- A `familyID` present, with a value in the reserved range `0xe48bff58` through `0xe48bff5b` or a user family ID configured in a partition table (see table in [Section 5.5.3](#)).
- A `payload_size` of `256`.

All data must be destined for (and fit entirely within) the following memory ranges (depending on the type of binary being downloaded which is determined by the address of the first UF2 block encountered):

- A regular flash image
  - `0x1000000-0x12000000` *flash*: All blocks must be targeted at 256 byte alignments. Writes beyond the end of physical flash will wrap back to the beginning of flash.
- A *RAM only* image
  - `0x2000000-0x20082000` *main RAM*: Blocks can be positioned with byte alignment.
  - `0x13ffc000-0x14000000` *XIP RAM*: (since flash isn't being targeted, the flash cache is available for use as RAM with same properties as *main RAM*).

- `INFO_UF2.TXT` 包含UF2引导程序及版本的字符串描述。
- `INDEX.HTM` 重定向到有关RP2350设备的信息。

RP2350 A2 的默认 `INDEX.HTM` 地址为 <https://raspberrypi.com/device/RP2?version=5A09D5312E22>。对于其他 RP2350 版本，version 参数将有所变化；前六个字符来自芯片的 git 哈希，后六个字符来自 bootrom 的 git 哈希。这些文件的内容及驱动器名称均可进行定制。更多信息请参见第5.7节。

主机可以向 USB 驱动器写入任何类型的文件；然而，通常这些文件并未实际存储，其显示存在仅因主机端缓存所致。

当写入合适的 UF2 文件到设备时，设备会识别特殊内容，并将数据写入 RAM 或闪存的指定位置。

RP2350 上写入闪存的 UF2 文件位置由 UF2 内容的*family id*及分区表决定。

如果不存在分区表，则UF2文件存储于其指定地址；否则（特殊的 *ABSOLUTE*系列ID除外），它们存储于单一分区中，其中UF2闪存地址 `0x10000000`映射至该分区起始位置。

基于分区表或系列ID，UF2文件可能无法下载至闪存的任何位置，此时该文件将被忽略。可通过GET\_INFO - UF2\_STATUS 命令获取更多详细信息。在完整下载一个有效的UF2文件后，RP2350会自动重启以执行新下载的代码。

无效的UF2文件可能完全无法写入，或仅部分写入至RP2350后失败。并非所有操作系统在写入失败后都会通知磁盘写入错误。您可以使用 `picotool verify`命令验证UF2文件是否已正确写入RP2350。

### 5.5.2. UF2格式详情

本节描述了UF2文件下载有效性的必要约束条件。

#### 💡 提示

要生成 UF2 文件，您可以使用位于 `picotool` 中的 `picotool uf2 conver t` 功能。

所有发送至设备的数据必须为符合以下条件的 UF2 块：

- 必须存在一个 `familyID`，其值位于保留范围 `0xe48bff58` 至 `0xe48bff5b` 之间，或为分区表中配置的用户 `family ID`（参见 第 5.5.3 节的表格）。
- 一个大小为 256 的 `payload_size`。

所有数据必须发送到以下内存范围内（依据下载的二进制文件类型，该类型由第一个遇到的 UF2 块的地址决定），且必须完全位于该范围内：

- 常规闪存映像
  - `0x10000000-0x12000000` 闪存：所有块必须以 256 字节对齐为目标地址。超出物理闪存末端的写入将回绕至闪存起始地址。
- 仅限 RAM 映像
  - `0x20000000-0x20082000` 主 RAM：块可按字节对齐定位。
  - `0x13ffc000-0x14000000` XIP RAM：（由于未针对闪存，闪存缓存可用作与 `main RAM` 属性相同的 RAM）

**NOTE**

Traditionally UF2 has only been used to write to flash, but this is more a limitation of using the metadata-free `.BIN` file as the source to generate the UF2 file. RP2350 takes full advantage of the inherent flexibility of UF2 to support the full range of binaries in the richer `.ELF` format produced by the build to be used as the source for the UF2 file.

- The `numBlocks` must specify a total size of the binary that fits in the regions specified above
- A change of `numBlocks` or the binary type (determined by UF2 block target address) will discard the current transfer in progress.
- A change in the `familyID` will discard the current transfer in progress.
- All device destined data must be in blocks without the `UF2_FLAG_NOT_MAIN_FLASH` marking which relates to content to be ignored rather than flash vs RAM.

**NOTE**

When targeting flash, the UF2 block target addresses are interpreted to be in the content of a flash binary that starts at `0x10000000`. The UF2 image may be downloaded into a partition that starts somewhere else in flash, so the actual storage address is `uf2_image_target_base + uf2_block_target_addr - 0x10000000`.

The flash is always erased a 4 kB sector at a time, so including data for only a subset of the 256-byte pages within a sector in a flash-binary UF2 will leave the remaining 256-byte pages of the sector erased but undefined.

A binary is considered "downloaded" when each of the `numBlocks` blocks has been seen at least once in the course of a single valid transfer. The data for a block is only written the first time in case of the host resending duplicate blocks.

After a UF2 is completely downloaded, the RP2350 reboots, ostensibly to run the new binary. Since RP2350 supports downloading a variety of executable and non-executable UF2s into partitions, the partition contains a flag which can be used to turn off this reboot behaviour on a case by case basis.

**NOTE**

When rebooting after a flash download, a `flash update boot` is performed. As a result, the newly written partition is preferred when considered in an A/B choice, but it doesn't boot if another bootable image is found in an earlier partition. When rebooting after a RAM download, then the image search starts at the lowest address of a downloaded block (with main RAM considered lower than flash cache if both are present, and the search only spanning one of either main RAM or the flash cache)

It is possible for host software to temporarily disable UF2 writes via the PICOBEST interface to prevent interference with operations being performed via that interface (see below), in which case any UF2 file write in progress will be aborted.

**NOTE**

If a problem is encountered downloading the UF2, then it will appear as if *nothing has happened* since the device will not reboot. The `picotool` command `uf2 info` can be used to determine the status of the last download in this case (see also [GET\\_INFO - UF2\\_STATUS](#)).

### 5.5.3. UF2 targeting rules

When the first block of a UF2 is downloaded, a choice is made where to store the UF2 in flash based on the *family ID* of the UF2. This choice is performed by the same code as the `get_uf2_target_partition()` API (see [Section 5.4.8.18](#)).

The following family IDs are defined by the bootrom. However, the user can use their own for more specific targeting:

**i 注意**

传统上，UF2仅用于写入闪存，但这主要是因为使用无元数据的.BIN文件作为生成UF2文件源的限制。RP2350充分利用UF2固有的灵活性，支持由构建生成的更丰富的.ELF格式二进制文件作为UF2文件的源。

- numBlocks必须指定适合上述区域的二进制总大小。
- 更改 numBlocks或二进制类型（由 UF2块目标地址确定）将丢弃当前正在进行的传输。
- 更改 familyID将丢弃当前正在进行的传输。
- 所有面向设备的数据必须存在于未标记为UF2\_FLAG\_NOT\_MAIN\_FLASH的块中，该标记表示内容应被忽略，而非区分闪存与RAM。

**i 注意**

当定位到闪存时，UF2块目标地址被解释为位于以 0x1为起始地址的闪存二进制内容中。0000000. UF2映像可能被下载到闪存中其他位置起始的分区，因此实际存储地址为uf2\_image\_target\_base + uf2\_block\_target\_addr - 0x1。0000000.

闪存始终以4 KB扇区为单位擦除，因此在闪存二进制UF2中仅包含扇区内部分256字节页的数据时，扇区内其余的256字节页将保持擦除但内容未定义。

当在单次有效传输过程中，每个 numBlocks块至少被接收一次时，该二进制文件即被视为“已下载”。为防止主机重复发送重复块，块的数据仅在首次接收时写入。

UF2完全下载后，RP2350将重新启动，表面目的是运行新的二进制文件。鉴于RP2350支持向分区下载多种可执行及非可执行UF2，分区中包含一标志，可用于逐案关闭该重启行为。

**i 注意**

在闪存下载后重新启动时，将执行闪存更新引导。因此，在A/B选择中会优先考虑新写入的分区，但如果在较早的分区中发现另一个可引导映像，则不会启动。在RAM下载后重新启动时，映像搜索从下载块的最低地址开始（若主RAM与闪存缓存共存，则主RAM视为较低地址，且搜索范围仅限主RAM或闪存缓存中的一个）。

主机软件可以通过PICOBOOT接口临时禁用UF2写入，以防止与该接口执行的操作相冲突（见下文）；在此情况下，任何正在进行的UF2文件写入将被中止。

**i 注意**

若在下载UF2时发生问题，则表现为设备不会重新启动，即看似未发生任何情况。picotool命令uf2 info可用于查询最后一次下载的状态（另见GET\_INFO - UF2\_STATUS）。

### 5.5.3. UF2目标规则

当下载UF2的第一个块时，系统依据UF2的family ID选择将UF2存储于闪存中的位置。此选择由与get\_uf2\_target\_partition() API（见第5.4.8.18节）相同的代码执行。

以下family ID由bootrom预定义。然而，用户可使用自定义ID以实现更精确的目标定位：

Table 455. Table of standard UF2 family IDs understood by the RP2350 bootrom

| Name          | Value      | Description                                                                                                                                                |
|---------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| absolute      | 0xe48bff57 | Special family ID for content intended to be written directly to flash, ignoring partitions.                                                               |
| rp2040        | 0xe48bff56 | RP2040 executable image.                                                                                                                                   |
| data          | 0xe48bff58 | Generic catch-all for data UF2s.                                                                                                                           |
| rp2350_arm_s  | 0xe48bff59 | RP2350 Arm Secure image (one intended to be booted by the bootrom).                                                                                        |
| rp2350_riscv  | 0xe48bff5a | RP2350 RISC-V image.                                                                                                                                       |
| rp2350_arm_ns | 0xe48bff5b | RP2350 Arm Non-secure image. Not directly bootable by the bootrom. However, Secure user code is likely to want to be able to locate binaries of this type. |

### **i** NOTE

The only information available to the algorithm that makes the choice of where to store the UF2, is the UF2 family ID; the algorithm can't look inside at the UF2 contents as UF2 data sectors may appear at the device in any order.

