------------|------|------------|
| 31:0 | High half of mstatus, hardwired to 0. | RO   | 0x00000000 |

## RVCSR: MENVCFGH Register

**Offset:** 0x31a

### Description

Machine environment configuration register, high half

This register is fully reserved, as Hazard3 does not implement the relevant extensions. It is implemented as hardwired-0.

## RVCSR: MCOUNTEREN 寄存器

偏移: 0x306

### 描述

计数器使能。控制来自用户态（U态）对计数器的访问。不可与mcountinhibit混淆。

表 374.  
MCOUNTEREN  
寄存器

| 位    | 描述                                                                                                                | 类型 | 复位  |
|------|-------------------------------------------------------------------------------------------------------------------|----|-----|
| 31:3 | 保留。                                                                                                               | -  | -   |
| 2    | <b>IR</b> : 若值为 1, U 模式允许访问 <code>instret</code> / <code>instreth</code> 指令退休计数器 CSR。否则，U 模式对这些 CSR 的访问将触发异常。     | 读写 | 0x0 |
| 1    | <b>TM</b> : 无硬件效应，因为未实现 <code>time</code> / <code>timeh</code> CSR。<br>但该字段仍然存在，供 M 模式软件用于跟踪是否应仿真 U 模式尝试访问这些 CSR。 | 读写 | 0x0 |
| 0    | <b>CY</b> : 若值为 1, U 模式允许访问 <code>cycle</code> / <code>cycleh</code> 周期计数器 CSR。<br>否则，U 模式对这些 CSR 的访问将触发异常。       | 读写 | 0x0 |

## RVCSR: MENVCFG 寄存器

偏移: 0x30a

### 描述

机器环境配置寄存器，低半字节

表375. MENVCFG  
寄存器

| 位    | 描述                                                                                                                                             | 类型 | 复位  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31:1 | 保留。                                                                                                                                            | -  | -   |
| 0    | <b>FIOM</b> : 设置后，在低于M模式权限的模式中，指定IO内存访问有序的fence 指令，也将导致主存访问的有序。<br><br>FIOM在Hazard3中硬连线为零，因其不支持S模式，且fence指令执行时均作为NOP（除 <code>fence.i</code> 外） | 只读 | 0x0 |

| Bits | Description                                            | Type | Reset      |
|------|--------------------------------------------------------|------|------------|
| 31:0 | Machine bad address or instruction. Hardwired to zero. | RO   | 0x00000000 |

**RVCSR: MIP Register**

Offset: 0x344

**Description**

Machine interrupt pending

**描述**

机器陷阱原因进入陷阱时设置，用以指示陷阱的原因。软件可读写。

表 382. MCAUSE  
寄存器

| 位    | 描述                                                                                                                            | 类型 | 复位  |
|------|-------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31   | 中断: 若值为1，则陷阱由中断引起。若值为0，则由异常引起。                                                                                                | 读写 | 0x0 |
| 30:4 | 保留。                                                                                                                           | -  | -   |
| 3:0  | 代码: 若 <code>interrupt</code> 被设置, <code>code</code> 表示引发陷阱的mip位索引 (3=软中断, 7=定时器中断, 11=外部中断) ; 否则, <code>code</code> 根据异常原因设定。 | 读写 | 0x0 |
|      | 枚举值:                                                                                                                          |    |     |
|      | 0x0 → INSTR_ALIGN: 指令取指地址未对齐。由于启用了C扩展, 此项在RP2350上永不触发。                                                                        |    |     |
|      | 0x1 → INSTR_FAULT: 指令访问错误。指令获取未通过PMP检查, 或遇到下游总线故障, 随后越过不可推测点。                                                                 |    |     |
|      | 0x2 → ILLEGAL_INSTR: 执行了非法指令 (包括非法CSR访问)。                                                                                     |    |     |
|      | 0x3 → BREAKPOINT: 断点。当相关dcsr.ebreak位清除时执行ebreak指令。                                                                            |    |     |
|      | 0x4 → LOAD_ALIGN: 加载地址未对齐。Hazard3要求所有访问均为自然对齐。                                                                                |    |     |
|      | 0x5 → LOAD_FAULT: 加载访问错误。加载未通过PMP检查, 或遇到下游总线故障。                                                                               |    |     |
|      | 0x6 → STORE_ALIGN: 存储/AMO地址未对齐。Hazard3要求所有访问均为自然对齐。                                                                           |    |     |
|      | 0x7 → STORE_FAULT: 存储/AMO访问错误。存储/AMO未通过PMP检查, 或遇到下游总线故障。若对不支持原子操作的区域尝试执行AMO (RP2350上除SRAM外的任何区域), 该标志亦将被设定。                   |    |     |
|      | 0x8 → U_ECALL: 来自U模式的环境调用。                                                                                                    |    |     |
|      | 0xb → M_ECALL: 来自M模式的环境调用。                                                                                                    |    |     |

| 28:27 | <b>R3_A</b> : Address matching type for region 3. Writing an unsupported value (TOR) will set the region to OFF.                 | RW   | 0x0   |
|       | Enumerated values:                                                                                                               |      |       |
|       | 0x0 → OFF: Disable region                                                                                                        |      |       |
|       | 0x2 → NA4: Naturally aligned 4-byte                                                                                              |      |       |
|       | 0x3 → NAPOT: Naturally aligned power-of-two (8 bytes to 4 GiB)                                                                   |      |       |
| 26    | <b>R3_R</b> : Read permission for region 3. Note R and X are transposed from the standard bit order due to erratum RP2350-E6.    | RW   | 0x0   |
| 25    | <b>R3_W</b> : Write permission for region 3                                                                                      | RW   | 0x0   |
| 24    | <b>R3_X</b> : Execute permission for region 3. Note R and X are transposed from the standard bit order due to erratum RP2350-E6. | RW   | 0x0   |
| 23    | <b>R2_L</b> : Lock region 2, and apply it to M-mode as well as U-mode.                                                           | RW   | 0x0   |
| 22:21 | Reserved.                                                                                                                        | -    | -     |
| 20:19 | <b>R2_A</b> : Address matching type for region 2. Writing an unsupported value (TOR) will set the region to OFF.                 | RW   | 0x0   |

表384. MIP 寄存器

| 位     | 描述                                                                                                                                                                                                                                                                                                                              | 类型 | 复位  |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-----|
| 31:12 | 保留。                                                                                                                                                                                                                                                                                                                             | -  | -   |
| 11    | <b>MEIP</b> : 外部中断挂起。当 <code>mie.meie</code> 、 <code>mip.meip</code> 及 <code>mstatus mie</code> 均为1时，处理器跳转至外部中断向量。<br><br>Hazard3 具有内部寄存器，可单独过滤哪些外部 IRQ 会出现在 <code>meip</code> 中。当 <code>meip</code> 为1时，表示至少有一个外部中断被断言（故在 <code>meipa</code> 中挂起）、在 <code>meiea</code> 中启用，且优先级大于或等于当前 <code>meicontext.preempt</code> 中的抢占级别。 | 只读 | 0x0 |
| 10:8  | 保留。                                                                                                                                                                                                                                                                                                                             | -  | -   |
| 7     | <b>MTIP</b> : 定时器中断挂起。当 <code>mie.mtie</code> 、 <code>mip.mtip</code> 及 <code>mstatus mie</code> 均为1时，处理器跳转至定时器中断向量，除非此时软件或外部中断请求亦处于挂起且使能状态。                                                                                                                                                                                    | 读写 | 0x0 |
| 6:4   | 保留。                                                                                                                                                                                                                                                                                                                             | -  | -   |
| 3     | <b>MSIP</b> : 软件中断挂起。当 <code>mie.msie</code> 、 <code>mip.msip</code> 和 <code>mstatus mie</code> 均为1时，处理器将跳转至软件中断向量，除非此时同时有外部中断请求处于待处理且已使能状态。                                                                                                                                                                                    | 读写 | 0x0 |
| 2:0   | 保留。                                                                                                                                                                                                                                                                                                                             | -  | -   |

## RVCSR: PMPCFG0 寄存器

偏移: 0x3a0

### 描述

物理内存保护配置，适用于区域0至区域3

表385. PMPCFG0 寄存器

| 位     | 描述                                                  | 类型 | 复位  |
|-------|-----------------------------------------------------|----|-----|
| 31    | <b>R3_L</b> : 锁定区域3，并应用于M模式和U模式。                    | 读写 | 0x0 |
| 30:29 | 保留。                                                 | -  | -   |
| 28:27 | <b>R3_A</b> : 区域3的地址匹配类型。写入不支持的值 (TOR) 将使该区域被禁用。    | 读写 | 0x0 |
|       | 枚举值：                                                |    |     |
|       | 0x0 → 关闭：禁用该区域                                      |    |     |
|       | 0x2 → NA4：自然对齐4字节                                   |    |     |
|       | 0x3 → NAPOT：自然对齐的二次幂（8字节至4 GiB）                     |    |     |
| 26    | <b>R3_R</b> : 区域3的读取权限。注意：由于RP2350-E6缺陷，R与X与标准位序相反。 | 读写 | 0x0 |
| 25    | <b>R3_W</b> : 区域3的写入权限。                             | 读写 | 0x0 |
| 24    | <b>R3_X</b> : 区域3的执行权限。注意：由于RP2350-E6缺陷，R与X与标准位序相反。 | 读写 | 0x0 |
| 23    | <b>R2_L</b> : 锁定区域2，并应用于M模式和U模式。                    | 读写 | 0x0 |
| 22:21 | 保留。                                                 | -  | -   |
| 20:19 | <b>R2_A</b> : 第2区域的地址匹配类型。写入不支持的值 (TOR) 将使该区域被禁用。   | 读写 | 0x0 |

| Bits  | Description                                                                                                                     | Type | Reset |
|-------|---------------------------------------------------------------------------------------------------------------------------------|------|-------|
|       | Enumerated values:                                                                                                              |      |       |
|       | 0x0 → OFF: Disable region                                                                                                       |      |       |

| 31:30 | Reserved.                                                                                           | -    | -          |
| 29:0  | Physical memory protection address for region 2. Note all PMP addresses are in units of four bytes. | RW   | 0x00000000 |

## RVCSR: PMPADDR3 Register

Offset: 0x3b3

Table 392. PMPADDR3 Register

| Bits  | Description | Type | Reset |
|-------|-------------|------|-------|
| 31:30 | Reserved.   | -    | -     |

| 位   | 描述                                                      | 类型 | 复位  |
|-----|---------------------------------------------------------|----|-----|
| 7   | <b>R12_L</b> : 锁定区域12，并同时应用于M模式及U模式。                    | 只读 | 0x0 |
| 6:5 | 保留。                                                     | -  | -   |
| 4:3 | <b>R12_A</b> : 区域12的地址匹配类型。写入不支持的值(TOR)将使该区域被禁用。        | 只读 | 0x0 |
|     | 枚举值:                                                    |    |     |
|     | 0x0 → 关闭: 禁用该区域                                         |    |     |
|     | 0x2 → NA4: 自然对齐4字节                                      |    |     |
|     | 0x3 → NAPOT: 自然对齐的二次幂(8字节至4 GiB)                        |    |     |
| 2   | <b>R12_R</b> : 区域12的读取权限。注意: 由于RP2350-E6缺陷, R与X与标准位序相反。 | 只读 | 0x0 |
| 1   | <b>R12_W</b> : 区域12的写入权限。                               | 只读 | 0x0 |
| 0   | <b>R12_X</b> : 区域12的执行权限。注意: 由于RP2350-E6缺陷, R与X与标准位序相反。 | 只读 | 0x0 |

## RVCSR: PMPADDR0寄存器

偏移: 0x3b0

表389. PMPADDR0  
寄存器

| 位     | 描述                               | 类型 | 复位         |
|-------|----------------------------------|----|------------|
| 31:30 | 保留。                              | -  | -          |
| 29:0  | 第0区的物理内存保护地址。注意, 所有PMP地址单位均为4字节。 | 读写 | 0x00000000 |

## RVCSR: PMPADDR1寄存器

偏移: 0x3b1

表390. PMPADDR1  
寄存器

| 位     | 描述                               | 类型 | 复位         |

## RVCSR: TDATA1 Register

Offset: 0x7a1

### Description

Trigger configuration data 1

Hazard 3 only supports address/data match triggers (type=2) so this register description includes the `mcontrol` fields for this type.

More precisely, Hazard3 only supports exact instruction address match triggers (hardware breakpoints) so many of this register's fields are hardwired.

Table 406. TDATA1 Register

| Bits  | Description                                                                                                                                                                                                                                                                                                                       | Type | Reset |

## RVCSR: TDATA1 寄存器

偏移: 0x7a1

### 描述

触发器配置数据1

Hazard 3 仅支持地址/数据匹配触发器 (type=2)，因此该寄存器描述包含此类型对应的 `mcontrol` 字段。

更准确地说，Hazard3 仅支持精确指令地址匹配触发器（硬件断点），因此本寄存器的许多字段均为固定连线。

表 406。TDATA1  
寄存器

| 位     | 描述                                                                                                                                                                                            | 类型 | 复位   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|------|
| 31:28 | <b>TYPE:</b> 触发类型。硬连线为type=2，表示地址/数据匹配触发器。                                                                                                                                                    | 只读 | 0x2  |
| 27    | <b>D MODE:</b> 若为0，调试模式和M模式均可写入选定的 <code>tselect</code> 下的 <code>tdata</code> 寄存器。<br><br>若为1，仅调试模式可写入选定的 <code>tselect</code> 下的 <code>tdata</code> 寄存器。<br>其他模式的写入将被忽略。<br><br>该位仅可由调试模式写入。 | 读写 | 0x0  |
| 26:21 | <b>MASKMAX:</b> 值为0表示仅支持精确地址匹配。                                                                                                                                                               | 只读 | 0x00 |
| 20    | <b>HIT:</b> 触发命中标志。未实现，硬连线为0。                                                                                                                                                                 | 只读 | 0x0  |
| 19    | <b>SELECT:</b> 硬连线值为0表示仅支持地址匹配，不支持数据匹配。                                                                                                                                                       | 只读 | 0x0  |
| 18    | <b>TIMING:</b> 硬连线值为0表示触发在触发指令执行之前发生，而非之后。                                                                                                                                                    | 只读 | 0x0  |
| 17:16 | <b>SIZEL0:</b> 硬连线值为0表示不支持访问大小匹配。                                                                                                                                                             | 只读 | 0x0  |
| 15:12 | <b>ACTION:</b> 触发发生时选择执行的操作。                                                                                                                                                                  | 读写 | 0x0  |
|       | 枚举值：                                                                                                                                                                                          |    |      |

| Bits | Description                                                                                                   | Type | Reset |
|------|---------------------------------------------------------------------------------------------------------------|------|-------|
|      | 0x0 → EBREAK: Raise a breakpoint exception, which can be handled by the M-mode exception handler              |      |       |
|      | 0x1 → DEBUG: Enter debug mode. This action is only selectable when <code>tdata1.dmode</code> is 1.            |      |       |
| 11   | <b>CHAIN:</b> Hardwired to 0 to indicate trigger chaining is not supported.                                   | RO   | 0x0   |
| 10:7 | <b>MATCH:</b> Hardwired to 0 to indicate match is always on the full address specified by <code>tdata2</code> | RO   | 0x0   |
| 6    | <b>M:</b> When set, enable this trigger in M-mode                                                             | RW   | 0x0   |
| 5:4  | Reserved.                                                                                                     | -    | -     |
| 3    | <b>U:</b> When set, enable this trigger in U-mode                                                             | RW   | 0x0   |
| 2    | <b>EXECUTE:</b> When set, the trigger fires on the address of an instruction that is executed.                | RW   | 0x0   |
| 1    | <b>STORE:</b> Hardwired to 0 to indicate store address/data triggers are not supported                        | RO   | 0x0   |
| 0    | <b>LOAD:</b> Hardwired to 0 to indicate load address/data triggers are not supported                          | RO   | 0x0   |

## RVCSR: DCSR Register

Offset: 0x7b0

### Description

Debug control and status register. Access outside of Debug Mode will cause an illegal instruction exception.

Table 408. DCSR Register

| Bits  | Description                                                                                                                       | Type | Reset |
|-------|-----------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | <b>XDEBUGVER:</b> Hardwired to 4: external debug support as per RISC-V 0.13.2 debug specification.                                | RO   | 0x4   |
| 27:16 | Reserved.                                                                                                                         | -    | -     |
| 15    | <b>EBREAKM:</b> When 1, <code>ebreak</code> instructions executed in M-mode will break to Debug Mode instead of trapping          | RW   | 0x0   |
| 14:13 | Reserved.                                                                                                                         | -    | -     |
| 12    | <b>EBREAKU:</b> When 1, <code>ebreak</code> instructions executed in U-mode will break to Debug Mode instead of trapping.         | RW   | 0x0   |
| 11    | <b>STEPIE:</b> Hardwired to 0: no interrupts are taken during hardware single-stepping.                                           | RO   | 0x0   |
| 10    | <b>STOPCOUNT:</b> Hardwired to 1: <code>mcycle/mcycleh</code> and <code>minstret/minstreth</code> do not increment in Debug Mode. | RO   | 0x1   |

| 位    | 描述                                                    | 类型 | 复位  |
|------|-------------------------------------------------------|----|-----|
|      | 0x0 → EBREAK：引发断点异常，该异常可由M模式异常处理程序处理。                 |    |     |
|      | 0x1 → 调试：进入调试模式。仅当 tdata1.dmode为1时，方可选择此操作。           |    |     |
| 11   | <b>CHAIN</b> ：硬连线为0，表示不支持触发链。                         | 只读 | 0x0 |
| 10:7 | <b>MATCH</b> ：硬连线为0，表示匹配始终针对 <b>tdata2</b> 指定的完整地址有效。 | 只读 | 0x0 |
| 6    | <b>M</b> ：设置后，启用 M 模式下的此触发器。                          | 读写 | 0x0 |
| 5:4  | 保留。                                                   | -  | -   |
| 3    | <b>U</b> ：设置后，启用 U 模式下的此触发器。                          | 读写 | 0x0 |
| 2    | <b>EXECUTE</b> ：设置后，触发器将在执行指令的地址处触发。                  | 读写 | 0x0 |
| 1    | <b>STORE</b> ：硬连线为0，表示不支持存储地址/数据触发器。                  | 只读 | 0x0 |
| 0    | <b>LOAD</b> ：硬连线为0，表示不支持加载地址/数据触发器。                   | 只读 | 0x0 |

## RVCSR：DCSR 寄存器

偏移：0x7b0

### 说明

调试控制与状态寄存器。在调试模式之外访问将触发非法指令异常。

表 408. DCSR 寄存器

| 位     | 描述                                                                                    | 类型 | 复位  |
|-------|---------------------------------------------------------------------------------------|----|-----|
| 31:28 | <b>XDEBUGVER</b> ：硬连线为4，符合RISC-V 0.13.2调试规范的外部调试支持。                                   | 只读 | 0x4 |
| 27:16 | 保留。                                                                                   | -  | -   |
| 15    | <b>EBREAKM</b> ：当该位为1时，M模式执行的 <b>ebreak</b> 指令将跳转至调试模式，而非产生陷阱。                        | 读写 | 0x0 |
| 14:13 | 保留。                                                                                   | -  | -   |
| 12    | <b>EBREAKU</b> ：当该位为1时，U模式执行的 <b>ebreak</b> 指令将跳转至调试模式，而非产生陷阱。                        | 读写 | 0x0 |
| 11    | <b>STEPIE</b> ：硬连线为0，硬件单步期间不接收中断。                                                     | 只读 | 0x0 |
| 10    | <b>STOPCOUNT</b> ：硬连线为1， <b>mcycle/mcycleh</b> 及 <b>minstret/minstreth</b> 在调试模式下不递增。 | 只读 | 0x1 |

| Bits | Description                                                                                                                                                        | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 9    | <b>STOPTIME</b> : Hardwired to 1: core-local timers don't increment in debug mode. External timers (e.g. hart-shared) may be configured to ignore this.            | RO   | 0x1   |
| 8:6  | <b>CAUSE</b> : Set by hardware when entering debug mode.                                                                                                           | RO   | 0x0   |
|      | Enumerated values:                                                                                                                                                 |      |       |
|      | 0x1 → EBREAK: An ebreak instruction was executed when the relevant <code>dcsr.ebreakx</code> bit was set.                                                          |      |       |
|      | 0x2 → TRIGGER: The trigger module caused a breakpoint exception.                                                                                                   |      |       |
|      | 0x3 → HALTREQ: Processor entered Debug Mode due to a halt request, or a reset-halt request present when the core reset was released.                               |      |       |
|      | 0x4 → STEP: Processor entered Debug Mode after executing one instruction with single-stepping enabled.                                                             |      |       |
| 5:3  | Reserved.                                                                                                                                                          | -    | -     |
| 2    | <b>STEP</b> : When 1, re-enter Debug Mode after each instruction executed in M-mode or U-mode.                                                                     | RW   | 0x0   |
| 1:0  | <b>PRV</b> : Read the privilege mode the core was in when entering Debug Mode, and set the privilege mode the core will execute in when returning from Debug Mode. | RW   | 0x3   |

## RVCSR: DPC Register

Offset: 0x7b1

Table 409. DPC Register

| Bits | Description                                                                                                                                                                                                                                                                                                     | Type | Reset      |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:1 | Debug program counter. When entering Debug Mode, <code>dpc</code> samples the current program counter, e.g. the address of an <code>ebreak</code> which caused Debug Mode entry. When leaving debug mode, the processor jumps to <code>dpc</code> . The host may read/write this register whilst in Debug Mode. | RW   | 0x00000000 |
| 0    | Reserved.                                                                                                                                                                                                                                                                                                       | -    | -          |

| 15:0 | <p>PMP M-mode configuration. One bit per PMP region. Setting a bit makes the corresponding region apply to M-mode (like the <code>pmpcfg.L</code> bit) but does not lock the region.</p> <p>PMP is useful for non-security-related purposes, such as stack guarding and peripheral emulation. This extension allows M-mode to freely use any currently unlocked regions for its own purposes, without the inconvenience of having to lock them.</p> <p>Note that this does not grant any new capabilities to M-mode, since in the base standard it is already possible to apply unlocked regions to M-mode by locking them. In general, PMP regions should be locked in ascending region number order so they can't be subsequently overridden by currently unlocked regions.</p> <p>Note also that this is not the same as the rule locking bypass bit in the ePMP extension, which does not permit locked and unlocked M-mode regions to coexist.</p> <p>This is a Hazard3 custom CSR.</p> | RW   | 0x0000 |

## RVCSR: MEIEA Register

**Offset:** 0xbe0

### Description

External interrupt enable array.

The array contains a read-write bit for each external interrupt request: a 1 bit indicates that interrupt is currently enabled. At reset, all external interrupts are disabled.

If enabled, an external interrupt can cause assertion of the standard RISC-V machine external interrupt pending flag (`mip.meip`), and therefore cause the processor to enter the external interrupt vector. See `meipa`.

There are up to 512 external interrupts. The upper half of this register contains a 16-bit window into the full 512-bit vector. The window is indexed by the 5 LSBs of the write data.

Table 417. MEIEA Register

| Bits  | Description                                                                                                                                  | Type | Reset  |

## RVCSR: MEIPA Register

**Offset:** 0xbe1

### Description

External interrupt pending array

Contains a read-only bit for each external interrupt request. Similarly to `meiea`, this register is a window into an array of up to 512 external interrupt flags. The status appears in the upper 16 bits of the value read from `meipa`, and the lower 5 bits of the value written by the same CSR instruction (or 0 if no write takes place) select a 16-bit window of the full interrupt pending array.

A 1 bit indicates that interrupt is currently asserted. IRQs are assumed to be level-sensitive, and the relevant `meipa` bit is

| 位    | 描述                                                                                                                                                                                                                                                                                                                                                       | 类型 | 复位     |

| 15:0 | <p>PMP M 模式配置。每个 PMP 区域对应一位。设置该位后，相应区域将应用于 M 模式（类似 <code>pmpcfg.L</code> 位），但不会锁定该区域。</p> <p>PMP 适用于非安全相关用途，例如堆栈保护和外设仿真。该扩展允许 M 模式自由使用当前所有未锁定区域，用于自身目的，无需锁定带来的限制。</p> <p>请注意，这并不授予 M 模式新的权限，因为在基础标准中，已可通过锁定将未锁定区域应用于 M 模式。通常，应按区域编号升序锁定 PMP 区域，防止后续未锁定区域覆盖已锁定区域。</p> <p>另请注意，此规则不同于 ePMP 扩展中的规则锁定绕过位，后者不允许已锁定与未锁定的 M 模式区域共存。</p> <p>这是Hazard3定制的CSR。</p> | 读写 | 0x0000 |

## RVCSR：MEIEA 寄存器

偏移量: 0xbe0

### 说明

外部中断使能数组。

该数组包含每个外部中断请求的可读写位：值为 1 表示该中断目前处于使能状态。  
复位时，所有外部中断均被禁用。

使能时，外部中断可触发标准RISC-V机器外部中断挂起标志  
(`mip.meip`)，从而导致处理器进入外部中断向量。详见 `meipa`。

最多支持512个外部中断。本寄存器的高半部分包含对完整512位向量的16位窗口。窗口索引由写入数据的最低5位决定。

表417. MEIEA 寄存器

| 位     | 描述                                                            | 类型 | 复位     |

## RVCSR：MEIPA 寄存器

偏移量: 0xbe1

### 描述

外部中断挂起数组

包含针对每个外部中断请求的只读位。与 `meiea` 类似，该寄存器是最多 512 个外部中断标志数组的窗口。状态显示在从 `meip` 读取值的高 16 位，且同一 CSR 指令写入的值的低 5 位（若未写入则为 0）用于选择完整中断挂起数组的 16 位窗口。

位 1 表示该中断当前处于断言状态。中断请求 (IRQ) 假定为电平敏感，相应的 `meipa` 位通过服务请求方清除，以取消其中断请求的断言。

cleared by servicing the requestor so that it deasserts its interrupt request.

When any interrupt of sufficient priority is both set in `meipa` and enabled in `meiea`, the standard RISC-V external interrupt pending bit `mip.meip` is asserted. In other words, `meipa` is filtered by `meiea` to generate the standard `mip.meip` flag.

Table 418. MEIPA Register

| Bits  | Description                                                                                                                                   | Type | Reset |

## RVCSR: MEIFA Register

Offset: 0xbe2

### Description

External interrupt force array

Contains a read-write bit for every interrupt request. Writing a 1 to a bit in the interrupt force array causes the corresponding bit to become pending in `meipa`. Software can use this feature to manually trigger a particular interrupt.

There are no restrictions on using `meifa` inside of an interrupt. The more useful case here is to schedule some lower-priority handler from within a high-priority interrupt, so that it will execute before the core returns to the foreground code. Implementers may wish to reserve some external IRQs with their external inputs tied to 0 for this purpose.

Bits can be cleared by software, and are cleared automatically by hardware upon a read of `meinext` which returns the corresponding IRQ number in `meinext.irq` with `mienext.noirq` clear (no matter whether `meinext.update` is written).

`meifa` implements the same array window indexing scheme as `meiea` and `meipa`.

Table 419. MEIFA Register

| Bits  | Description                                                                                                                                   | Type | Reset  |

## RVCSR: MEIPRA Register

Offset: 0xbe3

### Description

External interrupt priority array

Each interrupt has an (up to) 4-bit priority value associated with it, and each access to this register reads and/or writes a 16-bit window containing four such priority values. When less than 16 priority levels are available, the LSBs of the priority fields are hardwired to 0.

When an interrupt's priority is lower than the current preemption priority `meicontext.preempt`, it is treated as not being pending for the purposes of `mip.meip`. The pending bit in `meipa` will still assert, but the machine external interrupt pending bit `mip.meip` will not, so the processor will ignore this interrupt. See `meicontext`.

Table 420. MEIPRA Register

| Bits  | Description                                                                                                                | Type | Reset  |
|-------|----------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | <b>WINDOW:</b> 16-bit read/write window into the external interrupt priority array, containing four 4-bit priority values. | RW   | 0x0000 |
| 15:5  | Reserved.                                                                                                                  | -    | -      |

当任何优先级足够的中断在meipa中被设置且在meiea中被使能时，标准的RISC-V外部中断挂起位mip.meip将被断言。

换言之，`meipa`经`meiea`过滤后生成标准的`mip.meip`标志。换言之，`meipa`经由`meiea`过滤以生成标准`mip.meip`标志。

## RVCSR：MEIFA 寄存器

偏移：0xbe2

### 描述

外部中断强制数组

包含每个中断请求的读写位。向中断强制数组中的某个位写入1，将导致对应位在`meipa`中变为挂起状态。软件可利用此功能手动触发特定中断。

在中断处理程序中使用`meifa`没有任何限制。更为实用的情况是在高优先级中断中调度低优先级处理程序，以便其在核心返回前台代码之前执行。实现者可考虑保留部分外部IRQ，其外部输入固定接地（连接至0）以供此用途。

相关位可由软件清除，并且在读取`meinext`时会由硬件自动清除，读取时返回对应的IRQ编号于`meinext.irq`，同时使用`minext.noirq`清除（无论是否写入`meinext.update`）。

`meifa`实现了与`meiea`和`meipa`相同的数组窗口索引方案。

## RVCSR：MEIPRA 寄存器

偏移：0xbe3

### 描述

外部中断优先级数组

每个中断均关联一个（最多）4位优先级值，对该寄存器的每次访问均读取和/或写入包含四个此类优先级值的16位窗口。当可用优先级级别少于16级时，优先级字段的最低有效位固定为0。

当中断优先级低于当前抢占优先级`meicontext.preempt`时，针对`mip.meip`，该中断将视为未挂起状态。`meipa`中的挂起位仍会置位，但机器外部中断挂起位`mip.meip`不会置位，因此处理器将忽略该中断。详见`meicontext`。

## RVCSR: MEINEXT Register

Offset: 0xbe4

### Description

Get next external interrupt

Contains the index of the highest-priority external interrupt which is both asserted in `meipa` and enabled in `meiea`, left-shifted by 2 so that it can be used to index an array of 32-bit function pointers. If there is no such interrupt, the MSB is set.

When multiple interrupts of the same priority are both pending and enabled, the lowest-numbered wins. Interrupts with priority less than `meicontext.ppreempt` – the previous preemption priority – are treated as though they are not pending. This is to ensure that a preempting interrupt frame does not service interrupts which may be in progress in the frame that was preempted.

Table 421. MEINEXT Register

| Bits  | Description                                                                                                                                                                                                                                                                                         | Type | Reset |

| 0     | <b>UPDATE:</b> Writing 1 (self-clearing) causes hardware to update <code>meicontext</code> according to the IRQ number and preemption priority of the interrupt indicated in <code>noirq/irq</code> . This should be done in a single atomic operation, i.e. <code>csrrsi a0, meinext, 0x1</code> . | SC   | 0x0   |

## RVCSR: MEICONTEXT Register

Offset: 0xbe5

### Description

External interrupt context register

Configures the priority level for interrupt preemption, and helps software track which interrupt it is currently in. The latter is useful when a common interrupt service routine handles interrupt requests from multiple instances of the same peripheral.

A three-level stack of preemption priorities is maintained in the `preempt`, `ppreempt` and `pppreempt` fields. The priority stack is saved when hardware enters the external interrupt vector, and restored by an `mret` instruction if `meicontext.mreteirq` is set.

The top entry of the priority stack, `preempt`, is used by hardware to ensure that only higher-priority interrupts can preempt the current interrupt. The next entry, `ppreempt`, is used to avoid servicing interrupts which may already be in progress in a frame that was preempted. The third entry, `pppreempt`, has no hardware effect, but ensures that `preempt` and `ppreempt` can be correctly saved/restored across arbitrary levels of preemption.

## RVCSR: MEINEXT寄存器

偏移: 0xbe4

### 描述

获取下一个外部中断

包含在 `meipa` 中断请求且在 `meiea` 中使能的最高优先级外部中断的索引，左移2位，以用于索引32位函数指针数组。如果不存在此类中断，则最高有效位（MSB）被置位。

当多个相同优先级的中断既处于挂起状态又被使能时，编号最低者优先。优先级低于 `meicontext.ppreempt` ——前一个抢占优先级——的中断，视同未挂起。

此机制确保抢占中断帧不会处理中断帧中可能正在执行的中断。

| 位     | 描述                                                                                                                                                      | 类型 | 复位    |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------|----|-------|
| 31    | <b>NOIRQ</b> : 当不存在已启用、挂起且优先级大于或等于 <code>meicontext.ppreempt</code> 的外部中断时设置。可通过 <code>bltz</code> 或 <code>bgez</code> 指令高效测试。                          | 只读 | 0x0   |
| 30:11 | 保留。                                                                                                                                                     | -  | -     |
| 10:2  | <b>IRQ</b> : 最高优先级活动外部中断的索引。当不存在满足优先级条件且已挂起且已启用的外部中断时，值为零。                                                                                              | 只读 | 0x000 |
| 1     | 保留。                                                                                                                                                     | -  | -     |
| 0     | <b>UPDATE</b> : 写入1（自清除）将根据 <code>noirq/irq</code> 中指示的中断编号和抢占优先级，硬件更新 <code>meicontext</code> 。此操作应作为单个原子操作完成，即 <code>csrrsi a0, meinext, 0x1</code> 。 | SC | 0x0   |

## RVCSR: MEICONTEXT寄存器

偏移: 0xbe5

### 描述

外部中断上下文寄存器

配置中断抢占的优先级等级，帮助软件跟踪当前所处的中断状态。当通用中断服务程序处理来自同一外设多个实例的中断请求时，此功能尤为重要。

在 `preempt`、`ppreempt` 和 `pppreempt` 字段中维护了三级抢占优先级栈。当硬件进入外部中断向量时，优先级栈会被保存；若设置了 `meicontext.mreteirq`，则通过 `mret` 指令恢复该栈。

优先级栈的顶部条目 `preempt` 被硬件用以确保仅更高优先级的中断能够抢占当前中断。下一个条目 `ppreempt` 用于避免在已被抢占的帧中服务的中断被重复处理。第三个条目 `pppreempt` 无硬件效应，但确保 `preempt` 和 `ppreempt` 可以在任意抢占层级间被正确保存与恢复。

表422。  
MEICONTEXT寄存器

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Type | Reset |

| 3     | <b>MTIESAVE:</b> Reads as the current value of <code>mie.mtie</code> , if <code>clearts</code> is set by the same CSR access instruction. Otherwise reads as 0. Writes are ORed into <code>mie.mtie</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        | RO   | 0x0   |
| 2     | <b>MSIESAVE:</b> Reads as the current value of <code>mie.msie</code> , if <code>clearts</code> is set by the same CSR access instruction. Otherwise reads as 0. Writes are ORed into <code>mie.msie</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                        | RO   | 0x0   |
| 1     | <b>CLEARTS:</b> Write-1 self-clearing field. Writing 1 will clear <code>mie.mtie</code> and <code>mie.msie</code> , and present their prior values in the <code>mtiesave</code> and <code>msiesave</code> of this register. This makes it safe to re-enable IRQs (via <code>mstatus mie</code> ) without the possibility of being preempted by the standard timer and soft interrupt handlers, which may not be aware of Hazard3's interrupt hardware.<br><br>The clear due to <code>clearts</code> takes precedence over the set due to <code>mtiesave</code> / <code>msiesave</code> , although it would be unusual for software to write both on the same cycle. | SC   | 0x0   |
| 0     | <b>MRETEIRQ:</b> If 1, enable restore of the preemption priority stack on <code>mret</code> . This bit is set on entering the external interrupt vector, cleared by <code>mret</code> , and cleared upon taking any trap other than an external interrupt.<br><br>Provided <code>meicontext</code> is saved on entry to the external interrupt vector (before enabling preemption), is restored before exiting, and the standard software/timer IRQs are prevented from preempting (e.g. by using <code>clearts</code> ), this flag allows the hardware to safely manage the preemption priority stack even when an external interrupt handler may take exceptions. | RW   | 0x0   |

| 位     | 描述                                                                                                                                                                                                                                                                                                                                                                     | 类型 | 复位    |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|-------|
| 31:28 | <b>PPPREEMPT:</b> 先前的 <code>ppreempt</code> 。优先级保存时设为 <code>ppreempt</code> , 优先级恢复时设为零。无硬件效应, 但确保当 <code>meicontext</code> 被正确保存和恢复时, <code>preempt</code> 及 <code>ppreempt</code> 在任意多抢占帧中能正确维护栈状态。                                                                                                                                                                  | 读写 | 0x0   |
| 27:24 | <b>PPREEMPT:</b> 先前的 <code>preempt</code> 。在优先级保存时设置为 <code>preempt</code> , 优先级恢复时恢复为 <code>ppreempt</code> 。<br><br>低于 <code>ppreempt</code> 优先级的 IRQ 不会在 <code>meinext</code> 中显示, 以防止在抢占帧中重新抢占被抢占者。                                                                                                                                                                | 读写 | 0x0   |
| 23:21 | 保留。                                                                                                                                                                                                                                                                                                                                                                    | -  | -     |
| 20:16 | <b>PREEMPT:</b> 抢占当前中断的最低中断优先级。<br>低于 <code>preempt</code> 优先级的中断不会导致核心跳转至中断处理程序。写入 <code>meinext.update</code> 或硬件进入外部中断向量时由硬件更新。<br><br>如果此字段更新时 <code>meinext</code> 中存在中断, 则 <code>preempt</code> 被设置为该中断优先级高一级。否则, <code>ppreempt</code> 被设置为高于最大中断优先级一级, 禁止抢占。                                                                                                   | 读写 | 0x00  |
| 15    | <b>NOIRQ:</b> 非中断状态 (读/写)。复位时设置为 1。写入 <code>meinext.update</code> 时将设置为 <code>meinext.noirq</code> 。无硬件影响。                                                                                                                                                                                                                                                             | 读写 | 0x1   |
| 14:13 | 保留。                                                                                                                                                                                                                                                                                                                                                                    | -  | -     |
| 12:4  | <b>IRQ:</b> 当前 IRQ 编号 (可读写)。在写入 <code>meinext.update</code> 时设置为 <code>meinext.irq</code> 。无硬件影响。                                                                                                                                                                                                                                                                      | 读写 | 0x000 |
| 3     | <b>MTIESAVE:</b> 如果 <code>clearts</code> 由同一 CSR 访问指令设置, 则读取为 <code>mie.mtie</code> 的当前值; 否则读取为 0。写入值将与 <code>mie.mtie</code> 执行逻辑或操作。                                                                                                                                                                                                                                 | 只读 | 0x0   |
| 2     | <b>MSIESAVE:</b> 如果 <code>clearts</code> 由同一 CSR 访问指令设置, 则读取为 <code>mie.msie</code> 的当前值; 否则读取为 0。写入值将与 <code>mie.msie</code> 执行逻辑或操作。                                                                                                                                                                                                                                 | 只读 | 0x0   |
| 1     | <b>CLEARTS:</b> 写 1 即自清字段。写入 1 将清除 <code>mie.mtie</code> 和 <code>mie.msie</code> , 并在该寄存器的 <code>mtiesave</code> 和 <code>msiesave</code> 字段中保存其先前值。此操作确保通过 <code>mstatus.mie</code> 重新启用 IRQ 时安全无虞, 避免被标准定时器及软中断处理程序抢占, 而这些程序可能不识别 Hazard3 中断硬件。<br><br>由于 <code>clearts</code> 导致的清除优先于由于 <code>mtiesave</code> / <code>msiesave</code> 设置的清除, 尽管软件在同一周期内写入两者的情况异常罕见。 | SC | 0x0   |
| 0     | <b>MRETEIRQ:</b> 如果为 1, 则启用在 <code>mret</code> 指令上恢复抢占优先级堆栈。此位在进入外部中断向量时被置位, 在执行 <code>mret</code> 时清除, 并且在触发任何非外部中断陷阱时亦被清除。<br><br>前提是 <code>meicontext</code> 在进入外部中断向量时被保存 (在启用抢占之前)、在退出前被恢复, 且通过使用 <code>clearts</code> 等方式防止标准软件/定时器 IRQ 的抢占, 本标志允许硬件即使在外部中断处理程序可能引发异常的情况下, 也能安全管理抢占优先级堆栈。                                                                        | 读写 | 0x0   |

## RVCSR: MSLEEP 寄存器

偏移量: 0xbf0

**Description**

M-mode sleep control register

Table 423. MSLEEP Register

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Type | Reset |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:3 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                            | -    | -     |
| 2    | <b>SLEEPONBLOCK:</b> Enter the deep sleep state configured by msleep.deepsleep/msleep.powerdown on a <code>h3.block</code> instruction, as well as a standard <code>wfi</code> . If this bit is clear, a <code>h3.block</code> is always implemented as a simple pipeline stall.                                                                                                                                                                                     | RW   | 0x0   |
| 1    | <b>POWERDOWN:</b> Release the external power request when going to sleep. The function of this is platform-defined – it may do nothing, it may do something simple like clock-gating the fabric, or it may be tied to some complex system-level power controller.<br><br>When waking, the processor reasserts its external power-up request, and will not fetch any instructions until the request is acknowledged. This may add considerable latency to the wakeup. | RW   | 0x0   |
| 0    | <b>DEEPSLEEP:</b> Deassert the processor clock enable when entering the sleep state. If a clock gate is instantiated, this allows most of the processor (everything except the power state machine and the interrupt and halt input registers) to be clock gated whilst asleep, which may reduce the sleep current. This adds one cycle to the wakeup latency.                                                                                                       | RW   | 0x0   |

## 3.9. Arm/RISC-V architecture switching

RP2350 supports both Arm and RISC-V processor architectures. SDK-based programs that don't contain assembly code typically run unmodified on either architecture by providing the appropriate build flag.

There are two processor sockets on RP2350, referred to as core 0 and core 1 throughout this document. Each socket can be occupied *either* by a Cortex-M33 processor (implementing the Armv8-M Main architecture, plus extensions) or by a Hazard3 processor (implementing the RV32IMAC architecture, plus extensions).

When a processor reset is removed, hardware samples the [ARCHSEL](#) register in the OTP control register block to determine which processor to connect to that socket. The unused processor is held in reset indefinitely, with its clock inputs gated. The default and allowable values of the [ARCHSEL](#) register are determined by critical OTP flags:

1. If [CRIT0\\_ARM\\_DISABLE](#) is set, only RISC-V is allowed.
2. Else if [CRIT0\\_RISCV\\_DISABLE](#) is set, only Arm is allowed.
3. Else if [CRIT1\\_SECURE\\_BOOT\\_ENABLE](#) is set, only Arm is allowed.
4. Else if [CRIT1\\_BOOT\\_ARCH](#) is set, both architectures are permitted, and the default is RISC-V.
5. If none of the above flags are set, both architectures are permitted, and the default is Arm.

No [CRIT1](#) flags are set by default, so on devices where both architectures are available, the default is Arm. To change the default architecture to RISC-V, set the [CRIT1\\_BOOT\\_ARCH](#) flag to 1.

Enabling secure boot disables the RISC-V cores because the RP2350 bootrom does not implement secure boot for RISC-V. This prevents a bad actor from side-stepping secure boot by switching architectures.

**NOTE**

As of RP2350 A3 the [CRIT0\\_ARM\\_DISABLE](#) flag has no effect, removing a potential unlock path for debug on a secured RP2350. Additionally, the combination of [CRIT0\\_RISCV\\_DISABLE=1](#) and [CRIT1\\_BOOT\\_ARCH=1](#) is decoded to an invalid state, preventing boot.

RP2350 only samples the [ARCHSEL](#) register when a processor is reset. Its value is ignored at all other times, so software can program the register before a watchdog reset to implement a software-initiated switch between architectures.

Read the [ARCHSEL\\_STATUS](#) register to check the ARCHSEL value most recently sampled by each processor.

### 3.9.1. Automatic switching

RP2350 binaries contain a binary marker recognised by the bootrom. This marker:

- contains additional information such as the binary's entry point and the intended architecture: Arm, RISC-V, or both
- helps detect when a flash device is connected
- helps verify that the flash device was accessed using the correct SPI parameters

When booting with core 0 in Arm architecture mode, upon detecting a bootable RISC-V binary, the bootrom automatically resets both cores and switches them to RISC-V architecture mode. After the reset, the bootrom detects that the binary and processor architectures match, so the binary launches normally.

Likewise, when booting with core 0 in RISC-V architecture mode, upon detecting a bootable Arm binary, the bootrom automatically resets both cores and switches them to Arm architecture mode.

|------|-------------------|----|------------|
| 31:0 | 指向配置数据结构的指针（固定为0） | 只读 | 0x00000000 |

## 3.9. Arm/RISC-V 架构切换

RP2350 支持 Arm 和 RISC-V 两种处理器架构。基于 SDK 的程序通常不包含汇编代码，通过提供适当的构建标志，即可在任一架构上无修改运行。

RP2350 配备两个处理器插槽，在本文档中分别称为核心0和核心1。每个插槽可由 Cortex-M33 处理器（实现 Armv8-M 主架构及扩展）或 Hazard3 处理器（实现 RV32IMAC 架构及扩展）占用。

当处理器复位解除时，硬件会采样 OTP 控制寄存器块中的 ARCHSEL 寄存器，以确定连接至该插槽的处理器类型。未使用的处理器将无限期保持复位状态，其时钟输入被门控。ARCHSEL 寄存器的默认值及允许值由关键 OTP 标志决定：

- 如果 CRIT0\_ARM\_DISABLE 被设置，则仅允许使用 RISC-V。
- 否则，如果 CRIT0\_RISCV\_DISABLE 被设置，则仅允许使用 Arm。
- 否则，如果 CRIT1\_SECURE\_BOOT\_ENABLE 被设置，则仅允许使用 Arm。
- 否则，如果 CRIT1\_BOOT\_ARCH 被设置，则两种架构均被允许，且默认使用 RISC-V。
- 如果上述标志均未设置，则两种架构均被允许，且默认使用 Arm。

默认情况下，未设置任何 CRIT1 标志，因此在同时支持两种架构的设备上，默认架构为 Arm。要将默认架构更改为 RISC-V，请将 CRIT1\_BOOT\_ARCH 标志设置为 1。

启用安全启动后，RISC-V 内核将被禁用，因为 RP2350 启动只读存储器（bootrom）未对 RISC-V 实施安全启动。这有效防止恶意行为者通过切换架构绕过安全启动机制。

### ① 注意

自 RP2350 A3 版本起，CRIT0\_ARM\_DISABLE 标志不再生效，消除了在受保护的 RP2350 上调试时可能存在的解锁路径。此外，CRIT0\_RISCV\_DISABLE=1 与 CRIT1\_BOOT\_ARCH=1 的组合被解码为无效状态，阻止了启动。

RP2350 仅在处理器复位时采样 ARCHSEL 寄存器。该寄存器在其他时间点的值将被忽略，因此软件可在看门狗复位前对其进行编程，以实现软件发起的架构切换。

读取 ARCHSEL\_STATUS 寄存器以检查各处理器最近采样的 ARCHSEL 值。

### 3.9.1. 自动切换

RP2350 的二进制文件包含由只读存储器引导程序识别的二进制标记。该标记：

- 包含二进制入口点及目标架构（Arm、RISC-V 或两者）的附加信息；
- 帮助检测闪存设备是否已连接；
- 帮助验证访问闪存设备时是否采用了正确的 SPI 参数；

当核心 0 以 Arm 架构模式启动时，若检测到可引导的 RISC-V 二进制文件，引导只读存储器会自动重置两个核心，并切换为 RISC-V 架构模式。复位后，bootrom 检测到二进制文件与处理器架构匹配，因而正常启动该二进制文件。

同样，当以 RISC-V 架构模式在核心 0 启动时，bootrom 在检测到可启动的 Arm 二进制文件后，会自动复位两个核心，并将其切换至 Arm 架构模式。

As a result, the USB bootloader, which runs on both Arm and RISC-V, can accept a UF2 image download for either architecture, and automatically boot it using the correct processors.