A UF2 with the `absolute` family ID is downloaded without regard to partition boundaries. A partition table (if present) or OTP configuration can define whether `absolute` family ID downloads are allowed, and download to the start of flash. The default factory settings allow for `absolute` family ID downloads

If there is a partition table present, any other family IDs download to a single partition; if there is no partition table present then the `data`, `rp2350-arm-s` (if Arm architecture is enabled) and `rp2350-riscv` (if RISC-V architecture is enabled) family IDs are allowed by default, and the UF2 is always downloaded to the start of flash.

If a partition table is present, then up to four passes are made over the partition table (from first to last partition encountered) until a matching partition is found; Each pass has different selection criteria:

1. Look for an (unowned) `A` partition, ignoring those marked `NOT_BOOTABLE` for the current CPU architecture

Use of the `NOT_BOOTABLE` flags allows you to have separate boot partitions for each CPU architecture (Arm or RISC-V); were you not to use `NOT_BOOTABLE` flags in this scenario, and say the first encountered partition has an Arm `IMAGE_DEF`, then, when booting under the RISC-V architecture with auto architecture switching enabled, the bootrom would just switch back into the Arm architecture to boot the Arm binary. Marking the first partition as `NOT_BOOTABLE_RISCV` in the partition table solves this problem.

The correct CPU architecture refers to a match between the architecture of the UF2 (determined by family ID of `rp2350_arm_s` or `rp2350_riscv`) and the current CPU architecture.

This pass allows the user to drop either Arm or RISC-V UF2s, and have them stored as you'd want for the `NOT_BOOTABLE` flag scenario.

2. If auto architecture switching is enabled and the other architecture is available, look for an (unowned) `A` partition, ignoring those marked `NOT_BOOTABLE` for that CPU architecture.

This pass is designed to match the boot use case of booting images from the other architecture as a fallback. If there is a partition that would be booted as a result auto architecture switching then this a reasonable place to store this UF2 for the alternative architecture.

3. Look for any unowned `A` partition that accepts the family ID

This pass provides a way to target any UF2s to a partitions based on family ID, but assumes that you'd prefer a UF2 to go into a matching top-level partition vs an owned partition.

4. Finally, look for any `A` partition that accepts the family ID

This pass implicitly only looks at owned partitions, since unowned partitions would have been matched in the previous pass.

If none of the passes find a match, the UF2 contents aren't then downloaded. The `picotool` command `uf2 info` can be

表 455。 RP2350  
bootrom 认可的标  
准 UF2 family ID 表

| 名称                         | 值                       | 描述                                                          |
|----------------------------|-------------------------|-------------------------------------------------------------|
| <code>absolute</code>      | <code>0xe48bff57</code> | 特定 family ID，用于内容直接写入闪存，忽略所有分区。                             |
| <code>rp2040</code>        | <code>0xe48bff56</code> | RP2040 可执行映像。                                               |
| <code>data</code>          | <code>0xe48bff58</code> | 通用数据型 UF2 的通配类别。                                            |
| <code>rp2350_arm_s</code>  | <code>0xe48bff59</code> | RP2350 Arm 安全映像（由 bootrom 负责启动）。                            |
| <code>rp2350_riscv</code>  | <code>0xe48bff5a</code> | RP2350 RISC-V 镜像。                                           |
| <code>rp2350_arm_ns</code> | <code>0xe48bff5b</code> | RP2350 Arm 非安全镜像。不能被只读存储器直接启动。<br>然而，安全用户代码可能需要能够定位此类二进制文件。 |

### 注意

决定存储 UF2 位置的算法唯一可用信息是 UF2 系列 ID；  
该算法无法查看 UF2 内容，因为 UF2 数据扇区可能按任意顺序出现在设备中。

带有 `absolute` 家族 ID 的 UF2 文件下载时不考虑分区边界。分区表（如存在）或 OTP 配置可定义是否允许 **绝对** 系列 ID 下载，并下载至闪存起始地址。默认出厂设置允许 **绝对** 系列 ID 下载。

若存在分区表，其他系列 ID 将下载至单一分区；若不存在分区表，则默认允许 `data`、`rp2350-arm-s`（启用 Arm 架构时）及 `rp2350-riscv`（启用 RISC-V 架构时）系列 ID，并且 UF2 始终下载至闪存起始地址。

如果存在分区表，则最多对分区表进行四次遍历（从遇到的第一个分区开始至最后一个），直到找到匹配的分区；每次遍历的选择标准各不相同：

1. 查找一个（未被占用的）**A** 分区，忽略那些为当前 CPU 架构标记为 `NOT_BOOTABLE` 的分区

使用 `NOT_BOOTABLE` 标志可让您为每种 CPU 架构（Arm 或 RISC-V）设置独立的启动分区；若未在此场景中使用 `NOT_BOOTABLE` 标志，假设首次遇到的分区是 Arm `IMAGE_DEF`，则在启用自动架构切换的 RISC-V 架构下启动时，bootrom 会直接切换回 Arm 架构以便启动 Arm 二进制文件。在分区表中将第一个分区标记为 `NOT_BOOTABLE_RISCV` 可解决此问题。

所谓正确的 CPU 架构，指的是 UF2 的架构（由 `rp2350_arm_s` 或 `rp2350_riscv` 的家族 ID 确定）与当前 CPU 架构相匹配。

此过程允许用户放置 Arm 或 RISC-V UF2 文件，并根据 `NOT_BOOTABLE` 标志的情况，将其存储为所需的格式。

2. 如果启用了自动架构切换且另一架构可用，则查找（未拥有的）**A** 分区，忽略针对该 CPU 架构标记为 `NOT_BOOTABLE` 的分区。

此过程旨在匹配从另一架构启动映像作为后备启动的场景。如果存在因自动架构切换而可能启动的分区，则此处是存储该替代架构 UF2 的合理位置。

3. 查找任何未拥有且接受该系列 ID 的 **A** 分区。

此过程提供根据系列 ID 将任何 UF2 定位至分区的方法，但默认您更倾向于将 UF2 放入匹配的顶级分区，而非已拥有的分区。

4. 最后，查找任何接受该系列 ID 的 **A** 分区。

此过程隐含仅检查已拥有的分区，因为未拥有的分区已在前一过程被匹配。

如果没有任何通道找到匹配，则不会下载 UF2 内容。可以使用 `picotool` 命令 `uf2 info`

used to determine the status of the last download in this case (see also [GET\\_INFO - UF2\\_STATUS](#)).

### 5.5.3.1. A/B partitions and ownership

Each of the above passes refers to finding an **A** partition. Any partition that isn't a **B** partition is an **A** partition; an unpaired partition is classed as an **A** partition.

If the found **A** partition doesn't have a **B** partition paired with it, then the **A** partition is the UF2 target partition.

If however, the **A** partition has a **B** partition, then a further choice must be made as to which of the **A/B** partitions should be targeted.

1. If the **A** partition is unowned, then the partition choice is made based on any current valid **IMAGE\_DEF** in those partitions. The valid partition with the higher version number isn't chosen; in the case of executable **IMAGE\_DEF**s, this is the opposite of what would happen during boot; this makes sense as you want to drop the UF2 on the partition which isn't currently booting.
2. If the **A** partition is marked owned, then the contents of the **A** partition and **B** partition are assumed not to contain **IMAGE\_DEF**s which can be used to make a version based choice. Therefore, the owner of the **A** partition ( $A_{owner}$ ) and its **B** partition ( $B_{owner}$ ) are used to make the choice

It is however dependent on the use case whether you would want a UF2 that is destined for partition **A** / partition **B** to go into partition **A** when partition  $A_{owner}$  has an **IMAGE\_DEF** with the higher version (would boot if the **IMAGE\_DEF** was executable) or when  $B_{owner}$  has an **IMAGE\_DEF** with the higher version. By default, the bootrom picks partition **A** when partition  $A_{owner}$  has the higher versioned **IMAGE\_DEF**, however this can be changed by setting the **UF2\_DOWNLOAD\_AB\_NON\_BOOTABLE\_OWNER\_AFFINITY** flag in partition **A**.

### 5.5.3.2. Multiple UF2 families

It is possible to include sectors targeting different family IDs in the same UF2 file. The intention in the UF2 specification is to allow one file to be shipped for multiple different devices, but the expectation is that each device only accepts one UF2 family ID.

Similarly on RP2350, it is only supported to download a UF2 file containing multiple family IDs if *only one* of those family IDs is acceptable for download to the device according to the above rules.

## 5.6. USB PICOBLOCK interface

The PICOBLOCK interface is a low level USB protocol for interacting with the RP2350 while it is in BOOTSEL mode. This interface may be used concurrently with the USB Mass Storage Interface.

It provides for flexible reading from and writing to RAM or flash, rebooting, executing code on the device and a handful of other management functions.

Constants and structures related to the interface can be found in the SDK header [picoblock.h](#) in the [SDK](#)

### 5.6.1. Identifying the device

A RP2350 device can be recognised by the Vendor ID and Product ID in its device descriptor (shown in [Table 456](#)), unless different values have been set in OTP (see [Section 5.7](#))

*Table 456. RP2350 Boot Device Descriptor*

| Field           | Value |
|-----------------|-------|
| bLength         | 18    |
| bDescriptorType | 1     |

来确定最后一次下载的状态（参见GET\_INFO - UF2\_STATUS）。

### 5.5.3.1. A/B 分区及所有权

上述每个通道均指寻找一个 A分区。任何非 B分区均视为 A分区；未配对的分区归类为 A分区。

若找到的 A分区未与 B分区配对，则该 A分区为UF2目标分区。

然而，若 A分区对应有 B分区，则须进一步决定应针对哪个 A/B分区。

1. 若 A分区无所有者，则根据这些分区中任何当前有效的 IMAGE\_DEF 来确定分区选择。没有选择版本号更高的有效分区；在可执行的 IMAGE\_DEF 情况下，情况与启动时相反；这是合理的，因为您希望将UF2文件放到当前未启动的分区。
2. 如果 A分区已标记为已拥有，则假定 A分区和 B分区内不包含可用于基于版本选择的IMAGE\_DEF。因此，使用 A分区（A所有者）及其B分区（B所有者）的所有者信息来进行选择。

然而，是否希望目标为分区 A或分区 B的UF2文件写入A分区，取决于具体使用场景；当A所有者拥有的 IMAGE\_DEF 版本较高（若该 IMAGE\_DEF 可执行则会启动）或当 B所有者拥有的IMAGE\_DEF 版本较高时，选择可能不同。默认情况下，bootrom 会选择分区A，前提是分区A所有者的 IMAGE\_DEF 版本较高，但此行为可通过设置分区 A中的 UF2\_DOWNLOAD\_AB\_ON\_BOOTABLE\_OWNER\_AFFINITY 标志进行更改。

### 5.5.3.2. 多个 UF2 系列

在同一 UF2 文件中包含针对不同系列 ID 的扇区是允许的。UF2 规范旨在允许单一文件支持多种不同设备，但每个设备预期仅接受一个 UF2 系列 ID。

类似地，在 RP2350 上，仅支持下载包含多个系列 ID 的 UF2 文件，条件是根据上述规则，只有其中一个系列 ID 被允许下载至设备。

## 5.6. USB PICOBLOCK 接口

PICOBLOCK 接口是一种用于 RP2350 处于 BOOTSEL 模式时进行交互的低级 USB 协议。此接口可与 USB 大容量存储接口并行使用。

它支持对RAM或闪存的灵活读写、设备重启、在设备上执行代码以及其他若干管理功能。

与接口相关的常量和结构体定义可在SDK头文件 `picoblock.h` 中找到。

### 5.6.1. 设备识别

RP2350设备可通过其设备描述符中的供应商ID和产品ID识别（见表456），除非在OTP中设置了不同的值（参见第5.7节）。

表456。RP2350  
引导设备  
描述符

| 字段              | 值  |
|-----------------|----|
| bLength         | 18 |
| bDescriptorType | 1  |

| Field              | Value                                        |
|--------------------|----------------------------------------------|
| bcdUSB             | 2.10                                         |
| bDeviceClass       | 0                                            |
| bDeviceSubClass    | 0                                            |
| bDeviceProtocol    | 0                                            |
| bMaxPacketSize0    | 64                                           |
| idVendor           | 0x2e8a - this value may be overridden in OTP |
| idProduct          | 0x000f - this value may be overridden in OTP |
| bcdDevice          | 1.00 - this value may be overridden in OTP   |
| iManufacturer      | 1                                            |
| iProduct           | 2                                            |
| iSerial            | 3                                            |
| bNumConfigurations | 1                                            |

### 5.6.2. Identifying the interface

The PICOBOOT interface is recognised by the vendor-specific Interface Class, the zero Interface Sub Class, and Interface Protocol (shown in [Table 457](#)).

Don't rely on the interface number, because that is dependent on whether the device is currently exposing the Mass Storage Interface. The device might not be currently exposing the PICOBOOT interface at all, so you mustn't assume it's present.

*Table 457. PICOBOOT Interface Descriptor*

| Field              | Value                  |
|--------------------|------------------------|
| bLength            | 9                      |
| bDescriptorType    | 4                      |
| bInterfaceNumber   | varies                 |
| bAlternateSetting  | 0                      |
| bNumEndpoints      | 2                      |
| bInterfaceClass    | 0xff (vendor specific) |
| bInterfaceSubClass | 0                      |
| bInterfaceProtocol | 0                      |
| iInterface         | 0                      |

### 5.6.3. Identifying the endpoints

The PICOBOOT interface provides a single `BULK_OUT` and a single `BULK_IN` endpoint. These can be identified by their direction and type. You mustn't rely on endpoint numbers.

| 字段                 | 值                      |
|--------------------|------------------------|
| bcdUSB             | 2.10                   |
| bDeviceClass       | 0                      |
| bDeviceSubClass    | 0                      |
| bDeviceProtocol    | 0                      |
| bMaxPacketSize0    | 64                     |
| idVendor           | 0x2e8a - 此值可在OTP中覆盖    |
| idProduct          | 0x000f - 此值可在OTP中覆盖    |
| bcdDevice          | 1.00 - 此值可能会在 OTP 中被覆盖 |
| iManufacturer      | 1                      |
| iProduct           | 2                      |
| iSerial            | 3                      |
| bNumConfigurations | 1                      |

### 5.6.2. 接口识别

PICOBOOT 接口通过厂商特定的接口类、接口子类为零以及接口协议（见表 457）进行识别。

请勿依赖接口编号，该编号取决于设备当前是否暴露大容量存储接口。设备可能根本未暴露 PICOBOOT 接口，因此不可假定其存在。

表 457。PICOBOOT  
接口描述符

| 字段                 | 值           |
|--------------------|-------------|
| bLength            | 9           |
| bDescriptorType    | 4           |
| bInterfaceNumber   | 可变          |
| bAlternateSetting  | 0           |
| bNumEndpoints      | 2           |
| bInterfaceClass    | 0xff (厂商特定) |
| bInterfaceSubClass | 0           |
| bInterfaceProtocol | 0           |
| iInterface         | 0           |

### 5.6.3. 端点识别

PICOBOOT 接口提供一个 **BULK\_OUT** 端点和一个 **BULK\_IN** 端点。这些端点可通过其方向和类型进行识别。禁止依赖端点编号。

## 5.6.4. PICOBLOCK Commands

The two bulk endpoints are used for sending commands and retrieving successful command results. All commands are exactly 32 bytes (see [Table 458](#)) and sent to the **BULK\_OUT** endpoint.

*Table 458. PICOBLOCK Command Definition*

| Offset | Name            | Description                                                                                |
|--------|-----------------|--------------------------------------------------------------------------------------------|
| 0x00   | dMagic          | The value 0x431fd10b                                                                       |
| 0x04   | dToken          | A user provided token to identify this request by                                          |
| 0x08   | bCmdId          | The ID of the command. Note that the top bit indicates data transfer direction (0x80 = IN) |
| 0x09   | bCmdSize        | Number of bytes of valid data in the args field                                            |
| 0x0a   | reserved        | 0x0000                                                                                     |
| 0x0c   | dTransferLength | The number of bytes the host expects to send or receive over the bulk channel              |
| 0x10   | args            | 16 bytes of command-specific data padded with zeros                                        |

If a command sent is invalid or not recognised, the bulk endpoints will be stalled. Further information will be available via the [GET\\_COMMAND\\_STATUS](#) request (see [Section 5.6.5.2](#)).

Following the initial 32 byte packet, if [dTransferLength](#) is non-zero, then that many bytes are transferred over the bulk pipe and the command is completed with an empty packet in the opposite direction. If [dTransferLength](#) is zero then command success is indicated by an empty IN packet.