### 3.9.2. Mixed architecture combinations

The `ARCHSEL` register has one bit for each processor socket, so it is possible to request mixed combinations of Arm and RISC-V processors: either Arm core 0 and RISC-V core 1, or RISC-V core 0 and Arm core 1.

Practical applications for this are limited, since this requires two separate program images. The two cores interoperate normally, including shared exclusives via the global monitor: a shared variable can be safely, concurrently accessed by an Arm processor performing `ldrex`, `strex` instructions and a RISC-V processor performing `amoadd.w` instructions, for example.

Hardware supports debugging for a mixture of Arm and RISC-V processors, though this may prove challenging on the host software side. Debug resources for unused processors are dynamically marked as non-PRESENT in the top-level CoreSight ROM table.

因此，运行于Arm和RISC-V架构上的USB引导加载程序能够接受任一架构的UF2镜像下载，并自动使用正确的处理器启动该镜像。

### 3.9.2. 混合架构组合

ARCHSEL寄存器为每个处理器插槽分配一位，因此可以请求Arm与RISC-V处理器的混合组合：例如Arm核心0与RISC-V核心1，或RISC-V核心0与Arm核心1。

实际应用受限，因为这需要两个独立的程序镜像。两个核心能够正常协作，包括通过全局监视器实现的共享排他访问：例如，Arm处理器执行 `ldrex` 和 `strex` 指令，RISC-V处理器执行 `amoadd.w` 指令时，能安全并发访问共享变量。

硬件支持Arm和RISC-V处理器的混合调试，尽管这在主机软件端可能存在一定挑战。未使用处理器的调试资源在顶层Core Sight只读存储器(ROM)表中动态标记为非PRESENT状态。

# Chapter 4. Memory

RP2350 has embedded ROM, OTP and SRAM. RP2350 provides access to external flash via a QSPI interface.

## 4.1. ROM

A 32 kB read-only memory (ROM) appears at address `0x00000000`. The ROM contents are fixed permanently at the time the silicon is manufactured. [Chapter 5](#) describes the ROM contents in detail, but in summary it contains:

- Core 0 Boot code ([Section 5.2](#))
- Core 1 Launch code ([Section 5.3](#))
- Runtime APIs ([Section 5.4](#)).
- USB bootloader
  - Mass storage interface for drag and drop of UF2 flash and SRAM binaries ([Section 5.5](#))
  - PICOBLOCK interface to support `picotool` and advanced operations like OTP programming ([Section 5.6](#))
  - Support for white-labelling all USB exposed information/identifiers ([Section 5.7](#))
- UART bootloader: minimal shell to load an SRAM binary from a host microcontroller ([Section 5.8](#))

The ROM offers single-cycle access, and has a dedicated AHB5 arbiter, so it can be accessed simultaneously with other memory devices. Writing to the ROM has no effect, and no bus fault is generated on write.

The ROM is covered by IDAU regions enumerated in [Section 10.2.2](#). These aid in partitioning the bootrom between Secure and Non-secure code: in particular the USB/UART bootloader runs as a Non-secure client application on Arm, to reduce the attack surface of the secure boot implementation.

Certain ROM features are not implemented on RISC-V, most notably secure boot.

## 4.2. SRAM

There is a total of 520 kB ( $520 \times 1024$  bytes) of on-chip SRAM. For performance reasons, this memory is physically partitioned into ten *banks*, but logically it still behaves as a single, flat 520 kB memory. RP2350 does not restrict the data stored in each bank: you can use any bank to store processor code, data buffers, or a mixture of the two. There are eight  $16,384 \times 32$ -bit banks (64 kB each) and two  $1024 \times 32$ -bit banks (4 kB each).

### NOTE

Banking is a *physical* partitioning of SRAM which improves performance by allowing multiple simultaneous accesses. *Logically*, there is a single 520 kB contiguous memory.

Each SRAM bank is accessed via a dedicated AHB5 arbiter. This means different bus managers can access different SRAM banks in parallel, so up to six 32-bit SRAM accesses can take place every system clock cycle (one per manager).

SRAM is mapped to system addresses starting at `0x20000000`. The first 256 kB address region, up to and including `0x2003ffff`, is word-striped across the first four 64 kB banks. The next 256 kB address region, up to `0x2007ffff` is word-striped across the remaining four 64 kB banks. The watermark between these two striped regions, at `0x20040000`, marks the boundary between the SRAM0 and SRAM1 power domains.

Consecutive words in the system address space are routed to different RAM banks as shown in [Table 434](#). This scheme is referred to as **sequential interleaving**, and improves bus parallelism for typical memory access patterns.

# 第4章 内存

RP2350内置只读存储器(ROM)、一次性可编程存储器(OTP)和静态随机存取存储器(SRAM)。RP2350通过QSPI接口提供对外部闪存的访问。

## 4.1. 只读存储器

一个32 kB只读存储器(ROM)位于地址 `0x00000000`。ROM内容在硅片制造时永久固定。第5章详细描述了ROM内容，简而言之，包括：

- 核心0启动代码（第5.2节）
- 核心1启动代码（第5.3节）
- 运行时API（第5.4节）。
- USB引导加载程序
  - 用于拖拽UF2闪存和SRAM二进制文件的大容量存储接口（第5.5节）
  - PICOBLOCK接口，支持 `picotool` 及OTP编程等高级操作（第5.6节）
  - 支持对白标化所有通过USB公开的信息/标识符（第5.7节）
- UART引导加载程序：用于从主机微控制器加载SRAM二进制文件的最小化shell（第5.8节）。

只读存储器提供单周期访问，并配备专用的AHB5仲裁器，因此可与其他存储设备同时访问。对只读存储器的写入无任何效果，且写入时不会产生总线错误。

只读存储器受第10.2.2节中列举的IDAU区域保护。该保护机制有助于将引导只读存储器划分为安全与非安全代码：尤其是USB/UART引导加载程序以非安全客户端应用程序身份在Arm上运行，以减少安全引导实现的攻击面。

部分只读存储器功能未在RISC-V上实现，尤以安全引导功能最为显著。

## 4.2. 静态随机存取存储器

片上SRAM总容量为520 kB（ $520 \times 1024$ 字节）。出于性能考虑，物理上将其划分为十个bank，但逻辑上仍表现为单一连续的520 kB内存。RP2350对每个bank中存储的数据不加限制：可以使用任何bank存储处理器代码、数据缓冲区或二者的混合。共有八个 $16,384 \times 32$ 位的bank（每个64 kB）和两个 $1024 \times 32$ 位的bank（每个4 kB）。

### 注意

Banking是对SRAM的物理分区，通过支持多路并行访问以提升性能。逻辑上，内存呈现为单一连续的520 kB空间。

每个SRAM bank均通过专用的AHB5仲裁器进行访问。这意味着不同的总线管理器可并行访问不同的SRAM bank，从而每个系统时钟周期最多可执行六次32位SRAM访问（每个管理器一次）。

SRAM在系统地址中的映射起始于 `0x20000000`。首个256 kB地址区域，直至包括 `0x2003ffff`，按照字(word)条纹方式分布于前四个64 kB bank。接下来的256 kB地址区域，直到 `0x2007ffff` 按字分条跨越剩余的四个64 kB存储区。这两个分条区域之间的分界水印，位于 `0x20040000`，标志着SRAM0和SRAM1电源域的边界。

系统地址空间中的连续字按照表434所示路由到不同的RAM存储区。该方案称为顺序交错，能够提升典型内存访问模式下的总线并行度。

Table 434. SRAM  
bank0/1/2/3 striped  
mapping.

| System address | SRAM Bank | SRAM word address |
|----------------|-----------|-------------------|
| 0x20000000     | Bank 0    | 0                 |
| 0x20000004     | Bank 1    | 0                 |
| 0x20000008     | Bank 2    | 0                 |
| 0x2000000c     | Bank 3    | 0                 |
| 0x20000010     | Bank 0    | 1                 |
| 0x20000014     | Bank 1    | 1                 |
| 0x20000018     | Bank 2    | 1                 |
| 0x2000001c     | Bank 3    | 1                 |
| 0x20000020     | Bank 0    | 2                 |
| 0x20000024     | Bank 1    | 2                 |
| 0x20000028     | Bank 2    | 2                 |
| 0x2000002c     | Bank 3    | 2                 |
| etc            |           |                   |

The top two 4 kB regions (starting at 0x20080000 and 0x20081000) map directly to the smaller 4 kB memory banks. Software may choose to use these for per-core purposes (e.g. stack and frequently-executed code), guaranteeing that the processors never stall on these accesses. Like all SRAM on RP2350, these banks have single-cycle access from all managers, (provided no other managers access the bank in the same cycle) so it is reasonable to treat memory as a single 520 kB device.

#### NOTE

RP2040 had a non-striped SRAM mirror. RP2350 no longer has a non-striped mirror, to avoid mapping the same SRAM location as both Secure and Non-secure. You can still achieve some explicit bandwidth partitioning by allocating data across two 256 kB blocks of 4-way-striped SRAM.

### 4.2.1. Other on-chip memory

Besides the 520 kB main memory, there are two other dedicated RAM blocks that may be used in some circumstances:

- Cache lines can be individually pinned within the XIP address space for use as SRAM, up to the total cache size of 16 kB (see [Section 4.4.1.3](#)). Unpinned cache lines remain available for transparent caching of XIP accesses.
- If USB is not used, the USB data DPRAM can be used as a 4 kB memory starting at 0x50100000.

There is also 1 kB of dedicated boot RAM, hardwired to Secure access only, whose contents and layout is defined by the bootrom – see [Chapter 5](#).

表434。SRAM  
存储区0/1/2/3交错  
映射。

| 系统地址       | SRAM存储区 | SRAM字地址 |
|------------|---------|---------|
| 0x20000000 | 存储区0    | 0       |
| 0x20000004 | 存储区1    | 0       |
| 0x20000008 | 存储区2    | 0       |
| 0x2000000c | 存储区3    | 0       |
| 0x20000010 | 存储区0    | 1       |
| 0x20000014 | 存储区1    | 1       |
| 0x20000018 | 存储区2    | 1       |
| 0x2000001c | 存储区3    | 1       |
| 0x20000020 | 存储区0    | 2       |
| 0x20000024 | 存储区1    | 2       |
| 0x20000028 | 存储区2    | 2       |
| 0x2000002c | 存储区3    | 2       |
| 等等         |         |         |

最高的两个4 KB区域（起始地址为 0x20080000 和 0x20081000）直接映射到较小的4 KB内存块。

软件可选择将这些区域用于每核用途（例如堆栈和频繁执行的代码），以确保处理器在此类访问中绝不阻塞。如同RP2350上的所有SRAM，这些内存块可被所有管理器单周期访问（前提是不同时有其他管理器在同一周期访问该内存块），因此合理地将内存作为单一520 KB设备处理。

### ① 注意

RP2040拥有非条带式SRAM镜像。RP2350不再拥有非条带式镜像，以避免将同一SRAM地址映射为安全和非安全两种状态。您仍可通过在两个256 KB的四路条带SRAM块间分配数据，实现明确的带宽划分。

## 4.2.1. 其他片上存储器

除520 kB主存储器外，还有两个专用RAM块，在某些情况下可用：

- 缓存行可在XIP地址空间内单独固定，用作SRAM，最高可达16 kB缓存总容量（参见第4.4.1.3节）。未固定的缓存行仍可用于透明缓存XIP访问。
- 若不使用USB，则USB数据DPRAM可用作起始地址为 0x50100000 的4 kB内存。

还有1 kB专用启动RAM，仅限安全访问，其内容和布局由只读存储器定义——详见第5章。

**NOTE**

Memory in the peripheral address space (addresses starting with `0x4`, `0x5` or `0xd`) does not support code execution. This includes USB RAM and boot RAM. These address ranges are made IDAU-Exempt to simplify assigning peripherals to security domains using ACCESSCTRL, and consequently must be made non-executable to avoid the possibility of Non-secure-writable, Secure-executable memory.

## 4.3. Boot RAM

Boot RAM is a 1 kB ( $256 \times 32$ -bit) SRAM dedicated for use by the boottrom. It is slower than main SRAM, as it is accessed over APB, taking three cycles for a read and four cycles for a write.

Boot RAM is used for myriad purposes during boot, including the initial pre-boot stack. After the boottrom enters the user application, boot RAM contains state for the user-facing ROM APIs, such as the resident partition table used for flash programming protection, and a copy of the flash XIP setup function (formerly known as `boot2`) to quickly re-initialise flash XIP modes following serial programming operations.

Boot RAM is hardwired to permit Secure access only (Arm) or Machine-mode access only (RISC-V). It is physically impossible to execute code from boot RAM, regardless of MPU configuration, as it is on the APB peripheral bus segment, which is not wired to the processor instruction fetch ports.

Since boot RAM is in the XIP RAM power domain, it is always powered when the switched core domain is powered. This simplifies SRAM power management in the boottrom, because it doesn't have to power up any RAM before it has a place to store the call stack.

Boot RAM supports the standard atomic set/clear/XOR accesses used by other peripherals on RP2350 (Section 2.1.3).

It is possible to use boot RAM for user-defined purposes, but this is not recommended, as it may cause ROM APIs to behave unpredictably. Calling into the ROM could modify data stored in boot RAM.

### 4.3.1. List of registers

A small number of registers are located on the same bus endpoint as boot RAM:

#### Write Once Bits

These are flags which once set, can only be cleared by a system reset. They are used in the implementation of certain boottrom security features.

#### Boot Locks

These function the same as the SIO spinlocks (Section 3.1.4), however they are normally reserved for boottrom purposes (Section 5.4.4).

These registers start from an offset of `0x800` above the boot RAM base address of `0x400e0000` (defined as `BOOTRAM_BASE` in the SDK).

Table 435. List of  
BOOTRAM registers

| Offset | Name                       | Info                                                                                                                                        |
|--------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 0x800  | <code>WRITE_ONCE0</code>   | This register always ORs writes into its current contents. Once a bit is set, it can only be cleared by a reset.                            |
| 0x804  | <code>WRITE_ONCE1</code>   | This register always ORs writes into its current contents. Once a bit is set, it can only be cleared by a reset.                            |
| 0x808  | <code>BOOTLOCK_STAT</code> | Bootlock status register. 1=unclaimed, 0=claimed. These locks function identically to the SIO spinlocks, but are reserved for boottrom use. |

### 注意

外设地址空间内的内存（地址以 `0x4`、`0x5` 或 `0xd` 开头）不支持代码执行。这包括USB RAM和启动RAM。为了简化通过ACCESSCTRL将外设分配至安全域的操作，这些地址范围被设为IDAU免除，因而必须设置为不可执行，以避免出现非安全可写且安全可执行内存的情况。

## 4.3. 启动RAM

Boot RAM 是一个 1 kB (256 × 32 位) SRAM，专用于 bootrom。其速度低于主 SRAM，因为通过 APB 总线访问，读取需三周期，写入需四周期。

Boot RAM 在启动过程中用途广泛，包括初始预启动堆栈。在 bootrom 进入用户应用程序后，boot RAM 保存面向用户的只读存储器 API 的状态信息，如用于闪存编程保护的常驻分区表，以及闪存 XIP 设置函数的副本（前称为 `boot2`），以便在串行编程操作后快速重新初始化闪存 XIP 模式。

Boot RAM 硬连线仅允许安全访问（Arm 架构）或机器模式访问（RISC-V 架构）。无论 MPU 配置如何，均无法从 boot RAM 执行代码，因为其位于 APB 外设总线段，且未连接至处理器指令取指端口。

由于启动RAM位于XIP RAM电源域内，因此只要切换的核心域通电，启动RAM始终保持通电状态。这简化了bootrom中的SRAM电源管理，因为在找到存储调用栈的位置之前，无需为任何RAM供电。

启动RAM支持RP2350其他外设所采用的标准原子设定/清除/XOR访问（第2.1.3节）。

虽然可以将启动RAM用于用户自定义用途，但不建议这样做，因为这可能导致只读存储器API行为异常。调用只读存储器可能会修改存储于启动RAM中的数据。

### 4.3.1. 寄存器列表

少数寄存器与启动RAM共享相同的总线端点：

#### 一次写入位

这些标志一旦设置，仅能通过系统复位清除。它们用于实现某些bootrom安全特性。

#### 启动锁

其功能与SIO自旋锁相同（第3.1.4节），但通常专用于bootrom（第5.4.4节）。

这些寄存器起始于引导RAM基址 `0x400e0000`（在SDK中定义为`BOOTRAM_BASE`）以上的偏移量 `0x800`处。

表435。BOOTRAM 寄存器列表

| 偏移量   | 名称                         | 说明                                                       |
|-------|----------------------------|----------------------------------------------------------|
| 0x800 | <code>WRITE_ONCE0</code>   | 该寄存器写入时总是对其当前内容执行位或操作。一旦某个位被置位，只能通过复位来清除。                |
| 0x804 | <code>WRITE_ONCE1</code>   | 该寄存器写入时总是对其当前内容执行位或操作。一旦某个位被置位，只能通过复位来清除。                |
| 0x808 | <code>BOOTLOCK_STAT</code> | Bootlock状态寄存器。1表示未声明，0表示已声明。这些锁的功能与SIO旋转锁相同，但专用于bootrom。 |

| Offset | Name      | Info                                                                                                                          |
|--------|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| 0x80c  | BOOTLOCK0 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x810  | BOOTLOCK1 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x814  | BOOTLOCK2 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x818  | BOOTLOCK3 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x81c  | BOOTLOCK4 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x820  | BOOTLOCK5 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x824  | BOOTLOCK6 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |
| 0x828  | BOOTLOCK7 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. |

## BOOTRAM: WRITE\_ONCE0, WRITE\_ONCE1 Registers

Offsets: 0x800, 0x804

Table 436.  
WRITE\_ONCE0,  
WRITE\_ONCE1  
Registers

| Bits | Description                                                                                                       | Type | Reset      |
|------|-------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | This registers always ORs writes into its current contents. Once a bit is set, it can only be cleared by a reset. | RW   | 0x00000000 |

## BOOTRAM: BOOTLOCK\_STAT Register

Offset: 0x808

Table 437.  
BOOTLOCK\_STAT  
Register

| Bits | Description                                                                                                                                | Type | Reset |
|------|--------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:8 | Reserved.                                                                                                                                  | -    | -     |
| 7:0  | Bootlock status register. 1=unclaimed, 0=claimed. These locks function identically to the SIO spinlocks, but are reserved for bootrom use. | RW   | 0xff  |

## BOOTRAM: BOOTLOCK0, BOOTLOCK1, ..., BOOTLOCK6, BOOTLOCK7 Registers

Offsets: 0x80c, 0x810, ..., 0x824, 0x828

Table 438.  
BOOTLOCK0,  
BOOTLOCK1, ...,  
BOOTLOCK6,  
BOOTLOCK7 Registers

| Bits | Description                                                                                                                   | Type | Reset      |
|------|-------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:0 | Read to claim and check. Write to unclaim. The value returned on successful claim is $1 \ll n$ , and on failed claim is zero. | RW   | 0x00000000 |

## 4.4. External flash and PSRAM (XIP)

RP2350 can access external flash and PSRAM via its **execute-in-place** (XIP) subsystem. The term execute-in-place refers to external memory mapped directly into the chip's internal address space. This enables you to execute code as-

| 偏移量   | 名称        | 说明                                            |
|-------|-----------|-----------------------------------------------|
| 0x80c | BOOTLOCK0 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x810 | BOOTLOCK1 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x814 | BOOTLOCK2 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x818 | BOOTLOCK3 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x81c | BOOTLOCK4 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x820 | BOOTLOCK5 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x824 | BOOTLOCK6 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |
| 0x828 | BOOTLOCK7 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 |

## BOOTRAM: WRITE\_ONCE0、WRITE\_ONCE1 寄存器

偏移量: 0x800, 0x804

表 436.  
WRITE\_ONCE0,  
WRITE\_ONCE1  
寄存器

| 位    | 描述                                        | 类型 | 复位         |
|------|-------------------------------------------|----|------------|
| 31:0 | 该寄存器写入时总是对其当前内容执行位或操作。一旦某个位被置位，只能通过复位来清除。 | 读写 | 0x00000000 |

BOOTLOCK7  
寄存器

| 位    | 描述                                            | 类型 | 复位         |
|------|-----------------------------------------------|----|------------|
| 31:0 | 读取以声明和检测，写入以取消声明。声明成功时返回值为 $1 \ll n$ ，失败时返回0。 | 读写 | 0x00000000 |

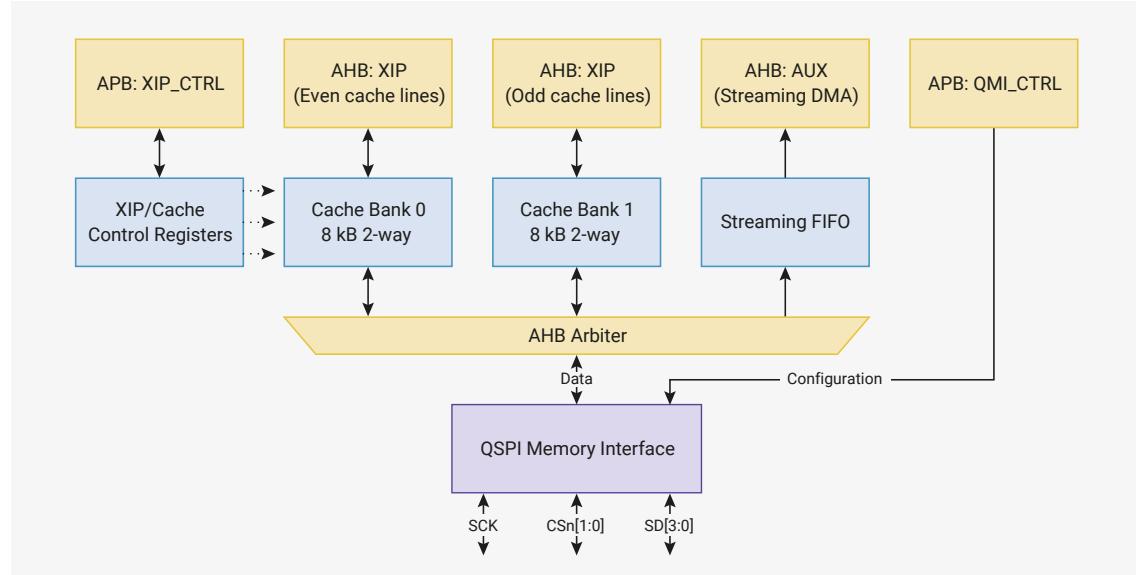

## 4.4. 外部闪存和PSRAM (XIP)

RP2350可通过其**execute-in-place** (XIP) 子系统访问外部闪存和PSRAM。术语**execute-in-place**指外部存储器直接映射到芯片内部地址空间。这使您能够执行

is from the external memory without explicitly copying into on-chip SRAM. For example, a processor instruction fetch from AHB address `0x10001234` results in a QSPI memory interface fetch from address `0x001234` in an external flash device.

A 16 kB on-chip cache retains the values of recent reads and writes. This reduces the chances that XIP bus accesses must go to external memory, improving the average throughput and latency of the XIP interface. The cache is physically structured as two 8 kB banks, interleaving odd and even cache lines of 8-byte granularity over the two banks. This allows processors to access multiple cache lines during the same cycle. Logically, the XIP cache behaves as a single 16 kB cache.

*Figure 16. Flash execute-in-place (XIP) subsystem. The cache is split into two banks for performance, but behaves as a single 16 kB cache. XIP accesses first query the cache. If a cache entry is not found, the QMI generates an external serial access, adds the resulting data to the cache, and forwards it on to the system bus (for reads) or merges it with the AHB write data (for writes).*

When booting from flash, the RP2350 bootrom ([Chapter 5](#)) sets up a baseline QMI execute-in-place configuration. User code may later reconfigure this to improve performance for a specific flash device. QSPI clock divisors can be changed at any time, including whilst executing from XIP. Other reconfiguration requires a momentary disable of the interface.

#### 4.4.1. XIP cache

The cache is 16 kB, two-way set-associative, 1 cycle hit. It is internal to the XIP subsystem, and only involved in accesses to the QSPI memory interface, so software does not have to consider cache coherence unless performing flash programming operations. It caches accesses to a 26-bit downstream XIP address space. On RP2350, the lower half of this space is occupied by two 16 MB windows for the two QMI chip selects. RP2350 reserves the remainder for future expansion, but you can use the space to pin cache lines outside of the QMI address space for use as cache-as-SRAM ([Section 4.4.1.3](#)). The 26-bit XIP address space is mirrored multiple times in the RP2350 address space, decoded on bits `27:26` of the system bus address:

- `0x10...` : Cached XIP access
- `0x14...` : Uncached XIP access
- `0x18...` : Cache maintenance writes
- `0x1c...` : Uncached, untranslated XIP access – bypass QMI address translation

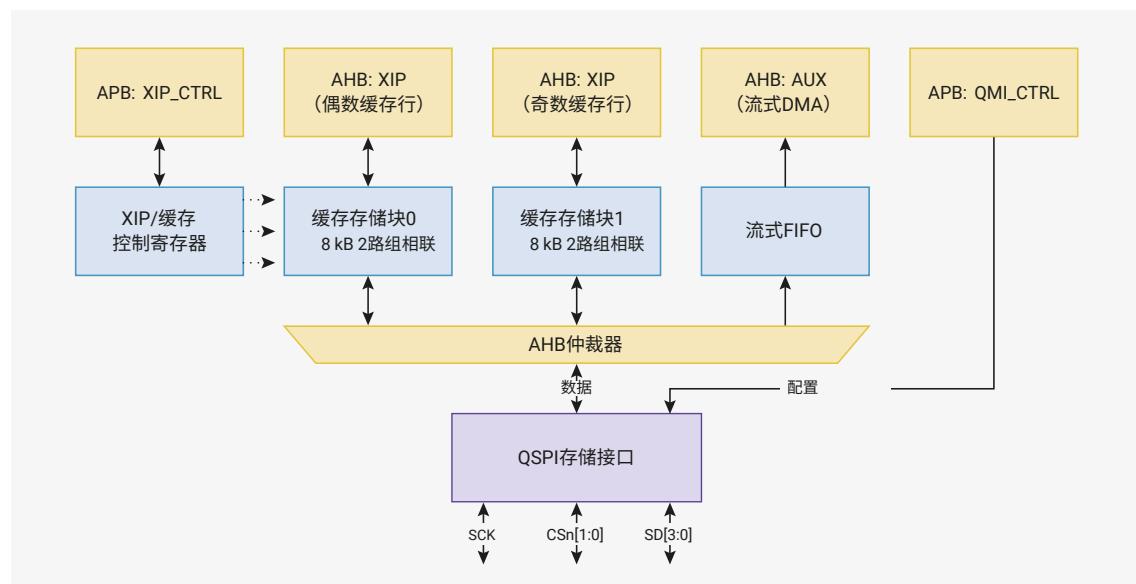

You can disable cache lookup separately for Secure and Non-secure accesses via the `CTRL.EN_SECURE` and `CTRL.EN_NONSECURE` register bits. The `CTRL` register contains controls to disable Secure/Non-secure access to the uncached and uncached/untranslated XIP windows, which avoids duplicate mappings that may otherwise require additional SAU or PMP regions.

来自外部存储器的代码，而无需显式复制至片上SRAM。例如，处理器从AHB地址 `0x10001234` 访问指令时，会导致QSPI存储器接口从外部闪存设备地址 `0x001234` 读取数据。

片上16 kB缓存保存最近读取和写入的数据。这减少了XIP总线访问必须访问外部存储器的次数，提高了XIP接口的平均吞吐量和延迟性能。缓存在物理上结构为两个8 kB的存储块，奇偶缓存行以8字节粒度交错分布于两块存储块中。这使得处理器能够在同一时钟周期内访问多个缓存行。逻辑上，XIP缓存表现为单一16 kB缓存。

图16。闪存

执行原地 (XIP) 子系统。缓存为提升性能分成两个存储区，但表现为单一16 kB缓存。XIP访问优先查询缓存。若未命中缓存，QMI将发起外部串行访问，将获取的数据加入缓存，并转发至系统总线（读取时）或与AHB写入数据合并（写入时）。

从闪存启动时，RP2350只读存储器启动程序（第5章）会设置基础的QMI执行原地配置。用户代码随后可重新配置此设置，以提升特定闪存设备的性能。QSPI时钟分频器可在任何时候更改，包括执行XIP时；其他重配置则需暂时禁用接口。

#### 4.4.1. XIP缓存

缓存容量为16 kB，2路组相联，命中延迟1个周期。该缓存位于XIP子系统内部，仅涉及QSPI存储接口访问，除非执行闪存编程操作，软件无需考虑缓存一致性。它缓存对26位下游XIP地址空间的访问。在RP2350上，该地址空间的下半部分被两个16 MB窗口占据，分别对应两个QMI芯片选择信号。RP2350为未来扩展保留了其余空间，但您可以使用该空间将缓存行固定在QMI地址空间之外，用作缓存即SRAM（见第4.4.1.3节）。在RP2350地址空间中，26位XIP地址空间多次镜像，并在系统总线地址的27:26位上进行解码：

- `0x10...` : 缓存的XIP访问
- `0x14...` : 非缓存的XIP访问
- `0x18...` : 缓存维护写入
- `0x1c...` : 非缓存且未转换的XIP访问 —— 绕过QMI地址转换

您可以通过`CTRL.EN_SECURE`和`CTRL.EN_NONSECURE`寄存器位，分别禁用安全和非安全访问的缓存查询。`CTRL`寄存器包含用于禁用对未缓存及未缓存/未翻译 XIP 窗口的安全/非安全访问的控制，从而避免了可能需要额外 SAU 或 PMP 区域的重复映射。

#### 4.4.1.1. Cache maintenance

Cache maintenance is performed on a line-by-line basis by writing into the cache maintenance mirror of the XIP address space, starting at `0x18000000`. Cache lines are 8 bytes in size. Write data is ignored; instead, the 3 LSBs of the address select the maintenance operation:

- `0x0`: Invalidate by set/way
- `0x1`: Clean by set/way
- `0x2`: Invalidate by address
- `0x3`: Clean by address
- `0x7`: Pin cache set/way at address ([Section 4.4.1.3](#))

##### Invalidate

Marks a cache line as no longer containing data; the next access to the same address will miss the cache. Does not write back any data to external memory. Used when external memory has been modified in a way that the cache would not automatically know about, such as a flash programming operation.

##### Clean

Instructs the cache to write out any data stored in the cache as a result of a previous cached write access that has not yet been written out to external memory. Used to make cached writes available to uncached reads. Also used when cache contents are about to be lost, but external memory is to stay powered (for example, when the system is about to power down).

##### By set/way

Selects a particular cache line to be maintained, out of the  $2048 \times 8$ -byte lines that make up the cache. Bit `13` of the system bus address selects the cache way. Bits `12:3` of the address select a particular cache line within that way. Mainly used to iterate exhaustively over all cache lines (for example, during a full cache flush).

##### By address

Looks up an address in the cache, then performs the requested maintenance if that line is currently allocated in the cache. Used when only a particular range of XIP addresses needs to be maintained, for example, a flash page that was just programmed. Usually faster than a full flush, because the real cost of a cache flush is not in the maintenance operations, but the large number of subsequent cache misses.

##### Pin

Prevents a particular cache line from being evicted. Used to mark important external memory contents that must get guaranteed cache hits, or to allocate cache lines for use as cache-as-SRAM. If a cached access to some other address misses the cache and attempts to evict a pinned cache line, the eviction fails, and the access is downgraded to an uncached access.

Cache maintenance operations operate on the cache's **tag memory**. This is the cache's metadata store, which tracks the state of each cache line. Maintenance operations do not affect the cache's **data memory**, which contains the cache's copy of data bytes from external memory.

By default, cache maintenance is Secure-only. Non-secure writes to the cache maintenance address window have no effect and return a bus error. Non-secure cache maintenance can be enabled by setting the `CTRL.MAINT_NONSEC` register bit, but this is not recommended if Secure software may perform cached XIP accesses.

#### 4.4.1.2. Cache line states

The changes to a cache line caused by cached accesses and maintenance operations can be summarised by a set of state transitions.

#### 4.4.1.1 缓存维护

缓存维护通过向 XIP 地址空间的缓存维护镜像逐行写入数据进行，起始地址为 `0x18000000`。缓存行大小为 8 字节。写入的数据会被忽略；地址的最低 3 位用于选择维护操作：

- `0x0`：按组/路使缓存失效
- `0x1`：按组/路清理缓存
- `0x2`：按地址使缓存失效
- `0x3`：按地址清理缓存
- `0x7`：固定地址处的缓存组/路（见第 4.4.1.3 节）

##### 使失效

将缓存行标记为不再包含有效数据；下一次访问相同地址时将导致缓存未命中。

不向外部存储器写回任何数据。用于外部存储器已被修改但缓存不会自动检测到此修改的情况，例如闪存编程操作。

##### 清除

指示缓存将任何由于之前缓存写访问而存储但尚未写回外部存储器的数据写出。用于使缓存写入的数据可被非缓存读取访问。

还用于缓存内容即将丢失但外部存储器仍保持供电时（例如系统即将断电）。

##### 按组/路

从构成缓存的 $2048 \times 8$ 字节行中选择特定缓存行进行维护。系统总线地址的第13位选择缓存路，第12至第3位选择该路中的特定缓存行。主要用于对所有缓存行进行遍历（例如在完全刷新缓存时使用）。

##### 按地址

在缓存中查找地址，若该缓存行当前已分配，则执行所请求的维护操作。仅当需要维护特定范围的XIP地址时使用，例如刚刚编程的闪存页。通常比完全刷新更快，因为缓存刷新的主要开销不在于维护操作，而在随之而来的大量缓存未命中。

##### 引脚

防止特定缓存行被驱逐。用于标记必须保证缓存命中的重要外部存储内容，或分配缓存行用作cache-as-SRAM。如果访问其他地址的缓存未命中且尝试驱逐被固定的缓存行，驱逐将失败，访问会降级为无缓存访问。

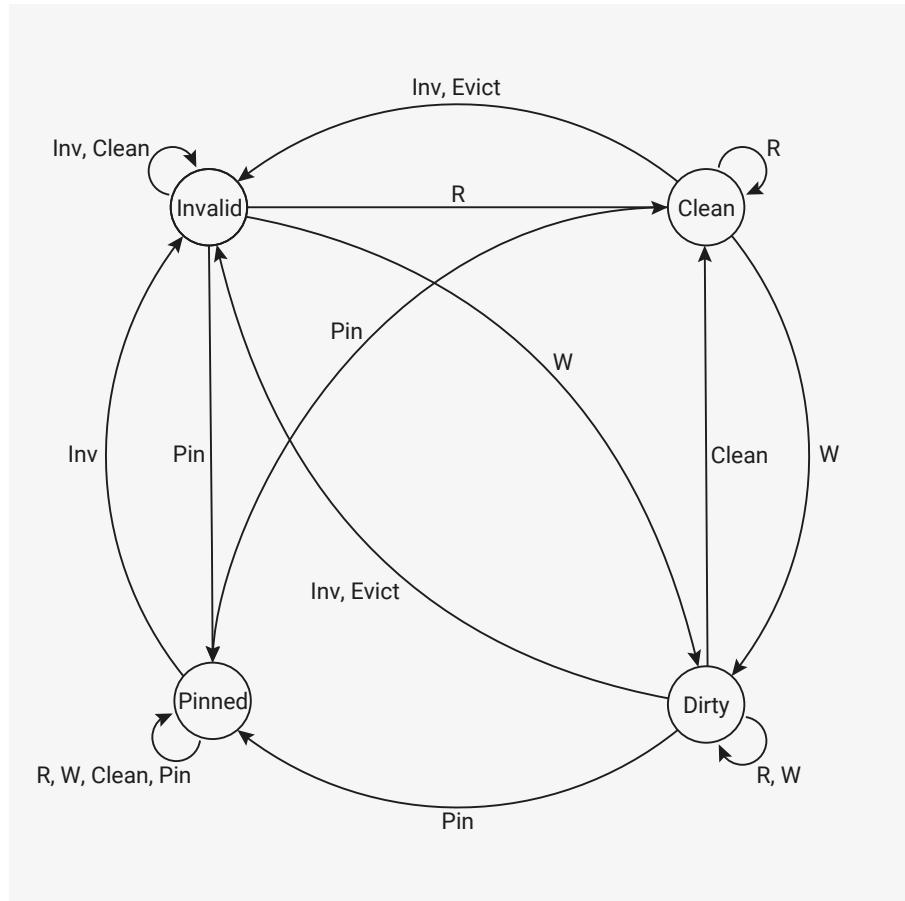

缓存维护操作作用于缓存的**tag memory**。这是缓存的元数据存储区，用于跟踪每条缓存行的状态。维护操作不影响缓存的**data memory**，后者包含来自外部存储的数据字节副本。

默认情况下，缓存维护仅限于安全模式。对缓存维护地址窗口的非安全写入无效且会返回总线错误。可以通过设置 CTRL\_MAINT\_NONSEC 寄存器位启用非安全缓存维护，但若安全软件可能执行缓存的 XIP 访问，则不建议启用该设置。

#### 4.4.1.2. 缓存行状态

缓存访问及维护操作所引起的缓存行状态变化，可归纳为一组状态转换。

Figure 17. State transition diagram for each cache line. Inv, Clean and Pin represent invalidate/clean/pin maintenance operations, respectively. R and W represent cached reads and writes. Evict represents a cache line deallocation to make room for a new allocation due to a read/write cache miss.

Initially, the state of all cache lines is undefined. When booting from flash, the bootrom performs an invalidate by set/way on every line of the cache to force them to a known state. In the diagram above, all states have an **Inv** arc to the invalid state.

A **dirty** cache line contains data not yet propagated to downstream memory.

A **clean** cache line contains data that matches the downstream memory contents.

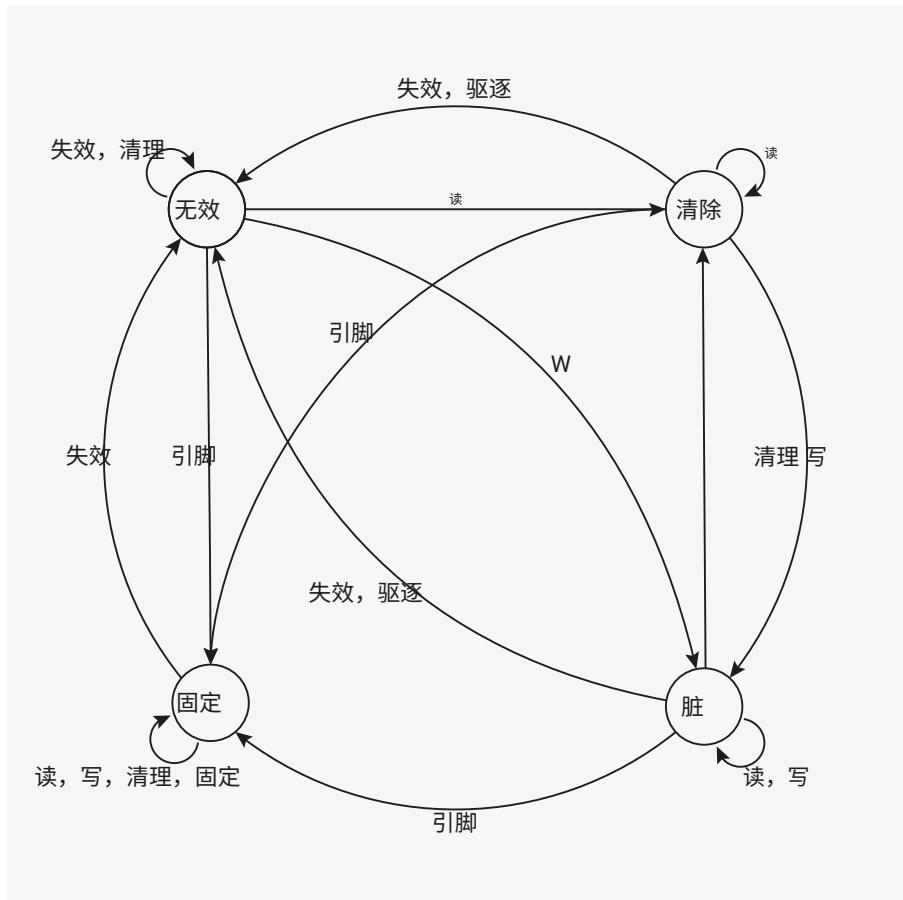

Accessing an invalid cache line causes an **allocation**: the cache fetches the corresponding data from downstream memory, stores it in the cache, then marks the cache line as clean or dirty. The cache also stores part of the downstream address, known as the **tag**, to recall the downstream address stored in each cache line. Read allocations enter the clean state, so the cache line can be safely freed at any time. Write allocations enter the dirty state, so the cache line must propagate downstream before it can be freed.

Writing to a clean cache line marks it as dirty because the cache now contains write data that has not propagated downstream. The line can be explicitly returned to the clean state using a clean maintenance operation (**0x1** or **0x3**), but this is not required. Typically, the cache automatically propagates dirty cache lines downstream when it needs to reallocate them.

Evictions happen when a cached read or write needs to allocate a cache line that is already in the clean or dirty state. The eviction transitions the line momentarily to the invalid state, ready for allocation. For clean cache lines, this happens instantaneously. For dirty cache lines, the cache must first propagate the cache line contents downstream before it can safely enter the invalid state.

Cache lines enter the pinned state using a pin maintenance operation (**0x7**) and exit only by an invalidate maintenance operation (**0x0** or **0x2**).

图 17。各缓存行的状态转换示意图。失效、清理和固定分别表示失效、清理和固定的维护操作。读和写分别表示缓存的读取和写入操作。Evict 表示因读/写缓存未命中，为新的分配腾出空间而进行的缓存行去分配操作。

初始时，所有缓存行的状态均为未定义。从闪存启动时，bootrom 对缓存的每一行执行基于集合/路经的失效操作，以强制其进入已知状态。如上图所示，所有状态均有一个 Inv 弧指向无效状态。

一个 **dirty** 缓存行包含尚未写回至下游存储器的数据。

一个 **clean** 缓存行包含与下游存储器内容一致的数据。

访问无效缓存行会导致一次 **allocation**：缓存从下游存储器提取对应数据，存储于缓存中，然后将缓存行标记为 clean 或 dirty。缓存还存储部分下游地址，称为 **tag**，用以标识各缓存行对应的下游地址。读分配进入 clean 状态，因此缓存行可在任何时刻安全释放。写分配使缓存行进入脏状态，因此缓存行必须在释放之前向下游传播。

对于干净缓存行的写入会将其标记为脏状态，因为缓存中包含尚未向下游传播的写入数据。可以通过清理维护操作（`0x1`或`0x3`）显式将缓存行恢复为干净状态，但这并非必需。通常，当缓存需要重新分配缓存行时，会自动向下游传播脏缓存行。

驱逐发生在缓存的读写操作需要分配已处于干净或脏状态的缓存行时。

驱逐会使缓存行瞬间转为无效状态，以待分配。对于干净缓存行，此过程会瞬时完成。对于脏缓存行，缓存必须首先将其内容向下游传播，才能安全进入无效状态。

缓存行通过固定维护操作（`0x7`）进入固定状态，仅能通过失效维护操作（`0x0`或`0x2`）退出。

**NOTE**

The pin maintenance operation only marks the line as pinned; it does not perform any copying of data. When pinning lines that exist in external memory devices, you must first pin the line, then copy the downstream data into the pinned line by reading from the uncached XIP window.

**4.4.1.3. Cache-as-SRAM**

When you disabled the cache of RP2040, the cache would map the entire cache memory at `0x15000000`. RP2350 replaces this with the ability to pin individual cache lines. You can use this in the following ways:

- Pin the entire cache at some address range to use the entire cache as SRAM
- Pin one full cache way to make half of the cache available for cache-as-SRAM use (the remaining cache way still functions as usual)
- Pin an address range that maps critical flash contents

**NOTE**

Pinned cache lines are not accessible when the cache is disabled via the `CTRL` register (`CTRL.EN_SECURE` or `CTRL.EN_NONSECURE` depending on security level of the bus access).

Because the QMI only occupies the lower half of the 64 MB XIP address space, you can pin cache lines outside of the QMI address range (e.g. at the top of the XIP space) to avoid interfering with any QMI accesses. As a general rule, the more cache you pin, the lower the cache hit rate for other accesses.

Cache lines are pinned using the pin maintenance operation (`0x7`), which performs the following steps:

1. An implicit invalidate-by-address operation (`0x2`) using the full address of the maintenance operation
  - This ensures that each address is allocated in only one cache way (required for correct cache operation)
2. Select the cache line to be pinned, using bit `13` to select the cache way, and bits `12:3` to select the cache set (as with `0x0/0x1` invalidate/clean by set/way commands)
3. Write the address to the cache line's tag entry
4. Change the cache line's state to pinned (as per the state diagram in [Section 4.4.1.2](#))
5. Update the cache line's tag with the full address of the maintenance operation

After a pin operation, cached reads and writes to the specified address always hit the cache until that cache line is either invalidated or pinned to a different address.

**NOTE**

Pinning two addresses that are equal modulo cache size pins the same cache line twice. It does *not* pin two different cache lines. The second pin will overwrite the first.

When a cached access hits a pinned cache line, it behaves the same as a dirty line. The cache reads and writes as if allocated in the cache by normal means.

Cache eviction policy is random, and the cache only makes one attempt to select an eviction way. If the cache selects to evict a pinned line, the eviction fails, and the access is demoted to an uncached access. As a result, a cache with one way pinned does not behave exactly the same as a direct-mapped 8 kB cache, but average-case performance is similar.

Cache line states are stored in the cache tag memory stored in the XIP memory power domain. This memory contents do not change on reset, so pinned lines remain pinned across resets. If the XIP memory power domain is not powered down, memory contents do not change across power cycles of the switched core reset domain. The bootrom clears the tag memory upon entering the flash boot or NSBOOT (USB boot) path, but watchdog scratch vector reboots can boot directly into pinned XIP cache lines.