The following commands are supported (note common fields [dMagic](#), [dToken](#), and [reserved](#) are omitted for clarity)

### 5.6.4.1. EXCLUSIVE\_ACCESS (0x01)

Claim or release exclusive access for writing to the RP2350 over USB (versus the Mass Storage Interface)

*Table 459. PICOBLOCK EXCLUSIVE\_ACCESS command structure*

| Offset | Name            | Value / Description     |                                                                                                                                               |
|--------|-----------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 0x08   | bCmdId          | 0x01 (EXCLUSIVE_ACCESS) |                                                                                                                                               |
| 0x09   | bCmdSize        | 0x01                    |                                                                                                                                               |
| 0x0c   | dTransferLength | 0x00000000              |                                                                                                                                               |
| 0x10   | bExclusive      | NOT_EXCLUSIVE (0)       | No restriction on USB Mass Storage operation                                                                                                  |
|        |                 | EXCLUSIVE (1)           | Disable USB Mass Storage writes (the host should see them as write protect failures, but in any case any active UF2 download will be aborted) |
|        |                 | EXCLUSIVE_AND_EJECT (2) | Lock the USB Mass Storage Interface out by marking the drive media as not present (ejecting the drive)                                        |

### 5.6.4.2. REBOOT (0x02)

Not supported on RP2350.

Use [Section 5.6.4.10](#) instead.

## 5.6.4. PICOBLOCK命令

这两个批量端点用于发送命令以及接收成功的命令结果。所有命令均为32字节（详见表458），并发送至 **BULK\_OUT** 端点。

表458 PICOBLOCK  
命令定义

| 偏移量  | 名称              | 描述                                 |
|------|-----------------|------------------------------------|
| 0x00 | dMagic          | 值为 0x431fd10b                      |
| 0x04 | dToken          | 用户提供的用于标识该请求的令牌                    |
| 0x08 | bCmdId          | 命令ID。注意，最高位指示数据传输方向<br>(0x80 = IN) |
| 0x09 | bCmdSize        | args字段中有效数据的字节数                    |
| 0x0a | 保留              | 0x0000                             |
| 0x0c | dTransferLength | 主机期望通过大容量通道发送或接收的字节数               |
| 0x10 | 参数              | 16字节的命令特定数据，零填充                    |

如果发送的命令无效或无法识别，大容量端点将被阻塞。更多信息可通过 **GET\_COMMAND\_STATUS** 请求获取（参见第5.6.5.2节）。

在初始32字节数据包之后，若 **dTransferLength** 非零，则通过大容量通道传输相应字节数，并以反向的空数据包完成命令。若 **dTransferLength** 为零，则以空的 **IN** 数据包表示命令成功。

支持以下命令（为更加清晰，省略了通用字段 **dMagic**、**dToken** 和 **reserved**）

### 5.6.4.1. EXCLUSIVE\_ACCESS (0x01)

声明或释放通过USB对RP2350进行写操作的独占访问权限（相较于大容量存储接口）

表459。PICOBLOCK  
EXCLUSIVE\_ACCESS  
命令结构

| 偏移量  | 名称              | 值 / 描述                  |                                               |
|------|-----------------|-------------------------|-----------------------------------------------|
| 0x08 | bCmdId          | 0x01 (EXCLUSIVE_ACCESS) |                                               |
| 0x09 | bCmdSize        | 0x01                    |                                               |
| 0x0c | dTransferLength | 0x00000000              |                                               |
| 0x10 | bExclusive      | NOT_EXCLUSIVE (0)       | 对USB大容量存储操作无任何限制                              |
|      |                 | EXCLUSIVE (1)           | 禁用USB大容量存储写入（主机应将其视为写保护失败，且任何正在进行的UF2下载均将被中止） |
|      |                 | EXCLUSIVE_AND_EJECT (2) | 通过将驱动介质标记为不存在（弹出驱动器）来锁定USB大容量存储接口             |

### 5.6.4.2. REBOOT (0x02)

RP2350 不支持该功能。

请改用第 5.6.4.10 节。

### 5.6.4.3. FLASH\_ERASE (0x03)

Erases a contiguous range of flash sectors.

Table 460. PICOBOOT  
FLASH\_ERASE  
command structure

| Offset | Name            | Value / Description                                                                          |
|--------|-----------------|----------------------------------------------------------------------------------------------|
| 0x08   | bCmdId          | 0x03 (FLASH_ERASE)                                                                           |
| 0x09   | bCmdSize        | 0x08                                                                                         |
| 0x0c   | dTransferLength | 0x00000000                                                                                   |
| 0x10   | dAddr           | The address in flash to erase, starting at this location. This must be sector (4 kB) aligned |
| 0x14   | dSize           | The number of bytes to erase. This must be an exact multiple of sectors (4 kB)               |

### 5.6.4.4. READ (0x84)

Read a contiguous memory (flash or RAM or ROM) range from the RP2350

Table 461. PICOBOOT  
Read memory  
command (flash, RAM,  
ROM) structure

| Offset | Name            | Value / Description                                     |
|--------|-----------------|---------------------------------------------------------|
| 0x08   | bCmdId          | 0x84 (READ)                                             |
| 0x09   | bCmdSize        | 0x08                                                    |
| 0x0c   | dTransferLength | Must be the same as dSize                               |
| 0x10   | dAddr           | The address to read from. May be in flash or RAM or ROM |
| 0x14   | dSize           | The number of bytes to read                             |

### 5.6.4.5. WRITE (0x05)

Writes a contiguous memory range of memory (flash or RAM) on the RP2350.

Table 462. PICOBOOT  
Write memory  
command (flash,  
RAM) structure

| Offset | Name            | Value / Description                                                                                                                                              |
|--------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x08   | bCmdId          | 0x05 (WRITE)                                                                                                                                                     |
| 0x09   | bCmdSize        | 0x08                                                                                                                                                             |
| 0x0c   | dTransferLength | Must be the same as dSize                                                                                                                                        |
| 0x10   | dAddr           | The address to write from. May be in flash or RAM, however must be page (256 byte) aligned if in flash. Flash must be erased first or the results are undefined. |
| 0x14   | dSize           | The number of bytes to write. If writing to flash and the size isn't an exact multiple of pages (256 bytes) then the last page is zero-filled to the end.        |

### 5.6.4.6. EXIT\_XIP (0x06)

A no-op provided for compatibility with RP2040. An XIP exit sequence (`flash_exit_xip()`) is issued once before entering the USB bootloader, which returns the external QSPI device from whatever XIP state it was in to a serial command state, and the external QSPI device then remains in this state until reboot.

### 5.6.4.3. FLASH\_ERASE (0x03)

擦除连续范围的闪存扇区。

表 460。PICOBOOT  
FLASH\_ERASE  
命令结构

| 偏移量  | 名称              | 值 / 描述                             |
|------|-----------------|------------------------------------|
| 0x08 | bCmdId          | 0x03 (FLASH_ERASE)                 |
| 0x09 | bCmdSize        | 0x08                               |
| 0x0c | dTransferLength | 0x00000000                         |
| 0x10 | dAddr           | 闪存中要擦除的地址，从该位置开始。该地址必须按照扇区（4 kB）对齐 |
| 0x14 | dSize           | 要擦除的字节数。该数值必须是扇区（4 kB）的整数倍         |

### 5.6.4.4. 读取 (0x84)

从 RP2350 读取连续内存区域（闪存、RAM 或只读存储器）

表 461。PICOBOOT  
读取内存  
命令（闪存、RAM、  
只读存储器）结构

| 偏移量  | 名称              | 值 / 描述                   |
|------|-----------------|--------------------------|
| 0x08 | bCmdId          | 0x84 (READ)              |
| 0x09 | bCmdSize        | 0x08                     |
| 0x0c | dTransferLength | 必须与 dSize 相同             |
| 0x10 | dAddr           | 要读取的地址。可位于闪存、RAM 或只读存储器中 |
| 0x14 | dSize           | 要读取的字节数                  |

### 5.6.4.5. 写入 (0x05)

在 RP2350 上写入连续内存区域（闪存或 RAM）。

表 462。PICOBOOT  
写内存  
命令（闪存、  
RAM）结构

| 偏移量  | 名称              | 值 / 描述                                                  |
|------|-----------------|---------------------------------------------------------|
| 0x08 | bCmdId          | 0x05 (写入)                                               |
| 0x09 | bCmdSize        | 0x08                                                    |
| 0x0c | dTransferLength | 必须与 dSize 相同                                            |
| 0x10 | dAddr           | 写入的起始地址。可以是闪存或RAM，但若为闪存，必须按页（256字节）对齐。闪存必须先擦除，否则结果无法预料。 |
| 0x14 | dSize           | 写入的字节数。若写入闪存且大小非页（256字节）的整倍数，则最后一页将以零填充至页尾。             |

### 5.6.4.6. EXIT\_XIP (0x06)

此为兼容RP2040而设的空操作。进入USB引导程序前，将执行一次XIP退出序列（`flash_exit_xip()`），使外部QSPI设备从任何XIP状态返回至串行命令状态，且外部QSPI设备将保持该状态直至重启。

Table 463. PICOBOOT  
EXIT\_XIP command  
structure

| Offset | Name            | Value / Description |
|--------|-----------------|---------------------|
| 0x08   | bCmdId          | 0x06 (EXIT_XIP)     |
| 0x09   | bCmdSize        | 0x00                |
| 0x0c   | dTransferLength | 0x00000000          |

#### 5.6.4.7. ENTER\_XIP (0x07)

A no-op provided for compatibility with RP2040. Note that, unlike RP2040, the low-level bootrom flash operations do not leave the QSPI interface in a state where XIP is inaccessible, therefore there is no need to reinitialise the interface each time. XIP setup is performed once before entering the USB bootloader, using an 03h command with a fixed clock divisor of 6.