**i 注意**

固定操作仅将该行标记为已固定；它不会执行任何数据复制。当固定存在于外部存储设备中的行时，必须先固定该行，然后通过从未缓存的XIP窗口读取，将下游数据复制到该固定行中。

**4.4.1.3. 作为SRAM的缓存**

当您禁用RP2040的缓存时，缓存会映射整个缓存内存于 **0x15000000** 地址。RP2350以固定单个缓存行的能力替代了此功能。您可以通过以下方式使用此功能：

- 固定某地址范围内的整个缓存，将整个缓存用作SRAM
- 固定一条完整的缓存路，使缓存的一半可用作SRAM（剩余的缓存路仍按常规工作）
- 固定映射关键闪存内容的地址范围

**i 注意**

当通过CTRL寄存器（根据总线访问的安全级别为CTRL.EN\_SECURE或CTRL.EN\_NONSECURE）禁用缓存时，固定的缓存行将无法访问。

由于QMI仅占用64 MB XIP地址空间的下半部分，您可以将缓存行固定在QMI地址范围之外（例如XIP空间顶部），以避免干扰任何QMI访问。一般而言，固定的缓存行越多，其他访问的缓存命中率越低。

缓存行通过固定维护操作（**0x7**）进行固定，该操作包括以下步骤：

1. 使用维护操作的完整地址执行隐式的按地址失效操作（**0x2**）
  - 确保每个地址仅分配到一个缓存路（这是正确缓存操作的前提）
2. 选择要固定的缓存行，使用位 **13** 选择缓存路，位 **12:3** 选择缓存组（与 **0x0/0x1** 按组/路失效或清理命令相同）
3. 将地址写入缓存行的标签项
4. 将缓存行的状态更改为固定状态（参见第4.4.1.2节的状态图）
5. 使用维护操作的完整地址更新缓存行的标签

执行固定操作后，对指定地址的缓存读写始终命中缓存，直到该缓存行被失效或重新固定到其他地址。

**i 注意**

固定两个模缓存大小相等的地址会导致同一缓存行被固定两次。它不会固定两条不同的缓存行。第二次固定会覆盖第一次。

当缓存访问命中固定的缓存行时，其行为与脏缓存行相同。缓存按常规方式读写，仿佛该缓存行已被正常分配。

缓存替换策略为随机，且仅尝试一次选择替换路径。如果缓存选择替换一个固定的缓存行，替换失败，该访问降级为非缓存访问。因此，具有一路固定缓存的缓存行为与直接映射的8kB缓存不完全相同，但平均性能相似。

缓存行状态存储于位于XIP存储器电源域内的缓存标签存储器中。该存储器内容在复位时不会更改，因此固定的缓存行在复位后仍保持固定状态。若XIP存储器电源域未关闭，内存内容在切换核心复位域的电源循环期间保持不变。引导只读存储器在进入闪存引导或NSBOOT（USB引导）路径时会清除标签存储器，但看门狗缓存向量重启可直接引导至固定的XIP缓存行。

## 4.4.2. QSPI Memory Interface (QMI)

Uncached accesses and cache misses require access to external memory. The QSPI memory interface (QMI) provides this access, as documented in [Section 12.14](#). The QMI supports:

- Up to two external QSPI devices, with separate chip selects and shared clock/data pins
  - Banked configuration registers, including different **SCK** frequencies and QSPI opcodes
- Memory-mapped reads and writes (writes must be enabled via **CTRL.WRITABLE\_M0**/**CTRL.WRITABLE\_M1**)
- Serial/dual/quad-SPI transfer formats
- SCK speeds as high as **clk\_sys**
- 8/16/32-bit accesses for uncached accesses, and 64-bit accesses for cache line fills
- Automatic chaining of sequentially addressed accesses into a single QSPI transfer
- Address translation ( $4 \times 4$  MB windows per QSPI device)
  - Flash storage addresses can differ from runtime addresses, e.g. for multiple OTA upgrade image slots
  - Allows code and data segments, or Secure and Non-secure images, to be mapped separately
- Direct-mode FIFO interface for programming and configuring external QSPI devices

XIP accesses via the two cache AHB ports, and from the DMA streaming hardware, arbitrate for access to the QMI. A separate APB port configures the QMI.

The QMI is a new memory interface designed for RP2350, replacing the SSI peripheral on RP2040.

## 4.4.3. Streaming DMA interface

As the flash is generally much larger than on-chip SRAM, it's often useful to stream chunks of data into memory from flash. It's convenient to have the DMA stream this data in the background while software in the foreground does other things. It's even more convenient if code can continue to execute from flash whilst this takes place.

This doesn't interact well with standard XIP operation because QMI serial transfers force lengthy bus stalls on the DMA. These stalls are tolerable for a processor because an in-order processor tends to have nothing better to do while waiting for an instruction fetch to retire, and because typical code execution tends to have much higher cache hit rates than bulk streaming of infrequently accessed data. In contrast, stalling the DMA prevents any other active DMA channels from making progress during this time, slowing overall DMA throughput.

The **STREAM\_ADDR** and **STREAM\_CTR** registers are used to program a linear sequence of flash reads. The XIP subsystem performs these reads in the background in a best-effort fashion. To minimise impact on code executed from flash whilst the stream is ongoing, the streaming hardware has lower priority access to the QMI than regular XIP accesses, and there is a brief cooldown (9 cycles) between the last XIP cache miss and resuming streaming. This avoids increases in initial access latency on XIP cache misses.

*Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/flash/xip\\_stream/flash\\_xip\\_stream.c](https://github.com/raspberrypi/pico-examples/blob/master/flash/xip_stream/flash_xip_stream.c) Lines 45 - 48*

```

45 while (!(xip_ctrl_hw->stat & XIP_STAT_FIFO_EMPTY))
46 (void) xip_ctrl_hw->stream_fifo;
47 xip_ctrl_hw->stream_addr = (uint32_t) &random_test_data[0];
48 xip_ctrl_hw->stream_ctr = count_of(random_test_data);

```

The streamed data is pushed to a small FIFO, which generates DREQ signals that tell the DMA to collect the streamed data. As the DMA does not initiate a read until *after* reading the data from flash, the DMA does not stall when accessing the data. The DMA can then retrieve this data through the auxiliary AHB port, which provides direct single-cycle access to the streaming data FIFO.

On RP2350, you can also use the auxiliary AHB port to access the QMI direct-mode FIFOs. This is faster than accessing

#### 4.4.2. QSPI存储器接口（QMI）

未缓存访问及缓存未命中需要访问外部存储器。QSPI存储器接口（QMI）提供此访问，详见第12.14节。QMI支持：

- 最多两个外部QSPI设备，具独立芯片选择及共享时钟/数据信号
  - 分组配置寄存器，含不同的 SCK频率及QSPI操作码
- 内存映射读写操作（写操作须通过CTRL.WRITABLE\_M0/CTRL.WRITABLE\_M1启用）
- 串行/双路/四路SPI传输格式
- SCK速度最高可达 `clk_sys`
- 对未缓存访问支持8/16/32位访问，对缓存行填充支持64位访问
- 顺序寻址访问可自动链式合并为单次QSPI传输
- 地址转换（每个QSPI设备支持4x4 MB窗口）
  - Flash存储地址可能与运行时地址不同，例如适用于多个OTA升级映像槽
  - 允许代码和数据段，或安全与非安全映像分别映射
- 用于编程和配置外部QSPI设备的直接模式FIFO接口

通过两个缓存AHB端口及DMA流硬件进行的XIP访问，对QMI访问权进行仲裁。QMI由单独的APB端口配置。

QMI是为RP2350设计的新型存储器接口，替代了RP2040上的SSI外设。

#### 4.4.3. 流式DMA接口

由于Flash容量通常远大于片上SRAM，将数据块从Flash流式传输至内存通常非常有用。在前台软件执行其他任务的同时，让DMA在后台传输这些数据是十分便利的。如果代码能在此过程中继续从闪存执行，则更加方便。

这与标准XIP操作不兼容，因为QMI串行传输会导致DMA出现长时间总线阻塞。

对于处理器而言，这种阻塞是可接受的，因为有序处理器在等待指令获取完成期间通常无其他任务可做，且典型代码执行相比于大量流式传输不常访问的数据，具有更高的缓存命中率。相反，DMA的阻塞会阻止其他活动的DMA通道在此期间继续运行，从而降低整体DMA吞吐量。

STREAM\_ADDR和STREAM\_CTR寄存器用于配置一系列线性闪存读取操作。XIP子系统以尽最大努力的方式在后台执行这些读取。为了最大限度减少流式传输期间对从闪存执行代码的影响，流式传输硬件对QMI的访问优先级低于常规XIP访问，并且在最后一次XIP缓存未命中与恢复流式传输之间设有短暂冷却时间（9个周期）。这避免了在XIP缓存未命中时初始访问延迟的增加。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/flash/xip\\_stream/flash\\_xip\\_stream.c](https://github.com/raspberrypi/pico-examples/blob/master/flash/xip_stream/flash_xip_stream.c) 第45-48行

```

45 while (!(xip_ctrl_hw->stat & XIP_STAT_FIFO_EMPTY))
46 (void) xip_ctrl_hw->stream_fifo;
47 xip_ctrl_hw->stream_addr = (uint32_t) &random_test_data[0];
48 xip_ctrl_hw->stream_ctr = count_of(random_test_data);

```

流式数据被推入一个小型FIFO，该FIFO生成DREQ信号，指示DMA收集流式数据。由于DMA在从闪存读取数据后才开始发起读取，因此在访问数据时DMA不会发生阻塞。随后，DMA可通过辅助AHB端口检索这些数据，该端口提供对流式数据FIFO的单周期直接访问。

在RP2350上，您还可以使用辅助AHB端口访问QMI直接模式FIFO。这种访问方式比通过QMI APB配置端口访问FIFO更为高效。

the FIFOs through the QMI APB configuration port. When QMI access chaining is enabled, the streaming XIP DMA is close to the maximum theoretical QSPI throughput, but the direct-mode FIFOs are available on AHB for situations that require 100% of the theoretical throughput.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/flash/xip\\_stream/flash\\_xip\\_stream.c](https://github.com/raspberrypi/pico-examples/blob/master/flash/xip_stream/flash_xip_stream.c) Lines 58 - 70

```

58 const uint dma_chan = 0;
59 dma_channel_config cfg = dma_channel_get_default_config(dma_chan);
60 channel_config_set_read_increment(&cfg, false);
61 channel_config_set_write_increment(&cfg, true);
62 channel_config_set_dreq(&cfg, DREQ_XIP_STREAM);
63 dma_channel_configure(
64 dma_chan,
65 &cfg,
66 (void *) buf, // Write addr
67 (const void *) XIP_AUX_BASE, // Read addr
68 count_of(random_test_data), // Transfer count
69 true // Start immediately!
70);

```

#### 4.4.4. Performance counters

The XIP subsystem provides two performance counters. These are 32 bits in size, saturate upon reaching `0xffffffff`, and are cleared by writing any value. They count:

1. The total number of XIP accesses, to any alias
2. The number of XIP accesses that resulted in a cache hit

This provides a way to profile the cache hit rate for common use cases.

#### 4.4.5. List of XIP\_CTRL registers

The XIP control registers start at a base address of `0x400c8000` (defined as `XIP_CTRL_BASE` in SDK).

Table 439. List of XIP registers

| Offset | Name                        | Info                                                         |
|--------|-----------------------------|--------------------------------------------------------------|
| 0x00   | <a href="#">CTRL</a>        | Cache control register. Read-only from a Non-secure context. |
| 0x08   | <a href="#">STAT</a>        |                                                              |
| 0x0c   | <a href="#">CTR_HIT</a>     | Cache Hit counter                                            |
| 0x10   | <a href="#">CTR_ACC</a>     | Cache Access counter                                         |
| 0x14   | <a href="#">STREAM_ADDR</a> | FIFO stream address                                          |
| 0x18   | <a href="#">STREAM_CTR</a>  | FIFO stream control                                          |
| 0x1c   | <a href="#">STREAM_FIFO</a> | FIFO stream data                                             |

#### XIP: CTRL Register

**Offset:** 0x00

##### Description

Cache control register. Read-only from a Non-secure context.

通过QMI APB配置端口访问FIFO。当启用QMI访问链时，流式XIP DMA表现接近理论最大QSPI吞吐量，但在需求达到理论最大吞吐量的场景中，直接模式FIFO可通过AHB端口访问。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/flash/xip\\_stream/flash\\_xip\\_stream.c](https://github.com/raspberrypi/pico-examples/blob/master/flash/xip_stream/flash_xip_stream.c) 第58至70行

```

58 const uint dma_chan = 0;
59 dma_channel_config cfg = dma_channel_get_default_config(dma_chan);
60 channel_config_set_read_increment(&cfg, false);
61 channel_config_set_write_increment(&cfg, true);
62 channel_config_set_dreq(&cfg, DREQ_XIP_STREAM);
63 dma_channel_configure(
64 dma_chan,
65 &cfg,
66 (void *) buf, // 写入地址
67 (const void *) XIP_AUX_BASE, // 读取地址
68 count_of(random_test_data), // 传输计数
69 true // 立即开始!
70);

```

#### 4.4.4. 性能计数器

XIP 子系统提供两个性能计数器。它们为 32 位，达到 `0x` 时饱和值`xffffffff`，写入任意值可清零。计数内容包括：

1. XIP 访问的总次数，针对任何别名地址

2. 导致缓存命中的 XIP 访问次数

这为常用场景下缓存命中率的性能分析提供了一种方法。

#### 4.4.5. XIP\_CTRL寄存器列表

XIP 控制寄存器起始地址为 `0x400c8000`（在 SDK 中定义为 `XIP_CTRL_BASE`）。

表 439. XIP  
寄存器列表

| 偏移量  | 名称                       | 说明                 |
|------|--------------------------|--------------------|
| 0x00 | <code>CTRL</code>        | 缓存控制寄存器。非安全上下文下只读。 |
| 0x08 | <code>STAT</code>        |                    |
| 0x0c | <code>CTR_HIT</code>     | 缓存命中计数器            |
| 0x10 | <code>CTR_ACC</code>     | 缓存访问计数器            |
| 0x14 | <code>STREAM_ADDR</code> | FIFO 流地址           |
| 0x18 | <code>STREAM_CTR</code>  | FIFO 流控制           |
| 0x1c | <code>STREAM_FIFO</code> | FIFO 流数据           |

#### XIP: CTRL 寄存器

偏移: 0x00

##### 说明

缓存控制寄存器。非安全上下文下只读。

Table 440. CTRL Register

| 11    | <p><b>WRITABLE_M1:</b> If 1, enable writes to XIP memory window 1 (addresses 0x11000000 through 0x11fffff, and their uncached mirrors). If 0, this region is read-only.</p> <p>XIP memory is <b>read-only by default</b>. This bit must be set to enable writes if a RAM device is attached on QSPI chip select 1.</p> <p>The default read-only behaviour avoids two issues with writing to a read-only QSPI device (e.g. flash). First, a write will initially appear to succeed due to caching, but the data will eventually be lost when the written line is evicted, causing unpredictable behaviour.</p> <p>Second, when a written line is evicted, it will cause a write command to be issued to the flash, which can break the flash out of its continuous read mode. After this point, flash reads will return garbage. This is a security concern, as it allows Non-secure software to break Secure flash reads if it has permission to write to any flash address.</p> <p>Note the read-only behaviour is implemented by downgrading writes to reads, so writes will still cause allocation of an address, but have no other effect.</p> | RW   | 0x0   |
| 10    | <p><b>WRITABLE_M0:</b> If 1, enable writes to XIP memory window 0 (addresses 0x10000000 through 0x10fffff, and their uncached mirrors). If 0, this region is read-only.</p> <p>XIP memory is <b>read-only by default</b>. This bit must be set to enable writes if a RAM device is attached on QSPI chip select 0.</p> <p>The default read-only behaviour avoids two issues with writing to a read-only QSPI device (e.g. flash). First, a write will initially appear to succeed due to caching, but the data will eventually be lost when the written line is evicted, causing unpredictable behaviour.</p> <p>Second, when a written line is evicted, it will cause a write command to be issued to the flash, which can break the flash out of its continuous read mode. | 15:0  | <p>With each byte clocked out on the serial interface, one byte will simultaneously be clocked in, and will appear in this FIFO. The serial interface will stall when this FIFO is full, to avoid dropping data.</p> <p>When 16-bit data is pushed into the TX FIFO, the corresponding RX FIFO push will also contain 16 bits of data. The least-significant byte is the first one received.</p> | RF   | 0x0000 |

## 4.5. OTP

RP2350 contains 8 kB of one-time-programmable storage (OTP), which stores:

- Manufacturing information such as unique device ID
- Boot configuration such as non-default crystal oscillator frequency
- Public key fingerprint(s) for boot signature enforcement
- Symmetric keys for decryption of external flash contents into SRAM
- User-defined contents, including bootable program images ([Section 5.10.7](#))

The OTP storage is structured as  $4096 \times 24$ -bit rows. Each row contains 16 bits of data and 8 bits of parity information, providing 8 kB of data storage. OTP bit cells are initially **0** and can be programmed to **1**. However, they cannot be cleared back to **0** under any circumstance. This ensures that security-critical flags, such as debug disables, are physically impossible to clear once set. However, you must also take care to program the correct values.

For more information about the OTP subsystem, see [Chapter 13](#).

| 31:16 | 保留。                                                                                                                                 | -  | -      |
| 15:0  | <p>串行接口每输出一个字节的同时，将同步时钟输入一个字节，该字节存入此FIFO。当FIFO满时，串行接口将暂停，以避免数据丢失。</p> <p>当16位数据写入TX FIFO时，相应的RX FIFO中也将写入16位数据。最低有效字节是第一个接收的字节。</p> | RF | 0x0000 |

## 4.5. OTP

RP2350包含8 kB一次性可编程存储器（OTP），其存储内容包括：

- 制造信息，例如唯一设备ID
- 启动配置，例如非默认晶体振荡器频率
- 用于启动签名强制执行的公钥指纹
- 用于将外部闪存内容解密至SRAM的对称密钥
- 用户自定义内容，包括可启动程序映像（第5.10.7节）

OTP存储结构为 $4096 \times 24$ 位的行。每行包含16位数据和8位奇偶校验信息，提供8 kB数据存储容量。OTP位单元初始值为0，可被编程为1。但在任何情况下均无法将其清除回0。这确保了安全关键标志（如禁用调试）一旦设置后在物理上不可清除。但您也必须谨慎编程正确的值。

有关OTP子系统的详细信息，请参见第13章。

# Chapter 5. Bootrom

Each RP2350 device contains 32 kB of mask ROM: a physically immutable memory resource described in [Section 4.1](#). The RP2350 bootrom is the binary image etched into this ROM that contains the first instructions executed at reset.

The bootrom concepts section ([Section 5.1](#)) covers the following topics, which are necessary background for understanding the bootrom features and their implementation:

- [Partition tables](#) and their associated [flash permissions](#)
- [Bootable images](#), and the [block loops](#) that store their metadata
- [Versioning](#) for images and partition tables, and [A/B versions](#) to support double-buffered upgrades
- [Hashing and signing](#) to support secure boot with public key fingerprint in OTP (see also [Section 10.1.1](#) in the security chapter)
- [Load maps](#) for bootable images, and [packaged binaries](#) that the bootrom loads from flash into RAM according to the image's load map
- [Anti-rollback protection](#) to revoke older, compromised versions of software
- Three forms of flash boot:
  - [Flash image boot](#), with a single binary image written directly into flash
  - [Flash partition boot](#), with the boot image selected from the partition table
  - [Partition-table-in-image boot](#), where the boot image is not contained in a partition table, but still embeds a partition table data structure to divide the flash address space
- [Boot slots](#) for A/B versions of partition tables
- [Flash update boot](#), a special one-time boot mode that enables version downgrades following an image download
- [Try before you buy](#) support for phased upgrades with image self-test
- [Address translation](#) for flash images, which provides a consistent runtime address to images regardless of physical storage location
- [Automatic architecture switch](#) when attempting to run a RISC-V binary on Arm, or vice versa
- [Targeting UF2 downloads](#) to different flash partitions based on their permissions and the UF2 family ID

Besides features mentioned as concepts above, the RP2350 bootrom implements:

- The core 0 initial boot sequence ([Section 5.2](#))
- The core 1 low-power wait and launch protocol ([Section 5.3](#))
- Runtime APIs ([Section 5.4](#)) exported through the ROM symbol table, such as flash and OTP programming
- A subset of runtime APIs available to Non-secure code, with permission for each API entry point individually configured by Secure code
- A USB MSC class-compliant bootloader with [UF2](#) support for downloading code/data to flash or RAM ([Section 5.5](#)), including support for versioning and A/B partitions
- The USB PICOBLOCK interface for advanced operations like OTP programming ([Section 5.6](#)) and to support [picotool](#) or other host side tools
- Support for white-labelling all USB exposed information/identifiers ([Section 5.7](#))
- A UART bootloader providing a minimal shell to load an SRAM binary from a host microcontroller ([Section 5.8](#))

You should read the bootrom concepts section before diving into the features in the list above. RP2350 adds a considerable amount of new functionality compared to the RP2040 bootrom. If you are in a terrible hurry, [Section 5.9.5](#) covers the absolute minimum requirements for a binary to be bootable on RP2350 when secure boot is not enabled.

# 第5章 Bootrom

每个RP2350设备包含32 kB的掩模只读存储器（mask ROM）：一种物理不可变的存储资源，详见第4.1节。RP2350 bootrom是刻录于该只读存储器中的二进制映像，包含复位时执行的第一条指令。

bootrom概念部分（第5.1节）涵盖以下主题，是理解bootrom功能及其实现的必要基础：

- 分区表及其相关的闪存权限
- 可启动映像及存储其元数据的块循环
- 映像和分区表的版本控制，以及支持双缓冲升级的A/B版本
- 用于OTP中公钥指纹的安全启动的哈希和签名（另见安全章节第10.1.1节）
- 可启动映像的加载映射，以及bootrom根据加载映射从闪存加载至RAM的打包二进制文件
- 防回滚保护，用于撤销较旧且已被破坏的软件版本
- 闪存启动的三种形式：
  - 闪存镜像启动，即单个二进制镜像直接写入闪存
  - 闪存分区启动，从分区表中选择启动镜像
  - 分区表内嵌镜像启动，启动镜像不包含分区表，但嵌入了分区表数据结构以划分闪存地址空间
- 针对分区表A/B版本的启动槽
- 闪存更新启动，一种特殊的一次性启动模式，支持下载镜像后的版本回退
- 支持“先测试后升级”的分阶段升级以及镜像自检
- 闪存镜像地址转换，确保镜像的运行时地址与物理存储位置无关
- 尝试在Arm上运行RISC-V二进制文件或反之自动切换架构
- 根据权限和UF2 family ID，将UF2下载定向到不同的闪存分区

除上述功能外，RP2350只读存储器还实现了：

- 核心0的初始启动序列（第5.2节）
- 核心1低功耗等待与启动协议（第5.3节）
- 通过只读存储器符号表导出的运行时API（第5.4节），例如flash和OTP编程
- 可供非安全代码使用的运行时API子集，每个API入口点的权限由安全代码单独配置
- 支持UF2的符合USB MSC类的引导加载程序，用于向flash或RAM下载代码/数据（第5.5节），包括版本控制和A/B分区支持
- 用于高级操作如OTP编程的USB PICOBLOCK接口（第5.6节），并支持 `picotool` 或其他主机端工具
- 支持对白标记所有通过USB公开的信息/标识符（第5.7节）
- 提供最小化shell的UART引导加载程序，用于从主控微控制器加载SRAM二进制文件（第5.8节）

在深入了解上述功能列表之前，您应先阅读启动只读存储器概念章节。RP2350相较于RP2040启动只读存储器添加了大量新功能。如时间紧迫，第5.9.5节涵盖了在未启用安全启动情况下，二进制文件在RP2350上可启动的最低要求。

**Bootrom source code**

All source files for the RP2350 bootrom are available under the terms of the 3-clause BSD licence:

[github.com/raspberrypi/pico-bootrom-rp2350](https://github.com/raspberrypi/pico-bootrom-rp2350)

## 5.1. Bootrom concepts

Bold type in the following sections introduces a **concept**. This chapter frequently refers back to these concepts.

### 5.1.1. Secure and Non-secure

This datasheet uses the (capitalised) terms **Secure** and **Non-secure** to refer to the Arm execution states of the same name, defined in the [Armv8-M Architecture Reference Manual](#). The uncapitalised term "secure" has no special meaning.

In some contexts, Secure can also refer to a RISC-V core, usually one running at the Machine privilege level. For example, the low-level flash APIs are exported to Arm Secure code and RISC-V code only, so Secure serves as a shorthand for this type of API.

A **secured RP2350** is a device where secure boot is enabled ([Section 5.10.1](#)). This is not the same as the Secure state, since the device may run a mixture of Secure and Non-secure code after completing the secure boot process.

### 5.1.2. Partition tables

A **partition table** divides flash into a maximum of 16 distinct regions, known as **partitions**. Each partition defines attributes such as [flash permissions](#) for a contiguous range of flash addresses. The [PARTITION\\_TABLE](#) data structure describes a partition table, and is an example of a **block**. Use of partition tables is strictly optional.

Dividing flash into multiple partitions enables you to:

- Store more than one executable image on the device. For example:
  - For A/B boot versions ([Section 5.1.7](#))
  - For different architectures (Arm/RISC-V) or Secure/Non-secure
  - For use with a custom bootloader
- Provision space for data. For example:
  - Embedded file systems
  - Shared Wi-Fi firmware
  - Application resources
- Provide different security attributes for different regions of flash ([Section 5.1.3](#))
- Target UF2 downloads to different partitions based on family ID ([Section 5.1.18](#)), including custom-defined UF2 families specific to your platform

For more information about [PARTITION\\_TABLE](#) discovery during flash boot, see [Section 5.1.5.2](#).

Partition tables can be [versioned](#) to support A/B upgrades. They can also be [hashed and signed](#) for security and integrity purposes. We recommend hashing partition tables to ensure that they haven't been corrupted. This is especially important when using [boot slots](#) to update your partition table, since a corrupted partition table with a higher version could be chosen over a non-corrupted partition table with a lower version.

**Bootrom 源代码**

RP2350 bootrom 的所有源文件均依据三条款 BSD 许可证条款提供：

[github.com/raspberrypi/pico-bootrom-rp2350](https://github.com/raspberrypi/pico-bootrom-rp2350)

## 5.1. 启动只读存储器概念

下文各节中的粗体字介绍了一个概念。本章节频繁引用这些概念。

### 5.1.1. 安全与非安全

本数据手册采用（大写）术语 **Secure** 和 **Non-secure**，指代 Armv8-M 架构参考手册中定义的同名 Arm 执行状态。非大写的“secure”无特殊含义。

在某些情况下，Secure 也可指代 RISC-V 核心，通常是运行于机器特权级别的核。例如，低级闪存 API 仅向 Arm Secure 代码和 RISC-V 代码导出，因此 Secure 作为此类 API 的简写。

所谓**secured RP2350**是指启用了安全引导（第 5.10.1 节）的设备。此状态不同于 Secure 状态，因为设备在完成安全引导后，可能会运行 Secure 和 Non-secure 代码的混合。

### 5.1.2. 分区表

分区表将闪存划分为最多16个独立区域，称为分区。每个分区定义连续闪存地址范围的闪存权限等属性。**PARTITION\_TABLE** 数据结构描述分区表，是块的一个示例。分区表的使用完全是可选的。

将闪存划分为多个分区，可以使您：

- 在设备上存储多个可执行映像。例如：
  - 用于A/B启动版本（第5.1.7节）
  - 用于不同架构（Arm/RISC-V）或安全/非安全模式
  - 用于自定义引导加载程序
- 为数据预留空间。例如：
  - 嵌入式文件系统
  - 共享Wi-Fi固件
  - 应用程序资源
- 为闪存不同区域提供不同的安全属性（第5.1.3节）
- 根据系列ID将UF2下载目标定向至不同分区（第5.1.18节），包括针对您平台自定义定义的UF2系列

有关闪存启动期间**PARTITION\_TABLE**发现的更多信息，请参见第5.1.5.2节。

分区表可进行版本控制以支持A/B升级。分区表还可被哈希和签名，以保障安全性和完整性。我们建议对分区表进行哈希处理，以确保其未被损坏。当使用启动槽更新分区表时，这一点尤为重要，因为损坏的高版本分区表可能会被选择，而非低版本但未损坏的分区表。

### 5.1.2.1. Partition attributes

Each partition specifies **partition attributes** for the flash addresses it encompasses, including:

- Start/end offsets within the logical 32 MB address space of the two flash windows; these offsets are specified in multiples of a flash sector (4 kB)
  - Bootable partitions must reside wholly in the first 16 MB flash window, due to limitations of the [address translation](#) hardware
- Access permissions for the partition: read/write for each of Secure ([S](#)), Non-secure ([NS](#)) and bootloader ([BL](#)) access
- Information on which UF2 family IDs may be dropped into the partition via the UF2 bootloader
- An optional 64-bit identifier
- An optional name (a string for human-readable identification)
- Whether to ignore the partition during Arm or RISC-V boot
- Information to group partitions together (see [Section 5.1.7](#) and [Section 5.1.18](#))

[Section 5.9.4](#) documents the full list of partition attributes, along with the [PARTITION\\_TABLE](#) binary format.

If there is no partition table, the entirety of flash is considered a single region, with no restricted permissions. Without a partition table, there is no support for custom UF2 family IDs, therefore you must use one of the standard IDs specified in [Table 455](#).

### 5.1.3. Flash permissions

One of the roles of the partition tables introduced in [Section 5.1.2](#) is to define **flash permissions**, or simply permissions. The partition table stores one set of permission flags for each partition: all bytes covered by a single partition have the same permissions. The partition table separately defines permissions for **unpartitioned space**: flash addresses which do not match any of partitions defined in the partition table.

Separate read/write permissions are specified for each of Secure ([S](#)), Non-secure ([NS](#)) and bootloader ([BL](#)) access. Bootloader permissions control where UF2s can be written to, and what can be accessed via [picotool](#) when the device is in BOOTSEL mode.

Because flash permissions may be changed dynamically at runtime, part of the partition table is resident in RAM at runtime. You can modify this table to add permissions for other areas of flash at runtime, without changing the partition table stored in flash itself. There is no bootrom API for this, however the in-memory partition table format is documented, and a pointer is available in the ROM table. The SDK provides APIs to wrap this functionality.

### 5.1.4. Image definitions

An **image** is a contiguous data blob which may contain code, or data, or a mixture. An **image definition** is a block of metadata embedded near the start of an image. The metadata stored in the image definition allows the bootrom to recognise valid executable and non-executable images. The [IMAGE\\_DEF](#) data structure represents the image definition in a binary format, and is an example of a [block](#).

For executable images, the [IMAGE\\_DEF](#) could be considered similar to an ELF header, as it can include image attributes such as architecture/chip, entry-point, load addresses, etc.

All [IMAGE\\_DEF](#)s can contain version information and be hashed or signed. Whilst the bootrom only directly boots executable images, it does provide facilities for selecting a valid (possibly signed) data image from one or more partitions on behalf of a user application.

The presence of a valid [IMAGE\\_DEF](#) allows the bootrom to discern a valid application in flash from random data. As a result, you must include a valid [IMAGE\\_DEF](#) in any executable binary that you intend to boot.

For more information about how the bootrom discovers [IMAGE\\_DEF](#)s, see the section on [block loops](#).

### 5.1.2.1. 分区属性

每个分区指定其所涵盖闪存地址的分区属性，包括：

- 两个闪存窗口内32 MB逻辑地址空间的起始/结束偏移量；偏移量以闪存扇区（4 kB）的倍数表示。
- 可启动分区必须完全位于第一个16 MB闪存窗口内，因地址转换硬件的限制。
- 分区的访问权限：针对安全（**S**）、非安全（**NS**）和引导加载程序（**BL**）访问的读写权限。
- 通过UF2引导加载程序可写入该分区的UF2系列ID信息。
- 一个可选的64位标识符
- 一个可选名称（用于人类可识别的字符串）
- 是否在Arm或RISC-V启动过程中忽略该分区
- 用于将分区分组的信息（参见第5.1.7节及第5.1.18节）

[第5.9.4节](#)载明了完整的分区属性列表，及[PARTITION\\_TABLE二进制格式](#)。

若无分区表，则整个闪存视为单一区域，且无权限限制。无分区表时，不支持自定义UF2系列ID，必须使用表455中指定的标准ID之一。

### 5.1.3. 闪存权限

分区表（详见第5.1.2节）的一项作用是定义**闪存权限**，简称权限。

分区表为每个分区保存一组权限标志：单个分区覆盖的所有字节权限一致。分区表单独定义了**未分区空间**的权限，即不匹配任何分区表定义分区的闪存地址。

分别为安全区（**S**）、非安全区（**NS**）和引导加载程序（**BL**）访问设置读写权限。

引导加载程序权限控制UF2文件的写入位置，以及设备处于BOOTSEL模式时通过 **picotool** 可访问的内容。

由于闪存权限可能在运行时动态更改，部分分区表在运行时驻留于RAM中。您可以在运行时修改此表，为闪存的其他区域添加权限，而无需更改存储于闪存中的分区表本身。虽然没有bootrom API支持此功能，但内存中的分区表格式已被记录，且ROM表中提供了相关指针。SDK提供了封装此功能的API接口。

### 5.1.4. 镜像定义

镜像（**image**）是连续的数据块，可能包含代码、数据或两者的混合。镜像定义（**image definition**）是嵌入在镜像起始位置附近的元数据块。镜像定义中存储的元数据使bootrom能够识别有效的可执行与非可执行镜像。**IMAGE\_DEF** 数据结构以二进制格式表示映像定义，是块的一个示例。

对于可执行映像，**IMAGE\_DEF** 可视为类似 **ELF** 头部，因为其可包含映像属性，例如架构/芯片、入口点、加载地址等。

所有 **IMAGE\_DEF** 均可包含版本信息，且可被哈希或签名。尽管 bootrom 仅直接引导可执行映像，但它为用户应用程序提供了从一个或多个分区中选择有效（可能已签名）数据映像的功能。

有效的 **IMAGE\_DEF** 存在使 bootrom 能够区分闪存中的有效应用与随机数据。因此，任何拟引导的可执行二进制文件中均必须包含有效的 **IMAGE\_DEF**。

有关 bootrom 如何发现 **IMAGE\_DEF** 的详细信息，请参见块循环章节。

For details about the `IMAGE_DEF` format itself, see [Section 5.9.3](#).

For a description of the minimum requirements for a bootable image, see [Section 5.9.5](#).

## 5.1.5. Blocks and block loops

### 5.1.5.1. Blocks

`IMAGE_DEFs` and `PARTITION_TABLEs` are both examples of **blocks**. A block is a recognisable, self-checking data structure containing one or more distinct data **items**. The type of the first item in a block defines the type of that entire block.

Blocks are backwards and forwards compatible; item types will not be changed in the future in ways that could cause existing code to misinterpret data. Consumers of blocks (including the bootrom) must skip items within the block whose types are currently listed as reserved; encountering reserved item types must not cause a block to fail validation.

To be considered **valid**, a block must have the following properties:

- it must begin with the 4 byte magic header, `PICOBIN_BLOCK_MARKER_START` (`0xffffded3`)
- the end of each (variably-sized) item must also be the start of another valid item
- the last item must have type `PICOBIN_BLOCK_ITEM_2BS_LAST` and specify the correct full length of the block
- it must end with the 4 byte magic footer, `PICOBIN_BLOCK_MARKER_END` (`0xab123579`)

The magic header and footer values are chosen to be unlikely to appear in executable Arm and RISC-V code. For more information about the block format, see [Section 5.9.1](#).

Given a region of memory or flash (such as a partition), blocks are found by searching the first 4 kB of that given region (for flash boot) or the entire region (for RAM/OTP image boots) for a valid block which is part of a valid **block loop**.

Currently `IMAGE_DEFs` and `PARTITION_TABLEs` are the only types of block used by the RP2350 bootrom, but the block format reserves encoding space for future expansion.

### 5.1.5.2. Block loops

A **block loop** is a cyclic linked list of blocks (a linked loop). Each block has a relative pointer to the next block, and the last block must link to the first. A single block can form a block loop by linking back to itself with a relative pointer of 0. The first block in a loop must have the lowest address of all blocks in the loop.

The purpose of a block loop is threefold:

- to discover which blocks belong to the same image without a brute-force search
- to allow metadata to be appended in post-link processing steps
- to detect parts of the binary being overwritten in a way that breaks the loop

For [flash image boot](#) the bootrom searches the first 4 kB of flash; the 4 kB size is a compromise between allowing flexibility for different languages' memory layouts, while avoiding scanning too much flash when trying different flash access modes and QSPI clock frequencies. [flash partition boot](#) also limits its search to the first 4 kB of the partition.

The search window may be larger, such as a RAM image boot following a UF2 SRAM download, where the search window is all of SRAM. For the fastest boot time, locate the first block as close to the beginning of the binary as possible.

Block loops support multiple blocks because:

- Signing an image duplicates the existing `IMAGE_DEF` and adds another (bigger) `IMAGE_DEF` with additional signature information.
- An image may contain multiple `IMAGE_DEFs`, for example, with different signing keys.

有关 `IMAGE_DEF` 格式的详细说明，请参见第5.9.3节。

有关可引导镜像最低要求的说明，请参见第5.9.5节。

## 5.1.5. 块及块循环

### 5.1.5.1. 块

`IMAGE_DEF` 和 `PARTITION_TABLE` 均为块的示例。块是一种可识别且自检的数据结构，包含一个或多个不同的数据项。块中首个项的类型决定了整个块的类型。

块具有向前与向后兼容性；项类型今后不会以导致现有代码误解数据的方式进行更改。块的使用者（包括只读存储器）必须跳过块内当前标记为保留的项类型；遇到保留项类型时，不得导致块校验失败。

为了被视为有效块，必须具备以下特性：

- 它必须以4字节魔术头 `PICOBIN_BLOCK_MARKER_START` (`0xffffded3`) 开头
- 每个（可变大小）项的结束位置必须同时为另一个有效项的起始位置
- 最后一项必须具有类型 `PICOBIN_BLOCK_ITEM_2BS_LAST` 且指定区块的正确完整长度
- 它必须以4字节魔术尾部 `PICOBIN_BLOCK_MARKER_END` (`0xab123579`) 结束

魔术头部和尾部的值被选为在可执行的Arm和RISC-V代码中极不可能出现。有关区块格式的详细信息，请参见第5.9.1节。

在给定的内存或闪存区域（如分区）中，通过搜索该区域的前4KB（用于闪存启动）或整个区域（用于RAM/OTP镜像启动）以定位属于有效块环的有效区块。

目前，RP2350启动只读存储器仅使用 `IMAGE_DEF` 和 `PARTITION_TABLE` 两种区块类型，但区块格式预留了编码空间以支持未来扩展。

### 5.1.5.2. 块循环

块循环是一种块的循环链表（一个链环）。每个块都具有指向下一个块的相对指针，且最后一个块必须链接回第一个块。单个块可以通过相对指针为0链接回自身，从而形成块循环。

循环中的第一个块必须具有所有块中最低的地址。

块循环的目的有三点：

- 发现哪些块属于同一镜像，避免暴力搜索。
- 允许在后链接处理步骤中追加元数据。
- 检测二进制部分被覆盖，从而破坏循环的情况。

对于闪存镜像启动，bootrom会搜索闪存的前4 kB；4 kB大小是在兼顾不同语言内存布局灵活性与避免在尝试不同闪存访问模式和QSPI时钟频率时扫描过多闪存之间的折衷。闪存分区启动同样将搜索限制在分区的前4 kB范围内。

搜索窗口可能更大，例如在UF2 SRAM下载后引导RAM镜像时，搜索窗口涵盖整个SRAM。为实现最快启动时间，应尽量将第一个块定位于二进制文件的开头附近。

块循环支持多个块，原因如下：

- 签署镜像时，会复制现有的 `IMAGE_DEF`，并添加一个更大的 `IMAGE_DEF`，内含附加的签名信息。
- 一个镜像可能包含多个 `IMAGE_DEF`，例如使用不同的签名密钥。

- Placing a block at both the beginning and end of an image can detect some partial overwrites of the image (for example, due to an overly enthusiastic absolute-addressed UF2 download). The SDK does this by default. Hashing or signing the entire image is more robust, since it detects corruption in the middle of the image.
- A universal binary image might contain code for both Arm and RISC-V, including `IMAGE_DEF`s for both.
- `PARTITION_TABLE`s and `IMAGE_DEF`s are both present in the same block loop in the case of an [embedded partition table](#).

If a block loop contains multiple `IMAGE_DEF`s or multiple `PARTITION_TABLE`s, the winner is generally the last one seen in linked-list order. The exception is the case of two `IMAGE_DEF`s for different architectures (Arm and RISC-V); an `IMAGE_DEF` for the architecture currently executing the bootrom is always preferred over one for a different architecture.

### 5.1.6. Block versioning

Any block may contain a `version`. Version information consists of a tuple of either two or three 16-bit values: `(rollback).major.minor`, where the rollback part is optional. An item of type `VERSION` contains the binary data structure which defines the version of a block.

The rollback version may only be specified for `IMAGE_DEF`s and defaults to zero if not present. You cannot specify this version for partition tables. The rollback version can be used on a [secured RP2350](#), where it, along with a current rollback version number stored in OTP, can prevent installation of older, vulnerable code once a newer version is installed ([Section 5.1.11](#)).

The full version number can be used to pick the latest version between two `IMAGE_DEF`s or two `PARTITION_TABLE`s (see [Section 5.1.7](#)). Versions compare in lexicographic order:

1. If version  $x$  has a different rollback version than version  $y$ , then the greater rollback version determines which version is greater overall
2. Else if version  $x$  has a different major version than version  $y$ , then the greater major version determines which version is greater overall
3. Else the minor version determines which of  $x$  and  $y$  is greater

See [Section 5.9.2.1](#) for full details on the `VERSION` item in a block.

### 5.1.7. A/B versions

A pair of partitions may be grouped into an **A/B** pair. By logically grouping A and B partitions, you can keep the current executable image (or data) in one partition, and write a newer version into the other partition. When you finish writing a new version, you can safely switch to it, reverting to the older version if problems arise. This avoids partially written states that could render RP2350 un-bootable.

- When booting an A/B partition pair, the bootrom typically uses the partition with the higher version. For scenarios where this is not the case, see [Section 5.1.16](#).
- When dragging a UF2 onto the BOOTSEL USB drive, the UF2 targets the opposite A/B partition to the one preferred at boot. See [Section 5.1.18](#) for more details.

#### **i** NOTE

It is also possible to have A/B versions of the partition table. For more information about this advanced topic, see [Section 5.1.15](#).

### 5.1.8. Hashing and signing

Any block may be **hashed** or **signed**. A hashed block stores the image hash value (see [Section 5.9.2.3](#)). At runtime, the bootrom calculates a hash and compares it to the stored hash to determine if the block is valid. Hashes guard against

- 将块同时置于镜像的开头和结尾，可检测镜像的部分覆盖（例如由过度热情使用绝对地址 UF2 下载导致的覆盖）。此功能为 SDK 默认设置。对整个镜像进行哈希或签名更为稳健，因为它能检测镜像中间的损坏。

- 通用二进制镜像可能包含 Arm 和 RISC-V 代码，包括两者的 `IMAGE_DEF`。
- 在嵌入式分区表情况下，`PARTITION_TABLE` 与 `IMAGE_DEF` 可同时存在于同一块循环中。

如果一个块循环包含多个 `IMAGE_DEF` 或多个 `PARTITION_TABLE`，通常最后一个被链表遍历到的将被视为胜出者。例外情况为针对不同架构（Arm 和 RISC-V）的两个 `IMAGE_DEF`；当前正在执行 bootrom 的架构对应的 `IMAGE_DEF` 始终优先于其他架构的 `IMAGE_DEF`。

### 5.1.6. 块版本控制

任何块都可以包含一个 `version`。版本信息由包含两个或三个16位值的元组组成：  
`(rollback).major.minor`，其中 `rollback` 部分为可选。类型为 `VERSION` 的条目包含定义块版本的二进制数据结构。

`rollback` 版本仅可为 `IMAGE_DEF` 指定，未指定时默认为零。您不能为分区表指定此版本。`rollback` 版本可用于安全的 RP2350，该版本与存储于 OTP 中的当前 `rollback` 版本号配合使用，能够防止在安装新版本后重新安装旧版本的易受攻击代码（参见第 5.1.11 节）。

完整版本号可用于在两个 `IMAGE_DEF` 或两个 `PARTITION_TABLE` 之间选择最新版本（详见第 5.1.7 节）。版本按字典序排序比较：

- 如版本 `x` 的回滚版本与版本 `y` 不同，则较大的回滚版本决定整体较高版本
- 如版本 `x` 的主版本与版本 `y` 不同，则较大的主版本决定整体较高版本
- 否则，次版本决定 `x` 与 `y` 中较高的版本

有关区块中 `VERSION` 项的详细信息，请参见第 5.9.2.1 节。

### 5.1.7. A/B 版本

一对分区可被组合为一个 **A/B** 对。通过逻辑分组 A 和 B 分区，您可将当前可执行映像（或数据）保存在一个分区中，并将新版本写入另一分区。写入新版本完成后，您可安全切换至该版本，如有问题可回退至旧版本。此操作可避免产生可能导致 RP2350 无法启动的部分写入状态。

- 启动 A/B 分区对时，启动只读存储器通常优先使用版本较高的分区。如遇非上述情况，详见第 5.1.16 节。
- 将 UF2 文件拖放至 BOOTSEL USB 驱动器时，UF2 针对的分区与启动时优先的 A/B 分区相反。详情请参见第 5.1.18 节。

#### ① 注意

分区表亦可具有 A/B 版本。有关该高级主题的更多信息，请参考第 5.1.15 节。

### 5.1.8. 哈希与签名

任意块均可被哈希或签名。哈希块存储映像哈希值（见第 5.9.2.3 节）。运行时，启动只读存储器计算哈希值并与存储的哈希进行比对，以验证该块的有效性。哈希用于防止

corruption of an image, but do not provide any security guarantees.

On a secured RP2350, a hash is not sufficient for an image to be considered valid. All images must have a **signature**: a hash encrypted by a private key, plus metadata (also covered by the hash) describing how the hash was generated. This signature is stored as part of an [IMAGE\\_DEF](#) block. An image with a signature in its [IMAGE\\_DEF](#) block is called a **signed image**.

#### NOTE

For background on signatures and boot keys, see the introduction to secure boot in the security chapter ([Section 10.1.1](#)).

To verify a signed image, the boottrom decrypts the hash stored in the signature using a `secp256k1` public key. The boottrom also computes its own hash of the image and compares its measured hash value with the one in the signature.

The public key is also stored in the block via a [SIGNATURE](#) item (see [Section 5.9.2.4](#)): this key's (SHA-256) hash must match one of the boot key hashes stored in OTP locations `BOOTKEY0_0` onwards. Up to four public keys can be registered in OTP, with the count defined by `BOOT_FLAGS1.KEY_VALID` and `BOOT_FLAGS1.KEY_INVALID`. A hash of a key is also referred to as a **key fingerprint**.

The data to be hashed is defined by a [HASH\\_DEF](#) item (see [Section 5.9.2.2](#)), which indicates the type of hash. It also indicates how much of the block itself is to be hashed. For a signed block, the hash *must* contain all contents of the block up to the final [SIGNATURE](#) item.

To be useful your hash or signature must cover actual image data in addition to the metadata stored in the block. The block's [load map](#) item specifies which data the boottrom hashes during hash or signature verification.

The above discussion mostly applies to [IMAGE\\_DEFS](#). On a secured RP2350 with the `BOOT_FLAGS0.SECURE_PARTITION_TABLE` flag set, the boottrom also enforces signatures on [PARTITION\\_TABLES](#).

### 5.1.9. Load maps

A **load map** describes regions of the binary and what to do with them before the boottrom runs the binary.

The load map supports:

- Copying portions of the binary from flash to RAM (or to the XIP cache)
- Clearing parts of RAM (either `.bss` clear, or erasing uninitialised memory during secure boot)
- Defining what parts of the binary are included in a [hash or signature](#)
- Preventing the flushing of the XIP cache when to keep loaded lines pinned up to the point the binary starts

For full details on the [LOAD\\_MAP](#) item type of [IMAGE\\_DEF](#) blocks, see [Section 5.9.3.2](#).

When booting a signed binary from flash, it is desirable to load the signed data and code into RAM *before* checking the signature and subsequently executing it. Otherwise, an adversary could replace the flash device in between the signature check and execution, subverting the check. For this reason, the load map also serves as a convenient description of what to include in a hash or signature. The load map itself is covered by the hash or signature, and the entire metadata [block](#) is loaded into RAM before processing, so it is not itself subject to this time-of-check versus time-of-use concern.

### 5.1.10. Packaged binaries

As described in [Section 5.1.9](#), signed binaries in flash on a secured RP2350 are commonly loaded from flash into RAM, go through signature verification in RAM, and then execute from the verified version in RAM.

A **packaged binary** is a binary stored in flash that runs entirely from RAM. The binary is likely compiled to run from RAM as a RAM-only binary (unfortunately named `no_flash` in SDK parlance), but subsequently post-processed for flash

映像损坏，但不提供任何安全保障。

在受保护的 RP2350 上，仅凭哈希值不足以使映像被视为有效。所有映像必须具有签名：由私钥加密的哈希值，以及描述哈希生成过程的元数据（亦包含于哈希中）。此签名作为 **IMAGE\_DEF** 块的一部分进行存储。在 **IMAGE\_DEF** 块中包含签名的映像称为**签名映像**。

### 注意

有关签名和启动密钥的背景信息，请参见安全章节中安全启动的介绍（第10.1.1节）。

要验证签名映像，bootrom 使用 secp256k1公钥解密存储在签名中的哈希值；同时，bootrom 还会计算自身的映像哈希值，并将计算结果与签名中的哈希值进行比对。

公钥也通过 **SIGNATURE**项存储于区块中（参见第5.9.2.4节）：该密钥的（SHA-256）哈希必须与存储在 OTP 位置 BOOTKEY\_Y0\_0 及后续位置的启动密钥哈希之一相匹配。最多可在OTP中注册四个公钥，数量由BOOT\_FLAGS1.KEY\_VALID和BOOT\_FLAGS1.KEY\_INVALID确定。密钥的哈希值亦称为**密钥指纹**。

待哈希的数据由 **HASH\_DEF**项定义（详见第5.9.2.2节），该项指明哈希类型。此外，该项还指示应哈希的块本身的数据量。对于已签名块，哈希值必须包含直到最终 **SIGNATURE**项的所有块内容。

为确保有效，您的哈希或签名必须涵盖实际映像数据及块中存储的元数据。块的加载映射项指定bootrom在哈希或签名验证过程中需哈希的数据。

上述讨论主要适用于**IMAGE\_DEF**。在设置了`BOOT_FLAGS0.SECURE_PARTITION_TABLE`标志的安全型RP2350上，bootrom也强制对 `PARTITION_TABLE`进行签名验证。

## 5.1.9. 加载映射

加载映射描述二进制文件中的区域及在只读存储器启动程序执行二进制文件前应如何处理这些区域。

加载映射支持：

- 将二进制文件的部分内容从闪存复制到RAM（或XIP缓存）
- 清除部分RAM（包括 `.bss`段的清零，或在安全启动期间擦除未初始化内存）
- 定义二进制文件中哪些部分包含在哈希或签名中
- 防止刷新XIP缓存，以保持已加载的缓存行固定，直到二进制文件启动

有关 `LOAD_MAP`项类型在 **IMAGE\_DEF** 块中的详细说明，请参见第5.9.3.2节。

从闪存启动签名二进制文件时，应在验证签名并随后执行该二进制文件之前，将签名的数据和代码加载到RAM。否则，攻击者可能在签名验证和执行之间替换闪存设备，从而破坏验证过程。因此，加载映射还可作为哈希或签名所包含内容的便捷描述。加载映射本身受哈希或签名保护，且整个元数据块在处理前已加载至RAM，因此本身不涉及时序检查（time-of-check）与使用时检查（time-of-use）的问题。

## 5.1.10. 打包二进制文件

如第5.1.9节所述，受保护的RP2350上的签名二进制文件通常从闪存加载至RAM，在RAM中进行签名验证，随后从已验证的RAM版本执行。

打包二进制文件是指存储于闪存中、完全从RAM运行的二进制文件。该二进制文件通常编译为仅从RAM运行的RAM专用二进制文件（SDK中称为no\_flash），但随后经过闪存驻留的后处理。

residence. The bootrom **unpackages** the binary into RAM before execution.

As part of the packaging process, tooling like `picotool` adds a `LOAD_MAP` that tells the bootrom which parts of the flash-resident image it must load into RAM, and where to put them. This tooling may also **hash** or **sign** the binary in the same step. In this case, the bootrom hashes the data it loads as it unpackages the binary, as well as relevant metadata such as the `LOAD_MAP` itself. The bootrom compares the resulting hash to the precomputed hash or signature in the `IMAGE_DEF` to verify the unpackaged contents in RAM before running those contents.

Compare this with RP2040, where a flash-resident binary which executes from RAM (a `copy_to_ram` binary in SDK parlance) must begin by executing from flash, then copy itself to RAM before continuing from there. In the RP2040 case, the loader itself (or rather the SDK `crt0`) executes in-place in flash to perform the copy. This makes it impossible to perform any trustworthy level of verification, because the loader itself executes in untrusted memory.

### 5.1.11. Anti-rollback protection

**Anti-rollback** on a secured RP2350 prevents booting an older binary which may have known vulnerabilities. It prevents this even if the binary is correctly signed and meets all other requirements for bootability.

Full `IMAGE_DEF` version information is of the form `(rollback).major.minor`, where the rollback part is optional. If a **rollback version** is present, it is accompanied by a list of OTP rows whose ordered values are used to form a **thermometer** of bits indicating the minimum rollback version that may run on the device.

A thermometer code is a base-1 (unary) number where the integer value is one plus the index of the most-significant set bit. For example, the bit strings `00001111`, `00001001`, and `00001000` all encode a value of four, and the all-zeroes bit pattern encodes a value of zero. The bootrom uses this encoding because:

- it allows OTP rows containing counters to be incremented, and
- it does not allow them to be decremented

On a secured RP2350, the bootrom compares the rollback version of the `IMAGE_DEF` against the thermometer-coded minimum rollback version stored in OTP. If the `IMAGE_DEF` value is lower, the bootrom refuses to boot the image.

The `IMAGE_DEF` rollback version is covered by the image's signature, thus cannot be modified by an adversary who does not know the signing key. The list of OTP rows which define the chip's minimum rollback version is also stored in the program image, and also covered by the image signature.

The list of OTP rows in the `IMAGE_DEF` must always have at least one bit spare beyond the `IMAGE_DEF`'s rollback version (enforced by `picotool`). As a result, older binaries always contain enough information for the bootrom to detect that the chip's minimum rollback version has been incremented past the rollback version in the `IMAGE_DEF`. You can append more rows to the list on newer binaries to accommodate higher rollback versions without ambiguity.

When an executable image with a non-zero rollback version is successfully booted, its rollback version is written to the OTP thermometer. The `BOOT_FLAGS0.ROLLBACK_REQUIRED` flag may be used to require an `IMAGE_DEF` have a rollback version on a secured RP2350. This flag is set automatically when updating the rollback version in OTP.

#### NOTE

An `IMAGE_DEF` with a rollback version of 0 will not automatically set the `BOOT_FLAGS0.ROLLBACK_REQUIRED` flag, so it is recommended that the minimum rollback version used is 1, unless the `BOOT_FLAGS0.ROLLBACK_REQUIRED` flag is manually set during provisioning.

### 5.1.12. Flash image boot

RP2350 is designed primarily to run code from a QSPI flash device, either in-package or soldered separately to the circuit board. Code runs either in-place in flash, or in SRAM after being loaded from flash. **Flash boot** is the process of discovering that code and preparing to run it. **Flash image boot** uses a program binary stored directly in flash rather than in a **flash partition**. Flash image boot requires the bootrom to discover a block loop starting within the first 4 kB of flash which contains a valid `IMAGE_DEF` (and no `PARTITION_TABLE`).

驻留。启动只读存储器（bootrom）在执行前将二进制文件解包至RAM。

作为打包流程的一部分，诸如 `picotool` 的工具会添加 `LOAD_MAP`，指示启动只读存储器将闪存驻留映像的哪些部分加载至RAM及其存放位置。该工具可能在同一过程中对二进制文件进行哈希或签名。在此情况下，只读存储器在解包二进制文件时对所加载的数据进行哈希处理，以及对相关元数据（例如 `LOAD_MAP` 本身）进行哈希处理。只读存储器将生成的哈希值与 `IMAGE_DEF` 中预先计算的哈希值或签名进行比较，以验证解包后位于RAM中的内容，然后才运行该内容。

相比之下，RP2040中从RAM执行的闪存驻留二进制文件（SDK术语中的`copy_to_ram`二进制）必须先从闪存执行，然后将自身复制到RAM，再从RAM继续执行。在RP2040的情形中，加载程序自身（或更准确地说，SDK的 `crt0`）在闪存中就地执行以完成复制。这使得进行任何可信赖级别的验证变得不可能，因为加载程序本身是在不受信任的内存中执行。

### 5.1.11. 防回滚保护

RP2350上的防回滚功能可防止启动存在已知漏洞的旧版本二进制文件。即使该二进制文件已正确签名且满足启动的所有其他要求，防回滚功能仍将阻止其启动。

完整的 `IMAGE_DEF` 版本信息格式为 `(rollback).major.minor`，其中 `rollback` 部分为可选。若存在 `rollback` 版本，则附带一份OTP行列表，其有序值用于形成一个表示设备可运行的最小回退版本的比特 `thermometer`。

`thermometer` 编码是一种基数为1（单元制）的数字，其中整数值为最高位已置位比特的索引加一。例如，比特串 `00001111`、`00001001` 与 `00001000` 均编码为数值4，而全零比特模式编码为数值0。bootrom采用此编码的原因包括：

- 它允许包含计数器的OTP行递增，且
- 不允许其递减。

在受保护的RP2350上，bootrom将 `IMAGE_DEF` 的回退版本与存储在OTP中的 `thermometer` 编码的最小回退版本进行比较。若 `IMAGE_DEF` 值较低，bootrom将拒绝启动该映像。

`IMAGE_DEF` 的回滚版本受映像签名保护，故无法被不知签名密钥的对手修改。定义芯片最小回滚版本的OTP行列表亦存储于程序映像中，且同样受映像签名保护。

`IMAGE_DEF` 中的OTP行列表必须始终比 `IMAGE_DEF` 的回滚版本多至少一位（由 `picotool` 强制执行）。因此，旧版二进制文件始终包含足够信息，使 bootrom 能检测芯片的最小回滚版本已超出 `IMAGE_DEF` 中的回滚版本。在新版二进制文件中，您可向列表追加更多行，从而支持更高的回滚版本而无歧义。

当具有非零回滚版本的可执行映像成功启动时，其回滚版本将写入OTP温度计。`BOOT_FLAGS0.ROLLBACK_REQUIRED` 标志可用于要求 `IMAGE_DEF` 在受保护的 RP2350 上具有回滚版本。该标志在更新 OTP 中的回滚版本时自动设置。

#### 注意

带有回滚版本号为0的 `IMAGE_DEF` 不会自动设置 `BOOT_FLAGS0.ROLLBACK_REQUIRED` 标志，因此建议使用的最小回滚版本号为1，除非在预配置时手动设置了 `BOOT_FLAGS0.ROLLBACK_REQUIRED` 标志。

### 5.1.12. 闪存镜像启动

RP2350主要设计用于从QSPI闪存设备运行代码，该设备可为封装内或焊接至电路板。代码可直接在闪存中就地运行，或从闪存加载后在SRAM中执行。闪存启动指发现代码并准备运行的过程。闪存映像启动使用直接存储于闪存中的程序二进制文件，而非闪存分区中的文件。闪存映像启动要求启动只读存储器发现闪存前4 kB内开始的块循环，其中包含有效的 `IMAGE_DEF`（且不包含 `PARTITION_TABLE`）。

Flash image boot has no partition table, so it cannot be used with A/B version checking, which requires separate A/B partitions. The `IMAGE_DEF` will boot if it is valid (which includes requiring a signature on a secured RP2350).

For the non-signed case, the `IMAGE_DEF` can be as small as a 20-bytes; see [Section 5.9.5](#).

#### TIP

A more complicated version of this scenario stores multiple `IMAGE_DEF`s in the block loop. In this case, the last `IMAGE_DEF` for the current architecture is booted, if valid. You can use this to implement universal binaries for various supported architectures, or to include multiple signatures for targeting devices with different keys.

### 5.1.13. Flash partition boot

If a `PARTITION_TABLE`, but no `IMAGE_DEF`, is found in the valid block loop that starts within the first 4 kB of flash, and it is valid (including signature if necessary on a secured RP2350), the bootrom searches that partition table's partitions for an executable image to boot. This process, when successful, is referred to as **flash partition boot**.

The partitions are searched in order, skipping those marked as ignored for the current architecture. The bootrom ignores partitions as an optimisation, or to prevent [automatic architecture switching](#).

If the partition is not part of an A/B pair, the first 4 kB is searched for the start of a valid block loop. If a valid block loop is found, and it contains an executable image with a valid (including signature on a secured RP2350) `IMAGE_DEF`, then that executable image is chosen for boot.

If the partition is the A partition of an A/B pair, the bootrom searches both partitions as described above. If both partitions result in a bootable `IMAGE_DEF`, the `IMAGE_DEF` with the higher version number is chosen. Otherwise, the valid `IMAGE_DEF` is chosen. There are some exceptions to this rule in advanced scenarios; see [Section 5.1.16](#) and [Section 5.1.17](#) for details.

### 5.1.14. Partition-Table-in-Image boot

If both a `PARTITION_TABLE` and an `IMAGE_DEF` block are found in the valid block loop that starts within the first 4 kB of flash, a third type of flash boot takes place. The `IMAGE_DEF` and `PARTITION_TABLE` must only be recognised, not necessarily valid or correctly signed. This stipulation prevents a causality loop.

This is known as **partition-table-in-image** boot, since the application contains the partition table (instead of vice versa). This partition table is referred to as an **embedded partition table**.

The `PARTITION_TABLE` is loaded as the current partition table, and the `IMAGE_DEF` is launched directly. The table defined by the `PARTITION_TABLE` is not searched for `IMAGE_DEF`s to boot.

The following common cases might use this scenario:

- You are only using the `PARTITION_TABLE` for flash permissions. You want to load that partition table, then boot as normal.
- The `IMAGE_DEF` contains a small bootloader stored alongside the partition table. In this case, the partition table will once again be loaded, and the associated image entered. The entered image will then likely pick a partition from the partition table, and launch an image from there itself.

### 5.1.15. Flash boot slots

The previous sections within this chapter discuss block loops starting within the first 4 kB of flash. Such a block loop contained either an `IMAGE_DEF`, a partition table (searched for `IMAGE_DEF`s), or an `IMAGE_DEF` and a `PARTITION_TABLE` (not searched).

All the previously mentioned cases discovered their block loop in **slot 0**. Under certain circumstances, the neighbouring **slot 1** is also searched.

闪存映像启动无分区表，因此不能用于需要独立A/B分区的A/B版本校验。如果 **IMAGE\_DEF**有效（包括在受保护的RP2350上需要签名），则会启动该映像。

对于未签名的情况，**IMAGE\_DEF**的大小可小至20字节；详见第5.9.5节。

#### 💡 提示

此场景的更复杂版本是在块循环中存储多个 **IMAGE\_DEF**。在此情况下，如有效，则启动当前架构的最后一个**IMAGE\_DEF**。您可使用此方法为多种支持的架构实现通用二进制文件，或包含多个签名以面向不同密钥的设备。

### 5.1.13. 闪存分区启动

如果在从闪存前4 kB起始的有效块循环中找到**PARTITION\_TABLE**，但未找到 **IMAGE\_DEF**，且该**PARTITION\_TABLE**有效（包括在受保护的RP2350上需要签名），引导只读存储器将搜索该分区表内的分区以启动可执行映像。该过程成功时，称为flash partition boot。

分区按顺序搜索，跳过当前架构下标记为忽略的分区。只读存储器忽略分区是一种优化手段，也用于防止自动架构切换。

如果分区不是A/B配对的一部分，则在前4 kB内搜索有效块循环的起始位置。若发现有效块循环，且其中包含带有有效（包括在安全的RP2350上签名）**IMAGE\_DEF**的可执行映像，则选择该可执行映像引导。

若该分区为A/B配对中的A分区，只读存储器将按上述方式搜索两个分区。若两分区均包含可启动的 **IMAGE\_DEF**，则选择版本号较高的 **IMAGE\_DEF**。否则，选择有效的**IMAGE\_DEF**。该规则在高级场景中存在例外；详情请参见第5.1.16节及第5.1.17节。

### 5.1.14. 镜像内分区表启动

若在前4 kB闪存内启动的有效块循环中同时找到**PARTITION\_TABLE**和 **IMAGE\_DEF**块，则执行第三种类型的闪存引导。**IMAGE\_DEF**和**PARTITION\_TABLE**必须仅被识别，但不必是有效的或正确签名的。该规定旨在防止因果循环。

这称为**partition-table-in-image**启动，因为应用程序包含分区表（而非反之）。

该分区表被称为**嵌入式分区表**。

**PARTITION\_TABLE**被加载为当前分区表，**IMAGE\_DEF**则被直接启动。**PARTITION\_TABLE**定义的表中不会搜索用于启动的**IMAGE\_DEF**。

以下常见情况可能采用此方案：

- 您仅使用**PARTITION\_TABLE**来管理闪存权限。您希望先加载该分区表，然后按正常方式启动。
  
- **IMAGE\_DEF**含有一个与分区表一同存放的小型引导程序。在此情况下，分区表将被再次加载，并进入相应映像。进入的映像随后很可能自分区表中选取分区，并从中启动映像。

### 5.1.15. 闪存启动槽

本章前述部分讨论了起始于首个4 kB闪存区内的块循环。该块循环包含了 **IMAGE\_DEF**、分区表（查找 **IMAGE\_DEF**）或 **IMAGE\_DEF**和**PARTITION\_TABLE**（未查找）。

上述所有情况均在**slot 0**中发现其块循环。在某些情况下，相邻的**slot 1**也会被搜索。

Slot 0 starts at the beginning of flash, and has a size of  $n \times 4$  kB sectors. Slot 1 has the same size and follows immediately after slot 0. The value of  $n$  defaults to 1. Both slots are 4 kB in size, but you can override this value by specifying a value in `FLASH_PARTITION_SLOT_SIZE` and then setting `BOOT_FLAGS0.OVERRIDE_FLASH_PARTITION_SLOT_SIZE`.

Similarly to how a choice can be made between `IMAGE_DEF`s in A/B partitions, a choice can be made between A/B `PARTITION_TABLE`s via the two **boot slots**. This allows for versioning partition tables, targeted drag and drop of UF2s (Section 5.1.18) containing partition tables, etc. similar to the process used for images.

Slot 1 is only of use when potentially using partition tables. In the simple case of an `IMAGE_DEF` and no `PARTITION_TABLE` found in a block loop starting in slot 0, that image likely actually overlays the space where slot 1 would be, but in any case, slot 1 is ignored since there is no `PARTITION_TABLE`.

If slot 0 contains a `PARTITION_TABLE` or does not contain an `IMAGE_DEF` (including nothing/garbage in slot 0), slot 1 can be considered. As an optimisation, in the former case, the scanning of slot 1 can be prevented by setting the singleton flag in the `PARTITION_TABLE`.

#### NOTE

When `IMAGE_DEF`s are also present in the slots, the `PARTITION_TABLE`'s `VERSION` item determines which of slot 0 and slot 1 to use. The `IMAGE_DEF` metadata is ignored for the purpose of version comparison.

### 5.1.16. Flash update boot and version downgrade

Normally the choice of slot 0 versus slot 1, and partition A versus partition B, is made based on the `version` of the valid `PARTITION_TABLE` or `IMAGE_DEF` in those slots or partitions respectively. The greater of the two versions wins.

It is however perfectly valid to downgrade to a lower-versioned `IMAGE_DEF` when using A/B partitions, provided this does not violate `anti-rollback` rules on a secured RP2350.

Downloading the new image (and its `IMAGE_DEF`) into the non-currently-booting partition and doing a normal reboot will not work in this case, as the newly downloaded image has a lower version.

For this purpose, you can enable a **flash update boot** boot by passing the `FLASH_UPDATE` boot type constant flag through the watchdog scratch registers and a pointer to the start of the region of flash that has just been updated.

The bootrom automatically performs a flash update boot after programming a flash UF2 written to the USB Mass Storage drive. You can also invoke a flash update boot programmatically via the `reboot()` API (see Section 5.4.8.24).

The flash address range passed through the reboot parameters is treated specially during a flash update boot. A `PARTITION_TABLE` in a slot, or `IMAGE_DEF` in a partition, will be chosen for boot irrespective of version, if the start of the region is the start of the respective slot or partition.

In order for the downgrade to persist, the first sector of the previously booting slot or partition must be erased so that the newly installed `PARTITION_TABLE` or `IMAGE_DEF` will continue to be chosen on subsequent boots. This erase is performed as follows during a `FLASH_UPDATE` boot.

1. When a `PARTITION_TABLE` is valid (and correctly signed if necessary) and its slot is chosen for boot, the first sector of the other slot is erased.
2. When a valid (and correctly signed if necessary) `IMAGE_DEF` is launched, the first sector of the other image is erased.
3. On explicit request by the image, after it is launched, the first sector of the other image is erased. This is an alternative to the standard behaviour in the previous bullet, and is selected by a special "Try Before You Buy" flag in the `IMAGE_DEF`. For more information about this feature, see Section 5.1.17.

Slot 0起始于闪存起始处，大小为  $n \times 4$  kB扇区。Slot 1大小相同，紧随slot 0之后。 $n$ 的默认值为1。两个slot均为4 kB大小，但可以通过指定一个值在 `FLASH_PARTITION_SLOT_SIZE` and 然后设置 `BOOT_FLAGS0.OVERRIDE_FLASH_PARTITION_SLOT_SIZE`来覆盖此值。

类似于在A/B分区间选择 `IMAGE_DEF`的方式，可以通过两个启动槽在A/B分区表之间进行选择。此功能支持对分区表进行版本控制，针对性地拖放包含分区表的UF2文件（参见第5.1.18节），类似于映像的处理流程。

槽1仅在有可能使用分区表时才有效。在简单情况下，如果在从槽0开始的块循环中检测到 `IMAGE_DEF`且未检测到`PARTITION_TABLE`，则该映像很可能实际上覆盖了槽1所在的空间，但由于没有`PARTITION_TABLE`，槽1会被忽略。

如果槽0包含`PARTITION_TABLE`或不包含 `IMAGE_DEF`（包括槽0为空或含有无效数据），则可以考虑使用槽1。作为一种优化，前述情况下可通过在`PARTITION_TABLE`中设置单例标志来阻止对槽1的扫描。

### **① 注意**

当槽中同时存在 `IMAGE_DEF`时，`PARTITION_TABLE`中的 `VERSION`字段决定使用槽0还是槽1。版本比较时会忽略 `IMAGE_DEF`的元数据。

## 5.1.16. 闪存更新启动及版本降级

通常情况下，槽位0与槽位1的选择，以及分区A与分区B的选择，是基于各槽位或分区中有效的 `PARTITION_TABLE`或 `IMAGE_DEF`的版本来决定的。两个版本中较高的版本将优先采用。

然而，在使用 A/B 分区时，允许降级到较低版本的 `IMAGE_DEF`，前提是不违反受保护 RP2350 上的防回滚规则。

在此情况下，将新映像（及其 `IMAGE_DEF`）下载到当前非启动分区并执行正常重启将无效，因为新下载的映像版本较低。

为此，您可以通过看门狗擦写寄存器传递`FLASH_UPDATE`启动类型常量标志及指向刚更新的闪存区域起始位置的指针，启用 `flash update boot` 启动。

`bootrom` 在对写入 USB 大容量存储驱动器的闪存 UF2 进行编程后，会自动执行闪存更新启动。您也可以通过 `reboot()` API（参见第5.4.8.24节）以编程方式调用闪存更新启动程序。

通过重启参数传递的闪存地址范围在闪存更新启动过程中会被特殊处理。如区域起点为相应槽位或分区的起始位置，槽位中的`PARTITION_TABLE`或分区中的`IMAGE_DEF`将被选作启动，版本无关。

为确保保持降级持续，必须擦除之前启动槽位或分区的第一个扇区，以使新安装的`PARTITION_TABLE`或 `IMAGE_DEF`在后续启动中持续被选用。该擦除操作于`FLASH_UPDATE`启动期间按以下方式执行。

1. 当`PARTITION_TABLE`有效（且如有需要已正确签名）且其槽位被选为启动时，另一个槽位的第一个扇区将被擦除。
2. 当有效的（且如有需要已正确签名） `IMAGE_DEF` 被启动时，另一个镜像的第一个扇区将被擦除。
3. 在镜像明确请求时，启动后将擦除另一个镜像的第一个扇区。这是前述标准行为的替代方案，通过 `IMAGE_DEF` 中的特殊“先试后买”标志进行选择。有关此功能的详细信息，请参见第5.1.17节。

**NOTE**

Flash update and version downgrade have no effect when using a single slot, or standalone (non A/B) partitions.

### 5.1.17. Try before you buy

**Try before you buy** (abbreviated **TBYB**) is an [IMAGE\\_DEF](#)-only feature that allows for a completely safe cycle of version upgrade:

1. An executable image is running from say partition B.
2. A new image is downloaded into partition A.
3. On download completion, a [FLASH\\_UPDATE](#) reboot is performed for the newly updated partition A.
4. The bootrom will preferentially try to boot partition A (due to the flash update). Note that a non TBYB image will always be chosen over a TBYB image in A/B partitions during a normal non-[FLASH\\_UPDATE](#) boot.
  - o If the new image fails validation/signature then the old image in partition B will be used on subsequent (non-[FLASH\\_UPDATE](#)) boots, recovering from the failed upgrade.
5. If the new image is valid (and correctly signed if necessary), it is entered under a watchdog timer, and has 16.7 seconds to mark itself OK via the [explicit\\_buy\(\)](#) function.
  - o If the image calls back, the first 4 kB sector of the other partition (containing image B) is erased, and the TBYB flag of the current image is cleared, so that A becomes the preferred partition for subsequent boots.
  - o If the image does not call back within the allotted time, then the system reboots, and will continue to boot partition B (containing the original image) as partition A is still marked as TBYB image.

The erase of the first sector of the opposite partition in the A/B pair severs its image's [block loop](#), rendering it unbootable. This ensures the tentative image booted under TBYB becomes the preferred boot image going forward, even if the opposite image had a higher version.

The watchdog timeout is fixed at 16.7 seconds (24-bit count on a 1-microsecond timebase). This can be shortened after entering the target image, for example if it only needs a few hundred milliseconds for its self-test routine. It can also be extended by reloading the watchdog counter, at the risk of getting stuck in the tentative image if it fails in a way that repeatedly reloads the watchdog.

### 5.1.18. UF2 targeting

[Section 5.5](#) describes the USB Mass Storage drive, and the ability to download UF2 files to that drive to store and/or execute code/data on the RP2350.

Since RP2350 supports multiple processor architectures, and partition tables with multiple partitions, some information on the device must be used to determine what to do with a flash-addressed UF2. Depending on the context, the flash addresses in the UF2 may be absolute flash storage addresses (as was always the case on RP2040), or runtime addresses of code and data within a flash partition. **UF2 targeting** refers to the rules the bootrom applies to interpret flash addresses in a UF2 file.

UF2 supports a 32-bit family ID embedded in the file. This enables the device to recognise firmware that targets it specifically, as opposed to firmware intended for some other device. The RP2350 bootrom recognises some standard UF2 family IDs ([rp2040](#), [rp2350-arm-s](#), [rp2350-arm-ns](#), [rp2350-riscv](#), [data](#) and [absolute](#)) defined in [Table 455](#). You may define your own family IDs in the partition table for more refined targeting.

The UF2 family ID is used as follows:

1. A UF2 with the [absolute](#) family ID is downloaded without regard to partition boundaries. A partition table (if present) or OTP configuration define whether [absolute](#) family ID downloads are allowed. The default factory settings do allow for [absolute](#) family ID downloads.

### ⓘ 注意

在使用单槽或独立（非A/B）分区时，闪存更新和版本降级无效。

## 5.1.17. 试用功能

“先试后买”（缩写为TBYB）是一个仅限于IMAGE\_DEF的功能，允许进行完全安全的版本升级流程：

1. 可执行镜像当前正在，例如，分区B中运行。
2. 新的镜像被下载至分区A。
3. 下载完成后，将针对新更新的分区A执行一次FLASH\_UPDATE重启。
4. 只读存储器将优先尝试启动分区A（因闪存更新而设置）。请注意，在正常的非FLASH\_UPDATE启动过程中，非TBYB镜像在A/B分区中始终优先于TBYB镜像被选择。
  - 如果新映像未通过验证或签名，则后续的（非FLASH\_UPDATE）启动将使用分区B中的旧映像，以实现升级失败的恢复。
5. 如果新映像有效（且在必要时签名正确），则其将在看门狗定时器监控下运行，拥有16.7秒的时间通过explicit\_buy() 函数显式标记自身为OK。
  - 若映像完成回调，则擦除另一个分区（包含映像B）的首个4 KB扇区，且清除当前映像的TBYB标志，从而使A分区成为后续启动的首选分区。
  - 若映像未在指定时间内回调，系统将自动重启，并持续启动分区B（包含原始映像），因分区A仍标记为TBYB映像。

擦除A/B配对中对应分区的首个扇区，将切断其映像的块循环，使其无启动能力。此机制确保在TBYB下启动的临时映像即使版本低于对立映像，也会成为后续的首选启动映像。

看门狗超时时间固定为16.7秒（基于1微妙时间基准的24位计数）。进入目标映像后，该时间可以缩短，例如在自检例程仅需数百毫秒的情况下。也可以通过重新加载看门狗计数器来延长超时，但如果因故障导致反复重新加载看门狗，系统可能会停留在暂存映像中。

## 5.1.18. UF2 目标支持

第5.5节描述了USB大容量存储驱动器及其下载UF2文件功能，用于在RP2350上存储和/或执行代码或数据。

鉴于RP2350支持多处理器架构和多分区分区表，部分设备信息需用于确定如何处理基于闪存地址的UF2。根据具体情况，UF2中的闪存地址可能为绝对闪存存储地址（如RP2040一贯采用），也可能为闪存分区内的代码及数据的运行时地址。**UF2 targeting**指只读存储器引导程序（bootrom）用于解释UF2文件中闪存地址的规则。

UF2文件支持在文件中嵌入32位家族ID。该机制使设备能够识别专门针对其的固件，而非针对其他设备的固件。RP2350只读存储器引导程序识别表455中定义的标准UF2家族ID（rp2040、rp2350-arm-s、rp2350-arm-ns、rp2350-riscv、data及absolute）。您可在分区表中定义自有家族ID，以实现更精确的定位。

UF2家族ID的使用方式如下：

1. 带有absolute家族ID的UF2文件下载时不考虑分区边界。是否允许absolute家族ID下载，由分区表（如存在）或只读存储器配置（OTP）决定。默认出厂设置允许absolute家族ID的下载。

2. If there is no partition table, then the `data`, `rp2350-arm-s` (if Arm is enabled) and `rp2350-riscv` (if RISC-V is enabled) family IDs are allowed by default. The UF2 is always downloaded to the start of flash.
3. If there is a partition table, then non-`absolute` family IDs target a single partition under the control of the partition table:
  - a. A UF2 will not be downloaded to a partition that doesn't have `BL`-write flash permissions
  - b. Each partition lists which family IDs it accepts (both RP2350 standard and user defined)
  - c. With A/B partitions; the A partition indicates the family IDs supported, and the UF2 goes to the partition that isn't the currently booting one (strictly the one that won't be the one chosen if the device were rebooted now).
  - d. Further refinement with A/B is allowed to support secondary A/B partitions containing data/executables used (owned) by the main partitions; see [Section 5.1.18.1](#) for detailed information.

For details of the exact rules used when picking a UF2 target partition, see [Section 5.5.3](#).

#### NOTE

UF2 family ids are used for partition targeting when copying UF2s to the USB drive, or when using `picotool load -p`. When using `picotool load` without the `-p` flag images can be written anywhere in flash that has `BL`-write permissions.

### 5.1.18.1. Owned partitions

An executable might require data from another partition (such as Wi-Fi firmware). When the main executable is stored in [A/B partitions](#), for safe upgrades, it may be desirable to associate two other partitions C and D with the primary A and B partitions, such that:

- the data in partition C is used for executable in partition A, and
- the data in partition D is used for the executable in partition B.

In this scenario A is marked as the **owner** of C in the partition table, and C is A's **owned partition**. This affects UF2 image downloads which (due to their UF2 family ID) target partitions C and D.

When a UF2 download targets the C/D partition pair, the bootrom checks the state of the A and B owning partitions to determine which of the owned partitions (C and D) receives the download. By default:

- If B would be the target partition for a UF2 with an A/B-compatible family ID, then D is the target for a UF2 with the C/D compatible family ID.
- Conversely, when A is the target partition for A/B downloads, C is the target partition for C/D downloads.

The `FLAGS_UF2_DOWNLOAD_AB_NON_BOOTABLE_OWNER_AFFINITY` flag in the partition table reverses this mapping.

### 5.1.19. Address translation

RP2040 required images to be stored at the beginning of flash (`0x10000000`). RP2350 supports storing executable images in partitions at arbitrary locations, to support more robust upgrade cycles via [A/B versions](#), among other uses. This presents the issue that the address an executable is linked at, and therefore the binary contents of the image, would have to depend on the address it is stored at. This can be worked around to an extent with position-independent code, at cost to code size and performance.

RP2350 avoids this pitfall with hardware and bootrom support for **address translation**. An image stored at any 4 kB-aligned location in flash can appear at flash address `0x10000000` at runtime. The SDK continues to assume an image base of `0x10000000` by default.

When launching an image from a partition, the bootrom initialises QMI registers `ATRANS0` through `ATRANS3` to map a flash **runtime address** of `0x10000000` (by default) to the flash **storage address** of the start of the partition. It sets the total size of the mapped region to the size of the partition, with a maximum size of 16 MB. Accessing flash addresses beyond the size of the booted partition (but below the `0x11000000` chip select watermark) returns a bus fault.

2. 如果不存在分区表，则默认允许 `data`、`rp2350-arm-s`（若启用Arm）和`rp2350-riscv`（若启用RISC-V）系列ID。UF2始终下载到闪存起始位置。
3. 若存在分区表，则非绝对系列ID定位于由分区表管理的单个分区：
  - a. UF2不会下载到无 `BL`写入闪存权限的分区。
  - b. 各分区会列出其接受的系列ID（包括RP2350标准与用户自定义ID）。
  - c. 对于A/B分区；A分区指示支持的系列ID，UF2将下载至非当前启动的分区（即若设备立即重启，此分区不会被选中）。
  - d. 允许对A/B分区进行进一步细分，以支持包含主分区使用（拥有）的数据/可执行文件的辅助A/B分区；详见第5.1.18.1节。

有关选择UF2目标分区时所采用的具体规则，详见第5.5.3节。

#### 注意

UF2系列ID用于在将UF2文件复制至USB驱动器时，或执行`picotool load -p`操作时进行分区定位。  
当使用`picotool load`命令且未使用`-p`标志时，映像可写入任何具有`BL`写权限的闪存区域。

### 5.1.18.1 所有权分区

可执行文件可能需要来自其他分区的数据（如Wi-Fi固件）。当主可执行文件存储于A/B分区中时，为确保安全升级，可能需要将两额外分区C和D与主分区A和B关联，使得：

- 分区C中的数据供分区A中的可执行文件使用，
- 分区D中的数据供分区B中的可执行文件使用。

此情况下，分区表中标记A为C的所有者，C为A的**所有权分区**。这会影响UF2镜像的下载，由于其UF2家族ID，目标分区为C和D。

当UF2下载定位于C/D分区时，bootrom会检查A和B所属分区的状态，以决定受到控制的分区（C或D）接收下载。默认情况下：

- 如果B是具有A/B兼容家族ID的UF2的目标分区，则具有C/D兼容家族ID的UF2的目标分区为D。
- 反之，当A是A/B下载的目标分区时，C就是C/D下载的目标分区。

分区表中的`FLAGS_UF2_DOWNLOAD_AB_NON_BOOTABLE_OWNER_AFFINITY`标志会颠倒此映射关系。

### 5.1.19. 地址转换

RP2040要求镜像存储于闪存起始位置（`0x10000000`）。RP2350允许在分区中的任意位置存储可执行镜像，以支持通过A/B版本实现更为稳健的升级周期及其他用途。这导致可执行文件的链接地址及其二进制内容必须依赖于存储地址。该问题在一定程度上可通过位置无关代码规避，但会牺牲代码体积和性能。

RP2350通过硬件和bootrom对**地址转换**的支持，避免了此类问题。存储于闪存任意4 kB对齐位置的映像可映射至闪存地址`0x10000000`，且生效于运行时。SDK默认继续假设映像基址为`0x10000000`。

从分区启动映像时，bootrom会初始化QMI寄存器ATRANS0至ATRANS3，将闪存的运行时地址`0x10000000`（默认）映射至该分区的闪存存储地址起始处。映射区域的总大小被设置为分区大小，最大不得超过16 MB。访问超过启动分区大小的闪存地址（但低于`0x11000000`芯片选择水位标界限）时，将导致总线错误。

As an example, if the booted partition was 6 MB big, starting 1 MB into flash, the registers would be set up as follows:

| Name / Memory Start               | Flash Start             | Size |
|-----------------------------------|-------------------------|------|
| ATRANS0 / <code>0x10000000</code> | <code>0x10100000</code> | 4 MB |
| ATRANS1 / <code>0x10400000</code> | <code>0x10500000</code> | 2 MB |
| ATRANS2 / <code>0x10800000</code> | -                       | 0    |
| ATRANS3 / <code>0x10c00000</code> | -                       | 0    |

This maps the physical flash range from `0x10100000-0x10700000` to flash addresses `0x10000000-0x10600000`, ensuring the partition appears at the start of flash at runtime.

In this case, since ATRANS2 and ATRANS3 aren't needed to map the partition, they could be used by the application to map another part of flash.

Mapping the start of the partition to a runtime address of `0x10000000` is the default behaviour, but you may choose a different address, with some restrictions. The bootrom allows for runtime address values of `0x10000000`, `0x10400000`, `0x10800000`, and `0x10c00000` for the beginning of the mapped regions, with the choice specified in the IMAGE\_DEF. You must link your binary to run at the correct, higher base address. This is useful, for example, when an application runs from a high flash address and remains mapped there while launching a second application at address `0x10000000`. You might use this setup when a Secure image provides services to a Non-secure client image.

This custom address translation is enabled by a negative ROLLING\_WINDOW\_DELTA value (see Section 5.9.3.5). The above four runtime addresses translate to a ROLLING\_WINDOW\_DELTA of `0`, `-0x400000`, `-0x800000`, or `-0xc00000`, which are the only supported non-positive values. The delta indicates how many bytes into the partition the runtime address `0x10000000` appears. A negative delta value indicates that address `0x10000000` appears before the start of the partition; the partition starts that many bytes higher than `0x10000000`.

Positive values are also useful, for example, when prepending data to an already linked image as a post-processing step. Positive deltas must be multiples of 4 kB. For example, a ROLLING\_WINDOW\_DELTA of `0x1000` will set up address translation so that the image data starting at offset `0x1000` within the partition is mapped to `0x10000000` at runtime, omitting the first 4 kB of the image from the mapped region. The first 4 kB is inaccessible except through the untranslated XIP window, which defaults to Secure access only.

#### NOTE

Because address translation within the `0x10000000 → 0x11000000` and `0x11000000 → 0x12000000` windows is independent, it is only possible to boot from partitions which are entirely contained within the first 16 MB of flash.

This address translation is performed by hardware in the QMI. For more information, see Section 12.14.4.

### 5.1.20. Automatic architecture switching

If the bootrom encounters a valid and correctly signed IMAGE\_DEF for the non-current architecture (RISC-V when booted in Arm mode, or Arm when booted in RISC-V), it performs an **automatic architecture switch**. The bootrom initiates a reboot into the correct architecture for the binary it discovered, which then boots successfully on the second attempt. Information passed in watchdog scratch registers (such as a RAM image boot type) is retained, so that the second boot makes the same decisions as the first, and arrives at the same preferred image to boot.

This happens only when:

- The architecture to be switched to is available according to OTP critical flags
- The architecture switch feature is not disabled by the BOOT\_FLAGS0.DISABLE\_AUTO\_SWITCH\_ARCH flag
- The bootrom found no valid binary for the *current* architecture before finding one for the *other* architecture

例如，若启动分区大小为 6 MB，且起始于闪存第 1 MB 处，则寄存器配置如下：

| 名称 / 内存起始地址                       | 闪存起始地址                  | 大小   |
|-----------------------------------|-------------------------|------|
| ATRANS0 / <code>0x10000000</code> | <code>0x10100000</code> | 4 MB |
| ATRANS1 / <code>0x10400000</code> | <code>0x10500000</code> | 2 MB |
| ATRANS2 / <code>0x10800000</code> | -                       | 0    |
| ATRANS3 / <code>0x10c00000</code> | -                       | 0    |

这将物理闪存范围从 `0x10100000` 至 `0x10700000` 映射至闪存地址 `0x10000000` 至 `0x10600000`，确保该分区在运行时出现在闪存起始位置。

在本例中，由于 ATRANS2 和 ATRANS3 不需要映射该分区，它们可由应用程序用于映射闪存的其他部分。

将分区起始映射到运行时地址 `0x10000000` 是默认行为，但您可以选择不同的地址，需遵循某些限制。Bootrom 允许运行时地址值为 `0x10000000`、`0x10400000`、`0x10800000`，以及 `0x10c00000` 作为映射区域的起始地址，具体选择由 `IMAGE_DEF` 指定。您必须将二进制文件链接至正确的、更高的基址以确保运行。例如，当应用程序从高闪存地址运行并保持映射，同时在地址 `0x1` 启动第二个应用程序时，此功能尤为有用。`0000000`。当安全映像为非安全客户端映像提供服务时，可能会采用此配置。

该自定义地址转换由负的 `ROLLING_WINDOW_DELTA` 值启用（详见第 5.9.3.5 节）。上述四个运行时地址对应的 `ROLLING_WINDOW_DELTA` 值分别为 `0`、`-0x400000`、`-0x800000` 或 `-0xc00000`，且仅支持这些非正值。该增量表示运行时地址 `0x1` 相对于分区起始位置的字节偏移量。`0000000` 出现。负的增量值表示地址 `0x10000000` 出现在分区起始地址之前；分区起始地址比 `0x1` 高出相应字节数。`0000000`。

正值同样有用，例如在作为后处理步骤时，将数据预置到已链接镜像的前端。正的增量必须是 4 KB 的倍数。例如，`ROLLING_WINDOW_DELTA` 为 `0x1000` 将设置地址转换，使分区内偏移 `0x1000` 处开始的镜像数据映射到 `0x10000000` 在运行时，映射区域中省略镜像的首个 4 KB。首个 4 KB 不可访问，除非通过未转换的 XIP 窗口，该窗口默认仅允许安全访问。

### 注意

由于 `0x10000000` → `0x11000000` 和 `0x11000000` → `0x12000000` 两个窗口内的地址转换是独立的，因此仅能从完全位于前 16 M B 闪存内的分区启动。

该地址转换由 QMI 中的硬件执行。详情请参见第 12.14.4 节。

### 5.1.20. 自动架构切换

如果 bootrom 遇到一个针对非当前架构的有效且正确签名的 `IMAGE_DEF`（如 Arm 模式启动时为 RISC-V，或 RISC-V 模式启动时为 Arm），则会执行一次 **自动架构切换**。bootrom 将重新启动至其发现的二进制文件对应的正确架构，该二进制文件随后在第二次尝试时成功启动。

传递至看门狗临时寄存器的信息（例如 RAM 映像的启动类型）将被保留，因此第二次启动时会作出与第一次相同的决策，最终选择相同的首选映像启动。

仅在以下情况发生此操作：

- 根据 OTP 关键标志，待切换的架构可用
- `BOOT_FLAGS0.DISABLE_AUTO_SWITCH_ARCH` 标志未禁用自动架构切换功能
- bootrom 在找到另一个架构的有效二进制文件之前，未发现针对当前架构的有效二进制文件

 **TIP**

When storing executable images for both architectures in flash, it's usually preferable to boot an image for the *current* architecture. To do this, keep the images in different partitions, marking the partition for Arm as ignored during boot under RISC-V and vice versa. This avoids always picking the image in the first partition and auto-switching to run it under the other architecture.

For hardware support details for architecture switching, see [Section 3.9](#).

## 5.2. Processor-controlled boot sequence

The bootrom contains the first instructions the processors execute following a reset. Both processors enter the bootrom at the same time, and in the same location, but the boot sequence runs mostly on core 0.

Core 1 redirects very early in the boot sequence to a low-power state where it waits to be launched, after boot, by user software on core 0. If core 1 is unused, it remains in this low-power state.

**Source Code Reference**

The sequence described in this section is implemented on Arm by the source files `arm8_bootrom_rt0.S` and `varm_boot_path.c` in the bootrom source code repository. RISC-V cores instead begin from `riscv_bootrom_rt0.S`, but share the boot path implementation with Arm.