Table 464. PICOBOOT  
Enter Execute in place  
(XIP) command

| Offset | Name            | Value / Description |
|--------|-----------------|---------------------|
| 0x08   | bCmdId          | 0x07 (ENTER_XIP)    |
| 0x09   | bCmdSize        | 0x00                |
| 0x0c   | dTransferLength | 0x00000000          |

#### 5.6.4.8. EXEC (0x08)

Not supported on RP2350.

#### 5.6.4.9. VECTORIZE\_FLASH (0x09)

Not supported on RP2350.

#### 5.6.4.10. REBOOT2 (0x0a)

Reboots the RP2350 out of BOOTSEL mode. Note that BOOTSEL mode may be re-entered if no valid bootable image is found.

The parameters *flags*, *delay\_ms*, *p0*, *p1* are the same as for [api\\_reboot\(\)](#)

Table 465. PICOBOOT  
REBOOT2 command  
structure

| Offset | Name            | Value / Description |
|--------|-----------------|---------------------|
| 0x08   | bCmdId          | 0x0a (REBOOT2)      |
| 0x09   | bCmdSize        | 0x10                |
| 0x0c   | dTransferLength | 0x00000000          |
| 0x10   | dAddr           | flags               |
| 0x14   | dSize           | delay_ms            |
| 0x18   | dSize           | p0                  |
| 0x1c   | dSize           | p1                  |

#### 5.6.4.11. GET\_INFO (0x8b)

Generic conduit for retrieving information from the device.

表463。PICOBEST  
EXIT\_XIP命令  
结构

| 偏移量  | 名称              | 值 / 描述          |
|------|-----------------|-----------------|
| 0x08 | bCmdId          | 0x06 (EXIT_XIP) |
| 0x09 | bCmdSize        | 0x00            |
| 0x0c | dTransferLength | 0x00000000      |

#### 5.6.4.7. ENTER\_XIP (0x07)

为兼容 RP2040 而提供的空操作指令。请注意，与 RP2040 不同，低级 bootrom 闪存操作不会使 QSPI 接口处于 XIP 无法访问的状态，因此无需每次重新初始化该接口。XIP 设置在进入 USB 引导加载程序之前执行一次，使用固定时钟分频为 6 的 03h 命令。

表 464。PICOBEST  
进入执行就地 (XIP)  
命令

| 偏移量  | 名称              | 值 / 描述           |

| 0x09 | bCmdSize        | 0x00             |
| 0x0c | dTransferLength | 0x00000000       |

#### 5.6.4.8. EXEC (0x08)

RP2350 不支持该功能。

#### 5.6.4.9. VECTORIZE\_FLASH (0x09)

RP2350 不支持该功能。

#### 5.6.4.10. REBOOT2 (0x0a)

使 RP2350 从 BOOTSEL 模式重新启动。请注意，如果未找到有效的可启动映像，可能会重新进入BOOTSEL模式。

参数 flags、delay\_ms、p0、p1 与 api\_reboot() 相同

表465。PICOBEST  
REBOOT2命令  
结构体

| 偏移量  | 名称              | 值 / 描述         |
|------|-----------------|----------------|

#### 5.6.4.11. GET\_INFO (0x0b)

用于从设备检索信息的通用通道。

The transfer length indicates the maximum number of bytes to be retrieved. The first word returned indicates the number of significant words of data that follow. A full "transfer length" is always returned, padding with zeroes as necessary.

"Word 0", below, refers to the first word of the actual response (the word after the count word).

*Table 466. PICOBLOCK  
GET\_INFO command  
structure*

| Offset | Name            | Value / Description                                                                   |
|--------|-----------------|---------------------------------------------------------------------------------------|
| 0x08   | bCmdId          | 0x0b (GET_INFO)                                                                       |
| 0x09   | bCmdSize        | 0x10                                                                                  |
| 0x0c   | dTransferLength | the size of data to be received. Note this must be a multiple of 4, and less than 256 |

传输长度指示要检索的最大字节数。返回的第一个字表示随后数据的有效字数。始终返回完整的“传输长度”，必要时以零填充。

下文的“字0”指实际响应的第一个字（计数字之后的字）。

#### 5.6.4.12. OTP\_READ (0x8c)

Reads data out of OTP. (see also `otp_access()` which provides the data). Data returned is subject to the "BL" OTP permissions, which define bootloader OTP access permissions.

| 偏移量  | 名称    | 值 / 描述                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 0x12   | wRowCount       | the number of rows to read                                                                                                                                                                                        |
| 0x14   | bEcc            | <ul style="list-style-type: none"> <li>• 0 - if reading raw rows (32 bits are returned per row, the top 8 of which are zero)</li> <li>• 1 - if reading rows as ECC rows (16 bits per row are returned)</li> </ul> |

#### 5.6.4.13. OTP\_WRITE (0x0d)

Reads data out of OTP. (see also [otp\\_access\(\)](#) which performs the operation). Writing is subject to the "BL" OTP permissions, which define bootloader OTP access permissions.

| 0x10   | wRow            | the first row number to read                                                                                                                                                                                                                                               |
| 0x12   | wRowCount       | the number of rows to read                                                                                                                                                                                                                                                 |
| 0x14   | bEcc            | <ul style="list-style-type: none"> <li>• 0 - if writing raw rows (32 bits are provided per row, the top 8 of which are ignored)</li> <li>• 1 - if writing ECC rows (16 bits are provided per row, and are written with error correcting information to the OTP)</li> </ul> |

### 5.6.5. Control requests

The following requests are sent to the interface via the default control pipe.

#### 5.6.5.1. INTERFACE\_RESET (0x41)

The host sends this control request to reset the PICOBOOT interface. This command:

- Clears the HALT condition (if set) on each of the bulk endpoints
- Aborts any in-process PICOBOOT or Mass Storage transfer and any flash write (this method is the only way to kill a stuck flash transfer).
- Clears the previous command result
- Removes [EXCLUSIVE\\_ACCESS](#) and remounts the Mass Storage drive if it was ejected due to exclusivity.

| 0x14 | bEcc            | <ul style="list-style-type: none"> <li>• 0 - 读取原始行时（每行返回 32 位数据，最高 8 位为零）</li> <li>• 1 - 读取 ECC 行时（每行返回 16 位数据）</li> </ul> |

#### 5.6.4.13. OTP\_WRITE (0x0d)

从 OTP 中读取数据。（另请参见执行该操作的 otp\_access() 函数）写入受“BL”OTP 权限限制，该权限定义引导加载程序 OTP 访问权限。

表 468。PICOBOOT

| 0x0c | dTransferLength | $wRowCount \times (bEcc ? 2 : 4)$                                                                                                       |
| 0x10 | wRow            | 首个读取的行号                                                                                                                                 |
| 0x12 | wRowCount       | 读取的行数                                                                                                                                   |
| 0x14 | bEcc            | <ul style="list-style-type: none"> <li>• 0 - 若写入原始行（每行提供 32 位，其中最高 8 位被忽略）</li> <li>• 1 - 若写入 ECC 行（每行提供 16 位，并连同纠错信息写入 OTP）</li> </ul> |

### 5.6.5. 控制请求

以下请求通过默认控制管道发送至接口。

#### 5.6.5.1. INTERFACE\_RESET (0x41)

主机发送此控制请求以重置 PICOBOOT 接口。该命令：

- 清除每个大容量端点上的 HALT 状态（若已设置）
- 中止任何正在进行的 PICOBOOT 或大容量存储传输及任何闪存写入操作（此方法为终止卡顿闪存传输的唯一手段）
  -
- 清除先前的命令结果
- 移除 EXCLUSIVE\_ACCESS，若因独占访问被弹出，则重新挂载大容量存储驱动器。

*Table 469. PICOBOOT  
Reset PICOBOOT  
interface control*

| bmRequestType | bRequest  | wValue | wIndex    | wLength | Data |
|---------------|-----------|--------|-----------|---------|------|
| 01000001b     | 01000001b | 0000h  | Interface | 0000h   | none |

This command responds with an empty packet on success.

### 5.6.5.2. GET\_COMMAND\_STATUS (0x42)

Retrieve the status of the last command (which may be a command still in progress). Successful completion of a PICOBOOT Protocol Command is acknowledged over the bulk pipe, however if the operation is still in progress or has failed (stalling the bulk pipe), then this method can be used to determine the operation's status.

*Table 470. PICOBOOT  
Get last command  
status control*

| bmRequestType | bRequest  | wValue | wIndex    | wLength | Data |
|---------------|-----------|--------|-----------|---------|------|
| 11000001b     | 01000010b | 0000h  | Interface | 0000h   | none |

The command responds with the following 16 byte response

*Table 471. PICOBOOT  
Get last command  
status control  
response*

| Offset | Name   | Description                               |
|--------|--------|-------------------------------------------|
| 0x00   | dToken | The user token specified with the command |

表 469. PICOBOOT  
重置 PICOBOOT  
接口控制

| bmRequestType | bRequest  | wValue | wIndex | wLength | 数据 |
|---------------|-----------|--------|--------|---------|----|
| 01000001b     | 01000001b | 0000h  | 接口     | 0000h   | 无  |

该命令成功时返回空包。

#### 5.6.5.2. GET\_COMMAND\_STATUS (0x42)

获取最后一条命令的状态（该命令可能仍在执行中）。PICOBOOT协议命令成功完成后，通过大容量端点确认；若操作仍在执行或失败（致使大容量端点阻塞），则可通过此方法查询操作状态。

表 470. PICOBOOT  
获取最后命令  
状态控制

| bmRequestType | bRequest  | wValue | wIndex | wLength | 数据 |
|---------------|-----------|--------|--------|---------|----|
| 11000001b     | 01000010b | 0000h  | 接口     | 0000h   | 无  |

该命令响应以下16字节数据

表471. PICOBOOT

响应

| 偏移量  | 名称     | 描述         |
|------|--------|------------|
| 0x00 | dToken | 命令中指定的用户令牌 |

| Offset | Name        | Description                           |                                                                                                                                                                                       |
|--------|-------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x04   | dStatusCode | OK (0)                                | The command completed successfully (or is still in progress)                                                                                                                          |
|        |             | UNKNOWN_CMD (1)                       | The ID of the command was unrecognised                                                                                                                                                |
|        |             | INVALID_CMD_LENGTH (2)                | The length of the command request was incorrect                                                                                                                                       |
|        |             | INVALID_TRANSFER_LENGTH (3)           | The data transfer length was incorrect given the command                                                                                                                              |
|        |             | INVALID_ADDRESS (4)                   | The address specified was invalid for the command type; this means that the address didn't match the type (flash or RAM) that the command was expecting                               |
|        |             | BAD_ALIGNMENT (5)                     | The address specified was incorrectly aligned according to the requirements of the command                                                                                            |
|        |             | INTERLEAVED_WRITE (6)                 | A Mass Storage Interface UF2 write has interfered with the current operation. The command was abandoned with unknown status. This doesn't happen if you have <i>exclusive</i> access. |
|        |             | REBOOTING (7)                         | The device is in the process of rebooting, so the command has been ignored.                                                                                                           |
|        |             | UNKNOWN_ERROR (8)                     | Some non-specific error occurred.                                                                                                                                                     |
|        |             | INVALID_STATE (9)                     | Something happened or failed to happen in the past, and consequently the request can't (currently) be serviced.                                                                       |
|        |             | NOT_PERMITTED (10)                    | Permission violation, such as write to read-only flash partition.                                                                                                                     |
|        |             | INVALID_ARG (11)                      | Argument is outside of range of supported values.                                                                                                                                     |
|        |             | BUFFER_TOO_SMALL (12)                 | The provided buffer was too small to hold the result.                                                                                                                                 |
|        |             | PRECONDITION_NOT_MET (13)             | The operation failed because another bootrom function must be called first.                                                                                                           |
|        |             | MODIFIED_DATA (14)                    | Cached data was determined to be inconsistent with the full version of the data it was calculated from.                                                                               |
|        |             | INVALID_DATA (15)                     | A data structure failed to validate.                                                                                                                                                  |
|        |             | NOT_FOUND (16)                        | Attempted to access something that doesn't exist; or a search failed.                                                                                                                 |
|        |             | UNSUPPORTED_MODIFICATION (17)         | Write is impossible based on previous writes, such as attempting to clear an OTP bit.                                                                                                 |
| 0x08   | bCmdId      | The ID of the command                 |                                                                                                                                                                                       |
| 0x09   | bInProgress | 1 if the command is still in progress | 0 otherwise                                                                                                                                                                           |
| 0xa    | reserved    | (6 zero bytes)                        |                                                                                                                                                                                       |

## 5.7. USB white-labelling

To brand RP2350-based products, customers may replace identifying information exposed by USB interfaces. We call this **white-labelling**, and you can accomplish it in RP2350 by specifying values in OTP.

| 偏移量  | 名称          | 描述                            |                                                           |
|------|-------------|-------------------------------|-----------------------------------------------------------|
| 0x04 | dStatusCode | OK (0)                        | 命令成功完成（或仍在处理中）                                            |
|      |             | UNKNOWN_CMD (1)               | 未识别的命令ID                                                  |
|      |             | INVALID_CMD_LENGTH (2)        | 命令请求长度不正确                                                 |
|      |             | INVALID_TRANSFER_LENGTH (3)   | 根据命令，数据传输长度错误                                             |
|      |             | INVALID_ADDRESS (4)           | 指定的地址对该命令类型无效；<br>即地址与命令预期的类型（闪存或RAM）不匹配                  |
|      |             | BAD_ALIGNMENT (5)             | 指定的地址未按照命令要求正确对齐。                                         |
|      |             | INTERLEAVED_WRITE (6)         | 大容量存储接口 UF2 写操作干扰了当前操作。该命令因状态未知而被中止。如果您拥有独占访问权限，则不会发生此情况。 |
|      |             | REBOOTING (7)                 | 设备正在重启过程中，命令已被忽略。                                         |
|      |             | UNKNOWN_ERROR (8)             | 发生了某些非特定错误。                                               |
|      |             | INVALID_STATE (9)             | 过去发生或未发生某些事件，导致请求当前无法被处理。                                 |
|      |             | NOT_PERMITTED (10)            | 权限违规，例如对只读闪存分区的写入。                                        |
|      |             | INVALID_ARG (11)              | 参数超出支持的取值范围。                                              |
|      |             | BUFFER_TOO_SMALL (12)         | 提供的缓冲区过小，无法容纳结果。                                          |
|      |             | PRECONDITION_NOT_MET (13)     | 操作失败，须先调用另一个只读存储器引导函数。                                    |
|      |             | MODIFIED_DATA (14)            | 缓存数据已被判定与其计算来源的完整数据版本不一致。                                 |
|      |             | INVALID_DATA (15)             | 数据结构验证未通过。                                                |
|      |             | NOT_FOUND (16)                | 尝试访问不存在的对象；或搜索未果。                                         |
|      |             | UNSUPPORTED_MODIFICATION (17) | 基于之前的写入情况，写入操作不可执行，如尝试清除OTP位。                             |
| 0x08 | bCmdId      | 命令标识(ID)                      |                                                           |
| 0x09 | bInProgress | 当命令仍在执行中时返回1                  | 否则为0                                                      |
| 0x0a | 保留          | (6个字节零值)                      |                                                           |

## 5.7. USB白标化

针对基于RP2350的产品，客户可替换通过USB接口暴露的识别信息以进行品牌重塑。此过程称为**白标化**，可通过在RP2350中指定OTP值实现。

1. Write the OTP location of the white-label data structure via **USB\_WHITE\_LABEL\_ADDR** (see that register description for the data structure contents).
2. Initialise the fields you wish to override in the white-label data structure and mark them valid.
3. Set **USB\_BOOT\_FLAGS.WHILE\_LABEL\_ADDR\_VALID** to mark the white-labelling as valid.

The following fields can be modified:

### 5.7.1. USB device descriptor

The USB device descriptor includes the following 16-bit values:

- **VID** (default **0x2e8a**)
- **PID** (default **0x000f**)
- **BCD\_DEVICE** (default **0x0100**)
- **LANG\_ID** (default **0x0409**)

### 5.7.2. USB device strings

- **MANUFACTURER** (default "Raspberry Pi", max-length 30 UTF-16 or ASCII chars)
- **PRODUCT** (default "RP2350 Boot", max-length 30 UTF-16 or ASCII chars)
- **SERIAL\_NUMBER** (default uppercase hex string of the **device\_id**; first 4 rows of OTP, max-length 30 UTF-16 or ASCII chars)

### 5.7.3. USB configuration descriptor

The USB Configuration Description isn't strictly white-labelling, but is still helpful for users:

- **ATTRIBUTES\_MAX\_POWER\_VALUES** (default **0xfa80**, meaning **bMaxPower** of **0xfa** and **bmAttributes=0x80**)

### 5.7.4. MSD drive

- **VOLUME\_LABEL** (default "RP2350", max-length 11 ASCII chars)

### 5.7.5. UF2 INDEX.HTM file

This is of the form:

```
<html>
 <head>
 <meta http-equiv="refresh" content="0;URL='*REDIRECT_URL*' />
 </head>
 <body>Redirecting to <a href='`*REDIRECT_URL*`'*REDIRECT_NAME*</body>
</html>
```

- **REDIRECT\_URL** (default "https://raspberrypi.com/device/RP2?version=5A09D5312E22", note the 12 hex digits are the first 6 of the **SYSINFO\_GITREF\_RP2350** and the first 6 of the bootrom **gitref**, max-length 127 ASCII chars)
- **REDIRECT\_NAME** (default "raspberrypi.com", max-length 127 ASCII chars)

1. 通过USB\_WHITE\_LABEL\_ADDR寄存器写入白标数据结构的OTP地址（详见该寄存器说明以了解数据结构内容）。

2. 初始化您希望覆盖的白标数据结构字段，并将其标记为有效。

3. 设置USB\_BOOT\_FLAGS.WHITE\_LABEL\_ADDR\_VALID以标记白标为有效。

以下字段可修改：

### 5.7.1. USB设备描述符

USB设备描述符包含以下16位数值：

- VID (默认值 0x2e8a)
- PID (默认值 0x000f)
- BCD\_DEVICE (默认值 0x0100)
- LANG\_ID (默认值 0x0409)