### 5.2.1. Boot outcomes

The bootrom decides the **boot outcome** based on the following system state:

- The contents of the attached QSPI memory device on chip select 0, if any
- The contents of POWMAN registers `BOOT0` through `BOOT3`
- The contents of watchdog registers `SCRATCH4` through `SCRATCH7`
- The contents of OTP, particularly `CRIT1`, `BOOT_FLAGS0` and `BOOT_FLAGS1`
- The QSPI `CSn` pin being driven low externally (to select `BOOTSEL`)
- The QSPI `SD1` pin being driven high externally (to select `UART` boot in `BOOTSEL` mode)

Based on these, the outcome of the boot sequence may be to:

- Call code through a **vector** specified in `SCRATCH` or `BOOT` registers prior to the most recent reboot, for example, into code retained in RAM following a power-up from a low-power state.
- Run an image from external flash.
  - This can happen in one of two ways: either the image runs in-place directly from external flash, or the image is loaded into RAM during the boot sequence.
  - In-package flash on RP2354 is external for boot purposes. It's a separate silicon die, and the RP2350 die doesn't implicitly trust it.
- Run an image preloaded into SRAM (distinct from the vector case).
- Load and run an image from OTP into SRAM.
- Enter the USB bootloader.
- Enter the UART bootloader.
- Perform a one-shot operation requested via the `reboot()` API, such as a `flash update boot`. This may be requested

### 💡 提示

在闪存中存储适用于两种架构的可执行映像时，通常优先启动当前架构的映像。为此，应将映像保存在不同分区中，并在RISC-V架构下将Arm分区标记为忽略，反之亦然。这样可以避免始终选择第一个分区中的映像，并自动切换至另一架构下运行。

有关架构切换的硬件支持详细信息，请参见第3.9节。

## 5.2. 处理器控制的启动序列

启动只读存储器包含处理器复位后执行的第一条指令。两个处理器同时从相同位置进入启动只读存储器，但启动序列主要由核心0执行。

核心1在启动序列的早期阶段即被重定向至低功耗状态，等待核心0上的用户软件启动。若核心1未被使用，则保持在该低功耗状态。

### 源代码参考

本节描述的序列由启动只读存储器源代码仓库中的`arm8_bootrom_rt0.S`和`varm_boot_path.c`两个源文件实现。RISC-V内核则从`riscv_bootrom_rt0.S`开始，但与Arm共享启动路径的实现。

### 5.2.1. 启动结果

bootrom基于以下系统状态决定启动结果：

- 芯片选择信号0上的附加QSPI存储设备内容（如有）
- POWMAN寄存器BOOT0至BOOT3的内容
- 看门狗寄存器SCRATCH4至SCRATCH7的内容
- OTP内容，尤其是CRIT1、BOOT\_FLAGS0和BOOT\_FLAGS1
- QSPI CSn引脚被外部拉低（以选择BOOTSEL）
- QSPI SD1引脚被外部拉高（以在BOOTSEL模式下选择UART启动）

基于此，启动序列的结果可能为：

- 通过最近一次重启前SCRATCH或BOOT寄存器中指定的vector调用代码，例如进入从低功耗状态上电后保留在RAM中的代码。
- 从外部闪存运行映像。
  - 这可以通过两种方式之一实现：映像要么直接从外部闪存原地运行，要么在启动过程中被加载到RAM中。
  - RP2354上的封装内闪存在启动时视为外部存储。它是一个独立的硅片，RP2350芯片并不默认信任它。
- 运行预先加载至SRAM中的映像（不同于向量表情况）。
- 从OTP加载映像至SRAM并运行。
- 进入USB引导程序。
- 进入UART引导程序。
- 执行通过reboot() API请求的一次性操作，例如闪存更新启动。此操作可能由

by the user, or by the UART or UF2 bootloaders.

- Refuse to boot, due to lack of suitable images and the UART and USB bootloaders being disabled via OTP.

This section makes no distinction between the different types of flash boot ([flash image boot](#), [flash partition boot](#) and [flash partition-table-in-image boot](#)). Likewise, it does not distinguish these types from [packaged binaries](#), which are loaded into RAM at boot time, because these are just flash binaries with a special [load map](#). This section just describes the sequence of decisions the bootrom makes to decide which medium to boot from.

### 5.2.2. Sequence

This section enumerates the steps of the processor-controlled boot sequence for Arm processors. There are some minor differences on Arm versus RISC-V, which are discussed in [Section 5.2.2.2](#).

A **valid** image in [Table 451](#) refers to one that contains a valid [block loop](#), with one of those blocks being a valid [image definition](#). On a secured RP2350 this image must be (correctly) [signed](#), and must meet all other security requirements such as minimum [rollback version](#).

Shaded cells in the Action column of [Table 451](#) indicate a boot outcome as described in [Section 5.2.1](#). Other cells are transitory states which continue through the sequence. Both cores start the sequence at [Entry](#).

The main sequential steps in [Table 451](#) are:

- [Entry](#)
- [Core 1 Wait](#)
- [Boot Path Start](#)
- [Await Rescue](#)
- [Generate Boot Random](#)
- [Check POWMAN Vector](#)
- [Check Watchdog Vector](#)
- [Prepare for Image Boot](#)
- [Try RAM Image Boot](#)
- [Check BOOTSEL](#)
- [Try OTP Boot](#)
- [Try Flash Boot](#)
- [Prepare for BOOTSEL](#)
- [Enter USB Boot](#)
- [Enter UART Boot](#)
- [Boot Failure](#)

For a summary of [Table 451](#) in pseudocode form, see [Section 5.2.2.1](#).

*Table 451. Processor-controlled boot sequence*

| Condition (If...)  | Action (Then...)                                                                                                            |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Step: Entry</b> |                                                                                                                             |
| Always             | Check core number in <a href="#">CPUID</a> or <a href="#">MHARTID</a> .                                                     |
| Running on core 0  | Clear boot RAM (except for core 1 region and the <a href="#">always</a> region).<br>Go to <a href="#">Boot Path Start</a> . |
| Running on core 1  | Go to <a href="#">Core 1 Wait</a> .                                                                                         |

用户，或UART或UF2引导程序发起请求。

- 因缺少合适映像且通过OTP禁用UART和USB引导程序，拒绝启动。

本节不区分不同类型的闪存启动（闪存映像启动、闪存分区启动及闪存分区表映像启动）。同样，本节不区分这些类型与在启动时加载至RAM的封装二进制文件，因其本质上是具有特殊加载映射的闪存二进制文件。本节仅描述启动只读存储器进行启动介质选择时的决策流程。

### 5.2.2. 启动序列

本节列举了Arm处理器控制的启动序列步骤。Arm与RISC-V存在一些细微差异，详见第5.2.2.2节。

[表451中所示的有效镜像](#)，指包含有效块循环且其中之一为有效镜像定义的镜像。在安全的RP2350上，该镜像必须（正确）签名，且必须满足所有其他安全要求，如最低回滚版本。

表451中操作列的阴影单元指示启动结果，详见第5.2.1节。其他单元为继续执行的过渡状态。两个内核均从 [Entry](#) 开始此序列。

表451中的主要顺序步骤如下：

- [Entry](#)
- [核心1等待](#)
- [启动路径开始](#)
- [等待救援](#)
- [生成启动随机数](#)
- [检查POWMAN向量](#)
- [检查看门狗向量](#)
- [准备启动镜像](#)
- [尝试RAM镜像启动](#)
- [检查BOOTSEL](#)
- [尝试OTP启动](#)
- [尝试Flash启动](#)
- [准备BOOTSEL](#)
- [进入USB启动](#)
- [进入UART启动](#)
- [启动失败](#)

关于表451的伪代码形式摘要，详见第5.2.2.1节。

表451。处理器控制的启动序列

| 条件（如果...）    | 操作（则...）                     |
|--------------|------------------------------|
| <b>步骤：入口</b> |                              |
| 始终           | 检查 CPUID 或 MHARTID 中的核心编号。   |
| 在核心0上运行      | 清除启动RAM（核心1区域及始终区域除外）。       |
|              | <a href="#">转至启动路径开始。</a>    |
| 在核心1上运行      | <a href="#">前往Core 1 等待。</a> |

| Condition (If...)                      | Action (Then...)                                                                                                                                                                        |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step: Core 1 Wait</b>               |                                                                                                                                                                                         |
| Always                                 | Wait for RCP salt register to be marked valid by core 0.                                                                                                                                |
|                                        | Wait for core 0 to provide an entry point through Secure SIO FIFO, using the protocol described in <a href="#">Section 5.3</a> .                                                        |
|                                        | Outcome: Set Secure main <code>sp</code> and <code>VTOR</code> , then jump into the entry point provided.                                                                               |
| <b>Step: Boot Path Start</b>           |                                                                                                                                                                                         |
| Always                                 | Check rescue flag, <code>CHIP_RESET.RESCUE_FLAG</code>                                                                                                                                  |
| Rescue flag set                        | Go to <a href="#">Await Rescue</a> .                                                                                                                                                    |
| Rescue flag clear                      | Go to <a href="#">Generate Boot Random</a> .                                                                                                                                            |
| <b>Step: Await Rescue</b>              |                                                                                                                                                                                         |
| Always                                 | Clear the rescue flag to acknowledge the request.                                                                                                                                       |
|                                        | Outcome: Halt in place. The debugger attaches to give the processor further instruction.                                                                                                |
| <b>Step: Generate Boot Random</b>      |                                                                                                                                                                                         |
| Always                                 | Sample TRNG ROSC into the SHA-256 to generate a 256-bit per-boot random number.                                                                                                         |
|                                        | Store 128 bits in boot RAM for retrieval by <code>get_sys_info()</code> , and distribute the remainder to the RCP salt registers.                                                       |
|                                        | Go to <a href="#">Check POWMAN Vector</a> .                                                                                                                                             |
| <b>Step: Check POWMAN Vector</b>       |                                                                                                                                                                                         |
| Always                                 | Read <code>BOOT0</code> through <code>BOOT3</code> to determine requested boot type.                                                                                                    |
| Boot type parity is valid              | Clear <code>BOOT0</code> so this is ignored on subsequent boots.                                                                                                                        |
| A <code>BOOTDIS</code> flag is set     | Go to <a href="#">Check Watchdog Vector</a> .                                                                                                                                           |
| Boot type is <code>VECTOR</code>       | Outcome: Set Secure main <code>sp</code> , then call into the entry point provided.                                                                                                     |
| (Return from <code>VECTOR</code> )     | Go to <a href="#">Check Watchdog Vector</a> .                                                                                                                                           |
| Other or invalid boot type             | Go to <a href="#">Check Watchdog Vector</a> .                                                                                                                                           |
| <b>Step: Check Watchdog Vector</b>     |                                                                                                                                                                                         |
| Always                                 | Read watchdog <code>SCRATCH4</code> through <code>SCRATCH7</code> to determine requested boot type.                                                                                     |
| Boot type parity is valid              | Clear <code>SCRATCH4</code> so this is ignored on subsequent boots.                                                                                                                     |
| Boot type is <code>BOOTSEL</code>      | Make note for later: equivalent to selecting <code>BOOTSEL</code> by driving QSPI <code>CSn</code> low.                                                                                 |
| A <code>BOOTDIS</code> flag is set     | Go to <a href="#">Prepare for Image Boot</a> (so <code>BOOTSEL</code> is the only permitted type when the OTP <code>BOOTDIS.NOW</code> or POWMAN <code>BOOTDIS.NOW</code> flag is set). |
| Boot type is <code>VECTOR</code>       | Outcome: Set Secure main <code>sp</code> , then call into the entry point provided.                                                                                                     |
| (Return from <code>VECTOR</code> )     | Go to <a href="#">Prepare for Image Boot</a> .                                                                                                                                          |
| Boot type is <code>RAM_IMAGE</code>    | Make note for later: this requests a scan of a RAM region for a preloaded image.                                                                                                        |
| Boot type is <code>FLASH_UPDATE</code> | Make note for later: modifies some flash boot behaviour, as described in <a href="#">Section 5.1.16</a> .                                                                               |
| Always                                 | Go to <a href="#">Prepare for Image Boot</a> .                                                                                                                                          |
| <b>Step: Prepare for Image Boot</b>    |                                                                                                                                                                                         |

| 条件 (如果...)                      | 操作 (则...)                                                                                                             |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>步骤: Core 1 等待</b>            |                                                                                                                       |
| 始终                              | 等待核心0将RCP salt寄存器标记为有效。                                                                                               |
|                                 | 等待核心0通过安全SIO FIFO提供入口点，使用第5.3节描述的协议。                                                                                  |
|                                 | 结果：设置安全主 <code>sp</code> 和 <code>VTOR</code> ，然后跳转至提供的入口点。                                                            |
| <b>步骤: 启动路径开始</b>               |                                                                                                                       |
| 始终                              | 检查救援标志，CHIP_RESET.RESCUE_FLAG                                                                                         |
| 救援标志已设置                         | 前往等待救援。                                                                                                               |
| 救援标志已清除                         | 前往生成启动随机数。                                                                                                            |
| <b>步骤: 等待救援</b>                 |                                                                                                                       |
| 始终                              | 清除救援标志以确认请求。                                                                                                          |
|                                 | 结果：在原地暂停。调试器连接以向处理器提供进一步指令。                                                                                           |
| <b>步骤: 生成启动随机数</b>              |                                                                                                                       |
| 始终                              | 将TRNG ROSC采样输入SHA-256以生成每次启动的256位随机数。                                                                                 |
|                                 | 在启动RAM中存储128位以供get_sys_info()检索，余数分配至RCP salt寄存器。                                                                     |
|                                 | 前往检查 POWMAN 向量。                                                                                                       |
| <b>步骤: 检查 POWMAN 向量</b>         |                                                                                                                       |
| 始终                              | 读取 BOOT0 至 BOOT3 以确定请求的启动类型。                                                                                          |
| 启动类型奇偶校验有效                      | 清除 BOOT0，以便在后续启动时忽略该值。                                                                                                |
| 已设置 <code>BOOTDIS</code> 标志     | 前往查看门狗向量。                                                                                                             |
| 启动类型为 <code>VECTOR</code>       | 结果：设置安全主 <code>sp</code> ，然后调用提供的入口点。                                                                                 |
| (从 <code>VECTOR</code> 返回)      | 前往查看门狗向量。                                                                                                             |
| 其他或无效的启动类型                      | 前往查看门狗向量。                                                                                                             |
| <b>步骤: 查看门狗向量</b>               |                                                                                                                       |
| 始终                              | 读取看门狗 SCRATCH4 至 SCRATCH7 以确定请求的启动类型。                                                                                 |
| 启动类型奇偶校验有效                      | 清除 SCRATCH4，以便在后续启动时忽略该值。                                                                                             |
| 启动类型为 <code>BOOTSEL</code>      | 备注：相当于通过拉低 QSPI <code>C<sub>n</sub></code> 线来选择 <code>BOOTSEL</code> 。                                                |
| 已设置 <code>BOOTDIS</code> 标志     | 前往准备镜像启动（因此当 <code>OTP BOOTDIS.NOW</code> 或 <code>POWMAN BOOTDIS.NOW</code> 标志被设置时， <code>BOOTSEL</code> 为唯一允许的启动类型）。 |
| 启动类型为 <code>VECTOR</code>       | 结果：设置安全主 <code>sp</code> ，然后调用提供的入口点。                                                                                 |
| (从 <code>VECTOR</code> 返回)      | 前往准备镜像启动。                                                                                                             |
| 启动类型为 <code>RAM_IMAGE</code>    | 请注意：此操作请求扫描已预装映像的RAM区域。                                                                                               |
| 启动类型为 <code>FLASH_UPDATE</code> | 请注意：修改部分闪存启动行为，详见第5.1.16节。                                                                                            |
| 始终                              | 前往准备镜像启动。                                                                                                             |
| <b>步骤: 准备映像启动</b>               |                                                                                                                       |

| Condition (If...)                                              | Action (Then...)                                                                                                                                                                                    |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Always                                                         | Clear <code>BOOTDIS</code> flags (OTP <code>BOOTDIS.NOW</code> and POWMAN <code>BOOTDIS.NOW</code> ).                                                                                               |
|                                                                | Power up SRAM0 and SRAM1 power domains (XIP RAM domain is already powered).                                                                                                                         |
|                                                                | Reset all PADS and IO registers, and remove isolation from QSPI pads.                                                                                                                               |
|                                                                | Release USB reset and clear upper 3 kB of USB RAM (for search workspace).                                                                                                                           |
|                                                                | Go to <a href="#">Try RAM Image Boot</a> .                                                                                                                                                          |
| <b>Step: Try RAM Image Boot</b>                                |                                                                                                                                                                                                     |
| Watchdog type is not <code>RAM_IMAGE</code>                    | Go to <a href="#">Check BOOTSEL</a> .                                                                                                                                                               |
| <code>BOOT_FLAGS0.DISABLE_SR</code> AM_WINDOW_BOOT is set      | Go to <a href="#">Check BOOTSEL</a> .                                                                                                                                                               |
| Otherwise                                                      | Scan indicated RAM address range for a valid image (base in <code>SCRATCH2</code> , length in <code>SCRATCH3</code> ). This is used to boot into a RAM image downloaded via UF2, for example.       |
| RAM image is valid                                             | Outcome: Enter RAM image in the manner specified by its image definition.                                                                                                                           |
| No valid image                                                 | Go to <a href="#">Prepare for Bootsel</a> (skipping flash and OTP boot).                                                                                                                            |
| <b>Step: Check BOOTSEL</b>                                     |                                                                                                                                                                                                     |
| Always                                                         | Check BOOTSEL request: QSPI <code>CSn</code> is low (BOOTSEL button), watchdog type is <code>BOOTSEL</code> , or RUN pin double-tap was detected (enabled by <code>BOOT_FLAGS1.DOUBLE_TAP</code> ). |
| BOOTSEL requested                                              | Go to <a href="#">Prepare for BOOTSEL</a> (skipping flash and OTP boot).                                                                                                                            |

| 始终                     | 检查BOOT_FLAGS0.DISABLE_BOOTSEL_UART_BOOT以确认是否允许UART引导。                                                                                                                                                                                                                                                                                          |
| UART引导已禁用              | 前往启动失败。                                                                                                                                                                                                                                                                                                                                        |
| 否则                     | 结果：进入UART引导程序。下载镜像后，引导程序将重启，启动类型为 RAM_IMAGE，引导路径将从 Entry重新开始。有效镜像可引导；无效镜像通常会返回UART引导程序。                                                                                                                                                                                                                                                        |
| <b>步骤：启动失败</b>         |                                                                                                                                                                                                                                                                                                                                                |
| 始终                     | 结果：不采取进一步操作。未发现有效启动镜像，且所选BOOTSEL接口已被禁用。连接调试器以向处理器提供进一步指令。查看启动RAM中的启动原因，以诊断启动失败的原因。                                                                                                                                                                                                                                                             |

 **TIP**

The bootrom internally refers to BOOTSEL mode as NSBOOT, because the USB and UART bootloaders run in the Non-secure state under Arm. This chapter may also occasionally refer to BOOTSEL as NSBOOT.

### 5.2.2.1. Boot sequence pseudocode

The following pseudocode summarises [Table 451](#).

```

if (powman_vector_valid && powman_reboot_mode_is_pcsp) {
 // This call may return and continue the boot path
 if (correct_arch) powman_vector_pc(); else hang();
}
if (watchdog_vector_valid) {
 // Make note of RAM_IMAGE, FLASH_UPDATE, BOOTSEL reboot types
 check_special_reboot_mode();
 if (watchdog_reboot_mode_is_pcsp) {
 // This call may return and continue the boot path
 if (correct_arch) watchdog_vector_pc(); else hang();
 }
}

// RAM image window specified by watchdog_scratch, e.g. after a UF2 RAM
// download: either execute the RAM image or fall back to UART/USB boot.
if (watchdog_reboot_mode_is_ram_image && !ram_boot_disabled_in_otp) {
 // This only returns if there is no valid RAM image to enter.
 // You can't return from the RAM image.
 try_boot_ram_image(ram_image_window);
} else {
 // Otherwise try OTP and flash boot (unless there is a request to skip)
 skip_flash_and_otp_boot =
 bootsel_button_pressed() ||
 watchdog_reboot_mode_is_bootsel ||
 (double_tap_enabled_in_otp() && double_run_reset_detected());

 if (!skip_flash_and_otp_boot) {
 if (otp_boot_enabled_in_otp && !otp_boot_disabled_in_otp) {
 // This only returns if there is no valid OTP image to enter.
 // You can't return from the OTP image.
 try_otp_boot();
 }
 if (!flash_boot_disabled_in_otp) {
 // This only returns if there is no valid flash image to enter.
 // You can't return from the flash image.
 try_flash_boot();
 }
 }
}
// Failed to find an image, so drop down into one of the bootloaders
if (sd1_high_select_uart) {
 // Does not return except via reboot
 if (nsboot_uart_disabled) hang(); else nsboot(uart);
} else {
 // Does not return except via reboot
 if (nsboot_usb_disabled) hang(); else nsboot(usb);
}

```

### 💡 提示

引导只读存储器（bootrom）内部将 BOOTSEL 模式称为 NSBOOT，原因在于 USB 和 UART 引导加载程序于 Arm 的非安全状态下运行。本章有时亦用 NSBOOT 表述 BOOTSEL。

#### 5.2.2.1. 引导序列伪代码

下列伪代码概述了表 451。

```

if (powman_vector_valid && powman_reboot_mode_is_pcsp) { //
 若 (correct_arch), 本调用可能返回并继续引导流程 powman_
 vector_pc(); else hang();
}
if (watchdog_vector_valid) {
 // 记录 RAM_IMAGE、FLASH_UPDATE、BOOTSEL 重启类型
 check_special_reboot_mode();
 if (watchdog_reboot_mode_is_pcsp) {
 //若 (correct_arch), 本调用可能返回并继续引导流程 watch
 dog_vector_pc(); else hang();
 }
}

// RAM 镜像窗口由 watchdog_scratch 指定, 例如 UF2 RAM // 下载后: 执行 RAM 镜像, 或
// 退至 UART/USB 引导。
if (watchdog_reboot_mode_is_ram_image && !ram_boot_disabled_in_otp) { //
 //仅当不存在有效的RAM映像可供进入时, 才会返回。
 //无法从RAM映像返回。
 try_boot_ram_image(ram_image_window);
} else {
 //否则尝试OTP和闪存启动 (除非有请求跳过)
 skip_flash_and_otp_boot =
 bootsel_button_pressed() ||
 watchdog_reboot_mode_is_bootsel ||
 (double_tap_enabled_in_otp() && double_run_reset_detected());

 if (!skip_flash_and_otp_boot) {
 if (otp_boot_enabled_in_otp && !otp_boot_disabled_in_otp) {
 //仅当不存在有效的OTP映像可供进入时, 才会返回。
 //无法从OTP映像返回。
 try_otp_boot();
 }
 if (!flash_boot_disabled_in_otp) {
 //仅当不存在有效的闪存映像可供进入时, 才会返回。
 //无法从闪存映像返回。
 try_flash_boot();
 }
 }
}
//未找到镜像, 因此切换到其中一个引导加载程序
if (sd1_high_select_uart) {
 //除非重新启动, 否则不返回
 if (nsboot_uart_disabled) hang(); else nsboot(uart);
} else {
 //除非重新启动, 否则不返回
 if (nsboot_usb_disabled) hang(); else nsboot(usb);
}

```

### 5.2.2.2. Differences between Arm and RISC-V

The boot sequence outlined in [Table 451](#) has the following differences on RISC-V:

- Secure boot is not supported (from any image source).
- Anti-rollback checking is not supported as it applies only to secure boot.
- Additional security checks such as the use of the RCP to validate booleans are disabled.
- The UART and USB bootloaders continue to run in Machine mode, rather than transitioning from the Arm Secure to Non-secure state, meaning there is no hardware-enforced security boundary between these boot phases.
- The XIP setup function written to boot RAM on a successful flash boot contains RISC-V rather than Arm instructions.

### 5.2.3. POWMAN boot vector

POWMAN contains scratch registers similar to the watchdog scratch registers, which persist over power-down of the switched core power domain, in addition to most system resets. These registers allow users to install their own boot handler, and divert control away from the main boot sequence on non-POR/BOR resets. It recognises the following values written to [BOOT0](#) through [BOOT3](#):

- [BOOT0](#): magic number `0xb007c0d3`
- [BOOT1](#): Entry point XORed with magic `-0xb007c0d3 (0x4ff83f2d)`
- [BOOT2](#): Stack pointer
- [BOOT3](#): Entry point

Use this to vector into code preloaded in RAM which was retained during a low-power state.

If either of the magic numbers mismatch, POWMAN vector boot does not take place. If the numbers match, the bootrom zeroes [BOOT0](#) before entering the vector, so that the behaviour does not persist over subsequent reboots.

The POWMAN boot vector is permitted to return. The boot sequence continues as normal after a return from POWMAN vector boot, as though the vector boot had not taken place. There is no requirement for the vector to preserve the global pointer ([gp](#)) register on RISC-V. Use this to perform any additional setup required for the boot path, such as issuing a power-up command to an external QSPI device that may have been powered down (for example, through a B9h power-down command).

The entry point ([pc](#)) must have the LSB set on Arm (the Thumb bit) and clear on RISC-V. If this condition is not met, the bootrom assumes you have passed a RISC-V function pointer to an Arm processor (or vice versa) and hangs the core rather than continuing, since executing code for the wrong architecture has spectacularly undefined consequences.

The linker should automatically set the Thumb bit appropriately for a function pointer relocation, but this is something to be aware of if you pass hardcoded values such as the base of SRAM: this is correctly passed as `0x20000001` on Arm (Thumb bit set) and `0x20000000` on RISC-V (no Thumb bit, halfword-aligned).

### 5.2.4. Watchdog boot vector

Watchdog boot allows users to install their own boot handler, and divert control away from the main boot sequence on non-POR/BOR resets. It recognises the following values written to the watchdog's upper scratch registers:

- [SCRATCH4](#): magic number `0xb007c0d3`
- [SCRATCH5](#): entry point XORed with magic `-0xb007c0d3 (0x4ff83f2d)`
- [SCRATCH6](#): stack pointer
- [SCRATCH7](#): entry point

If either of the magic numbers mismatch, watchdog boot does not take place. If the numbers match, the Bootrom

### 5.2.2.2. Arm与RISC-V的差异

表451中列出的引导序列在RISC-V上存在以下差异：

- 不支持安全启动（无论镜像来源为何）。
- 不支持防回滚检查，该项仅针对安全启动适用。
- 诸如使用RCP验证布尔值的额外安全检查已被禁用。
- UART和USB引导加载程序继续在机器模式下运行，未从Arm安全态切换至非安全态，意味着这些引导阶段间不存在硬件强制的安全边界。
- 成功闪存引导时写入引导RAM的XIP设置函数采用的是RISC-V指令，而非Arm指令。

### 5.2.3. POWMAN 启动向量

POWMAN 包含类似于看门狗临时寄存器的 scratch 寄存器，这些寄存器在切换核心电源域断电后仍然保持，且在大多数系统复位时亦保持不变。这些寄存器允许用户安装自定义引导处理程序，并在非 POR/BOR 复位时脱离主启动序列的控制流程。其识别写入 BOOT0 至 BOOT3 的以下数值：

- **BOOT0**: 魔数 `0xb007c0d3`
- **BOOT1**: 入口点与魔数异或-`0xb007c0d3` (`0x4ff83f2d`)
- **BOOT2**: 栈指针
- **BOOT3**: 入口点

利用此方法，可跳转至在低功耗状态下保留于 RAM 中预加载的代码。

若任一魔数不匹配，则不会执行 POWMAN 向量启动。若数值匹配，引导只读存储器将在进入向量前清零 BOOT0，以防该行为在后续重启时持续。

POWMAN 启动向量允许返回。从POWMAN向量引导返回后，引导序列依旧正常继续，仿佛向量引导未曾执行。RISC-V 架构下，向量不要求保护全局指针（`gp`）寄存器。可利用此特性执行启动路径的其他必要配置，例如向可能已断电的外部 QSPI 设备发送上电命令（如通过B9h断电命令）。

入口点（`pc`）在Arm架构上必须设置最低有效位（即Thumb位），而在RISC-V架构上必须清除该位。若未满足此条件，bootrom将假定您将RISC-V函数指针传递给Arm处理器（或反之），并使核心挂起，避免继续执行，因错误架构代码的执行将产生严重的不确定性后果。

链接器应自动为函数指针重定位正确设置Thumb位，但若传递硬编码值，如SRAM基址，需特别注意：在Arm架构中应传递为 `0x20000001`（Thumb位已设置），而为 `0x20000000` 基于RISC-V架构（无Thumb位，半字对齐）。

### 5.2.4. 看门狗启动向量

看门狗启动允许用户安装其自定义启动处理程序，并在非上电复位（POR）或掉电复位（BOR）情况下，将控制权从主启动序列转移。它识别写入看门狗上部临时寄存器的以下数值：

- **SCRATCH4**: 魔数 `0xb007c0d3`
- **SCRATCH5**: 入口点与魔数异或-`0xb007c0d3` (`0x4ff83f2d`)
- **SCRATCH6**: 堆栈指针
- **SCRATCH7**: 入口点

若任一魔数不匹配，则不执行看门狗启动。若数值匹配，Bootrom

zeroes **SCRATCH4** before transferring control, so that the behaviour does not persist over subsequent reboots.

Watchdog boot can also be used to select the bootrom's special one-shot boot modes, described in [Section 5.2.4.1](#). The term **one-shot** refers to the fact these only affect the next boot (and not subsequent ones) due to the bootrom clearing **SCRATCH4** each boot. These boot types are encoded by setting a special entry point (**pc**) value of **0xb007c0d3**, which is otherwise not a valid entry address, and then setting the boot type in the stack pointer (**sp**) value. [Section 5.2.4.1](#) lists the supported values.

The watchdog boot vector is permitted to return. The boot path continues as normal when it returns: use this to perform any additional setup required for the boot path, such as issuing additional commands to an external QSPI device. On RISC-V the vector is permitted to use its own global pointer (**gp**) value, as the bootrom only uses **gp** during USB boot, which installs its own value.

With the exception of the magic boot type entry point (**0xb007c0d3**), the vector entry point **pc** must have the LSB set on Arm (the Thumb bit) and clear on RISC-V. If this condition is not met, the bootrom assumes you have passed a RISC-V function pointer to an Arm processor (or vice versa) and hangs the core rather than continuing.

#### 5.2.4.1. Special watchdog boot types

The magic entry point **0xb007c0d3** indicates a special one-shot boot type, identified by the stack pointer value:

##### **BOOTSEL**

Selected by **sp = 2**. Boot into BOOTSEL mode. This will be either UART or USB boot depending on whether QSPI **SD1** is driven high (default pull-down selects USB boot). See [Section 5.2.8](#) for more details.

##### **RAM\_IMAGE**

Selected by **sp = 3**. Boot into an image stored in SRAM or XIP SRAM. BOOTSEL mode uses this to request execution of an image it loaded into RAM before rebooting. See [Section 5.2.5](#) for more details.

##### **FLASH\_UPDATE**

Selected by **sp = 4**. BOOTSEL selects this mode when rebooting following a flash download. Changes some flash boot behaviour, such as allowing older **versions** to boot in preference to newer ones. See [Section 5.1.16](#) for more details.

Parameters to the one-shot boot type are passed in:

- **SCRATCH2**: Parameter 0
- **SCRATCH3**: Parameter 1

These directly correspond to the **p0** and **p1** boot parameters passed into the **reboot()** API. For example, on a **RAM\_IMAGE** boot, this specifies the base and size of the RAM region to be searched for a valid **IMAGE\_DEF**. See the API listing in [Section 5.4.8.24](#) for more details. When not performing one of the listed boot types, **SCRATCH2** and **SCRATCH3** remain free for arbitrary user values, and the bootrom doesn't modify or interpret their contents.

#### 5.2.5. RAM image boot

The bootrom is directed (through values in the watchdog registers) to boot into an image in SRAM or XIP SRAM. The two parameters indicate the start and size of the region to search for a block loop containing a valid (and correctly signed if necessary) **IMAGE\_DEF**. These are passed as parameter 0/1, in watchdog scratch 2/3.

If the image to be booted is contained in XIP SRAM, the XIP SRAM must be pinned in place by the bootrom prior to launch. For this reason, if you are using XIP SRAM for your binaries, you must add a special entry to the **LOAD\_MAP** item (see [Section 5.9.3.2](#)).

在转移控制权前将SCRATCH4清零，以确保该行为不会在后续重启中持续。

看门狗启动亦可用来选择Bootrom的特殊一次性启动模式，该模式详见5.2.4.1节。术语 **one-shot** 意味着此类启动模式仅影响下一次启动（不影响后续启动），因Bootrom在每次启动时均会清除SCRATCH4。这些启动类型通过设置特殊入口点（`pc`）值为 `0xb007c0d3` 进行编码，该值在其他情况下并非有效入口地址，然后在堆栈指针（`sp`）值中设置启动类型。第5.2.4.1节列出了支持的值。

看门狗启动向量允许返回。返回时启动路径将正常继续：可借此执行启动路径所需的任何额外配置，例如向外部QSPI设备发出附加命令。在RISC-V架构中，向量允许使用其自身的全局指针（`gp`）值，因为启动只读存储器仅在USB启动期间使用 `gp`，并安装其自身的值。

除特别启动类型入口点（`0xb007c0d3`）外，向量入口点 `pc` 在Arm上必须设置最低有效位（Thumb位），而在RISC-V上必须清除该位。若不满足此条件，启动只读存储器将假定您向Arm处理器传递了RISC-V函数指针（或反之），并挂起内核而非继续执行。

#### 5.2.4.1. 特殊看门狗启动类型

魔术入口点 `0xb007c0d3` 指示一种特殊的一次性启动类型，其标识由栈指针值确定：

##### BOOTSEL

由 `sp = 2` 选择。进入BOOTSEL模式启动。启动方式为UART或USB，具体取决于QSPI SD1是否被拉高（默认下拉电阻选择USB启动）。详情请参见第5.2.8节。

##### RAM\_IMAGE

由 `sp = 3` 选择。启动存储于SRAM或XIP SRAM中的映像。BOOTSEL模式通过此方式请求执行在重启前加载到RAM的映像。详情请参见第5.2.5节。

##### FLASH\_UPDATE

由 `sp = 4` 选择。BOOTSEL在闪存下载后重启时选择此模式。更改部分闪存启动行为，例如允许旧版本启动优先于新版本。详情请参见第5.1.16节。

一次性启动类型的参数如下传入：

- SCRATCH2：参数0
- SCRATCH3：参数1

这些直接对应于传递给reboot() API的 `p0` 和 `p1` 启动参数。例如，在 RAM\_IMAGE 启动时，这指定用于搜索有效IMAGE\_DEF 的 RAM 区域的起始地址和大小。详情请参见第5.4.8.24节的API列表。当未执行所列任一启动类型时，SCRATCH2 和 SCRATCH3 保留为用户可自由使用的值，启动只读存储器不会修改或解释其内容。

#### 5.2.5. RAM 镜像启动

启动只读存储器通过看门狗寄存器中的值指示启动至SRAM或XIP SRAM中的图像。两个参数指示用于搜索包含有效（必要时经正确签名）IMAGE\_DEF 块环的区域的起始地址和大小。这些作为参数0/1传入，在看门狗擦写区2/3中。

如果待启动的映像包含于XIP SRAM中，bootrom必须在启动前将XIP SRAM固定到位。因此，若您使用XIP SRAM存放二进制文件，必须在 LOAD\_MAP 条目中添加特殊项（详见第5.9.3.2节）。

### 5.2.6. OTP boot

If OTP boot is enabled, then code from OTP is executed in preference to code from flash. Note that the OTP code is free to "chain" into an executable stored in flash.

Code from OTP is copied into SRAM at the specified location, then execution proceeds similarly to RAM Image Boot. The SRAM with the data copied from OTP is searched for a valid (and correctly signed if necessary) [IMAGE\\_DEF](#). If found, it is booted; otherwise OTP boot falls through to Flash Boot (if enabled).

OTP boot could, for example, be used to execute some hidden decryption code to decode a flash image on startup. The OTP boot code can hide itself (in OTP) even from Secure code, once it is done.

### 5.2.7. Flash boot

The bootrom scans flash up to 16 times until it finds a valid [IMAGE\\_DEF](#) or [PARTITION\\_TABLE](#). At this point, the flash settings are considered valid, and the flash boot proceeds if a valid bootable [IMAGE\\_DEF](#) is found with these settings. It uses the following combinations of flash read instruction and SCK divisor for the 16 attempts:

*Table 452. QSPI read modes supported by the bootrom, in the order it attempts them.*

| Mode       | Clock Divisor |
|------------|---------------|
| EBh quad   | 3             |
| BBh dual   | 3             |
| 0Bh serial | 3             |
| 03h serial | 3             |
| EBh quad   | 6             |
| BBh dual   | 6             |
| 0Bh serial | 6             |
| 03h serial | 6             |
| EBh quad   | 12            |
| BBh dual   | 12            |
| 0Bh serial | 12            |
| 03h serial | 12            |
| EBh quad   | 24            |
| BBh dual   | 24            |
| 0Bh serial | 24            |
| 03h serial | 24            |

QSPI does not provide a reliable method to detect whether a device is attached. However, this is not much of an issue for boot purposes: either there is a device with valid and bootable contents, or there are no such contents (either due to lack of a connected device, invalid device contents, or failure to communicate in the current QSPI mode).

When there is no device (or no recognisable contents), the bootrom tries all 16 modes in [Table 452](#) before finally giving up. The size of the initial search region is limited to 4 kB to minimise the time spent scanning flash before falling through to USB or UART boot. This same 4 kB limit also applies to search within a [flash partition](#), which allows the bootrom to reliably sever the contained image's block loop with a single 4 kB sector erase at the start of a partition, such as on a [version downgrade](#).

There are three main ways that the bootrom locates flash images:

### 5.2.6. OTP 启动

若启用OTP启动，则优先执行OTP中的代码，而非闪存中的代码。请注意，OTP代码可自由“链入”存储于闪存中的可执行程序。

OTP中的代码被复制到SRAM指定位置，随后执行流程类似于RAM映像启动。

在复制自OTP的SRAM中搜索有效的（若必要且已正确签名）[IMAGE\\_DEF](#)，找到则启动；否则，OTP启动将退回执行闪存启动（若已启用）。

一次性可编程（OTP）启动代码例如可用于执行隐藏的解密代码，以在启动时解码闪存映像。一旦完成，OTP启动代码甚至可以在安全代码中将自身隐藏（存于OTP中）。

### 5.2.7. 闪存启动

只读存储器启动程序会扫描闪存最多16次，直到找到有效的[IMAGE\\_DEF](#)或[PARTITION\\_TABLE](#)。此时，闪存设置被视为有效，如在这些设置下找到有效的可启动[IMAGE\\_DEF](#)，则闪存启动程序将继续执行。它使用以下闪存读取指令与SCK除数组合进行16次尝试：

表452。只读存储器按尝试顺序支持的QSPI/读取模式。

| 模式       | 时钟除数 |
|----------|------|
| EBh 四线模式 | 3    |
| BBh 双线模式 | 3    |
| 0Bh 串行模式 | 3    |
| 03h 串行模式 | 3    |
| EBh 四线模式 | 6    |
| BBh 双线模式 | 6    |
| 0Bh 串行模式 | 6    |
| 03h 串行模式 | 6    |
| EBh 四线模式 | 12   |
| BBh 双线模式 | 12   |
| 0Bh 串行模式 | 12   |
| 03h 串行模式 | 12   |
| EBh 四线模式 | 24   |
| BBh 双线模式 | 24   |
| 0Bh 串行模式 | 24   |
| 03h 串行模式 | 24   |

QSPI无法提供可靠方法检测设备是否已连接。不过，这对启动过程来说并非重大问题：要么存在具有有效且可启动内容的设备，要么不存在此类内容（可能由于设备未连接、设备内容无效，或当前QSPI模式下通信失败）。

当无设备（或无可识别内容）时，bootrom 会依次尝试表 452 中的全部 16 种模式，最终放弃。初始搜索区域限制为 4 kB，以最大限度减少扫描闪存所耗费的时间，随后再尝试 USB 或 UART 启动。该 4 kB 限制同样适用于闪存分区内的搜索，使得 bootrom 能够通过在分区起始处擦除单个 4 kB 扇区，可靠切断所含映像的块循环，例如用于版本降级。

bootrom 定位闪存映像的三种主要方式为：

### Flash image boot

A flash image can be written directly to flash storage address `0x0`, and the bootrom will find it from there. This is the most similar to flash boot on RP2040 (the main differences being the removal of a `boot2` in the first 256 bytes of the image, and the new requirement for a valid `image definition` anywhere within the first 4 kB of the image).

### Flash partition boot

A flash image can be written into a partition of a `partition table`. The partition table is described by a `PARTITION_TABLE` block stored at the start of flash. The bootrom finds the partition table and scans its partitions to look for bootable images.

### Partition-table-in-image boot

A flash image containing an `IMAGE_DEF` and `PARTITION_TABLE` block in a single `block loop` is written to the start of flash. The bootrom loads the embedded partition table, and enters the image in the same way as the `flash image boot` case.

Revisit the linked bootrom concepts sections to get the fullest understanding of each of these three forms of flash boot. For the purposes of this section, all that matters is whether the bootrom can discover a valid, bootable image or not. In all three cases, the image must have a valid `IMAGE_DEF`, and meet all relevant security requirements such as being correctly `signed`, and having a `rollback version` greater than or equal to the one stored in OTP.

The bootrom enters the flash image in whatever QSPI mode it discovered to work during flash programming. Any further setup (such as prefixless continuous read modes) is performed by the flash image itself. This setup code, referred to as an `XIP setup function`, is usually copied into RAM before execution to avoid running from flash whilst the XIP interface is being reconfigured.

#### TIP

The `PICO_EMBED_XIP_SETUP=1` flag in the SDK enables inclusion and execution of an XIP setup function on RP2350 builds. In this case the function executes on the core 0 stack during early startup, so no additional static memory need be allocated. This is not the case for subsequent calls, because the stack is often not executable post-startup.

You should save your XIP setup function in the first 256 bytes of boot RAM to make it easily locatable when the XIP mode is re-initialised following a serial flash programming operation which had to drop out of XIP mode. The bootrom writes a default XIP setup function to this address before entering the flash image, which restores the mode the bootrom discovered during flash programming.

#### NOTE

You cannot execute an XIP setup function directly from boot RAM, because boot RAM is never executable. You must copy it into SRAM before execution.

XIP setup functions should be fully position-independent, and no more than 256 bytes in size. If you are unable to meet these requirements, you should install a stub function which calls your XIP setup function elsewhere in RAM.

## 5.2.8. BOOTSEL (USB/UART) boot

The bootrom samples the state of QSPI `CSn` shortly after reset. Based on the result, the bootrom decides whether to enter BOOTSEL mode, which refers collectively to the USB and UART bootloaders.

The bootrom initialises the chip select to the following state:

- Output disabled
- Pulled high (note `CSn` is an active-low signal, so this deselects the external QSPI device if there is one)

If the chip select remains high, the bootrom continues with its normal, non-BOOTSEL sequence. By default on a blank device, this means driving the chip select low and attempting to boot from an external flash or PSRAM device.

If chip select is driven low externally, the bootrom enters BOOTSEL mode. You must drive the chip select low with a

### 闪存映像启动

闪存映像可直接写入闪存存储地址 `0x0`, bootrom 将从该地址查找映像。此方式最类似于 RP2040 上的闪存启动（主要差别是映像前 256 字节内不再包含 `boot2`, 并且新增要求映像前 4 kB 内必须存在有效的映像定义）。

### 闪存分区启动

闪存映像可写入分区表中的某个分区。分区表由存储于闪存起始处的 `PARTITION_TABLE` 块描述。启动只读存储器定位分区表并扫描其分区以查找可启动映像。

### 镜像中分区表启动

包含 `IMAGE_DEF` 与 `PARTITION_TABLE` 块的闪存映像，在单个循环块中写入闪存起始位置。

启动只读存储器加载嵌入的分区表，并以与闪存映像启动相同的方式加载映像情况。

请重新查阅相关启动只读存储器概念章节，以全面理解这三种闪存启动方式。

本节关注启动只读存储器是否能发现有效可启动映像。在三种情形中，映像须具备有效的 `IMAGE_DEF`，且满足所有相关安全要求，例如正确签名及回滚版本不低于 OTP 存储版本。

只读存储器启动程序以在闪存编程期间发现的任何可用 QSPI 模式进入闪存镜像。任何后续设置（例如无前缀连续读取模式）由闪存镜像本身执行。此设置代码称为 **XIP 设置函数**，通常在执行前复制到 RAM 中，以避免在重新配置 XIP 接口时从闪存执行。

#### 💡 提示

SDK 中的 `PICO_EMBED_XIP_SETUP=1` 标志启用在 RP2350 构建中包含并执行 XIP 设置函数。在此情况下，该函数在早期启动阶段于核心 0 堆栈上执行，因此无需分配额外的静态内存。后续调用情况不同，因为启动后堆栈通常不可执行。

您应将 XIP 设置函数保存在启动 RAM 的前 256 字节内，以便在因串行闪存编程操作必须退出 XIP 模式后重新初始化 XIP 模式时能够轻松定位。bootrom 在进入闪存映像之前，会将默认的 XIP 设置函数写入该地址，以恢复 bootrom 在闪存编程期间检测到的模式。

#### ⚠ 注意

启动 RAM 不可执行，因此您无法直接从启动 RAM 执行 XIP 设置函数。必须先将其复制到 SRAM 中方可执行。

XIP 设置函数应完全位置无关，且大小不得超过 256 字节。如无法满足上述要求，应安装一个存根函数，在 RAM 其他位置调用该 XIP 设置函数。

### 5.2.8. BOOTSEL (USB/UART) 启动

bootrom 在复位后不久采样 QSPI `CSn` 的状态。bootrom 根据采样结果决定是否进入 BOOTSEL 模式，该模式包括 USB 和 UART 启动加载程序。

bootrom 将芯片选择信号初始化为以下状态：

- 输出禁止
- 被拉高（注意 `CSn` 为低电平有效信号，故此操作取消对外部 QSPI 设备的选择（若存在））

若芯片选择保持高电平，bootrom 则继续其正常的非 BOOTSEL 流程。默认情况下，对于空白设备，这意味着将芯片选择信号拉低并尝试从外部闪存或 PSRAM 设备启动。

如果芯片选择信号由外部拉低，bootrom 将进入 BOOTSEL 模式。您必须以

sufficiently low impedance to overcome the internal pull-up. A 4.7 kΩ resistance to ground is a good intermediate value which reliably creates a low input logic level, but will not affect the output levels when RP2350 drives the chip select.

The QSPI `SD1` line, which RP2350 initially pulls low, selects which bootloader to enter:

- `SD1` remains pulled low: enter USB bootloader
- `SD1` driven high: enter UART bootloader

USB boot is a low-friction method for programming an RP2350 from a sophisticated host like a Linux PC. It also directly exposes more advanced options like OTP programming. See [Section 5.5](#) for the drag-and-drop mass storage interface, or [Section 5.6](#) for the PICOBLOCK vendor interface.

UART boot is a minimal interface for bootstrapping a flashless RP2350 from another microcontroller. UART boot uses QSPI `SD2` for UART TX, and QSPI `SD3` for UART RX, at a fixed baud rate of 1 Mbaud. For more details about UART boot, see [Section 5.8](#).

#### 5.2.8.1. BOOTSEL clock requirements

BOOTSEL mode requires either a crystal attached across the `XIN` and `XOUT` pins, or a clock signal from an external oscillator driven into the `XIN` pin. See [Table 1439](#) for the electrical specifications of these two XOSC pins.

The bootrom assumes a default XOSC frequency of 12 MHz. It configures the USB PLL to derive a fixed 48 MHz frequency from the XOSC reference. For USB, this must be a precise frequency. If you use a non-12 MHz crystal, and intend to use USB boot, program `BOOTSEL_PLL_CFG` and `BOOTSEL_XOSC_CFG` in OTP, and then set `BOOT_FLAGS0.ENABLE_BOOTSEL_NON_DEFAULT_PLL_XOSC_CFG`. For details about calculating the correct PLL parameters for your crystal, see [Section 8.6.3](#).

UART boot uses the same PLL configuration as USB boot. However, the permissible range of crystal frequencies under the default PLL configuration is wider. See [Section 5.8.1](#).

#### 5.2.9. Boot configuration (OTP)

User configuration stored in OTP can be found in [Section 13.10](#), starting at `CRIT1`.

The main controls for the bootrom are stored in `BOOT_FLAGS0` and `BOOT_FLAGS1`. These are both in page 1 of OTP, which has the following default permissions on a blank device:

- Read-write for Secure (`S`)
- Read-write for bootloader (`BL`)
- Read-only for Non-secure (`NS`)

Boot key hashes are stored in page 2 of OTP, starting from `BOOTKEY0_0`. There is space for up to four boot key hashes in this page. See [Section 5.10.1](#) for an example of how keys can be installed.

### 5.3. Launching code on Processor Core 1

As described in [Section 5.2](#), after reset, processor core 1 sleeps at start-up, and remains asleep until woken by core 0 via the SIO FIFOs.

If you are using the SDK then you can use the `multicore_launch_core1()` function to launch code on processor core 1. However this section describes the procedure to launch code on processor core 1 yourself.

The procedure to start running on processor core 1 involves both cores moving in lockstep through a state machine coordinated by passing messages over the inter-processor FIFOs. This state machine is designed to be robust enough to cope with a recently reset processor core 1 which may be anywhere in its boot code, up to and including going to sleep. As result, the procedure may be performed at any point after processor core 1 has been reset (either by system

足够低的阻抗拉低芯片选择信号，以克服内部的上拉电阻。一个接地的4.7 kΩ电阻是一个合适的中间值，能够可靠地产生低电平输入逻辑，但不会影响RP2350驱动芯片选择信号时的输出电平。

QSPI SD1 线由RP2350初始拉低，该线用于选择进入的引导加载程序：

- SD1 保持拉低：进入USB引导加载程序
- SD1 被拉高：进入UART引导加载程序

USB引导是一种操作简便的方法，可通过如Linux PC等高级主机对RP2350进行编程，同时还直接支持更高级的选项，如OTP编程。详见第5.5节拖放式大容量存储接口，或第5.6节的PICOBOOT供应商接口。

UART引导是用于从另一微控制器启动无闪存RP2350的最小接口。UART引导使用QSPI SD2作为UART TX，使用QSPI SD3作为UART RX，波特率固定为1 Mbaud。有关UART引导的更多详细信息，请参见第5.8节。

### 5.2.8.1. BOOTSEL时钟要求

BOOTSEL模式要求在 XIN 和 XOUT 引脚之间连接晶体，或由外部振荡器输出的时钟信号输入至 XIN 引脚。有关这两个XOSC 引脚的电气规格，请参见表1439。

Bootrom假定XOSC的默认频率为12 MHz，并配置USB PLL以从XOSC参考中派生固定的48 MHz频率。对于USB，此频率必须极其精确。如果您使用非12 MHz晶体且计划启用USB引导，请在OTP中编程BOOTSEL\_PLL\_Cfg 和 BOOTSEL\_XOSC\_Cfg，并设置BOOT\_FLAGS0.ENABLE\_BOOTSEL\_NON\_DEFAULT\_PLL\_XOSC\_Cfg。有关针对您的晶体计算正确PLL参数的详细说明，请参见第8.6.3节。

UART启动使用与USB启动相同的PLL配置。然而，在默认PLL配置下，晶振频率的允许范围更广。详见第5.8.1节。

### 5.2.9. 启动配置 (OTP)

存储在OTP中的用户配置详见第13.10节，自CRIT1起。

启动只读存储器(bootrom)的主要控制位存于BOOT\_FLAGS0和BOOT\_FLAGS1，二者均位于OTP的第1页，该页在空白设备上的默认权限如下：

- 安全区(S) 可读写
- 引导加载程序(BL) 可读写
- 非安全区(NS) 只读

启动密钥哈希存储于OTP第2页，从BOOTKEY0\_0开始。该页最多可存放四个启动密钥哈希。关于密钥安装的示例，详见第5.10.1节。

## 5.3. 在处理器核1上启动代码

如第5.2节所述，复位后，处理器核心1启动时保持休眠，直至由核心0通过SIO FIFO唤醒。

如果您正在使用SDK，您可以使用`multicore_launch_core1()`函数在处理器核心1上启动代码。

本节描述了自行在处理器核心1上启动代码的具体步骤。

在处理器核心1上启动运行的步骤涉及两个核心通过状态机协调同步执行，该状态机通过处理器间FIFO传递消息实现控制。此状态机设计稳健，可处理刚重置的处理器核心1，无论其启动代码执行到了哪一阶段，包括进入睡眠状态。因此，该步骤可在处理器核心1完成重置后（无论是系统重置，

reset, or explicitly resetting just processor core 1).

The following C code describes the procedure:

```
// values to be sent in order over the FIFO from core 0 to core 1
//
// vector_table is value for VTOR register
// sp is initial stack pointer (SP)
// entry is the initial program counter (PC) (don't forget to set the thumb bit!)
const uint32_t cmd_sequence[] =
 {0, 0, 1, (uintptr_t) vector_table, (uintptr_t) sp, (uintptr_t) entry};

uint seq = 0;
do {
 uint cmd = cmd_sequence[seq];
 // always drain the READ FIFO (from core 1) before sending a 0
 if (!cmd) {
 // discard data from read FIFO until empty
 multicore_fifo_drain();
 // execute a SEV as core 1 may be waiting for FIFO space
 __sev();
 }
 // write 32 bit value to write FIFO
 multicore_fifo_push_blocking(cmd);
 // read 32 bit value from read FIFO once available
 uint32_t response = multicore_fifo_pop_blocking();
 // move to next state on correct response (echo-d value) otherwise start over
 seq = cmd == response ? seq + 1 : 0;
} while (seq < count_of(cmd_sequence));
```

## 5.4. Bootrom APIs

Whilst some ROM space is dedicated to the implementation of the boot sequence and USB/UART boot interfaces, the bootrom also contains public functions that provide useful RP2350 functionality that may be useful for any code or runtime running on the device.

A categorised list is available in [Section 5.4.6](#).

The full alphabetical list is available in [Section 5.4.7](#).

### 5.4.1. Locating the API functions

The API functions are normally made available to the user by wrappers in the SDK. However, a lower level method is provided to locate them (since their locations may change with each bootrom release) for other runtimes, or those who wish to locate them directly.

[Table 453](#) shows the fixed memory layout of certain words in the bootrom used to locate these functions when using the Arm architecture. [Table 454](#) shows the additional entries for use when using the RISC-V architecture.

Table 453. Bootrom contents at fixed (well known) addresses for Arm code

| Address    | Contents       | Description                                 |
|------------|----------------|---------------------------------------------|
| 0x00000000 | 32-bit pointer | Initial boot stack pointer                  |
| 0x00000004 | 32-bit pointer | Pointer to boot reset handler function      |
| 0x00000008 | 32-bit pointer | Pointer to boot NMI handler function        |
| 0x0000000c | 32-bit pointer | Pointer to boot Hard fault handler function |

还是仅显式重置处理器核心 1) 任意时刻执行。以下 C 代码说明了该步骤：

```
// 从核心 0 到核心 1 顺序发送的 FIFO 值
//
// vector_table 为 VTOR 寄存器的值
// sp 是初始堆栈指针 (SP)
// entry 是初始程序计数器 (PC) (别忘了设置 thumb 位!)
const uint32_t cmd_sequence[] =
 {0, 0, 1, (uintptr_t) vector_table, (uintptr_t) sp, (uintptr_t) entry};

uint seq = 0;
do {
 uint cmd = cmd_sequence[seq];
 // 在发送0之前，始终清空读取FIFO (来自核心1)
 if (!cmd) {
 // 丢弃读取FIFO中的数据，直到为空
 multicore_fifo_drain();
 // 执行SEV指令，因为核心1可能正在等待FIFO空间
 __sev();
 }
 // 向写入FIFO写入32位值
 multicore_fifo_push_blocking(cmd);
 // 一旦可用，从读取FIFO读取32位值
 uint32_t response = multicore_fifo_pop_blocking();
 // 在获得正确响应 (回显值) 时转到下一状态，否则重新开始
 seq = cmd == response ? seq + 1 : 0;
} while (seq < count_of(cmd_sequence));
```

## 5.4. Bootrom API

尽管部分只读存储器空间专门用于实现引导序列及USB/UART引导接口，bootrom中亦包含提供有用RP2350功能的公共函数，这些函数可能对设备上运行的任何代码或运行时环境具有参考价值。

分类列表详见第5.4.6节。

完整字母顺序列表详见第5.4.7节。

### 5.4.1. 定位 API 函数

API函数通常通过SDK中的封装函数提供给用户，然而，为了适配其他运行时环境或满足用户直接定位函数位置的需求，亦提供了较低级别的方法来查找这些函数（因其地址可能随bootrom版本变动）。

表453展示了在采用Arm架构时，用于定位这些函数的bootrom中特定字的固定内存布局。表454展示了在采用RISC-V架构时可用的附加条目。

表453。用于Arm代码的bootrom内容  
固定（众所周知）  
地址

| 地址         | 内容    | 描述               |
|------------|-------|------------------|
| 0x00000000 | 32位指针 | 初始启动堆栈指针         |
| 0x00000004 | 32位指针 | 指向启动复位处理程序函数的指针  |
| 0x00000008 | 32位指针 | 指向启动NMI处理程序函数的指针 |
| 0x0000000c | 32位指针 | 指向启动硬故障处理程序函数的指针 |

| Address    | Contents       | Description                                             |
|------------|----------------|---------------------------------------------------------|
| 0x00000010 | 'M', 'u', 0x02 | Magic                                                   |
| 0x00000013 | byte           | Bootrom version                                         |
| 0x00000014 | 16-bit pointer | Pointer to ROM entry table (BOOTROM_ROMTABLE_START)     |
| 0x00000016 | 16-bit pointer | Pointer to a helper function (rom_table_lookup_val())   |
| 0x00000018 | 16-bit pointer | Pointer to a helper function (rom_table_lookup_entry()) |

Table 454. Bootrom contents at fixed (well known) addresses for RISC-V code

| Address    | Contents           | Description                                             |
|------------|--------------------|---------------------------------------------------------|
| 0x00007df6 | 16-bit pointer     | Pointer to ROM entry table (BOOTROM_ROMTABLE_START)     |
| 0x00007df8 | 16-bit pointer     | Pointer to a helper function (rom_table_lookup_val())   |
| 0x00007dfa | 16-bit pointer     | Pointer to a helper function (rom_table_lookup_entry()) |
| 0x00007dfc | 32-bit instruction | RISC-V Entry Point                                      |

Assuming the three bytes starting at address 0x00000010 are ('M', 'u', 0x02), the other fixed location fields can be assumed to be valid and used to lookup bootrom functionality.

The version byte at offset 0x00000013 is informational, and should not be used to infer the exact location of any functions. It has the value 2 for A2 silicon.

The following code from the SDK shows how the SDK looks up a bootrom function:

```

static __force_inline void *rom_func_lookup_inline(uint32_t code) {
#ifndef __riscv
 // on RISC-V the code (a jmp) is actually embedded in the table
 rom_table_lookup_fn rom_table_lookup =
 (rom_table_lookup_fn) (uintptr_t)*(uint16_t*)(BOOTROM_TABLE_LOOKUP_ENTRY_OFFSET
 + rom_offset_adjust);
 return rom_table_lookup(code, RT_FLAG_FUNC_RISCV);
#else
 // on Arm the function pointer is stored in the table, so we dereference it
 // via lookup() rather than lookup_entry()
 rom_table_lookup_fn rom_table_lookup =
 (rom_table_lookup_fn) (uintptr_t)*(uint16_t*)(BOOTROM_TABLE_LOOKUP_OFFSET);
 if (pico_processor_state_is_nonsecure()) {
 return rom_table_lookup(code, RT_FLAG_FUNC_ARM_NONSEC);
 } else {
 return rom_table_lookup(code, RT_FLAG_FUNC_ARM_SEC);
 }
#endif
}

```

As well as API functions, there are a few data values that can be looked up. The following code demonstrates:

```

void *rom_data_lookup(uint32_t code) {
 rom_table_lookup_fn rom_table_lookup =
 (rom_table_lookup_fn) (uintptr_t)*(uint16_t*)(BOOTROM_TABLE_LOOKUP_OFFSET);
 return rom_table_lookup(code, RT_FLAG_DATA);
}

```

The code parameter correspond to the CODE values in the tables below, and is calculated as follows:

| 地址         | 内容             | 描述                                     |
|------------|----------------|----------------------------------------|
| 0x00000010 | 'M', 'u', 0x02 | 魔数                                     |
| 0x00000013 | 字节             | Bootrom版本                              |
| 0x00000014 | 16位指针          | 指向只读存储器入口表的指针 (BOOTROM_ROMTABLE_START) |
| 0x00000016 | 16位指针          | 指向辅助函数的指针 (rom_table_lookup_val())     |
| 0x00000018 | 16位指针          | 指向辅助函数的指针 (rom_table_lookup_entry())   |

表454。RISC-V代码的只读存储器内容位于固定（广为人知的）地址

| 地址         | 内容    | 描述                                     |
|------------|-------|----------------------------------------|
| 0x00007df6 | 16位指针 | 指向只读存储器入口表的指针 (BOOTROM_ROMTABLE_START) |
| 0x00007df8 | 16位指针 | 指向辅助函数的指针 (rom_table_lookup_val())     |
| 0x00007dfa | 16位指针 | 指向辅助函数的指针 (rom_table_lookup_entry())   |
| 0x00007dfc | 32位指令 | RISC-V入口点                              |

假设从地址 0x00000010 开始的三个字节为 ('M'、 'u'、 0x02)，则其他固定位置字段可视为有效，并可用于查找只读存储器功能。

偏移量 0x00000013 处的版本字节仅供参考，不应用于推断任何函数的精确位置。该字节对 A2 硅片的值为 2。

以下 SDK 代码展示了 SDK 如何查找只读存储器中的函数：

```

static __force_inline void *rom_func_lookup_inline(uint32_t code) {
#ifndef __riscv
 // 在 RISC-V 架构上，代码 (jmp) 实际上嵌入于表中
 rom_table_lookup_fn rom_table_lookup =
 (rom_table_lookup_fn) (uintptr_t)*(uint16_t*)(BOOTROM_TABLE_LOOKUP_ENTRY_OFFSET
 + rom_offset_adjust);
 return rom_table_lookup(code, RT_FLAG_FUNC_RISCV);
#else
 // 在 Arm 架构中，函数指针存储于表中，因此通过 lookup() 函数而非 lookup_entry() 函数进行
 // 解引用
 rom_table_lookup_fn rom_table_lookup =
 (rom_table_lookup_fn) (uintptr_t)*(uint16_t*)(BOOTROM_TABLE_LOOKUP_OFFSET);
 if (pico_processor_state_is_nonsecure()) {
 return rom_table_lookup(code, RT_FLAG_FUNC_ARM_NONSEC);
 } else {
 return rom_table_lookup(code, RT_FLAG_FUNC_ARM_SEC);
 }
#endif
}

```

除了 API 函数外，亦可查询部分数据值。以下代码示例：

```

void *rom_data_lookup(uint32_t code) {
 rom_table_lookup_fn rom_table_lookup =
 (rom_table_lookup_fn) (uintptr_t)*(uint16_t*)(BOOTROM_TABLE_LOOKUP_OFFSET);
 return rom_table_lookup(code, RT_FLAG_DATA);
}

```

参数 code 对应下表中的 CODE 值，具体计算方法如下：

```
uint32_t rom_table_code(char c1, char c2) {
 return (c2 << 8) | c1;
}
```

These codes are also available in `bootrom.h` in the SDK as `#defines`.

### 5.4.2. API function availability

Some functions are not available under all architectures or security levels. The API listing in [Section 5.4.6](#) uses the following terms to list the availability of each individual API entry point:

#### Arm-S

The function is available to Secure Arm code. The majority of functions are available for [Arm-S](#) unless they deal specifically with RISC-V or Non-secure functionality.

#### RISC-V

The function is available to RISC-V code. Most of the functions that are available under [Arm-S](#) are also exposed under RISC-V unless they deal specifically with Arm security states.

#### Arm-NS

The function is available to Non-secure Arm code. The function in this case performs additional permission and argument checks to prevent Secure data from leaking or being corrupted.

Each individual [Arm-NS](#) API function must be explicitly enabled by Secure code before use, via `set_ns_api_permission()`. A disabled Non-secure API returns `BOOTROM_ERROR_NOT_PERMITTED` if disabled by Secure code. All Non-secure APIs are disabled initially. There is no permission control on Non-secure code calling Secure-only [Arm-S](#) functions, but such a call will crash when it attempts to access Secure-only hardware.

The [Arm-NS](#) functions may escalate through a Secure Gateway (SG) instruction to allow Non-secure code to perform limited operations on nominally Secure-only hardware, such as QSPI direct-mode interface used for flash programming.

The [RISC-V](#) functions do not have separate entry points based on privilege level. Both M-mode and U-mode software can call bootrom APIs, assuming they have execute permissions on ROM addresses in the PMP. However, U-mode calls will crash if they attempt to access M-mode-only hardware.

### 5.4.3. API function return codes

Some functions do not support returning any error, and are marked `void`. The remainder return either 0 (`BOOTROM_OK`) or a positive value (if data needs to be returned) for success. These bootrom error codes are identical to the error codes used by the SDK, so they can be used interchangeably. This explains the gaps in the numbering for SDK error codes that aren't used by the bootrom.

| Name                                     | Value    | Description                                                                                                                                                                                                  |
|------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value                                    | $\geq 0$ | The function succeeded and returned the value                                                                                                                                                                |
| <code>BOOTROM_OK</code>                  | 0        | The function executed successfully                                                                                                                                                                           |
| <code>BOOTROM_ERROR_NOT_PERMITTED</code> | -4       | The operation was disallowed by a security constraint                                                                                                                                                        |
| <code>BOOTROM_ERROR_INVALID_ARG</code>   | -5       | One or more parameters passed to the function is outside the range of supported values;<br><code>BOOTROM_ERROR_INVALID_ADDRESS</code> and <code>BOOTROM_ERROR_BAD_ALIGNMENT</code> are more specific errors. |

```
uint32_t rom_table_code(char c1, char c2) {
 return (c2 << 8) | c1;
}
```

这些代码也可在 [SDK](#) 中的 `bootrom.h` 文件中以 `#define` 形式获得。

### 5.4.2. API 函数可用性

某些函数并非所有架构或安全级别均支持。第5.4.6节的 API 列表采用以下术语标明各个 API 入口点的可用性：

#### Arm-S

该函数适用于安全 Arm 代码。除专门涉及 RISC-V 或非安全功能外，大多数函数对 [Arm-S](#) 均可用。

#### RISC-V

该函数适用于 RISC-V 代码。除专门涉及 Arm 安全状态外，大多数在 [Arm-S](#) 下可用的函数在 RISC-V 下也适用。

#### Arm-NS

该函数适用于非安全 Arm 代码。该函数在此情况下执行额外的权限和参数检查，以防止安全数据泄露或损坏。

每个单独的 [Arm-NS](#) API 函数必须由 Secure 代码显式启用后方可使用，方法是调用 `set_ns_api_permission()`。若被 Secure 代码禁用，禁用的非安全 API 将返回 `BOOTROM_ERROR_NOT_PERMITTED`。所有非安全 API 初始状态均为禁用。非安全代码调用仅限 Secure 的 Arm-S 函数时无权限控制，但此类调用在尝试访问仅限 Secure 的硬件时将导致崩溃。

通过 Secure Gateway (SG) 指令，[Arm-NS](#) 函数可提升调用权限，允许非安全代码对名义上仅限 Secure 的硬件执行有限操作，例如用于闪存编程的 QSPI 直通模式接口。

对于 [RISC-V](#) 函数而言，基于特权级别无单独入口点。假设在 PMP 中拥有 ROM 地址的执行权限，M 模式和 U 模式软件均可调用 bootrom API，但若 U 模式调用尝试访问仅限 M 模式的硬件，则会导致崩溃。

### 5.4.3. API 函数返回码

某些函数不支持返回任何错误，标记为 `void`。其余返回值为 0 (`BOOTROM_OK`) 或正值 (如需返回数据) 表示成功。这些 bootrom 错误代码与 SDK 使用的错误代码完全相同，故可互换使用。这解释了 SDK 错误代码编号中未被 bootrom 使用的编号间隙。

| 名称                                       | 值        | 描述                                                                                                                    |
|------------------------------------------|----------|-----------------------------------------------------------------------------------------------------------------------|
| 值                                        | $\geq 0$ | 函数成功执行，返回该值                                                                                                           |
| <code>BOOTROM_OK</code>                  | 0        | 函数执行成功                                                                                                                |
| <code>BOOTROM_ERROR_NOT_PERMITTED</code> | -4       | 该操作因安全约束被禁止                                                                                                           |
| <code>BOOTROM_ERROR_INVALID_ARG</code>   | -5       | 传递给函数的一个或多个参数超出支持范围；<br><code>BOOTROM_ERROR_INVALID_ADDRESS</code> 和 <code>OOTROM_ERROR_BAD_ALIGNMENT</code> 为更具体的错误。 |

| Name                                   | Value | Description                                                                                                            |
|----------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------|
| BOOTROM_ERROR_INVALID_ADDRESS          | -10   | An address argument was out-of-bounds or was determined to be an address that the caller may not access.               |
| BOOTROM_ERROR_BAD_ALIGNMENT            | -11   | An address passed to the function was not correctly aligned.                                                           |
| BOOTROM_ERROR_INVALID_STATE            | -12   | Something happened or failed to happen in the past, and consequently the request cannot currently be serviced.         |
| BOOTROM_ERROR_BUFFER_TOO_SMALL         | -13   | A user-allocated buffer was too small to hold the result or working state of the function.                             |
| BOOTROM_ERROR_PRECONDITION_NOT_MET     | -14   | The call failed because another bootrom function must be called first.                                                 |
| BOOTROM_ERROR_MODIFIED_DATA            | -15   | Cached data was determined to be inconsistent with the full version of the data it was copied from.                    |
| BOOTROM_ERROR_INVALID_DATA             | -16   | The contents of a data structure are invalid                                                                           |
| BOOTROM_ERROR_NOT_FOUND                | -17   | An attempt was made to access something that does not exist; or, a search failed.                                      |
| BOOTROM_ERROR_UNSUPPORTED_MODIFICATION | -18   | Modification is impossible based on current state. This might occur, for example, when attempting to clear an OTP bit. |
| BOOTROM_ERROR_LOCK_REQUIRED            | -19   | A required lock is not owned. See <a href="#">Section 5.4.4</a> .                                                      |

#### 5.4.4. API functions and exclusive access

Various bootrom functions require access to parts of the system which:

- cannot be safely accessed by both cores at once, or
- limit the functionality of other hardware when in use

For example:

- Programming OTP: it is not possible to read from the memory mapped OTP data regions at the same time as accessing its serial programming interface.
- Use of the SHA-256 block: only one SHA-256 sum can be in progress at a time.
- Using the QSPI direct-mode interface to program the flash causes XIP access to return a bus fault.

It is beyond the purview of the bootrom to implement a locking strategy, as the style and scope of the locking required is entirely up to how the application itself uses these resources.

Nevertheless, it is important that, say, a Non-secure call to a flash programming API can't cause a hard fault in other Secure code running from flash. There must be some way for user software to coordinate with bootrom APIs on such changes of state. The bootrom implements the **mechanism** but not the **policy** for mutual exclusion over bootrom API calls.

The solution the bootrom provides is to use the boot locks (boot RAM registers `BOOTLOCK0` through `BOOTLOCK7`) to inform the bootrom which resources are currently owned by the caller and therefore safe for it to use.

To enable lock checking in bootrom APIs, set boot lock 7 (`LOCK_ENABLE`) to the claimed state. When enabled, bootrom functions which use certain hardware resources (listed below) will check the status of the boot lock assigned to that resource, and return `BOOTROM_ERROR_LOCK_REQUIRED` if that lock is not in the claimed state.

Before calling a bootrom function with locking enabled, you must claim the relevant locks. It may take multiple attempts

| 名称                                     | 值   | 描述                                       |
|----------------------------------------|-----|------------------------------------------|
| BOOTROM_ERROR_INVALID_ADDRESS          | -10 | 地址参数越界，或被判定为调用者无权访问的地址。                  |
| BOOTROM_ERROR_BAD_ALIGNMENT            | -11 | 传入地址未正确对齐。                               |
| BOOTROM_ERROR_INVALID_STATE            | -12 | 过去发生或未发生某事，因而请求当前无法处理。                   |
| BOOTROM_ERROR_BUFFER_TOO_SMALL         | -13 | 用户分配的缓冲区过小，无法容纳函数的结果或工作状态。               |
| BOOTROM_ERROR_PRECONDITION_NOT_MET     | -14 | 调用失败，因为必须先调用另一个只读存储器函数。                  |
| BOOTROM_ERROR_MODIFIED_DATA            | -15 | 缓存的数据被判定与其复制的完整版本数据不一致。                  |
| BOOTROM_ERROR_INVALID_DATA             | -16 | 数据结构内容无效。                                |
| BOOTROM_ERROR_NOT_FOUND                | -17 | 尝试访问不存在的对象；或者，搜索失败。                      |
| BOOTROM_ERROR_UNSUPPORTED_MODIFICATION | -18 | 基于当前状态，无法进行修改。此情况可能发生于尝试清除一次性可编程（OTP）位时。 |
| BOOTROM_ERROR_LOCK_REQUIRED            | -19 | 所需的锁未被持有。详见第5.4.4节。                      |

#### 5.4.4. API 函数与独占访问权限

各种只读存储器函数需要访问系统的部分区域，这些区域：

- 不可由两个核心同时安全访问，或者
- 使用时会限制其他硬件的功能。

例如：

- 编程一次性可编程（OTP）：无法在访问映射的OTP数据区域的同时访问其串行编程接口。
- 使用SHA-256模块：一次只能进行一项SHA-256校验和操作。
- 使用QSPI直接模式接口对闪存进行编程会导致XIP访问返回总线错误。

启动只读存储器程序的职责范围不包括实现锁定策略，因锁定的类型和范围完全取决于应用程序对这些资源的具体使用方式。

然而，重要的是，例如非安全调用闪存编程API时，不应引起运行于闪存中的其他安全代码发生硬故障。用户软件必须具备某种方式与启动只读存储器程序API在状态变更时进行协调。启动只读存储器程序实现了机制但不负责制定策略以实现对启动只读存储器程序API调用的互斥访问。

启动只读存储器程序提供的解决方案是利用启动锁（启动RAM寄存器BOOTLOCK0至BOOTLOCK7）告知启动程序当前哪些资源归调用者所有，从而可安全使用。

要启用启动只读存储器程序API中的锁检测，请将启动锁 7 (`LOCK_ENABLE`) 设置为申明状态。启用后，使用某些硬件资源（如下所列）的 bootrom 函数将检查分配给该资源的启动锁状态，如果该锁不处于声明状态，则返回`BOOTROM_ERROR_LOCK_REQUIRED`。

在调用启用锁定的 bootrom 函数前，必须先声明相关锁。可能需要多次尝试

to claim if the API is concurrently accessed from other contexts. Follow the same steps as the SIO spinlocks ([Section 3.1.4](#)) to claim a lock.

The following boot locks are assigned:

- `0x0 : LOCK_SHA_256` - if owned, then a bootrom API is allowed to use the SHA-256 block
- `0x1 : LOCK_FLASH_OP` - if owned, then a bootrom API is allowed to enter direct mode on the QSPI memory interface ([Section 12.14.5](#)) in order to perform low-level flash operations
- `0x2 : LOCK OTP` - if owned, then a bootrom API is allowed to access OTP via the serial interface
- `0x7 : LOCK_ENABLE` - if owned, then bootrom API resource ownership checking is enabled. This is off by default, since the bootrom APIs aim to be usable by default without additional setup.

#### 5.4.5. SDK access to the API

Bootrom functions are exposed in the SDK via the `pico_bootrom` library (see [pico\\_bootrom](#)).

Each bootrom function has a `rom_` wrapper function that looks up the bootrom function address and calls it.

The SDK provides a simple implementation of exclusive access via `bootrom_acquire_lock_blocking(n)` and `bootrom_release_lock(n)`. When enabled, as it is by default (`PICO_BOOTROM_LOCKING_ENABLED=1` is defined) the SDK enables bootrom locking via `LOCK_ENABLE`, and these two functions use the other `SHA_256/FLASH_OP/OTP` boot locks to take ownership of/release ownership of the corresponding bootrom resource.

The `rom_` wrapper functions the SDK call `bootrom_acquire_lock_locking` and `bootrom_relead_lock` functions around bootrom calls that have locking requirements.

#### 5.4.6. Categorised list of API functions and ROM data

The terms in parentheses after each function name ([Arm-S](#), [Arm-NS](#), [RISC-V](#)) indicate the architecture and security state combinations where that API is available:

- [Arm-S](#): Arm processors running in the Secure state
- [Arm-NS](#): Arm processors running in the Non-secure state
- [RISC-V](#): RISC-V processors

See [Section 5.4.2](#) for the full definitions of these terms.

List entries ending with parentheses, such as `flash_op()`, are callable functions. List entries without parentheses, such as `git_revision`, are pointers to ROM data locations.

##### 5.4.6.1. Low-level Flash access

These low-level (Secure-only) flash access functions are similar to the ones on RP2040:

- `connect_internal_flash()` ([Arm-S](#), [RISC-V](#))
- `flash_enter_cmd_xip()` ([Arm-S](#), [RISC-V](#))
- `flash_exit_xip()` ([Arm-S](#), [RISC-V](#))
- `flash_flush_cache()` ([Arm-S](#), [RISC-V](#))
- `flash_range_erase()` ([Arm-S](#), [RISC-V](#))
- `flash_range_program()` ([Arm-S](#), [RISC-V](#))

These are new with RP2350:

才能成功声明锁，尤其当该 API 被其他上下文并发访问时。声明锁时，请遵循与 SIO 自旋锁（第3.1.4节）相同的步骤。

以下启动锁已被分配：

- `0x0 : LOCK_SHA_256` - 拥有该锁时，bootrom API 允许使用 SHA-256 模块
- `0x1 :LOCK_FLASH_OP` - 拥有该锁时，bootrom API 允许在 QSPI 存储接口（第12.14.5节）进入直接模式，以执行低级闪存操作
- `0x2 :LOCK OTP` - 拥有该锁时，bootrom API 允许通过串行接口访问 OTP
- `0x7 :LOCK_ENABLE` - 若拥有，则启用只读存储器API资源所有权检查。此项默认关闭，因为只读存储器API旨在默认即可使用，无需额外设置。

### 5.4.5. SDK 对 API 的访问

只读存储器功能通过`pico_bootrom`库（详见`pico_bootrom`）在SDK中提供。

每个只读存储器函数均有`rom_`包装函数，该函数查找只读存储器函数地址并进行调用。

SDK通过`bootrom_acquire_lock_blocking(n)`和`bootrom_release_lock(n)`实现了简易的独占访问控制。默认启用时（定义了`PICO_BOOTROM_LOCKING_ENABLED=1`），SDK通过`LOCK_ENABLE`启用只读存储器锁定，这两个函数利用其他`SHA_256/FLASH_OP/OTP`只读存储器锁来获取或释放对应只读存储器资源的所有权。

SDK中的`rom_`包装函数在对具备锁定需求的只读存储器函数调用时，会在前后分别调用`bootrom_acquire_lock_blocking`和`bootrom_release_lock`函数。

### 5.4.6. API函数及只读存储器数据的分类列表

每个函数名称后括号中的术语（`Arm-S`、`Arm-NS`、`RISC-V`）指示该API可用的架构及安全状态组合：

- `Arm-S`：运行于安全状态下的Arm处理器
- `Arm-NS`：运行于非安全状态下的Arm处理器
- `RISC-V`：RISC-V处理器

有关这些术语的完整定义，请参见第5.4.2节。

以括号结尾的列表项，例如`flash_op()`，表示可调用函数。不带括号的列表项，例如`git_revision`，表示指向只读存储器数据位置的指针。

#### 5.4.6.1 低级Flash访问

这些低级（仅限安全状态）Flash访问函数与RP2040上的类似：

- `connect_internal_flash()` (`Arm-S`、`RISC-V`)
- `flash_enter_cmd_xip()` (`Arm-S`、`RISC-V`)
- `flash_exit_xip()` (`Arm-S`、`RISC-V`)
- `flash_flush_cache()` (`Arm-S`, `RISC-V`)
- `flash_range_erase()` (`Arm-S`, `RISC-V`)
- `flash_range_program()` (`Arm-S`, `RISC-V`)

`-V`）这是 RP2350 新增的：

- [flash\\_reset\\_address\\_trans\(\)](#) (Arm-S, RISC-V)
- [flash\\_select\\_xip\\_read\\_mode\(\)](#) (Arm-S, RISC-V)

#### 5.4.6.2. High-level flash access

The higher level access functions, provide functionality that is safe to expose (with permissions) to Non-secure code as well.

- [flash\\_op\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [flash\\_runtime\\_to\\_storage\\_addr\(\)](#) (Arm-S, Arm-NS, RISC-V)

#### 5.4.6.3. System information

- [flash\\_devinfo16\\_ptr\(\)](#) (Arm-S, RISC-V)
- [get\\_partition\\_table\\_info\(\)](#) (Arm-S, Arm-NS RISC-V)
- [get\\_sys\\_info\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [git\\_revision](#) (Arm-S, Arm-NS, RISC-V)

#### 5.4.6.4. Partition tables

- [get\\_b\\_partition\(\)](#) (Arm-S, RISC-V)
- [get\\_uf2\\_target\\_partition\(\)](#) (Arm-S, RISC-V)
- [pick\\_ab\\_partition\(\)](#) (Arm-S, RISC-V)
- [partition\\_table\\_ptr](#) (Arm-S, RISC-V)
- [load\\_partition\\_table\(\)](#) (Arm-S, RISC-V)

#### 5.4.6.5. Bootrom memory and state

- [set\\_bootrom\\_stack\(\)](#) (RISC-V)
- [xip\\_setup\\_func\\_ptr](#) (Arm-S, RISC-V)
- [bootrom\\_state\\_reset\(\)](#) (Arm-S, RISC-V)

#### 5.4.6.6. Executable image management

- [chain\\_image\(\)](#) (Arm-S, RISC-V)
- [\(explicit\\_buy\(\)\)](#) (Arm-S, RISC-V)

#### 5.4.6.7. Security

These Secure-only functions control access for Non-secure code:

- [set\\_ns\\_api\\_permission\(\)](#) (Arm-S)
- [set\\_rom\\_callback\(\)](#) (Arm-S, RISC-V)
- [validate\\_ns\\_buffer\(\)](#) (Arm-S, RISC-V)

- [flash\\_reset\\_address\\_trans\(\)](#) (Arm-S, RISC-V)
- [flash\\_select\\_xip\\_read\\_mode\(\)](#) (Arm-S, RISC-V)

#### 5.4.6.2. 高级闪存访问

更高层次的访问函数，提供在授权许可下对非安全代码暴露的安全功能。

- [flash\\_op\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [flash\\_runtime\\_to\\_storage\\_addr\(\)](#) (Arm-S, Arm-NS, RISC-V)

#### 5.4.6.3. 系统信息

- [flash\\_devinfo16\\_ptr\(\)](#) (Arm-S, RISC-V)
- [get\\_partition\\_table\\_info\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [get\\_sys\\_info\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [git\\_revision\(\)](#) (Arm-S, Arm-NS, RISC-V)

#### 5.4.6.4. 分区表

- [get\\_b\\_partition\(\)](#) (Arm-S, RISC-V)
- [get\\_uf2\\_target\\_partition\(\)](#) (Arm-S, RISC-V)
- [pick\\_ab\\_partition\(\)](#) (Arm-S, RISC-V)
- [partition\\_table\\_ptr\(\)](#) (Arm-S, RISC-V)
- [load\\_partition\\_table\(\)](#) (Arm-S, RISC-V)

#### 5.4.6.5. Bootrom 只读存储器及状态

- [set\\_bootrom\\_stack\(\)](#) (RISC-V)
- [xip\\_setup\\_func\\_ptr\(\)](#) (Arm-S, RISC-V)
- [bootrom\\_state\\_reset\(\)](#) (Arm-S, RISC-V)

#### 5.4.6.6. 可执行镜像管理

- [chain\\_image\(\)](#) (Arm-S, RISC-V)
- [\(explicit\\_buy\(\)\)](#) (Arm-S, RISC-V)

#### 5.4.6.7. 安全性

这些仅限安全的函数用于控制非安全代码的访问权限：

- [set\\_ns\\_api\\_permission\(\)](#) (Arm-S)
- [set\\_rom\\_callback\(\)](#) (Arm-S, RISC-V)
- [validate\\_ns\\_buffer\(\)](#) (Arm-S, RISC-V)

### 5.4.6.8. Miscellaneous

These functions are provided to all platforms and security levels, but perform additional checks when called from Non-secure Arm code:

- [reboot\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [otp\\_access\(\)](#) (Arm-S, Arm-NS, RISC-V)

### 5.4.6.9. Non-secure only

- [secure\\_call\(\)](#) (Arm-NS)

### 5.4.6.10. Bit manipulation

Unlike RP2040, the bootrom doesn't contain bit manipulation functions. Processors on RP2350 implement hardware instructions for these operations which are far faster than the software implementations in the RP2040 bootrom.

### 5.4.6.11. Memcpy and Memset

Unlike RP2040, the bootrom doesn't provide memory copy or clearing functions, as your language runtime is expected to already provide well-performing implementations of these on Cortex-M33 or Hazard3.

The bootrom does contain private implementations of standard C [memcpy\(\)](#) and [memset\(\)](#), for both Arm and RISC-V, but these are optimised for size rather than performance. They are not exported in the ROM table.

### 5.4.6.12. Floating point

Unlike RP2040 the bootrom doesn't contain functions for floating point arithmetic. On Arm there is standard processor support for single-precision arithmetic via the Cortex-M FPU, and RP2350 provides an Arm coprocessor which dramatically accelerates double-precision arithmetic (the DCP, [Section 3.6.2](#)). The SDK defaults to the most performant hardware or software implementation available.

## 5.4.7. Alphabetical list of API functions and ROM data

- [bootrom\\_state\\_reset\(\)](#) (Arm-S, RISC-V)
- [chain\\_image\(\)](#) (Arm-S, RISC-V)
- [connect\\_internal\\_flash\(\)](#) (Arm-S, RISC-V)
- [flash\\_devinfo16\\_ptr\(\)](#) (Arm-S, RISC-V)
- [flash\\_enter\\_cmd\\_xip\(\)](#) (Arm-S, RISC-V)
- [flash\\_exit\\_xip\(\)](#) (Arm-S, RISC-V)
- [flash\\_flush\\_cache\(\)](#) (Arm-S, RISC-V)
- [flash\\_op\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [flash\\_range\\_erase\(\)](#) (Arm-S, RISC-V)
- [flash\\_range\\_program\(\)](#) (Arm-S, RISC-V)
- [flash\\_reset\\_address\\_trans\(\)](#) (Arm-S, RISC-V)
- [flash\\_runtime\\_to\\_storage\\_addr\(\)](#) (Arm-S, Arm-NS, RISC-V)

### 5.4.6.8. 其他

这些函数适用于所有平台及安全级别，但当由非安全Arm代码调用时，会执行额外的检查：

- [reboot\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [otp\\_access\(\)](#) (Arm-S, Arm-NS, RISC-V)

### 5.4.6.9. 仅限非安全

- [secure\\_call\(\)](#) (Arm-NS)

### 5.4.6.10. 位操作

与RP2040不同，bootrom不包含位操作函数。RP2350 上的处理器实现了这些操作的硬件指令，其速度远远超过 RP2040 只读存储器中软件实现的版本。

### 5.4.6.11. Memcpy 和 Memset

与 RP2040 不同，只读存储器不提供内存复制或清零函数，因为您的语言运行时预计已在 Cortex-M33 或 Hazard3 上提供了高性能实现。

只读存储器确实包含了标准 C [memcpy\(\)](#) 和 [memset\(\)](#) 的私有实现，适用于 Arm 和 RISC-V，但这些实现优化的是体积而非性能。它们未在只读存储器表中导出。

### 5.4.6.12. 浮点

与 RP2040 不同，只读存储器不包含浮点算术函数。在 Arm 架构上，Cortex-M FPU 提供了对单精度算术的标准处理器支持，RP2350 提供了一个 Arm 协处理器，大幅加速双精度算术（DCP，第 3.6.2 节）。SDK 默认选择性能最佳的硬件或软件实现。

## 5.4.7. API函数及只读存储器数据的字母顺序列表

- [bootrom\\_state\\_reset\(\)](#) (Arm-S, RISC-V)
- [chain\\_image\(\)](#) (Arm-S, RISC-V)
- [connect\\_internal\\_flash\(\)](#) (Arm-S、 RISC-V)
- [flash\\_devinfo16\\_ptr](#) (Arm-S, RISC-V)
- [flash\\_enter\\_cmd\\_xip\(\)](#) (Arm-S、 RISC-V)
- [flash\\_exit\\_xip\(\)](#) (Arm-S、 RISC-V)
- [flash\\_flush\\_cache\(\)](#) (Arm-S, RISC-V)
- [flash\\_op\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [flash\\_range\\_erase\(\)](#) (Arm-S, RISC-V)
- [flash\\_range\\_program\(\)](#) (Arm-S, RISC-V)
- [flash\\_reset\\_address\\_trans\(\)](#) (Arm-S, RISC-V)
- [flash\\_runtime\\_to\\_storage\\_addr\(\)](#) (Arm-S, Arm-NS, RISC-V)

- [flash\\_select\\_xip\\_read\\_mode\(\)](#) (Arm-S, RISC-V)
- [get\\_b\\_partition\(\)](#) (Arm-S, RISC-V)
- [get\\_partition\\_table\\_info\(\)](#) (Arm-S, Arm-NS RISC-V)
- [get\\_sys\\_info\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [get\\_uf2\\_target\\_partition\(\)](#) (Arm-S, RISC-V)
- [git\\_revision](#) (Arm-S, Arm-NS, RISC-V)
- [load\\_partition\\_table\(\)](#) (Arm-S, RISC-V)
- [otp\\_access\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [partition\\_table\\_ptr](#) (Arm-S, RISC-V)
- [pick\\_ab\\_partition\(\)](#) (Arm-S, RISC-V)
- [reboot\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [secure\\_call\(\)](#) (Arm-NS)
- [set\\_bootrom\\_stack\(\)](#) (RISC-V)
- [set\\_ns\\_api\\_permission\(\)](#) (Arm-S)
- [set\\_rom\\_callback\(\)](#) (Arm-S, RISC-V)
- [validate\\_ns\\_buffer\(\)](#) (Arm-S, RISC-V)
- [xip\\_setup\\_func\\_ptr](#) (Arm-S, RISC-V)

## 5.4.8. API function listings

### 5.4.8.1. bootrom\_state\_reset

Code: 'S','R'

Signature: `void bootrom_state_reset(uint32_t flags)`

Supported architectures: Arm-S, RISC-V

Resets internal bootrom state, based on the following flags:

- `0x0001 : STATE_RESET_CURRENT_CORE` - Resets any internal bootrom state for the current core to a known state. This method should be called prior to calling any other bootrom APIs on the current core, and is called automatically by the bootrom during normal boot of core 0 or launch of code on core 1.
- `0x0002 : STATE_RESET_OTHER_CORE` - Resets any internal bootrom state for the other core into a clean state. This is generally called by a debugger when resetting the state of one core via code running on the other.
- `0x0004 : STATE_RESET_GLOBAL_STATE` - Resets all non core-specific state, including:
  - Disables access to bootrom APIs from Arm-NS (see also [set\\_ns\\_api\\_permission\(\)](#)).
  - Unlocks all boot locks ([Section 5.4.4](#)).
  - Clears any Secure code callbacks. (see also [set\\_rom\\_callback\(\)](#))

Note that the SDK calls this method on runtime initialisation to put the boot RO into a known state. This allows the program to function correctly if it is entered via a debugger, or otherwise without taking the usual boot path through the bootrom, which itself would reset the state.

- [flash\\_select\\_xip\\_read\\_mode\(\)](#) (Arm-S, RISC-V)
- [get\\_b\\_partition\(\)](#) (Arm-S, RISC-V)
- [get\\_partition\\_table\\_info\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [get\\_sys\\_info\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [get\\_uf2\\_target\\_partition\(\)](#) (Arm-S, RISC-V)
- [git\\_revision](#) (Arm-S, Arm-NS, RISC-V)
- [load\\_partition\\_table\(\)](#) (Arm-S, RISC-V)
- [otp\\_access\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [partition\\_table\\_ptr](#) (Arm-S, RISC-V)
- [pick\\_ab\\_partition\(\)](#) (Arm-S, RISC-V)
- [reboot\(\)](#) (Arm-S, Arm-NS, RISC-V)
- [secure\\_call\(\)](#) (Arm-NS)
- [set\\_bootrom\\_stack\(\)](#) (RISC-V)
- [set\\_ns\\_api\\_permission\(\)](#) (Arm-S)
- [set\\_rom\\_callback\(\)](#) (Arm-S, RISC-V)
- [validate\\_ns\\_buffer\(\)](#) (Arm-S, RISC-V)
- [xip\\_setup\\_func\\_ptr](#) (Arm-S, RISC-V)

## 5.4.8. API函数清单

### 5.4.8.1. bootrom\_state\_reset

代码: 'S', 'R'

函数签名: void bootrom\_state\_reset(uint32\_t flags)

支持的架构: Arm-S, RISC-V

根据以下标志重置内部只读存储器状态:

- **0x0001 :STATE\_RESET\_CURRENT\_CORE-** 将当前核心的任何内部只读存储器状态重置为已知状态。该方法应在调用当前核心上的其他只读存储器API之前调用，并且在核心0正常启动或核心1代码启动时由只读存储器自动调用。
- **0x0002 :STATE\_RESET\_OTHER\_CORE-** 将另一个核心的所有内部只读存储器状态重置为干净状态。通常由调试器在通过另一个核心上运行的代码重置某个核心状态时调用。
- **0x0004 : STATE\_RESET\_GLOBAL\_STATE -** 重置所有非核心特定状态，包括：
  - 禁用来自Arm-NS的bootrom API访问（另见 set\_ns\_api\_permission()）。
  - 解锁所有启动锁（第5.4.4节）。
  - 清除所有安全代码回调。（另见 set\_rom\_callback()）

请注意，SDK在运行时初始化阶段调用此方法，以将启动只读存储器置于已知状态。此举允许程序在通过调试器进入，或未经过通常通过bootrom的启动路径时，仍能正确运行，因为后者自身会重置状态。

#### 5.4.8.2. `chain_image`

Code: 'C','I'

Signature: `int chain_image(uint8_t *workarea_base, uint32_t workarea_size, int32_t region_base, uint32_t region_size)`

Supported architectures: Arm-S, RISC-V. Note on RISC-V this function may require additional stack; see [Section 5.4.8.26](#).