### 5.7.2. USB设备字符串

- MANUFACTURER (默认“Raspberry Pi”，最大长度30个UTF-16或ASCII字符)
- PRODUCT (默认“RP2350 Boot”，最大长度30个UTF-16或ASCII字符)
- SERIAL\_NUMBER(默认为设备\_id的大写十六进制字符串；OTP的前4行，最大长度30个UTF-16或ASCII字符)

### 5.7.3. USB配置描述符

USB配置描述符虽非严格意义上的白标，但对用户仍有帮助：

- ATTRIBUTES\_MAX\_POWER\_VALUES (默认值0xfa80，表示bMaxPower为0xfa且bmAttributes=0x80)

### 5.7.4. MSD驱动

- VOLUME\_LABEL (默认值“RP2350”，最大长度11个ASCII字符)

### 5.7.5. UF2 INDEX.HTM文件

格式如下：

```
<html>
 <head>
 <meta http-equiv="refresh" content="0;URL='*REDIRECT_URL*' />
 </head>
 <body>正在重定向至 *REDIRECT_NAME*</body><ht
ml>
```

- REDIRECT\_URL (默认值“https://raspberrypi.com/device/RP2?version=5A09D5312E22”，请注意，该12位十六进制数字为SYSINFO\_GITREF\_RP2350的前6位和bootrom gitref的前6位，最大长度127个ASCII字符)

- REDIRECT\_NAME (默认值“raspberrypi.com”，最大长度127个ASCII字符)

## 5.7.6. UF2 INFO\_UF2.TXT file

This is of the form:

```
UF2 Bootloader v1.0
Model: MODEL
Board-ID: BOARD_ID
```

- **MODEL** (default "Raspberry Pi RP2350", max-length 127 ASCII chars)
- **BOARD\_ID** (default "RP2350", max-length 127 ASCII chars)

## 5.7.7. SCSI Inquiry

Returned via the SCSI Inquiry command:

- **VENDOR** (default "RPI", max-length 8 ASCII chars)
- **PRODUCT** (default "RP2350", max-length 16 ASCII chars)
- **VERSION** (default "1", max-length 4 ASCII chars)

## 5.7.8. Volume label simple example

Newer versions of `picotool` can load white-label data from a JSON file using the `picotool otp white-label -s <start row> <JSON filename>` command. An example JSON file to set the volume label to "SPOON" would be:

```
{
 "volume": {
 "label": "SPOON"
 }
}
```

The `<start row>` is the OTP row where the white-label structure will be written - for example `0x400`.

The full set of white-label fields which can be written using a JSON file are shown below. The `manufacturer`, `product` and `serial_number` fields support Unicode characters, if you need special characters or emoji in your product name, but this will take up twice as much room per character in the OTP for that field.

```
{
 "device": {
 "vid": "0x2e8b",
 "pid": "0x000e",
 "bcd": 2.15,
 "lang_id": "0x0c09",
 "manufacturer": "Test's Pis",
 "product": "Test RP2350?",
 "serial_number": "notnecessarilyanumber",
 "max_power": "0x20",
 "attributes": "0xe0"
 },
 "scsi": {
 "vendor": "TestPi",
 "product": "MyPi",
 "version": "v897"
 }
},
```

### 5.7.6. UF2 INFO\_UF2.TXT 文件

格式如下：

```
UF2 Bootloader v1.0
型号: MODEL
板卡 ID: BOARD_ID
```

- **MODEL** (默认值 "Raspberry Pi RP2350"，最大长度 127 个 ASCII 字符)
- **BOARD\_ID** (默认值 "RP2350"，最大长度127个ASCII字符)

### 5.7.7. SCSI 查询命令

通过 SCSI Inquiry 命令返回：

- **VENDOR** (默认值 "RPI"，最大长度8个ASCII字符)
- **PRODUCT** (默认值 "RP2350"，最大长度16个ASCII字符)
- **VERSION** (默认值 "1"，最大长度4个ASCII字符)

### 5.7.8. 卷标简单示例

较新版本的 `picotool` 可通过 `picotool otp white-label -s <start row> <JSON filename>` 命令从 JSON 文件加载白标数据。以下为将卷标设置为 "SPOON" 的示例 JSON 文件：

```
{
 "volume": {
 "label": "SPOON"
 }
}
```

<start row> 为写入白标结构的 OTP 行数，例如 0x400。

下方列出了可通过 JSON 文件写入的全部白标字段。`manufacturer`、`product` 及 `serial_number` 字段支持 Unicode 字符，若产品名称需包含特殊字符或表情符号，该字段在 OTP 中每个字符将占用两倍空间。

```
{
 "device": {
 "vid": "0x2e8b",
 "pid": "0x000e",
 "bcd": 2.15,
 "lang_id": "0x0c09",
 "manufacturer": "Test's Pis",
 "product": "Test RP2350?",
 "serial_number": "notnecessarilyanumber",
 "max_power": "0x20",
 "attributes": "0xe0"
 },
 "scsi": {
 "vendor": "TestPi",
 "product": "MyPi",
 "version": "v897"
 }
},
```

```

 "volume": {
 "label": "TestPi Boot",
 "redirect_url": "https://datasheets.raspberrypi.com/rp2350/rp2350-datasheet.pdf",
 "redirect_name": "The datasheet",
 "model": "My Test Pi",
 "board_id": "TPI-RP2350"
 }
}

```

### 5.7.9. Volume label in-depth example

The following example demonstrates how to manually change the volume label using `picotool` to the value "SPOON":

1. First, define the row of white label structure to be `0x400`:

```
$ picotool otp set -e OTP_DATA_USB_WHITE_LABEL_ADDR 0x400
```

2. Next, because the volume label is located at index `0x8` within `OTP_DATA_USB_WHITE_LABEL_ADDR`, write to `0x408`. Define the location of the volume label string to be offset from `OTP_DATA_USB_WHITE_LABEL_ADDR` by `0x30`. For this example, "SPOON" has 5 characters, so we write `0x3005` to `0x408`:

```
$ picotool otp set -e 0x408 0x3005
```

3. Then, write the "S" and "P" characters:

```
$ picotool otp set -e 0x430 0x5053
```

4. Then, write the "O" and "O" characters:

```
$ picotool otp set -e 0x431 0x4f4f
```

5. Then, write the "N" character:

```
$ picotool otp set -e 0x432 0x4
```

6. Finally, enable the valid override to use the new values (bit 8 marks the `VOLUME_LABEL` override as valid, and bit 22 marks the `OTP_DATA_USB_WHITE_LABEL_ADDR` override as valid):

```
$ picotool otp set -r OTP_DATA_USB_BOOT_FLAGS 0x400100
```

7. To put your changes into effect, reboot the device:

```
$ picotool reboot -u
```

```

"volume": {
 "label": "TestPi Boot",
 "redirect_url": "https://datasheets.raspberrypi.com/rp2350/rp2350-datasheet.pdf",
 "redirect_name": "数据手册", "model
 ":"My Test Pi", "board_
 id": "TPI-RP2350"
}
}

```

### 5.7.9. 卷标深入示例

以下示例演示如何使用 `picotool` 手动将卷标更改为“SPOON”：

- 首先，将白标结构行定义为 `0x400`：

```
$ picotool otp set -e OTP_DATA_USB_WHITE_LABEL_ADDR 0x400
```

- 接着，由于卷标位于 `OTP_DATA_USB_WHITE_LABEL_ADDR` 的索引 `0x8` 处，需写入地址 `0x408`。将卷标字符串的位置定义为相对于 `OTP_DATA_USB_WHITE_LABEL_ADDR` 偏移 `0x30`。在本例中，“SPOON” 包含 5 个字符，因此向 `0x408` 写入 `0x3005`：

```
$ picotool otp set -e 0x408 0x3005
```

- 随后，写入字符“S”和“P”：

```
$ picotool otp set -e 0x430 0x5053
```

- 然后，写入字符“O”和“O”：

```
$ picotool otp set -e 0x431 0x4f4f
```

- 接着，写入字符“N”：

```
$ picotool otp set -e 0x432 0x4e
```

- 最后，启用有效覆盖以使用新值（第 8 位标记 `VOLUME_LABEL` 覆盖为有效，第 22 位标记 `OTP_DATA_USB_WHITE_LABEL_ADDR` 覆盖为有效）：

```
$ picotool otp set -r OTP_DATA_USB_BOOT_FLAGS 0x400100
```

- 为使更改生效，请重启设备：

```
$ picotool reboot -u
```

## 5.8. UART boot

UART boot is a minimal interface for bootstrapping a flashless RP2350 from a simple host, such as another microcontroller. It is available by default on a blank device, so it allows RP2350 to be deployed into the field on multi-device boards without loading firmware or programming OTP bits in advance.

To select UART boot, drive QSPI **CSn** low (BOOTSEL mode) and drive QSPI **SD1** high. The bootrom checks these signals shortly after device reset is released. UART **TX** appears on QSPI **SD2**, and UART **RX** appears on QSPI **SD3**.

The UART mode is **8n1**: one start bit, eight data bits, no parity, one stop bit. Data within each UART frame is sent and received LSB-first. The baud rate is fixed at 1 Mbaud.

### 5.8.1. Baud rate and clock requirements

The nominal baud rate for UART boot is 1 Mbaud, divided from a nominal 48 MHz system clock frequency. UART boot uses the USB PLL to derive the system clock and UART baud clock, so you must either provide a crystal or drive a stable clock into the crystal oscillator XIN pad. The host baud rate must match the RP2350 baud rate within 3%.

By default the crystal is assumed to be 12 MHz, but the [BOOTSEL\\_PLL\\_CFG](#) and [BOOTSEL\\_XOSC\\_CFG](#) OTP locations override this to achieve a nominal 48 MHz system clock from any supported crystal. The same OTP configuration is used for both USB and UART boot.

#### TIP

You may drive a somewhat faster or slower clock into XIN without any OTP configuration, if you scale your UART baud rate appropriately. The permissible range is 7.5 to 16 MHz on XIN, limited by the PLL VCO frequency range.

### 5.8.2. UART boot shell protocol

After the bootrom samples QSPI **CSn** and **SD1**, there will be a delay of several milliseconds as the bootrom goes through some necessary steps such as switching from the ring oscillator to the PLL, and erasing SRAM before releasing it to the Non-secure UART bootloader.

The UART bootloader signals it is ready to begin by printing the ASCII splash string **RP2350**. In bytes, this is **0x52, 0x50, 0x32, 0x33, 0x35, 0x30**.

Before sending any commands, you must send a special knock sequence to unlock the interface. This is a measure to avoid transient effects due to noise on GPIOs and ensure the host and device are initially well-synchronised. The sequence is: **0x56, 0xff, 0x8b, 0xe4**. This is the RP2040 UF2 family ID, chosen as a well-known magic number. Any sequence of bytes ending with this four-byte sequence is detected.

A UART boot shell command is always in the host-to-device direction (RP2350 receives), and consists of a single command byte, optionally followed by a 32-byte write payload. RP2350 responds with an optional 32-byte read payload followed by an echo of the command byte. You should wait for the command echo before sending the next command.

The supported commands are:

Command (ASCII)	Command (hex)	Description
<b>n</b>	<b>0x6e</b>	No-op. Do nothing, and report back when you've done it. Used to ping the interface when recovering lost synchronisation. Echoes the command byte, ' <b>n</b> '.
<b>w</b>	<b>0x77</b>	Write a 32-byte payload to the current value of the read/write pointer. Increment the address pointer by 32. Echoes the command byte, ' <b>w</b> ', once all 32 bytes are written to memory.
<b>r</b>	<b>0x72</b>	Read a 32-byte payload from the current value of the read/write pointer. Increment the address pointer by 32. Echoes the command byte, ' <b>r</b> ', after transmitting the 32-byte read payload.

## 5.8. UART 启动

UART启动是一种用于从简单主机（如另一微控制器）引导无闪存RP2350的最小接口。该接口默认启用于空白设备，从而允许在多设备板上部署RP2350，无需预先加载固件或编程OTP位。

要选择UART启动，需要将QSPI CS<sub>n</sub>拉低（BOOTSEL模式），并将QSPI SD<sub>1</sub>拉高。只读存储器在设备复位释放后不久检查这些信号。UART TX信号出现在QSPI SD<sub>2</sub>，UART RX信号出现在QSPI SD<sub>3</sub>。

UART模式为 8n1：一个起始位，八个数据位，无奇偶校验，一个停止位。每个UART帧内的数据以最低有效位优先顺序发送和接收。波特率固定为1 Mbaud。

### 5.8.1. 波特率及时钟要求

UART启动的名义波特率为1 Mbaud，由标称48 MHz系统时钟频率分频获得。UART启动使用USB PLL产生系统时钟和UART波特率时钟，因此必须提供晶体振荡器或向XIN引脚输入稳定时钟。主机波特率须与RP2350的波特率匹配，误差不超过3%。

默认假定晶体振荡器频率为12 MHz，但通过BOOTSEL\_PLL\_CFG和BOOTSEL\_XOSC\_CFG的OTP设置可覆盖该假设，从而由任意支持的晶体产生标称48 MHz系统时钟。相同OTP配置适用于USB和UART启动。

#### 提示

您可以在无需任何OTP配置的情况下，将时钟输入至XIN端口，速度可略快或略慢，只要您相应调整UART波特率。XIN端口允许的频率范围为7.5至16 MHz，受PLL VCO频率范围限制。

### 5.8.2. UART 启动 Shell 协议

在bootrom采样QSPI CS<sub>n</sub>和 SD<sub>1</sub>信号后，bootrom会有数毫秒延迟，以完成从环形振荡器切换到PLL、擦除SRAM等必要步骤，随后将控制权交给非安全UART引导加载程序。

UART引导加载程序通过打印ASCII启动字符串 RP2350 来表明其已准备就绪。该字符串对应的字节依次为 0x52, 0x50, 0x33, 0x35, 0x30。

在发送任何命令前，必须发送特定的敲击序列以解锁该接口。此措施旨在避免GPIO上的噪声引起瞬态效应，确保主机与设备在初始阶段实现良好同步。序列为：0x56、0xff、0x8b、0xe4。这是RP2040 UF2系列ID，选取为一个广为人知的魔术数字。任何以该四字节序列结尾的字节序列均将被检测。

UART引导shell命令始终为主机至设备方向（RP2350接收），由单个命令字节组成，后可选跟随32字节写入负载。RP2350响应时可选附带32字节读取负载，随后回显命令字节。您应等待命令字节回显后再发送下一个命令。

支持的命令如下：

命令 (ASCII)	命令 (十六进制)	描述
n	0x6e	空操作。不执行任何操作，完成后返回确认。用于恢复丢失同步时对接口的ping操作。 回显命令字节 'n'。
w	0x77	向当前读写指针所在位置写入32字节负载。将地址指针增加32。在所有32字节写入内存后， 回显命令字节 'w'。
r	0x72	从当前读写指针的位置读取32字节的有效载荷。将地址指针增加32。在传输完32字节 读取的有效载荷后，回显命令字节 'r'。

Command (ASCII)	Command (hex)	Description
c	0x63	Clear the read/write pointer. The pointer resets to the first location in SRAM 0x20000000, and you can begin a new read or write sequence from there. Echoes the command byte, 'c'.
x	0x78	Execute the payload that has been written to memory. Echoes the command byte, 'x', and then reboots, passing a RAM boot search window spanning all of main SRAM. If a valid binary was successfully written into SRAM before sending this command, it will execute.

Unrecognised commands are echoed with no other effect. More commands may be added in future versions.

### 5.8.3. UART boot programming flow

1. Reset or power down the RP2350 device.
2. Drive CSn low to select BOOTSEL, and SD1 high to select UART.
3. Release the reset or power up the device.
4. Wait for the splash string to be transmitted on QSPI SD2 (TX).
5. Transmit the knock sequence 0x56, 0xff, 0x8b, 0xe4 on QSPI SD3 (RX)
6. Send a 'n' nop command to ensure the interface is awake; if there is no reply, send the knock sequence again.
7. Send 'w' commands until your entire write payload transfers.
8. (Optional) Send a 'c' clear command to reset the address pointer, and then send 'r' read commands to read back and verify the payload.
9. Send an 'x' execute command to attempt to run the payload.

There is no feedback from UART boot after echoing the final 'x' command. At this point the device reboots to attempt a RAM image boot on the data loaded by the Non-secure UART bootloader. If the RAM image boot fails, the bootrom falls through to the next boot source, continuing the normal boot flow. Maintaining CSn driven low and SD1 driven high will cause the bootrom to fall through back to UART boot a second time, re-sending the UART splash screen: this indicates the bootrom failed to recognise the UART boot binary.

### 5.8.4. Recovering from a stuck interface

Noise on the GPIOs may cause the UART boot shell to stop replying to commands, for example because it thinks the host is part way through a write payload, and the host thinks that it is not. To resynchronise to the start of the next command:

1. Wait 1 ms for the link to quiesce
2. Send 33 'n' NOP commands (size of longest command)
3. Wait 1 ms and flush your receive data
4. Send 1 'n' NOP command and confirm the device responds with an echoed NOP

If the interface fails to recover, reboot the device and try again. Failure may be caused by:

- Noise on GPIOs (particularly over long traces or wires)
- Incorrect baud rate matching
- An unstable frequency reference on XOSC XIN
- Mismatch of voltage levels (for example a QSPI\_IOVDD of 1.8 V on RP2350, and a 3.3 V IO voltage on the host)

命令 (ASCII)	命令 (十六进制)	描述
c	0x63	清除读写指针。指针重置到SRAM的起始位置 0x20000000，并可从此处开始新的读写序列。回显命令字节 'c'。
x	0x78	执行已写入内存的有效载荷。回显命令字节 'x'，然后重启，传递覆盖整个主SRAM的RAM启动搜索窗口。若在发送此命令前已成功写入有效二进制文件至SRAM，则将执行该文件。

未识别的