Returns: `BOOTROM_OK` (0) on success, or a negative error code on error.

Searches a memory region for a launchable image, and executes it if possible.

The `region_base` and `region_size` specify a word-aligned, word-multiple-sized area of RAM, XIP RAM or flash to search. The first 4 kB of the region must contain the start of a block loop with an `IMAGE_DEF`. If the new image is launched, the call does not return otherwise an error is returned.

The `region_base` is signed, as a negative value can be passed, which indicates that the (negated back to positive value) is *both* the `region_base` and the base of the "flash update" region.

This method potentially requires similar complexity to the boot path in terms of picking amongst versions, checking signatures etc. As a result it requires a user provided memory buffer as a work area. The work area should be word aligned, and of sufficient size or `BOOTROM_ERROR_BAD_ALIGNMENT` / `BOOTROM_ERROR_INSUFFICIENT_RESOURCES` will be returned. The work area size currently required is 3064, so 3 kB is a good choice.

This method is primarily expected to be used when implementing bootloaders.

##### NOTE

When chaining into an image, the `BOOT_FLAGS0.ROLLBACK_REQUIRED` flag will not be set, to prevent invalidating a bootloader without a rollback version by booting a binary which has one (see [Section 5.10.8](#)).

#### 5.4.8.3. `connect_internal_flash`

Code: 'I','F'

Signature: `void connect_internal_flash(void)`

Supported architectures: Arm-S, RISC-V

Restores all QSPI pad controls to their default state, and connects the QMI peripheral to the QSPI pads.

If a secondary flash chip select GPIO has been configured via OTP `FLASH_DEvinfos`, or by writing to the runtime copy of `FLASH_DEvinfos` in boot RAM, then this bank 0 GPIO is also initialised and the QMI peripheral is connected. Otherwise, bank 0 IOs are untouched.

#### 5.4.8.4. `explicit_buy`

Code: 'E','B'

Signature: `int explicit_buy(uint8_t *buffer, uint32_t buffer_size)`

Supported architectures: Arm-S RISC-V

Returns: `BOOTROM_OK` (0) on success, negative error code on error.

Perform an "explicit buy" of an executable launched via an `IMAGE_DEF` which was TBYB ([Section 5.1.17](#)) flagged. A "flash update" boot of such an image is a way to have the image execute once, but only become the "current" image if it safely calls back into the bootrom via this call.

This call may perform the following:

- Erase and rewrite the part of flash containing the TBYB flag in order to clear said flag.

### 5.4.8.2. chain\_image

代码: 'C', 'I'

函数签名: `int chain_image(uint8_t *workarea_base, uint32_t workarea_size, int32_t region_base, uint32_t region_size)`

支持架构: Arm-S, RISC-V。关于RISC-V的说明: 此函数可能需要额外的栈空间; 详见第5.4.8.26节。

返回值: 成功时返回`BOOTROM_OK(0)`, 失败时返回负错误代码。

搜索指定内存区域中的可启动映像, 并在条件允许时执行该映像。

`region_base`和`region_size`指定一个字对齐、大小为字倍数的RAM、XIP RAM或闪存区域以供搜索。

该区域的前4 kB必须包含带有`IMAGE_DEF`的块循环起始部分。若新映像被启动, 该调用不会返回, 否则将返回错误。

`region_base`为有符号值, 可传入负值, 该负值取反后表示既是`region_base`, 也是“闪存更新”区域的基址。

此方法在版本选择与签名校验等方面具备与引导路径类似的复杂性, 因此需要用户提供的内存缓冲区作为工作区。工作区应按字对齐且具备足够大小, 否则将返回`BOOTROM_ERROR_BAD_ALIGNMENT`或`BOOTROM_ERROR_INSUFFICIENT_RESOURCES`错误。当前所需的工作区大小为3064, 因此3 kB是合适的选择。

此方法主要预期用于实现引导加载程序时。

#### ① 注意

在链入映像时, `BOOT_FLAGS0.ROLLBACK_REQUIRED` 标志不会被设置, 以防止通过启动具有回滚版本的二进制文件使无回滚版本的引导加载程序失效 (详见第5.10.8节)。

### 5.4.8.3. connect\_internal\_flash

代码: 'I', 'F'

函数签名: `void connect_internal_flash(void)`

支持的架构: Arm-S, RISC-V

将所有QSPI引脚控制恢复到默认状态, 并将QMI外设连接至QSPI引脚。

如果通过OTP FLASH\_DEVINFO配置了次级闪存芯片选择GPIO, 或通过写入引导RAM中FLASH\_DEVINFO的运行时副本进行了配置, 则该bank 0的GPIO也将被初始化, 且QMI外设被连接。否则, bank 0的IO保持不变。

### 5.4.8.4. explicit\_buy

代码: 'E', 'B'

签名: `int explicit_buy(uint8_t *buffer, uint32_t buffer_size)`

支持的架构: Arm-S RISC-V

返回值: `BOOTROM_OK(0)` 表示成功, 出错时返回负错误代码。

对通过`IMAGE_DEF`启动且带有TBYB (第5.1.17节) 标记的可执行文件执行“显式购买”。对该映像执行“闪存更新”启动是一种仅运行映像一次的方式, 但只有当其通过此调用安全回调引导只读存储器时, 才会成为“当前”映像。

该调用可能执行以下操作:

- 擦除并重写包含TBYB标记的闪存区域以清除此标记。

- Erase the first sector of the other partition in an A/B partition scenario, if this new `IMAGE_DEF` is a version downgrade (so this image will boot again when not doing a normal boot)
- Update the rollback version in OTP if the chip is secure, and a rollback version is present in the image.

The first of the above requires 4 kB of scratch space, so you should pass a word aligned buffer of at least 4 kB to this method in this case, or `BOOTROM_ERROR_BAD_ALIGNMENT` / `BOOTROM_ERROR_INSUFFICIENT_RESOURCES` will be returned.

The device might reboot while updating the rollback version if multiple rollback rows need to be written. This occurs when the version crosses a multiple of 24 (for example, upgrading from version 23 to 25 requires a reboot, but 23 to 24 or 24 to 25 doesn't). The application must therefore be prepared to reboot when calling this function if rollback versions are in use.

#### 5.4.8.5. `flash_devinfo16_ptr`

Code: `'F','D'`

Type: `uint16_t *flash_devinfo16_ptr`

Pointer to the flash device info used by the flash APIs, for example, for bounds checking against size of flash devices, and configuring the GPIO used for secondary QSPI chip select.

If `BOOT_FLAGS0.FLASH_DEVINFO_ENABLE` is set, this boot RAM location is initialised from `FLASH_DEVINFO` at startup, otherwise it is initialised to:

- Chip select 0 size: 16 MB
- Chip select 1 size: 0 bytes
- No chip select 1 GPIO
- No D8h erase command support

The flash APIs use this boot RAM copy of `FLASH_DEVINFO`, so flash device info can be updated by Secure code at runtime by writing through this pointer.

#### 5.4.8.6. `flash_enter_cmd_xip`

Code: `'C','X'`

Signature: `void flash_enter_cmd_xip(void)`

Supported architectures: `Arm-S, RISC-V`

Compatibility alias for `flash_select_xip_read_mode(0, 12);`

Configure the QMI to generate a standard `03h` serial read command, with 24 address bits, upon each XIP access. This is a slow XIP configuration, but is widely supported. CLKDIV is set to 12. The debugger may call this function to ensure that flash is readable following a program/erase operation.

Note that the same setup is performed by `flash_exit_xip()`, and the RP2350 flash program/erase functions do not leave XIP in an inaccessible state, so calls to this function are largely redundant. It is provided for compatibility with RP2040.

#### 5.4.8.7. `flash_exit_xip`

Code: `'E','X'`

Signature: `void flash_exit_xip(void)`

Supported architectures: `Arm-S, RISC-V`

Initialise the QMI for serial operations (direct mode), and also initialise a basic XIP mode, where the QMI will perform `03h` serial read commands at low speed (CLKDIV=12) in response to XIP reads.

- 若此新 `IMAGE_DEF` 为版本降级，则在 A/B 分区方案中擦除另一分区的首个扇区，  
(使该映像在非正常启动时能够再次启动)
- 若芯片为安全芯片且映像中包含回滚版本，则更新 OTP 中的回滚版本。

上述第一个示例需要 4 kB 的临时缓冲区，因此在此情况下，应向此方法传递至少 4 kB 的字对齐缓冲区，否则将返回 `BOOTROM_ERROR_BAD_ALIGNMENT /BOOTROM_ERROR_INSUFFICIENT_RESOURCES`。

如果需要写入多个回滚记录行，设备在更新回滚版本时可能会重启。此情况发生于版本号跨越 24 的倍数时（例如，从版本 23 升级到 25 需要重启，但 23 到 24 或 24 到 25 则不需要）。因此，若使用回滚版本，应用程序必须准备在调用此函数时进行重启。

#### 5.4.8.5. `flash_devinfo16_ptr`

代码: 'F', 'D'

类型: `uint16_t *flash_devinfo16_ptr`

指向闪存设备信息的指针，该信息由闪存 API 使用，例如用于对闪存设备大小进行边界检查，以及配置用于次级 QSPI 片选的 GPIO 引脚。

如果 `BOOT_FLAGS0.FLASH_DEVINFO_ENABLE` 被设置，则此启动只读存储器位置将在启动时从 `FLASH_DEVINFO` 初始化，否则将初始化为：

- 芯片选择 0 大小：16 MB
- 芯片选择 1 大小：0 字节
- 无芯片选择 1 GPIO
- 不支持 D8h 擦除命令

闪存 API 使用此启动只读存储器中 `FLASH_DEVINFO` 的副本，因此安全代码可通过该指针在运行时更新闪存设备信息。

#### 5.4.8.6. `flash_enter_cmd_xip`

代码: 'C', 'X'

函数签名: `void flash_enter_cmd_xip(void)`

支持的架构: Arm-S, RISC-V

与 `flash_select_xip_read_mode(0, 12);` 的兼容别名。

配置 QMI 以在每次 XIP 访问时生成标准的 `03h` 串行读取命令，使用 24 位地址。这是较慢的 XIP 配置，但被广泛支持。CLKDIV 设置为 12。调试器可能会调用此函数，以确保程序/擦除操作后闪存可读。

请注意，`flash_exit_xip()` 也执行相同设置，且 RP2350 的闪存程序/擦除函数不会导致 XIP 处于无法访问状态，因此调用此函数通常是多余的。该函数为兼容 RP2040 而提供。

#### 5.4.8.7. `flash_exit_xip`

代码: 'E', 'X'

签名: `void flash_exit_xip(void)`

支持的架构: Arm-S, RISC-V

初始化 QMI 以支持串行操作（直接模式），并初始化基础 XIP 模式，在该模式下，QMI 会以低速（CLKDIV=12）执行 `03h` 串行读取命令以响应 XIP 读取。

Then, issue a sequence to the QSPI device on chip select 0, designed to return it from continuous read mode ("XIP mode") and/or QPI mode to a state where it will accept serial commands. This is necessary after system reset to restore the QSPI device to a known state, because resetting RP2350 does not reset attached QSPI devices. It is also necessary when user code, having already performed some continuous-read-mode or QPI-mode accesses, wishes to return the QSPI device to a state where it will accept the serial erase and programming commands issued by the bootrom's flash access functions.

If a GPIO for the secondary chip select is configured via `FLASH_DEVINFO`, then the XIP exit sequence is also issued to chip select 1.

The QSPI device should be accessible for XIP reads after calling this function; the name `flash_exit_xip` refers to returning the *QSPI* device from its XIP state to a serial command state.

#### 5.4.8.8. `flash_flush_cache`

Code: '`F`', '`C`'

Signature: `void flash_flush_cache(void)`

Supported architectures: `Arm-S, RISC-V`

Flush the entire XIP cache, by issuing an invalidate by set/way maintenance operation to every cache line ([Section 4.4.1](#)). This ensures that flash program/erase operations are visible to subsequent cached XIP reads.

Note that this unpins pinned cache lines, which may interfere with cache-as-SRAM use of the XIP cache.

No other operations are performed.

#### 5.4.8.9. `flash_op`

Code: '`F`', '`O`'

Signature: `int flash_op(uint32_t flags, uint32_t addr, uint32_t size_bytes, uint8_t *buf)`

Supported architectures: `Arm-S, Arm-NS, RISC-V`

Returns: `BOOTROM_OK` (0) on success, negative error code on error.

Perform a flash read, erase, or program operation. Erase operations must be sector-aligned (4096 bytes) and sector-multiple-sized, and program operations must be page-aligned (256 bytes) and page-multiple-sized; misaligned erase and program operations will return `BOOTROM_ERROR_BAD_ALIGNMENT`. The operation – erase, read, program – is selected by the `CFLASH_OP_BITS` bitfield of the `flags` argument:

`flags` is comprised of the following values:

| Address Translation (select one) |                                                                                                                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>0x00000000</code>          | No address translation; <code>addr</code> arg is the actual flash storage addresses.                                                                                                          |
| <code>0x00000001</code>          | Runtime address translation; <code>addr</code> arg is XIP memory address affected by address translation.                                                                                     |
| Security level (select one)      |                                                                                                                                                                                               |
| <code>0x00000100</code>          | Perform the operation using <i>secure</i> permissions. This is disallowed for a non-secure caller.                                                                                            |
| <code>0x00000200</code>          | Perform the operation using <i>non-secure</i> permissions.                                                                                                                                    |
| <code>0x00000300</code>          | Perform the operation using <i>boot-loader</i> permissions. This is disallowed for a non-secure caller.                                                                                       |
| Operation (select one)           |                                                                                                                                                                                               |
| <code>0x00000000</code>          | Erase <code>size_bytes</code> bytes of flash, starting at address <code>addr</code> . Both <code>addr</code> and <code>size_bytes</code> must be a multiple of 4096 bytes (one flash sector). |

然后，向芯片选择 0 上的 QSPI 设备发送一系列指令，旨在使其从连续读取模式（“XIP 模式”）和/或 QPI 模式恢复至可接受串行命令的状态。此步骤在系统复位后必不可少，以将 QSPI 设备恢复至已知状态，因为复位 RP2350 不会复位所连接的 QSPI 设备。当用户代码已执行若干连续读取模式或QPI模式访问后，若需将QSPI设备恢复至能接受引导只读存储器启动程序闪存访问功能发出的串行擦除及编程命令的状态，此操作亦属必要。

若通过`FLASH_DEVINFO`配置了辅助芯片选择的GPIO，则XIP退出序列亦将发送至芯片选择1。

调用此函数后，QSPI设备应可供XIP读取访问；名称`flash_exit_xip`表示将QSPI设备由XIP状态恢复至串行命令状态。

#### 5.4.8.8. `flash_flush_cache`

代码： '`F`'， '`C`'

函数签名： `void flash_flush_cache(void)`

支持的架构： `Arm-S, RISC-V`

通过对每条缓存行执行按组/路维护操作的失效操作（参见第4.4.1节），刷新整个XIP缓存，确保闪存编程与擦除操作对后续缓存的XIP读取生效。

请注意，此操作会解除固定的缓存行，可能会干扰XIP缓存作为SRAM的使用。

不执行其他任何操作。

#### 5.4.8.9. `flash_op`

代码： '`F`'， '`O`'

函数签名： `int flash_op(uint32_t flags, uint32_t addr, uint32_t size_bytes, uint8_t *buf)`

支持的架构： `Arm-S, Arm-NS, RISC-V`

返回值： `BOOTROM_OK(0)` 表示成功，出错时返回负错误代码。

执行闪存读取、擦除或编程操作。擦除操作必须扇区对齐（4096字节）且为扇区大小的整数倍，编程操作必须页对齐（256字节）且为页大小的整数倍；未对齐的擦除和编程操作将返回`BOOTROM_ERROR_BAD_ALIGNMENT`错误。通过`flags`参数中的`CFLASH_OP_BITS`位域选择操作类型——擦除、读取或编程：

`flags` 由以下值组成：

| 地址转换（请选择一项）             |                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>0x00000000</code> | 无地址转换； <code>addrarg</code> 是实际的闪存存储地址。                                                                                       |
| <code>0x00000001</code> | 运行时地址转换； <code>addrarg</code> 是受地址转换影响的XIP内存地址。                                                                               |
| 安全级别（请选择一项）             |                                                                                                                               |
| <code>0x00000100</code> | 使用安全权限执行操作。非安全调用者禁止执行此操作。                                                                                                     |
| <code>0x00000200</code> | 使用非安全权限执行操作。                                                                                                                  |
| <code>0x00000300</code> | 使用引导加载程序权限执行操作。非安全调用者禁止执行此操作。                                                                                                 |
| 操作（请选择一项）               |                                                                                                                               |
| <code>0x00000000</code> | 从地址 <code>addr</code> 开始擦除 <code>size_bytes</code> 字节的闪存。 <code>addr</code> 和 <code>size_bytes</code> 必须均为4096字节（一个闪存扇区）的整数倍。 |

|                         |                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>0x00010000</code> | Program <code>size_bytes</code> bytes of flash, starting at address <code>addr</code> . Both <code>addr</code> and <code>size_bytes</code> must be a multiple of 256 bytes (one flash page). |
| <code>0x00020000</code> | Read <code>size_bytes</code> bytes of flash, starting at address <code>addr</code> . There are no alignment restrictions on <code>addr</code> or <code>size_bytes</code> .                   |

These constants are also available in `bootrom_constants.h` in the SDK as `#defines`.

`addr` is the address of the first flash byte to be accessed, ranging from `XIP_BASE` to `XIP_BASE + 0xffffffff` inclusive. This may be a runtime or storage address. `buf` contains data to be written to flash, for program operations, and data read back from flash, for read operations. `buf` is never written by program operations, and is completely ignored for erase operations.

The flash operation is bounds-checked against the known flash devices specified by the runtime value of `FLASH_DEVINFO`, stored in boot RAM. This is initialised by the bootrom to the OTP value `FLASH_DEVINFO`, if `BOOT_FLAGS0.FLASH_DEVINFO_ENABLE` is set; otherwise it is initialised to 16 MB for chip select 0 and 0 bytes for chip select 1. `FLASH_DEVINFO` can be updated at runtime by writing to its location in boot RAM, the pointer to which can be looked up in the ROM table.

If a resident partition table is in effect, then the flash operation is also checked against the partition permissions. The Secure version of this function can specify the caller's effective security level (Secure, Non-secure, bootloader) using the `CFLASH_SECLEVEL_BITS` bitfield of the `flags` argument, whereas the Non-secure function is always checked against the Non-secure permissions for the partition. Flash operations which span two partitions are not allowed, and will fail address validation.

If `FLASH_DEVINFO.D8H_ERASE_SUPPORTED` is set, erase operations will use a D8h 64 kB block erase command where possible (without erasing outside the specified region), for faster erase time. Otherwise, only 20h 4 kB sector erase commands are used.

Optionally, this API can translate `addr` from flash runtime addresses to flash storage addresses, according to the translation currently configured by QMI address translation registers, `ATRANS0` through `ATRANS7`. For example, an image stored at a +2 MB offset in flash (but mapped at XIP address 0 at runtime), writing to an offset of +1 MB into the image, will write to a physical flash storage address of 3 MB. Translation is enabled by setting the corresponding bitfield in the `flags` argument.

When translation is enabled, flash operations that cross address holes in the XIP runtime address space (created by non-maximum `ATRANSx_SIZE`) will return an error response. This check may tear: the transfer may be partially performed before encountering an address hole and ultimately returning failure.

When translation is enabled, flash operations are permitted to cross chip select boundaries, provided this does not span an ATRANS address hole. When translation is disabled, the entire operation must target a single flash chip select (as determined by bits 24 and upward of the address), else address validation will fail.

A typical call sequence for erasing a flash sector in the runtime address space from Secure code would be:

- `connect_internal_flash();`
- `flash_exit_xip();`
- `flash_op((CFLASH_OP_VALUE_ERASE << CFLASH_OP_LSB) | (CFLASH_SECLEVEL_VALUE_SECURE << CFLASH_SECLEVEL_LSB) | (CFLASH_ASPACE_VALUE_RUNTIME << CFLASH_ASPACE_LSB), addr, 4096, NULL);`
- `flash_flush_cache();`
- Copy the XIP setup function from boot RAM to SRAM and execute it, to restore the original XIP mode
  - The bootrom will have written a default setup function which restores the mode/clkdiv parameters found during flash search; user code can overwrite this with its own custom setup function.

A similar sequence is required for program operations. Read operations can leave the current XIP mode in effect, so only the `flash_op(...);` call is required.

Note that the RP2350 bootrom leaves the flash in a basic XIP state in between program/erase operations. However, during a program/erase operation, the QMI is in direct mode (Section 12.14.5) and any attempted XIP access will return

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| <code>0x00010000</code> | 从地址addr开始写入 size_bytes字节的闪存。addr和size_bytes必须均为256字节（一个闪存页）的整数倍。 |
| <code>0x00020000</code> | 读取 size_bytes 字节闪存，起始地址为 addr 。 地址 addr 和字节数 size_bytes 均无对齐限制。  |

这些常量在 SDK 的 `bootrom_constants.h` 中也以 `#define` 形式提供。

地址 `addr` 是访问的第一个闪存字节地址，范围包括从 `XIP_BASE` 至 `XIP_BASE + 0x1fffff`。该地址可能为运行时地址或存储地址。缓冲区 `buf` 用于存放编程操作写入闪存的数据，及读取操作时从闪存回读的数据。缓冲区 `buf` 从不被编程操作写入，擦除操作完全忽略该缓冲区。

闪存操作会针对保存在启动 RAM 中的 `FLASH_DEVINFO` 运行时值所指定的已知闪存设备执行边界检查。若 `BOOT_FLAGS0.FLASH_DEVINFO_ENABLE` 被设置，则该值由启动只读存储器根据 OTP 中的 `FLASH_DEVINFO` 初始化；否则，芯片选择 0 初始化为 16 MB，芯片选择 1 初始化为 0 字节。`FLASH_DEVINFO` 可通过写入其在引导RAM中的位置来在运行时更新，该位置的指针可在只读存储器表中查找。

如果启用了常驻分区表，则闪存操作还需依据分区权限进行校验。本函数的安全版本可通过 `flags` 参数中的 `CFLASH_SECLEVEL_BITS` 位域指定调用者的有效安全级别（安全、非安全、引导加载程序），而非安全版本函数始终依据分区的非安全权限进行校验。不允许跨越两个分区的闪存操作，且此类操作将在地址验证时失败。

若 `FLASH_DEVINFO.D8H_ERASE_SUPPORTED` 被设置，则擦除操作将在可能范围内使用 D8h 64 kB 块擦除命令（不超出指定区域），以加快擦除速度。否则，仅使用 20h 4 kB 扇区擦除命令。

该API可根据当前由 QMI 地址转换寄存器 ATRANS0 至 ATRANS7 配置的转换，将 `addr` 从闪存运行时地址转换为闪存存储地址。例如，映像存储于闪存的 +2 MB 偏移处（运行时映射为 XIP 地址 0），对映像偏移 +1 MB 处写入时，实际写入物理闪存存储地址为 3 MB。通过设置 `flags` 参数中的相应位域启用此转换。

启用翻译时，跨越XIP运行时地址空间中地址空洞（由非最大`ATRANSx_SIZE`创建）的闪存操作将返回错误响应。此检查可能导致传输中断：传输可能在遇到地址空洞前部分完成，最终返回失败。

启用翻译时，允许闪存操作跨越芯片选择边界，前提是不跨越ATRANS地址空洞。禁用翻译时，整个操作必须针对单个闪存芯片选择（由地址第24位及以上位决定），否则地址验证将失败。

从安全代码在运行时地址空间中擦除闪存扇区的典型调用序列如下：

- `connect_internal_flash();`
- `flash_exit_xip();`
- `flash_op((CFLASH_OP_VALUE_ERASE << CFLASH_OP_LSB) | (CFLASH_SECLEVEL_VALUE_SECURE << CFLASH_SECLEVEL_LSB) | (CFLASH_ASPACE_VALUE_RUNTIME << CFLASH_ASPACE_LSB), addr, 4096, NULL);`
- `flash_flush_cache();`
- 将 XIP 设置函数从启动只读存储器复制到 SRAM 并执行，以恢复原始的 XIP 模式。
  - bootrom 会写入一个默认的设置函数，用以恢复闪存搜索期间检测到的 mode/clkdiv 参数；用户代码可以用自定义的设置函数覆盖该默认函数。

程序操作亦需类似流程。读取操作可保持当前 XIP 模式有效，因此仅需执行`flash_op(...);`调用。

请注意，RP2350 bootrom 在程序／擦除操作间将闪存保持在基础的 XIP 状态。但在程序／擦除操作期间，QMI 处于直接模式（详见第 12.14.5 节），任何 XIP 访问尝试均会返回

a bus error response.

#### 5.4.8.10. `flash_range_erase`

Code: 'R','E'

Signature: `void flash_range_erase(uint32_t addr, size_t count, uint32_t block_size, uint8_t block_cmd)`

Supported architectures: `Arm-S, RISC-V`

Erase `count` bytes, starting at `addr` (offset from start of flash). Optionally, pass a block erase command (for example, `D8h block erase`), and the size of the block erased by this command – this function will use the larger block erase where possible, for much higher erase speed. `addr` must be aligned to a 4096-byte sector, and `count` must be a multiple of 4096 bytes.

This is a low-level flash API, and no validation of the arguments is performed. See [flash\\_op\(\)](#) for a higher-level API which checks alignment, flash bounds and partition permissions, and can transparently apply a runtime-to-storage address translation.

The QSPI device must be in a serial command state before calling this API, which can be achieved by calling `connect_internal_flash()` followed by `flash_exit_xip()`. After the erase, the flash cache should be flushed via `flash_flush_cache()` to ensure the modified flash data is visible to cached XIP accesses.

Finally, the original XIP mode should be restored by copying the saved XIP setup function from boot RAM into SRAM, and executing it: the bootrom provides a default function which restores the flash mode/clkdiv discovered during flash scanning, and user programs can override this with their own XIP setup function.

For the duration of the erase operation, QMI is in direct mode ([Section 12.14.5](#)) and attempting to access XIP from DMA, the debugger or the other core will return a bus fault. XIP becomes accessible again once the function returns.

#### 5.4.8.11. `flash_range_program`

Code: 'R','P'

Signature: `void flash_range_program(uint32_t addr, const uint8_t *data, size_t count)`

Supported architectures: `Arm-S, RISC-V`

Program `data` to a range of flash storage addresses starting at `addr` (offset from the start of flash) and `count` bytes in size. `addr` must be aligned to a 256-byte boundary, and `count` must be a multiple of 256.

This is a low-level flash API, and no validation of the arguments is performed. See [flash\\_op\(\)](#) for a higher-level API which checks alignment, flash bounds and partition permissions, and can transparently apply a runtime-to-storage address translation.

The QSPI device must be in a serial command state before calling this API – see notes on [flash\\_range\\_erase\(\)](#).

#### 5.4.8.12. `flash_reset_address_trans`

Code: 'R','A'

Signature: `void flash_reset_address_trans(void)`

Supported architectures: `Arm-S, RISC-V`

Restore the QMI address translation registers, `ATRANS0` through `ATRANS7`, to their reset state. This makes the runtime-to-storage address map an identity map, meaning the mapped and unmapped address are equal, and the entire space is fully mapped. See [Section 12.14.4](#).

总线错误响应。

#### 5.4.8.10. `flash_range_erase`

代码: 'R', 'E'

函数签名: `void flash_range_erase(uint32_t addr, size_t count, uint32_t block_size, uint8_t block_cmd)`

支持的架构: Arm-S, RISC-V

擦除 `count`字节，从 `addr` (闪存起始位置偏移) 开始。可选传入块擦除命令 (例如, `D8h`块擦除) 及该命令擦除的块大小 – 该函数将在可能情况下使用更大块擦除，从而大幅提升擦除速度。`addr`必须对齐至4096字节扇区，且 `count`必须为4096字节的整数倍。

这是低级闪存API，不对参数进行任何有效性校验。详见 `flash_op()`，该高级API会校验对齐、闪存边界及分区权限，并能透明地实现运行时地址到存储地址的转换。

调用此API前，QSPI设备必须处于串行命令状态，通常通过依次调用 `connect_internal_flash()` 及 `flash_exit_xip()` 实现。擦除完成后，应调用 `flash_flush_cache()` 刷新闪存缓存，以确保修改后的闪存数据对缓存的XIP访问可见。

最后，应通过将保存在引导RAM中的XIP设置函数复制回SRAM并执行该函数来恢复原始XIP模式：`bootrom`提供一个默认函数，用于恢复闪存扫描期间检测到的闪存模式和时钟分频，用户程序可通过自定义XIP设置函数覆盖该默认设置。

在擦除操作期间，QMI处于直接模式（见第12.14.5节），尝试通过DMA、调试器或另一核心访问XIP将导致总线错误。函数执行返回后，XIP将重新可访问。

#### 5.4.8.11. `flash_range_program`

代码: 'R', 'P'

函数签名: `void flash_range_program(uint32_t addr, const uint8_t *data, size_t count)`

支持的架构: Arm-S, RISC-V

向从 `addr` (相对于闪存起点的偏移地址) 开始的闪存存储区域编程数据，大小为 `count`字节。`addr`必须按256字节边界对齐，`count`必须为256字节的整数倍。

这是低级闪存API，不对参数进行任何有效性校验。详见 `flash_op()`，该高级API会校验对齐、闪存边界及分区权限，并能透明地实现运行时地址到存储地址的转换。

调用此API之前，QSPI设备必须处于串行命令状态——详见 `flash_range_erase()`注释。

#### 5.4.8.12. `flash_reset_address_trans`

代码: 'R', 'A'

函数签名: `void flash_reset_address_trans(void)`

支持的架构: Arm-S, RISC-V

将QMI地址转换寄存器ATRANS0至ATRANS7恢复至复位状态。此操作使运行时到存储地址映射成为恒等映射，即映射地址与未映射地址相等，且整个地址空间完全映射。详见第12.14.4节。

### 5.4.8.13. `flash_runtime_to_storage_addr`

Code: 'F','A'

Signature: `int flash_runtime_to_storage_addr(uint32_t addr)`

Supported architectures: `Arm-S, Arm-NS, RISC-V`

Returns: A positive value on success (the translated address), or negative error code on error

Applies the address translation currently configured by QMI address translation registers, `ATRANS0` through `ATRANS7`. See [Section 12.14.4](#).

Translating an address outside of the XIP runtime address window, or beyond the bounds of an `ATRANSx_SIZE` field, returns `BOOTROM_ERROR_INVALID_ADDRESS`, which is not a valid flash storage address. Otherwise, return the storage address which QMI would access when presented with the runtime address `addr`. This is effectively a virtual-to-physical address translation for QMI.

### 5.4.8.14. `flash_select_xip_read_mode`

Code: 'X','M'

Signature: `void flash_select_xip_read_mode(bootrom_xip_mode_t mode, uint8_t clkdiv)`

Supported architectures: `Arm-S, RISC-V`

Configure QMI for one of a small menu of XIP read modes supported by the bootrom. This mode is configured for both memory windows (both chip selects), and the clock divisor is also applied to direct mode.

The available modes are:

- **0**: 03h serial read: serial address, serial data, no wait cycles
- **1**: 0Bh serial read: serial address, serial data, 8 wait cycles
- **2**: BBh dual-IO read: dual address, dual data, 4 wait cycles (including MODE bits, which are driven to 0)
- **3**: EBh quad-IO read: quad address, quad data, 6 wait cycles (including MODE bits, which are driven to 0)

The XIP write command/format are not configured by this function.

When booting from flash, the bootrom tries each of these modes in turn, from 3 down to 0. The first mode that is found to work is remembered, and a default XIP setup function is written into boot RAM that calls *this function* (`flash_select_xip_read_mode`) with the parameters discovered during flash scanning. This can be called at any time to restore the flash parameters discovered during flash boot.

All XIP modes configured by the bootrom have an 8-bit serial command prefix, so that the flash device can remain in a serial command state, meaning XIP accesses can be mixed more freely with program/erase serial operations. This has a performance penalty, so users can perform their own flash setup *after flash boot* using continuous read mode or QPI mode to avoid or alleviate the command prefix cost.

### 5.4.8.15. `get_b_partition`

Code: 'G','B'

Signature: `int get_b_partition(uint partition_a)`

Supported architectures: `Arm-S RISC-V`

Returns: The index of the B partition of partition A if a partition table is present and loaded, and there is a partition A with a corresponding B partition; otherwise returns `BOOTROM_ERROR_NOT_FOUND`.

### 5.4.8.13. `flash_runtime_to_storage_addr`

代码: 'F', 'A'

函数签名: `int flash_runtime_to_storage_addr(uint32_t addr)`

支持的架构: `Arm-S, Arm-NS, RISC-V`

返回值: 成功时为正数（转换后的地址），失败时为负错误码

应用当前由QMI地址转换寄存器ATRANS0至ATRANS7配置的地址转换。

详见第12.14.4节。

将地址转换到XIP运行时地址窗口之外，或超出`ATRANSx_SIZE`字段范围时，返回`BOOTROM_ERROR_INVALID_ADDRESS`，该值不是有效的闪存存储地址。否则，返回QMI在给定运行时地址 `addr`时实际访问的存储地址。这实质上是针对QMI的虚拟地址到物理地址的转换。

### 5.4.8.14. `flash_select_xip_read_mode`

代码: 'X', 'M'

签名: `void flash_select_xip_read_mode(bootrom_xip_mode_t mode, uint8_t clkdiv)`

支持的架构: `Arm-S, RISC-V`

配置QMI以支持bootrom提供的一组有限XIP读取模式之一。该模式同时配置两个内存窗口（两个芯片选择），且时钟分频也适用于直通模式。

可用模式如下：

- **0**: 03h 串行读取：串行地址，串行数据，无等待周期
- **1**: 0Bh 串行读取：串行地址，串行数据，8周期等待
- **2**: BBh 双IO读取：双地址、双数据，4个等待周期（包括驱动为0的MODE位）
- **3**: EBh 四IO读取：四地址、四数据，6个等待周期（包括驱动为0的MODE位）

XIP写入命令/格式不由此函数配置。

从闪存启动时，bootrom会依次尝试这些模式，从3向0递减。首次检测到可用模式后，会将其记录，并在启动RAM中写入一个调用此函数的默认XIP设置函数，

(`flash_select_xip_read_mode`)，参数为闪存扫描过程中发现的配置。此函数可随时调用，以恢复闪存启动时发现的闪存参数。

所有由bootrom配置的XIP模式均带8位串行命令前缀，使闪存设备能够保持在串行命令状态，从而更灵活地混合进行XIP访问与程序/擦除串行操作。此操作存在性能损失，因此用户可以在闪存启动后，通过使用连续读取模式或QPI模式自行完成闪存配置，以避免或减轻命令前缀带来的开销。

### 5.4.8.15. `get_b_partition`

代码: 'G', 'B'

函数签名: `int get_b_partition(uint partition_a)`

支持的架构: `Arm-S RISC-V`

返回值: 如果存在且已加载分区表，且分区A存在对应的分区B，则返回分区A对应的分区B索引；否则返回`BOOTROM_ERROR_NOT_FOUND`。

### 5.4.8.16. `get_partition_table_info`

Code: 'G','P'

Signature: `int get_partition_table_info(uint32_t *out_buffer, uint32_t out_buffer_word_size, uint32_t flags_and_partition)`

Supported architectures: Arm-S, Arm-NS, RISC-V

Returns: >= 0 on success (the number of words filled in out\_buffer), negative error code on error.

Fills a buffer with information from the partition table. Note that this API is also used to return information over the PICOBOT interface.

On success, the buffer is filled, and the number of words filled in the buffer is returned. If the partition table hasn't been loaded (for example, from a watchdog or RAM boot), this method returns `BOOTROM_ERROR_PRECONDITION_NOT_MET`, and you should load the partition table through `load_partition_table()` first.

Not all data from the partition table is kept resident in memory by the boottom due to size constraints. To protect against changes being made in flash after the boottom has loaded the resident portion, the boottom keeps a hash of the partition table as of the time it loaded it. If the hash has changed by the time this method is called, then it will return `BOOTROM_ERROR_INVALID_STATE`.

The information returned is chosen by the `flags_and_partition` parameter; the first word in the returned buffer, is the (sub)set of those flags that the API supports. You should always check this value before interpreting the buffer.

Following the first word, returns words of data for each present flag in order. With the exception of `PT_INFO`, all the flags select "per partition" information, so each field is returned in flag order for one partition after the next. The special `SINGLE_PARTITION` flag indicates that data for only a single partition is required. Flags include:

- `0x0001 - PT_INFO` : information about the partition table as a whole. The second two words for unpartitioned space in the same form described in [Section 5.9.4.2](#).
  - Word 0 : `partition_count` (low 8 bits), `partition_table_present` (bit 8)
  - Word 1 : `unpartitioned_space_permissions_and_location`
  - Word 2 : `unpartitioned_space_permissions_and_flags`
- `0x8000 - SINGLE_PARTITION` : only return data for a single partition; the partition number is stored in the top 8 bits of `flags_and_partition`

Per-partition fields:

- `0x0010 - PARTITION_LOCATION_AND_FLAGS` : the core information about a partition. The format of these fields is described in [Section 5.9.4.2](#).
  - Word 0 - `permissions_and_location`
  - Word 1 - `permissions_and_flags`
- `0x0020 - PARTITION_ID` : the optional 64-bit identifier for the partition. If the `HAS_ID` bit is set in the partition flags, then the 64 bit ID is returned:
  - Word 0 - first 32 bits
  - Word 1 - second 32 bits
- `0x0040 - PARTITION_FAMILY_IDS` : Any additional UF2 family IDs that the partition supports being downloaded into it via the MSD bootloader beyond the standard ones flagged in the `permissions_and_flags` field (see [Section 5.9.4.2](#)).
- `0x0080 - PARTITION_NAME` : The optional name for the partition. If the `HAS_NAME` field bit in `permissions_and_flags` is not set, then no data is returned for this partition; otherwise the format is as follows:
  - Byte 0 : 7 bit length of the name (LEN); top bit reserved
  - Byte 1 : first character of name
  - ...

### 5.4.8.16. `get_partition_table_info`

代码： 'G', 'P'

函数签名： `int get_partition_table_info(uint32_t *out_buffer, uint32_t out_buffer_word_size, uint32_t flags_and_partition)`

支持的架构： Arm-S, Arm-NS, RISC-V

返回值： 成功时返回非负值（填充至`out_buffer`中的字数），失败时返回负错误码。

用分区表信息填充缓冲区。请注意，该API也用于通过PICOBOOT接口返回信息。

成功时，缓冲区将被填充，并返回填充到缓冲区中的字数。如果分区表尚未加载（例如，从看门狗或RAM引导），此方法将返回`BOOTROM_ERROR_PRECONDITION_NOT_MET`，您应首先通过`load_partition_table()`函数加载分区表。

由于大小限制，bootrom并未将所有分区表数据常驻内存。为了防止bootrom加载常驻部分后闪存被修改，bootrom会保存加载时分区表的哈希值。如果调用此方法时哈希值已发生改变，则会返回`BOOTROM_ERROR_INVALID_STATE`。

返回的信息由`flags_and_partition`参数决定；返回缓冲区中的第一个字，为该API所支持标志的（子）集合。在解释缓冲区内容前，您应始终检查该值。

继第一个字之后，依序返回每个已置位标志对应的数据字。除`PT_INFO`外，所有标志均选择“每分区”信息，因此每个字段按标志顺序逐一返回各分区数据。特殊的`SINGLE_PARTITION`标志表示仅需要单个分区数据。标志包括：

- `0x0001 - PT_INFO`：关于整个分区表的整体信息。未分区空间的后两个字，其格式同第 5.9.4.2 节所述。
  - 字 0： `partition_count`（低 8 位），`partition_table_present`（第 8 位）
  - 字 1： `unpartitioned_space_permissions_and_location`
  - 字 2： `unpartitioned_space_permissions_and_flags`
- `0x8000 -SINGLE_PARTITION`：仅返回单个分区数据；分区号存储于`flags_and_partition`的高 8 位。

每个分区字段：

- `0x0010 -PARTITION_LOCATION_AND_FLAGS`：分区的核心信息。这些字段的格式详见第5.9.4.2节。
  - 字0 -permissions\_and\_location
  - 字1 -permissions\_and\_flags
- `0x0020 -PARTITION_ID`：分区的可选64位标识符。如果在分区标志中设置了`HAS_ID`位，则返回64位ID：
  - 字0 - 前32位
  - 字1 - 后32位
- `0x0040 -PARTITION_FAMILY_IDS`：分区支持通过MSD引导加载程序下载的除权限和标志字段中标记的标准ID外的任何额外UF2家族ID（详见第5.9.4.2节）。
- `0x0080 -PARTITION_NAME`：分区的可选名称。如果`permissions_and_flags`中的`HAS_NAME`字段位未设置，则该分区不返回任何数据；否则格式如下：
  - 字节 0：名称的7位长度（LEN）；最高位保留
  - 字节 1：名称的第一个字符
  - ...

- Byte LEN : last character of name
- ... (*padded up to the next word boundary*)

**NOTE**

Unpartitioned space is always reported in Word 1 as having a base offset of `0x0` and a size of `0x2000` sectors (32 MB). The bootrom applies unpartitioned space permissions to *any* flash storage address that is not covered by a partition.

#### 5.4.8.17. `get_sys_info`

Code: '`G`', '`S`'

Signature: `int get_sys_info(uint32_t *out_buffer, uint32_t out_buffer_word_size, uint32_t flags)`

Supported architectures: `Arm-S`, `Arm-NS`, `RISC-V`

Returns: A positive value on success (the number of words filled in `out_buffer`), negative error code on error.

Fills a buffer with various system information. Note that this API is also used to return information over the PICOBOOT interface.

The information returned is chosen by the `flags` parameter; the first word in the returned buffer, is the (sub)set of those flags that the API supports. You should always check this value before interpreting the buffer.

Following the first word, returns words of data for each present flag in order:

- `0x0001` : `CHIP_INFO` - unique identifier for the chip (3 words)
  - Word 0 : Value of the `CHIP_INFO_PACKAGE_SEL` register
  - Word 1 : RP2350 device id low
  - Word 2 : RP2350 device id high
- `0x0002` : `CRITICAL` (1 word)
  - Word 0 : Value of the OTP `CRITICAL` register, containing critical boot flags read out on last OTP reset event
- `0x0004` : `CPU_INFO` (1 word)
  - Word 0 : Current CPU architecture
    - 0 - Arm
    - 1 - RISC-V
- `0x0008` : `FLASH_DEV_INFO` (1 word)
  - Word 0 : Flash device info in the format of OTP `FLASH_DEvinfos`
- `0x0010` : `BOOT_RANDOM` - a 128-bit random number generated on each boot (4 words)
  - Word 0 : Per boot random number 0
  - Word 1 : Per boot random number 1
  - Word 2 : Per boot random number 2
  - Word 3 : Per boot random number 3
- `0x0020` : `NONCE` - not supported
- `0x0040` : `BOOT_INFO` (4 words)
  - Word 0 : `0xffffffff`
    - `tt` - recent boot TBYB and update info (updated on regular non BOOTSEL boots)

- 字节 LEN：名称的最后一个字符
- ... (填充至下一个字边界)

### 注意

未分区空间始终在字 1 中报告，基准偏移为 `0x0`，大小为 `0x2000`扇区（32 MB）。只读存储器引导程序将未分区空间权限应用于任何未被分区覆盖的闪存存储地址。

#### 5.4.8.17. `get_sys_info`

代码: '`G`', '`S`'

函数签名: `int get_sys_info(uint32_t *out_buffer, uint32_t out_buffer_word_size, uint32_t flags)`

支持的架构: `Arm-S`, `Arm-NS`, `RISC-V`

返回值: 成功时返回正值（填充到 `out_buffer` 的字数），失败时返回负错误代码。

填充缓冲区以包含各种系统信息。请注意，该API也用于通过PICOBOOT接口返回信息。

返回的信息由 `flags` 参数决定；返回缓冲区中的第一个字，为该API所支持标志的（子）集合。在解释缓冲区内容前，您应始终检查该值。

继第一个单词后，按顺序返回每个已设置标志对应的数据单词：

- `0x0001 : CHIP_INFO` - 芯片的唯一标识符（3 个单词）
  - 单词 0: `CHIP_INFO_PACKAGE_SEL` 寄存器的值
  - 单词 1: RP2350 设备 ID 低位
  - 单词 2: RP2350 设备 ID 高位
- `0x0002 : CRITICAL` (1 个单词)
  - 单词 0: OTP CRITICAL 寄存器的值，包含上一次 OTP 复位事件读取的关键启动标志
- `0x0004 : CPU_INFO` (1 个单词)
  - 单词 0: 当前 CPU 架构
    - 0 - Arm
    - 1 - RISC-V
- `0x0008 : FLASH_DEV_INFO` (1 个单词)
  - 单词 0: 以 OTP FLASH\_DEVINFO 格式表示的闪存设备信息
- `0x0010 : BOOT_RANDOM` - 每次启动时生成的 128 位随机数（4 个单词）
  - Word 0: 每次启动的随机数 0
  - Word 1: 每次启动的随机数 1
  - Word 2: 每次启动的随机数 2
  - Word 3: 每次启动的随机数 3
- `0x0020 : NONCE` - 不支持
- `0x0040 : BOOT_INFO` (4 个字)
  - Word 0: `0xffffffff`
    - `tt` - 最近启动的 TBYB 及更新信息（在常规非 BOOTSEL 启动时更新）

- **pp** - recent boot partition (updated on regular not BOOTSEL boots)
- **bb** - boot type of the most recent boot
- **dd** - recent boot diagnostic "partition"
- Word 1 : Recent boot diagnostic. Diagnostic information from a recent boot (with information from the partition (or slot) indicated by **dd** above. "partition" numbers here are:
  - 0-15 : a partition number
  - -1 : none
  - -2 : slot 0
  - -3 : slot 1
  - -4 : image (the diagnostic came from the launch of a RAM image, OTP boot image or user `chain_image()` call).
- Word 2 : Last reboot param 0
- Word 3 : Last reboot param 1

"Boot Diagnostic" information is intended to help identify the cause of a failed boot, or booting into an unexpected binary. This information can be retrieved via PICOBEST after a watchdog reboot, however it will not survive a reset via the RUN pin or POWMAN reset.

There is only one word of diagnostic information. What it records is based on the **pp** selection above, which is itself set as a parameter when rebooting programmatically into a normal boot.

To get diagnostic info, **pp** must refer to a slot or an "A" partition; image diagnostics are automatically selected on boot from OTP or RAM image, or when `chain_image()` is called.)

The diagnostic word thus contains data for either slot 0 and slot 1, or the "A" partition (and its "B" partition if it has one). The low half word of the diagnostic word contains information from slot 0 or partition A; the high half word contains information from slot 1 or partition B.

The format of each half-word is as follows (using the word *region* to refer to slot or partition)

- **0x0001 : REGION\_SEARCHED** - The region was searched for a block loop.
- **0x0002 : INVALID\_BLOCK\_LOOP** - A block loop was found but it was invalid
- **0x0004 : VALID\_BLOCK\_LOOP** - A valid block loop was found (Blocks from a loop wholly contained within the region, and the blocks have the correct structure. Each block consists of items whose sizes sum to the size of the block)
- **0x0008 : VALID\_IMAGE\_DEF** - A valid `IMAGE_DEF` was found in the region. A valid `IMAGE_DEF` must parse correctly and must be executable.
- **0x0010 : HAS\_PARTITION\_TABLE** - Whether a partition table is present. This partition table must have a correct structure formed if `VALID_BLOCK_LOOP` is set. If the partition table turns out to be invalid, then `INVALID_BLOCK_LOOP` is set too (thus both `VALID_BLOCK_LOOP` and `INVALID_BLOCK_LOOP` will both be set).
- **0x0020 : CONSIDERED** - There was a choice of partition/slot and this one was considered. The first slot/partition is chosen based on a number of factors. If the first choice fails verification, then the other choice will be considered.
  - the version of the `PARTITION_TABLE/IMAGE_DEF` present in the slot/partition respectively.
  - whether the slot/partition is the "update region" as per a `FLASH_UPDATE` reboot.
  - whether an `IMAGE_DEF` is marked as "explicit buy"
- **0x0040 : CHOSEN** - This slot/partition was chosen (or was the only choice)
- **0x0080 : PARTITION\_TABLE\_MATCHING\_KEY\_FOR\_VERIFY** - if a signature is required for the `PARTITION_TABLE` (via OTP setting), then whether the `PARTITION_TABLE` is signed with a key matching one of the four stored in OTP
- **0x0100 : PARTITION\_TABLE\_HASH\_FOR\_VERIFY** - set if a hash value check could be performed. In the case a signature is required, this value is identical to `PARTITION_TABLE_MATCHING_KEY_FOR_VERIFY`

- **pp** - 最近启动的分区（在常规非 BOOTSEL 启动时更新）
- **bb** - 最近启动的启动类型
- **dd** - 最近启动的诊断“分区”
- Word 1 : 最近启动的诊断信息。来自最近一次启动的诊断信息（含上述 dd 指示的分区或槽的信息）。
  - “分区”编号如下：
  - 0-15 : 分区编号
  - -1 : 无
  - -2 : 槽 0
  - -3 : 槽 1
  - -4 : 镜像（诊断来源于RAM镜像启动、OTP引导镜像或用户chain\_image()调用）。
- 字 2 : 上次重启参数 0
- 字 3 : 上次重启参数 1

“引导诊断”信息用于帮助识别启动失败的原因，或启动到意外二进制文件的情况。此信息可通过PICOBOOT在看门狗重启后获取，但在通过RUN引脚复位或POWMAN复位时不会保留。

诊断信息仅包含一个字。其记录内容基于上述 pp选择，后者作为编程方式重新启动至正常引导时的参数。

要获取诊断信息，**pp**必须指向一个槽或“A”分区；镜像诊断会在从OTP或RAM镜像引导时自动选择，或当chain\_image()被调用时自动选择。

因此，诊断字包含槽0和槽1的数据，或“A”分区及其存在的“B”分区的数据。  
诊断字的低半字包含来自槽0或分区A的信息；高半字包含来自槽1或分区B的信息。

每个半字的格式如下（使用单词 *region*指代槽或分区）：

- **0x0001 :REGION\_SEARCHED** - 该区域已搜索块循环。
- **0x0002 :INVALID\_BLOCK\_LOOP** - 发现了块循环，但该循环无效。
- **0x0004 :VALID\_BLOCK\_LOOP** - 发现了有效的块循环（由完全包含于该区域的循环中的块组成，且这些块具有正确的结构。每个块由大小总和等于块大小的项组成）。
- **0x0008 :VALID\_IMAGE\_DEF** - 该区域发现了有效的 IMAGE\_DEF。有效的 IMAGE\_DEF 必须能够正确解析且必须可执行。
- **0x0010 :HAS\_PARTITION\_TABLE** - 是否存在分区表。如若设置了 VALID\_BLOCK\_LOOP，分区表必须具备正确结构。若分区表被判定为无效，则INVALID\_BLOCK\_LOOP亦将设置（因而VALID\_BLOCK\_LOOP与INVALID\_BLOCK\_LOOP均被设置）。
- **0x0020 :CONSIDERED** - 已考虑该分区/槽的选择。第一个槽/分区的选择依据多项因素确定。若首选未通过验证，则考虑另一选项。
  - 槽/分区中所包含的PARTITION\_TABLE/ IMAGE\_DEF 版本信息。
  - 槽/分区是否作为FLASH\_UPDATE重启时的“更新区域”。
  - 是否将 IMAGE\_DEF 标记为“明确购买”。
- **0x0040 :CHosen** - 此槽/分区已选定（或为唯一选择）。
- **0x0080 :PARTITION\_TABLE\_MATCHING\_KEY\_FOR\_VERIFY** - 若PARTITION\_TABLE需签名以验证（通过OTP设置），则表明该PARTITION\_TABLE是否使用匹配OTP中四个密钥之一的密钥进行了签名。
- **0x0100 :PARTITION\_TABLE\_HASH\_FOR\_VERIFY** - 如果可以执行哈希值校验，则设置此值。如果需要签名，则此值与PARTITION\_TABLE\_MATCHING\_KEY\_FOR\_VERIFY相同。

- `0x0200 : PARTITION_TABLE_VERIFIED_OK` - whether the `PARTITION_TABLE` passed verification (signature/hash if present/required)
- `0x0400 : IMAGE_DEF_MATCHING_KEY_FOR_VERIFY` - if a signature is required for the `IMAGE_DEF` due to secure boot, then whether the `IMAGE_DEF` is signed with a key matching one of the four stored in OTP.
- `0x0800 : IMAGE_DEF_HASH_FOR_VERIFY` - set if a hash value check could be performed. In the case a signature is required, this value is identical to `IMAGE_DEF_MATCHING_KEY_FOR_VERIFY`
- `0x1000 : IMAGE_DEF_VERIFIED_OK` - whether the `PARTITION_TABLE` passed verification (signature/hash if present/required) and any `LOAD_MAP` is valid
- `0x2000 : LOAD_MAP_ENTRIES_LOADED` - whether any code was copied into RAM due to a `LOAD_MAP`
- `0x4000 : IMAGE_LAUNCHED` - whether an `IMAGE_DEF` from this region was launched
- `0x8000 : IMAGE_CONDITION_FAILURE` - whether the `IMAGE_DEF` failed final checks before launching; these checks include:
  - verification failed (if it hasn't been verified earlier in the `CONSIDERED` phase).
  - a problem occurred setting up any rolling window.
  - the rollback version could not be set in OTP (if required in Secure mode)
  - the image was marked as Non-secure
  - the image was marked as "explicit buy", and this was a flash boot, but then region was not the "flash update" region
  - the image has the wrong architecture, but architecture auto-switch is disabled (or the correct architecture is disabled)

**i NOTE**

The non-sensical combination of `BOOT_DIAGNOSTIC_INVALID_BLOCK_LOOP` and `BOOT_DIAGNOSTIC_VALID_BLOCK_LOOP` both being set is used to flag a `PARTITION_TABLE` which passed the initial verification (and hash/sig), but was later discovered to have invalid contents when it was fully parsed.

To get a full picture of a failed boot involving slots and multiple partitions, the device can be rebooted multiple times to gather the information.

#### 5.4.8.18. `get_uf2_target_partition`

Code: `'G','U'`

Signature: `int get_uf2_target_partition(uint8_t *workarea_base, uint32_t workarea_size, uint32_t family_id, resident_partition_t *partition_out)`

Supported architectures: `Arm-S RISC-V`. Note on `RISC-V` this function requires additional stack; see [Section 5.4.8.26](#).

Returns:  $\geq 0$  on success (the target partition index), or a negative error code on error.

This method performs the same operation to decide on a taget partition for a UF2 family ID as when a UF2 is dragged onto the USB drive in BOOTSEL mode.

This method potentially requires similar complexity to the boot path in terms of picking amongst versions, checking signatures etc. As a result it requires a user provided memory buffer as a work area. The work area should byte word-aligned and of sufficient size or `BOOTROM_ERROR_INSUFFICIENT_RESOURCES` will be returned. The work area size currently required is 3064, so 3K is a good choice.

If the partition table hasn't been loaded (for example, from a watchdog or RAM boot), then this method returns `BOOTROM_ERROR_PRECONDITION_NOT_MET`, and you should load the partition table via `load_partition_table()` first.

- 0x0200 :PARTITION\_TABLE\_VERIFIED\_OK- 表示PARTITION\_TABLE是否通过校验（如存在或必需，包含签名/哈希）。
- 0x0400 :IMAGE\_DEF\_MATCHING\_KEY\_FOR\_VERIFY - 若因安全启动要求为 IMAGE\_DEF 签名，则表示 IMAGE\_DEF 是否使用与OTP中存储的四个密钥之一匹配的密钥进行了签名。
- 0x0800 :IMAGE\_DEF\_HASH\_FOR\_VERIFY- 如果可以执行哈希值校验，则设置此值。如果需要签名，则此值与IMAGE\_DEF\_MATCHING\_KEY\_FOR\_VERIFY相同。
- 0x1000 :IMAGE\_DEF\_VERIFIED\_OK- 表示PARTITION\_TABLE是否通过校验（如存在或必需，包含签名/哈希），且任何 LOAD\_MAP 是否有效。
- 0x2000 :LOAD\_MAP\_ENTRIES\_LOADED- 是否因 LOAD\_MAP 将任何代码复制到RAM中
- 0x4000 :IMAGE\_LAUNCHED- 是否启动了该区域的 IMAGE\_DEF
- 0x8000 :IMAGE\_CONDITION\_FAILURE - 启动前 IMAGE\_DEF 未通过最终检查；这些检查包括：
  - 验证失败（如果之前在 CONSIDERED 阶段未验证）。
  - 设置任何滚动窗口时发生问题。
  - 在OTP中无法设置回滚版本（如安全模式要求）
  - 映像被标记为非安全
  - 映像被标记为“explicit buy”，且此次为闪存启动，但该区域并非“闪存更新”区域
  - 映像架构错误，但架构自动切换已禁用（或正确架构已禁用）

### **i 注意**

同时设置BOOT\_DIAGNOSTIC\_INVALID\_BLOCK\_LOOP和BOOT\_DIAGNOSTIC\_VALID\_BLOCK\_LOOP的矛盾组合用于标识一个PARTITION\_TABLE，该表在初步验证（包括散列/签名）后通过，但完全解析时发现内容无效。

为全面了解涉及槽位和多个分区的启动失败情况，设备可多次重启以收集相关信息。

#### 5.4.8.18. `get_uf2_target_partition`

代码: 'G', 'U'

签名: `int get_uf2_target_partition(uint8_t *workarea_base, uint32_t workarea_size, uint32_t family_id, resident_partition_t *partition_out)`

支持的架构: Arm-S RISC-V. 关于 RISC-V 的说明：此函数需要额外的栈空间；详见第5.4.8.26节。

返回值：成功时返回  $\geq 0$ （目标分区索引），失败时返回负错误代码。

该方法执行与在 BOOTSEL 模式下将 UF2 文件拖入 USB 驱动器时相同的操作，以确定 UF2 家族 ID 的目标分区。

此方法在版本选择与签名校验等方面具备与引导路径类似的复杂性，因此需要用户提供的内存缓冲区作为工作区。工作区应按字节和字对齐且大小充足，否则将返回BOOTROM\_ERROR\_INSUFFICIENT\_RESOURCES 错误。当前所需的工作区大小为3064，因此3K是较为合适的选择。

如果尚未加载分区表（例如，在看门狗或RAM启动时），该方法将返回BOOTROM\_ERROR\_PRECONDITION\_NOT\_MET，您应先通过load\_partition\_table()加载分区表。

### 5.4.8.19. `git_revision`

Code: `'G','R'`

Type: `const uint32_t git_revision`

The 8 most significant hex digits of the bootrom git revision. Uniquely identifies this version of the bootrom.

**ⓘ NOTE**

This is the git revision built at chip tapeout; the git hash in the public repository is different due to squashed history, even though the contents are identical. The contents can be verified by building the public bootrom source and comparing the resulting binary with one binary dumped from the chip.

### 5.4.8.20. `load_partition_table`

Code: `'L','P'`

Signature: `int load_partition_table(uint8_t *workarea_base, uint32_t workarea_size, bool force_reload)`

Supported architectures: `Arm-S, RISC-V`. Note on `RISC-V` this function requires additional stack; see [Section 5.4.8.26](#).

Returns: `BOOTROM_OK` (0) on success, or a negative error code on error.

Loads the current partition table from flash, if present.

This method potentially requires similar complexity to the boot path in terms of picking amongst versions, checking signatures etc. As a result it requires a user provided memory buffer as a work area. The work area should be word-aligned and of sufficient size or `BOOTROM_ERROR_INSUFFICIENT_RESOURCES` will be returned. The work area size currently required is 3064, so 3K is a good choice.

If `force_reload` is false, then this method will return `BOOTROM_OK` immediately if the bootrom is loaded, otherwise it will reload the partition table if it has been loaded already, allowing for the partition table to be updated in a running program.

### 5.4.8.21. `otp_access`

Code: `'O','A'`

Signature: `int otp_access(uint8_t *buf, uint32_t buf_len, uint32_t row_and_flags)`

Supported architectures: `Arm-S, Arm-NS, RISC-V`

Returns: `BOOTROM_OK` (0) on success, or a negative error code on error.

Writes data from a buffer into OTP, or reads data from OTP into a buffer.

- `0x0000ffff - ROW_NUMBER`: 16 low bits are row number (0-4095)
- `0x00010000 - IS_WRITE`: if set, do a write (not a read)
- `0x00020000 - IS_ECC`: if this bit is set, each value in the buffer is 2 bytes and ECC is used when read/writing from 24 bit value in OTP. If this bit is not set, each value in the buffer is 4 bytes, the low 24-bits of which are written to or read from OTP.

The buffer must be aligned to 2 bytes or 4 bytes according to the `IS_ECC` flag.

This method will read and write rows until the first row it encounters that fails a key or permission check at which it will return `BOOTROM_ERROR_NOT_PERMITTED`.

Writing will also stop at the first row where an attempt is made to set an OTP bit from a 1 to a 0, and `BOOTROM_ERROR_UNSUPPORTED_MODIFICATION` will be returned.

If all rows are read/written successfully, then `BOOTROM_OK` will be returned.

#### 5.4.8.19. git\_revision

代码: 'G', 'R'

类型:const uint32\_t git\_revision

Bootrom git修订版本的8位最高有效十六进制数字。唯一标识此版本的bootrom。

##### **i 注意**

该git修订版本为芯片版图确认时构建；由于历史被压缩，公共仓库中的git哈希不同，尽管内容一致。可通过构建公共bootrom源代码并将生成的二进制文件与芯片导出的二进制文件进行比对来验证内容一致性。

#### 5.4.8.20. load\_partition\_table

代码: 'L', 'P'

函数签名: int load\_partition\_table(uint8\_t \*workarea\_base, uint32\_t workarea\_size, bool force\_reload)

支持架构: Arm-S, RISC-V。关于 RISC-V 的说明: 此函数需要额外的栈空间；详见第5.4.8.26节。

返回值: 成功时返回 BOOTROM\_OK(0)，失败时返回负错误代码。

从闪存加载当前分区表（如果存在）。

此方法在版本选择与签名校验等方面具备与引导路径类似的复杂性，因此需要用户提供的内存缓冲区作为工作区。工作区域应按字节和字对齐且大小充足，否则将返回 BOOTROM\_ERROR\_INSUFFICIENT\_RESOURCES 错误。当前所需的工作区大小为 3064，因此 3K 是较为合适的选择。

如果 force\_reload 为假，则当 bootrom 已加载时本方法将立即返回 BOOTROM\_OK；否则，如果分区表已加载，将重新加载分区表，以允许在运行程序中更新分区表。

#### 5.4.8.21. otp\_access

代码: 'O', 'A'

函数签名: int otp\_access(uint8\_t \*buf, uint32\_t buf\_len, uint32\_t row\_and\_flags)

支持的架构: Arm-S, Arm-NS, RISC-V

返回值: 成功时返回 BOOTROM\_OK(0)，失败时返回负错误代码。

将缓冲区中的数据写入 OTP，或从 OTP 读取数据至缓冲区。

- 0x0000ffff - ROW\_NUMBER: 低16位为行号 (0-4095)
- 0x00010000 - IS\_WRITE: 设置此位时执行写操作 (非读操作)
- 0x00020000 - IS\_ECC: 若该位被设置，缓冲区中每个值为2字节，操作时针对OTP中24位值采用ECC；若未设置，缓冲区中每个值为4字节，其中低24位被写入或从OTP读取。

缓冲区必须根据 IS\_ECC 标志对齐至 2 字节或 4 字节。

该方法将持续读取和写入行，直到遇到首个未通过键值或权限检查的行，此时将返回 BOOTROM\_ERROR\_NOT\_PERMITTED。

写入操作也将在首次尝试将OTP位从1更改为0的行时停止，并返回 BOOTROM\_ERROR\_UNSUPPORTED\_MODIFICATION。

若所有行均成功读取/写入，则返回 BOOTROM\_OK。

#### 5.4.8.22. `partition_table_ptr`

Code: '`P`', '`T`'

Type: `resident_partition_table **partition_table_ptr`

A pointer to the pointer to the resident partition table info. The resident partition table is the subset of the full partition table that is kept in memory, and used for flash permissions.

The public part of the resident partition table info is of the form:

| Word  | Bytes        | Value                                                                                                                                                                                    |
|-------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | 1            | <code>partition_count</code> (0-16)                                                                                                                                                      |
|       | 1            | <code>partition_count_with_permissions</code> (0-16). Set this to > <code>partition_count</code> when adding extra permission regions at runtime (do not modify the original partitions) |
|       | 1            | <code>loaded</code> (0x01 if a partition table has been loaded from flash)                                                                                                               |
|       | 1            | 0x00 (pad)                                                                                                                                                                               |
| 1     | 1            | <code>unpartitioned_space_permissions_and_flags</code>                                                                                                                                   |
| 2-3   | Partition 0  |                                                                                                                                                                                          |
|       | 1            | <code>permissions_and_location</code> for partition 0                                                                                                                                    |
|       | 1            | <code>permissions_and_flags</code> for partition 0                                                                                                                                       |
| 4-5   | Partition 1  |                                                                                                                                                                                          |
|       | 1            | <code>permissions_and_location</code> for partition 1                                                                                                                                    |
|       | 1            | <code>permissions_and_flags</code> for partition 1                                                                                                                                       |
| ...   | ...          | ...                                                                                                                                                                                      |
| 32-33 | Partition 15 |                                                                                                                                                                                          |
|       | 1            | <code>permissions_and_location</code> for partition 15                                                                                                                                   |
|       | 1            | <code>permissions_and_flags</code> for partition 15                                                                                                                                      |

Details of the fields `permissions_and_location` and `permissions_and_flags` can be found in [Section 5.9.4](#).

#### 5.4.8.23. `pick_ab_partition`

Code: '`A`', '`B`'

Signature: `int pick_ab_partition(uint8_t *workarea_base, uint32_t workarea_size, uint partition_a_num)`

Supported architectures: Arm-S, RISC-V. Note on RISC-V this function requires additional stack; see [Section 5.4.8.26](#).

Returns: >= 0 on success (the partition index), or a negative error code on error.

Determines which of the partitions has the "better" `IMAGE_DEF`. In the case of executable images, this is the one that would be booted

This method potentially requires similar complexity to the boot path in terms of picking amongst versions, checking signatures etc. As a result it requires a user provided memory buffer as a work area. The work area should be word aligned, and of sufficient size or `BOOTROM_ERROR_INSUFFICIENT_RESOURCES` will be returned. The work area size currently required is 3064, so 3K is a good choice.

The passed partition number can be any valid partition number other than the "B" partition of an A/B pair.

This method returns a negative error code, or the partition number of the picked partition if (`partition_a_num` or the number of its "B" partition if any).

#### 5.4.8.22. `partition_table_ptr`

代码: '`P`', '`T`'

类型: `resident_partition_table **partition_table_ptr`

指向常驻分区表信息指针的指针。常驻分区表是完整分区表的子集，驻留于内存中，用于闪存权限控制。

常驻分区表信息的公开部分格式如下：

| 字     | 字节    | 值                                                                                                                    |
|-------|-------|----------------------------------------------------------------------------------------------------------------------|
| 0     | 1     | <code>partition_count (0-16)</code>                                                                                  |
|       | 1     | <code>partition_count_with_permissions (0-16)</code> 。运行时增加额外权限区域时，应将此值设置为大于 <code>partition_count</code> （请勿修改原有分区） |
|       | 1     | <code>loaded (0x01 表示已从闪存加载分区表)</code>                                                                               |
|       | 1     | <code>0x00</code> （填充）                                                                                               |
| 1     | 1     | 未分区空间权限及标志                                                                                                           |
| 2-3   | 分区 0  |                                                                                                                      |
|       | 1     | 分区 0 的权限与位置                                                                                                          |
|       | 1     | 分区 0 的权限及标志                                                                                                          |
| 4-5   | 分区 1  |                                                                                                                      |
|       | 1     | 分区 1 的权限与位置                                                                                                          |
|       | 1     | 分区 1 的权限及标志                                                                                                          |
| ...   | ...   | ...                                                                                                                  |
| 32-33 | 分区 15 |                                                                                                                      |
|       | 1     | 分区 15 的权限与位置                                                                                                         |
|       | 1     | 分区 15 的权限及标志                                                                                                         |

字段`permissions_and_location`及`permissions_and_flags`的详细信息见第 5.9.4 节。

#### 5.4.8.23. `pick_ab_partition`

代码: '`A`', '`B`'

函数签名: `int pick_ab_partition(uint8_t *workarea_base, uint32_t workarea_size, uint partition_a_num)`

支持架构: `Arm-S`, `RISC-V`。关于 `RISC-V` 的说明: 此函数需要额外的栈空间; 详见第 5.4.8.26 节。

返回值: 成功时返回  $\geq 0$  (分区索引)，失败时返回负错误代码。

确定哪个分区具有“更优”的 `IMAGE_DEF`。对于可执行映像，此分区将被引导启动。

此方法在版本选择与签名校验等方面具备与引导路径类似的复杂性，因此需要用户提供的内存缓冲区作为工作区。工作区应为字对齐且大小足够，否则将返回`BOOTROM_ERROR_INSUFFICIENT_RESOURCES`错误。当前所需的工作区大小为 3064，因此 3K 是较为合适的选择。

传入的分区编号可为除 A/B 对中“B”分区之外的任何有效分区编号。

本方法返回负错误代码，或选中分区的分区编号（即`partition_a_num`或其对应的“B”分区编号）。

**NOTE**

This method does not look at owner partitions, only the A partition passed and its corresponding B partition.

**5.4.8.24. reboot**

Code: 'R','B'

Signature: `int reboot(uint32_t flags, uint32_t delay_ms, uint32_t p0, uint32_t p1)`

Supported architectures: `Arm-S, Arm-NS, RISC-V`

Returns: `BOOTROM_OK` (or doesn't return) on success, a negative error code on error.

Resets the RP2350 and uses the watchdog facility to restart.

The `delay_ms` is the millisecond delay before the reboot occurs. Note: by default this method is asynchronous (unless `NO_RETURN_ON_SUCCESS` is set - see below), so the method will return and the reboot will happen this many milliseconds later.

The `flags` field contains one of the following values:

- `0x0000 : REBOOT_TYPE_NORMAL` - reboot into the normal boot path.
  - `p0` - the boot diagnostic "partition" (low 8 bits only)
- `0x0002 : REBOOT_TYPE_BOOTSEL` - reboot into BOOTSEL mode.
  - `p0` - a set of flags:
    - `0x01 : DISABLE_MSD_INTERFACE` - Disable the BOOTSEL USB drive (see [Section 5.5](#))
    - `0x02 : DISABLE_PICOBOOT_INTERFACE` - Disable the PICOBLOCK interface (see [Section 5.6](#)).
    - `0x10 : GPIO_PIN_ACTIVE_LOW` - The GPIO in `p1` is active low.
    - `0x20 : GPIO_PIN_ENABLED` - Enable the activity indicator on the specified GPIO.
  - `p1` - the GPIO number to use as an activity indicator (enabled by flag in `p0`) for the BOOTSEL USB drive.
- `0x0003 : REBOOT_TYPE_RAM_IMAGE` - reboot into an image in RAM. The region of RAM or XIP RAM is searched for an image to run. This is the type of reboot used when a RAM UF2 is dragged onto the BOOTSEL USB drive.
  - `p0` - the region start address (word-aligned).
  - `p1` - the region size (word-aligned).
- `0x0004 : REBOOT_TYPE_FLASH_UPDATE` - variant of `REBOOT_TYPE_NORMAL` to use when flash has been updated. This is the type of reboot used after dragging a flash UF2 onto the BOOTSEL USB drive.
  - `p0` - the address of the start of the region of flash that was updated. If this address matches the start address of a partition or slot, then that partition or slot is treated preferentially during boot (when there is a choice). This type of boot facilitates TBYB ([Section 5.1.17](#)) and version downgrades.
- `0x000d : REBOOT_TYPE_PC_SP` - reboot to a specific PC and SP. Note: this is not allowed in the `Arm-NS` variant.
  - `p0` - the initial program counter (PC) to start executing at. This must have the lowest bit set for Arm and clear for RISC-V
  - `p1` - the initial stack pointer (SP).

All of the above, can have optional flags ORed in:

- `0x0010 : REBOOT_TO_ARM` - switch both cores to the Arm architecture (rather than leaving them as is). The call will fail with `BOOTROM_ERROR_INVALID_STATE` if the Arm architecture is not supported.
- `0x0020 : REBOOT_TO_RISCV` - switch both cores to the RISC-V architecture (rather than leaving them as is). The call will fail with `BOOTROM_ERROR_INVALID_STATE` if the RISC-V architecture is not supported.

### ⓘ 注意

本方法不会检查所有者分区，仅对传入的 A 分区及其对应 B 分区进行判断。

#### 5.4.8.24. reboot

代码: 'R', 'B'

函数签名: `int reboot(uint32_t flags, uint32_t delay_ms, uint32_t p0, uint32_t p1)`

支持的架构: Arm-S, Arm-NS, RISC-V

返回值: `BOOTROM_OK` (或不返回) 表示成功，出错时返回负错误码。

复位RP2350并使用看门狗功能重启。

参数 `delay_ms` 是重启前的毫秒延迟时间。注意：默认情况下，此方法为异步（除非设置了`NO_RETURN_ON_SUCCESS`—详见下文），方法会立即返回，重启将在延迟的毫秒数后发生。

参数 `flags` 字段包含以下值之一：

- `0x0000 : REBOOT_TYPE_NORMAL` - 重新启动至正常启动路径。
  - `p0` — 引导诊断“分区”（仅限低8位）
- `0x0002 : REBOOT_TYPE_BOOTSEL` - 重新启动至BOOTSEL模式。
  - `p0` — 一组标志：
    - `0x01 : DISABLE_MSD_INTERFACE` - 禁用BOOTSEL USB驱动（详见第5.5节）
    - `0x02 : DISABLE_PICOBOOT_INTERFACE` - 禁用 PICOBLOCK 接口（参见第 5.6 节）。
    - `0x10 : GPIO_PIN_ACTIVE_LOW` - GPIO 在 `p1` 为低电平有效。
    - `0x20 : GPIO_PIN_ENABLED` - 启用指定 GPIO 上的活动指示灯。
  - `p1` - 用作 BOOTSEL USB 驱动器活动指示灯的 GPIO 编号（由 `p0` 中的标志启用）。
- `0x0003 :REBOOT_TYPE_RAM_IMAGE`- 重启至 RAM 中的映像。系统将搜索 RAM 或 XIP RAM 区域以运行映像。此类重启用于将 RAM UF2 文件拖拽至 BOOTSEL USB 驱动器时。
  - `p0` - 区域起始地址（字对齐）。
  - `p1` - 区域大小（字对齐）。
- `0x0004 :REBOOT_TYPE_FLASH_UPDATE- REBOOT_TYPE_NORMAL` 的变体，用于闪存更新后重启。这是在将闪存UF2文件拖放到 `BOOTSEL` USB 驱动器后使用的重启类型。
  - `p0`- 已更新闪存区域的起始地址。如果该地址与分区或槽的起始地址相符，则在启动（有多个选择时）期间，该分区或槽将被优先处理。
  - 此类启动支持 TBYB（第5.1.17节）及版本降级。
- `0x000d :REBOOT_TYPE_PC_SP`- 重启到指定的 PC 和 SP。注意：Arm-NS 变体中禁止使用此项。
  - `p0`- 用于开始执行的初始程序计数器（PC）。对 Arm 架构而言，最低位必须置位；对 RISC-V 架构而言，最低位必须清零。
  - `p1` - 初始堆栈指针（SP）。

上述所有项，都可以选择性地按位或（OR）以添加下列标志：

- `0x0010 :REBOOT_TO_ARM`- 将两个核心均切换至 Arm 架构（而非保持当前状态）。如果不支持 Arm 架构，调用将失败，返回`BOOTROM_ERROR_INVALID_STATE`错误。
- `0x0020 :REBOOT_TO_RISCV`— 将两个核心均切换至 RISC-V 架构（而非保持原状）。如果不支持 RISC-V 架构，调用将失败，返回`BOOTROM_ERROR_INVALID_STATE`错误。

- `0x0100 : NO_RETURN_ON_SUCCESS` - the watchdog hardware is asynchronous. Setting this bit forces this method not to return if the reboot is successfully initiated.

#### NOTE

The `p0` and `p1` parameters are generally written to watchdog scratch registers 2 & 3, and are interpreted post-reboot by the boot path code. The exception is `REBOOT_TYPE_NORMAL` where this API handles the `p0` value before rebooting; the boot path itself does not accept any parameters for `REBOOT_TYPE_NORMAL`.

#### 5.4.8.25. `secure_call`

Code: `'S','C'`

Signature: `int secure_call(...)`

Supported architectures: `Arm-NS`

Returns:  $\geq 0$  on success, a negative error code on error.

Call a Secure method from Non-secure code, passing the method to be called in the register `r4` (other arguments passed as normal).

This method provides the ability to decouple the Non-secure code from the Secure code, allowing the former to call methods in the latter without needing to know the location of the methods.

This call will always return `BOOTROM_ERROR_INVALID_STATE` unless Secure Arm code has provided a handler function via `set_rom_callback()`; if there is a handler function, this method will return the return code that the handler returns, with the convention that `BOOTROM_ERROR_INVALID_ARG` if the "function selector" (in `r4`) is not supported.

Certain well-known "function selectors" will be pre-defined to facilitate interaction between Secure and Non-secure SDK code, or indeed with other environments (for example, logging to secure UART/USB CDC, launch of core 1 from NS code, watchdog reboot from NS code back into NS code, etc.)

To avoid conflicts the following bit patterns are used for "function selectors":

- `0b0xxx xxxx xxxx xxxx xxxx xxxx xxxx` is a "well known" function selector; don't use for your own methods
- `0b10xx xxxx xxxx xxxx xxxx xxxx xxxx` is a "unique" function selector intended to be unlikely to clash with others'. The lower 30 bits should be chosen at random
- `0b11xx xxxx xxxx xxxx xxxx xxxx xxxx` is a "private" function selector intended for use by tightly coupled NS and S code

#### 5.4.8.26. `set_bootrom_stack`

Code: `'S','S'`

Signature: `int set_bootrom_stack(uint32_t base_size[2])`

Supported architectures: `RISC-V`

Returns: `BOOTROM_OK` (0) on success, a negative error code on error.

Most bootrom functions are written just once, in Arm code, to save space. As a result these functions are emulated when running under the RISC-V architecture. This is largely transparent to the user, however the stack used by the Arm emulation is separate from the calling user's stack, and is stored in boot RAM and is of quite limited size. When using certain of the more complex APIs or if nesting bootrom calls from within IRQs, you may need to provide a larger stack.

This method allows the caller to specify a region of RAM to use as the stack for the current core by passing a pointer to two values: the word aligned base address, and the size in bytes (multiple of 4).

The method fills in the previous base/size values into the passed array before returning.

- `0x0100 :NO_RETURN_ON_SUCCESS`— 看门狗硬件为异步模式。设置此位将在成功启动重启后强制方法不返回。

### 注意

参数 `p0` 和 `p1` 通常写入看门狗暂存寄存器 2 和 3，由启动路径代码在重启后进行解释。例外情况为 `REBOOT_TYPE_NORMAL`，调用此 API 会在重启前处理 `p0` 值；启动路径自身则不接受任何 `REBOOT_TYPE_NORMAL` 参数。

#### 5.4.8.25. `secure_call`

代码: '`S`' , '`C`'

签名: `int secure_call(...)`

支持的架构: `Arm-NS`

返回值: 成功时返回  $\geq 0$ ，出错时返回负数错误代码。

从非安全代码调用安全方法，将待调用的方法传递至寄存器 `r4`（其他参数按常规传递）。

该方法提供了将非安全代码与安全代码解耦的能力，使前者能够调用后者的方法，而无需知晓方法的具体位置。

此调用将始终返回 `BOOTROM_ERROR_INVALID_STATE`，除非安全 Arm 代码已通过 `set_rom_callback()` 提供了处理函数；若存在处理函数，该方法将返回该处理函数的返回码，约定如果“函数选择器”（位于 `r4`）不被支持，则返回 `BOOTROM_ERROR_INVALID_ARG`。

某些已知的“函数选择器”将被预先定义，以便促进安全与非安全 SDK 代码之间，或与其他环境（例如，向安全 UART/USB CDC 记录日志、从非安全代码启动核心 1、从非安全代码通过看门狗重启返回非安全代码等）的交互。为避免冲突，以下位模式将被用于“函数选择器”：

- `0b0xxx xxxx xxxx xxxx xxxx xxxx xxxx xxxx` 是一个“众所周知”的函数选择器；请勿用于您自己的方法
- `0b10xx xxxx xxxx xxxx xxxx xxxx xxxx xxxx` 是一个“唯一”的函数选择器，旨在避免与其他选择器冲突。低 30 位应随机选择
- `0b11xx xxxx xxxx xxxx xxxx xxxx xxxx xxxx` 是一个“私有”的函数选择器，仅供紧密耦合的非安全(NS)与安全(S)代码使用

#### 5.4.8.26. `set_bootrom_stack`

代码: '`S`' , '`S`'

签名: `int set_bootrom_stack(uint32_t base_size[2])`

支持的架构: `RISC-V`

返回值: `BOOTROM_OK(0)` 表示成功，负数错误代码表示失败。

大多数 bootrom 函数仅使用 Arm 代码编写一次，以节省空间。因此，在 RISC-V 架构下运行时，这些函数须模拟执行。这对用户基本透明，但 Arm 模拟使用的堆栈与调用用户的堆栈分开，存储于 boot RAM 中，且容量有限。在使用某些较复杂的 API 或从 IRQ 内嵌套调用 bootrom 时，可能需要分配更大的栈空间。

此方法允许调用者通过传入指向两个值的指针，指定 RAM 区域作为当前核心的栈使用：对齐的基地址和大小（以字节为单位，4 的倍数）。

该方法在返回前，会将之前的基地址和大小值写入传入的数组中。

### 5.4.8.27. `set_ns_api_permission`

Code: 'S','P'

Signature: `int set_ns_api_permission(uint ns_api_num, bool allowed)`

Supported architectures: Arm-S

Returns: `BOOTROM_OK` (0) on success, a negative error code on error.

Allow or disallow the specific NS API; all NS APIs default to disabled.

`ns_api_num` is one of the following, configuring Arm-NS access to the given API. When an NS API is disabled, calling it will return `BOOTROM_ERROR_NOT_PERMITTED`.

- 0x0: `get_sys_info`
- 0x1: `flash_op`
- 0x2: `flash_runtime_to_storage_addr`
- 0x3: `get_partition_table_info`
- 0x4: `secure_call`
- 0x5: `otp_access`
- 0x6: `reboot`
- 0x7: `get_b_partition`

#### NOTE

All permissions default to disallowed after a reset (see also `bootrom_state_reset()`).

### 5.4.8.28. `set_rom_callback`

Code: 'R','C'

Signature: `int set_rom_callback(uint callback_number, int (*callback)(…))`

Supported architectures: Arm-S, RISC-V

Returns: >= 0 (the old callback pointer) on success, a negative error code on error.

The only currently supported `callback_number` is 0 which sets the callback used for the `secure_call` API.

A callback pointer of 0 deletes the callback function, a positive callback pointer (all valid function pointers are on RP2350) sets the callback function, but a negative callback pointer can be passed to get the old value without setting a new value.

If successful, returns >=0 (the existing value of the function pointer on entry to the function).

### 5.4.8.29. `validate_ns_buffer`

Code: 'V','B'

Signature: `void *validate_ns_buffer(const void *addr, uint32_t size, uint32_t write, uint32_t *ok)`

Supported architectures: Arm-S

Returns: `addr` on success, or a negative error code on error. On RP2350 A3 and newer there are additional out-of-band return values, detailed below.

Utility method that can be used by Secure Arm code to validate a buffer passed to it from Non-secure code.

### 5.4.8.27. set\_ns\_api\_permission

代码: 'S', 'P'

函数签名: `int set_ns_api_permission(uint ns_api_num, bool allowed)`

支持架构: Arm-S

返回值: `BOOTROM_OK(0)` 表示成功, 负数错误代码表示失败。

允许或禁止特定的非安全 (NS) API; 所有非安全API默认均为禁用。

`ns_api_num` 为以下之一, 用于配置 Arm-NS 对指定API的访问权限。禁用状态的非安全API调用将返回`BOOTROM_ERROR_NOT_PERMITTED`。

- 0x0: `get_sys_info`
- 0x1: `flash_op`
- 0x2: `flash_runtime_to_storage_addr`
- 0x3: `get_partition_table_info`
- 0x4: `secure_call`
- 0x5: `otp_access`
- 0x6: `reboot`
- 0x7: `get_b_partition`

#### ① 注意

重置后, 所有权限默认均被拒绝 (详见 `bootrom_state_reset()`)。

### 5.4.8.28. set\_rom\_callback

代码: 'R', 'C'

函数签名: `int set_rom_callback(uint callback_number, int (*callback)(…))`

支持的架构: Arm-S, RISC-V

返回值: 成功时返回 `>=0` (旧的回调指针), 失败时返回负错误码。

当前唯一支持的`callback_number`是 0, 用于设置`secure_call`接口的回调函数。

回调指针为 0 时删除回调函数; 正值回调指针 (所有有效函数指针均在 RP2350 上) 设置回调函数; 负值回调指针则用于获取旧回调指针而不进行更改。

如果成功, 返回值 `>=0` (函数入口时函数指针的现有值)。

### 5.4.8.29. validate\_ns\_buffer

代码: 'V', 'B'

签名: `void *validate_ns_buffer(const void *addr, uint32_t size, uint32_t write, uint32_t *ok)`

支持架构: Arm-S

返回值: `addr` 成功时返回, 错误时返回负错误码。在 RP2350 A3 及更新版本中, 存在额外的带外返回值, 详见下文。

此工具方法可供安全 Arm 代码用于验证从非安全代码传入的缓冲区。

Both the `write` parameter and the (out) result parameter `ok` are RCP booleans, so `0xa500a500` for true, and `0x00c300c3` for false. This enables hardening of this function, and indeed the `write` parameter must be one of these values or the RCP will halt the system.

For success, the entire buffer must fit in range `XIP_BASE` → `SRAM_END`, and must be accessible by the Non-secure caller according to SAU + NS MPU (privileged or not based on current processor IPSR and NS CONTROL flag). Buffers in USB RAM are also allowed if access is granted to NS via ACCESSCTRL.

On RP2350 A3 and newer, additional out-of-band information is returned from this function to aid calling from assembly code:

- The RCP boolean value returned in the location pointed to by `ok` is now also returned in processor register `r1` (a valid `ok` pointer value or 0 must still be passed).
- The passed size is returned in register `r3`.
- The `N` flag is set based on the register `r1` value, so you can immediately branch with `bpl` for failure.

The A3 bootrom uses a call pattern similar to that shown below to help harden the code against hardware attacks, which might cause skipping of instructions:

```
// at this point, r0, r2, r3 already hold arguments for buffer, write, and *ok
1: movs r1, #0 // set r1 to invalid RCP_VALUE zero and set N=0
2: mov r1, ra // set r1 to size value (stored in another register a)
3: bl validate_ns_buffer // call the validate function
4: bpl buffer_invalid // N==0 is deemed to be false (invalid)
5: rcp_btrue r1 // negative value shoule be 0xa500a500
buffer_valid:
6: movs rb, ra // reload size for use
7: rcp_iequal r3, rb // check r3 has the correct size
 // r0 holds 'buffer' on success; this can be used as a check too if desired
8: // do some secure code with 'buffer' and 'size'
 ...
buffer_invalid:
 // r0 holds BOOTROM_ERROR_INVALID_ADDRESS
 ...
```

#### 5.4.8.30. `xip_setup_func_ptr`

Code: 'X','F'

Type: `void *(xip_setup_func_ptr)(void)`

## 5.5. USB mass storage interface

The bootrom provides a standard USB bootloader that makes a writeable drive available for copying code to the RP2350 using UF2 files (see [Section 5.5.2](#)).

A suitable UF2 file copied to the drive is downloaded and written to flash or RAM, and the device is automatically rebooted, making it trivial to download and run code on the RP2350 using only a USB connection.

### 5.5.1. The RP2350 drive

RP2350 appears as a standard 128MB flash drive named `RP2350` formatted as a single partition with FAT16. There are only ever two actual files visible on the drive specified.

`write` 参数及（输出）结果参数 `ok` 均为 RCP 布尔值，真值为 `0xa500a500`，假值为 `0x00c300c3`。此举增强了该函数的加固性，且 `write` 参数必须为上述值之一，否则 RCP 将终止系统运行。

为确保成功，整个缓冲区必须位于范围 `XIP_BASE` → `SRAM_END` 内，且必须依据 SAU 与 NS MPU 的配置（基于当前处理器的 IP SR 和 NS CONTROL 标志判断是否特权）对非安全调用者开放访问。若通过 ACCESSCTRL 授权，USB RAM 中的缓冲区亦允许非安全访问。

在 RP2350 A3 及更高版本中，该函数会返回额外的带外信息，以支持汇编代码的调用：

- 返回的 RCP 布尔值不仅存放在由 `ok` 指针指向的位置，还返回至处理器寄存器 `r1` 中（仍须传入有效的 `ok` 指针或 0）。
- 传入的大小参数则返回至寄存器 `r3` 中。
- 根据寄存器 `r1` 的值设置 `N` 标志，故可立即使用 `bpl` 指令进行失败分支。

A3 版本只读存储器启动代码采用如下所示的调用模式，以增强代码抵御硬件攻击的能力，防止指令跳过：

```
// 此时，r0、r2 和 r3 已分别保存 buffer、write 以及 *ok 的参数
1: movs r1, #0 // 将 r1 设为无效的 RCP_VALUE 零值，并将 N 置为 0
2: mov r1, ra // 将 r1 设为大小值（存储于另一个寄存器 a 中）
3: bl validate_ns_buffer // 调用验证函数
4: bpl buffer_invalid // N==0 被视为假（无效）
5: rcp_btrue r1 // 负值应为 0xa500a500
buffer_valid:
6: movs rb, ra // 重新加载大小以便使用
7: rcp_iequal r3, rb // 检查 r3 是否具有正确大小
 // 成功时 r0 保存 'buffer'；该值也可用作检查（如有需要）
8: // 对 `buffer` 和 `size` 执行部分安全代码
 ...
buffer_invalid:
 // r0 保存 BOOTROM_ERROR_INVALID_ADDRESS
 ...
```

#### 5.4.8.30. `xip_setup_func_ptr`

代码: 'X', 'F'

类型: `void *(xip_setup_func_ptr)(void)`

## 5.5. USB 大容量存储接口

只读存储器提供了一个标准 USB 引导程序，使通过 UF2 文件将代码复制到 RP2350 的可写驱动器成为可能（参见第 5.5.2 节）。

将合适的 UF2 文件复制到驱动器后，文件将被下载并写入闪存或 RAM，设备自动重启，使仅通过 USB 连接即可轻松下载和运行 RP2350 代码。

### 5.5.1. RP2350 驱动

RP2350 作为一个标准 128MB 闪存驱动器出现，命名为 `RP2350`，格式为单一 FAT16 分区。驱动器上仅显示两个实际文件。

- `INFO_UF2.TXT` contains a string description of the UF2 bootloader and version.
- `INDEX.HTM` redirects to information about the RP2350 device.

The default `INDEX.HTM` for RP2350 A2 is <https://raspberrypi.com/device/RP2?version=5A09D5312E22>. The version parameter is changed for other RP2350 revisions; the first 6 characters are from the git hash of the chip, and the next 6 characters are from the git hash of the bootrom. The contents of these files and the name of the drive may be customised. For more information, see [Section 5.7](#).

Any type of files may be written to the USB drive from the host; however, in general these aren't stored, and only appear to be so because of caching on the host side.

When a suitable UF2 file is written to the device, the special contents are recognised and data is written to specified locations in RAM or flash.

Where flash-targeted UF2s are written on RP2350 is determined by the *family id* of the UF2 contents and the partition table.

If there's no partition table, then UF2s are stored at the address they specify; otherwise they (with the exception of the special `ABSOLUTE` family id) are stored into a single partition, with UF2 flash address `0x1000000` mapping to the start of the partition.

It's possible, based on the partition table or family id, that the UF2 isn't downloadable anywhere in flash, in which case, it's ignored. Further detail can be discovered via `GET_INFO - UF2_STATUS`. On the completed download of an entire valid UF2 file, RP2350 automatically reboots to run the newly downloaded code.

Invalid UF2 files might not write at all or only write partially to RP2350 before failing. Not all operating systems notify you of disk write errors after a failed write. You can use `picotool verify` to verify that a UF2 file wrote correctly to RP2350.

### 5.5.2. UF2 format details

This section describes the constraints on a UF2 file to be valid for download.

 **TIP**

To generate UF2 files, you can use the `picotool uf2 convert` functionality in `picotool`.

All data destined for the device must be in UF2 blocks with:
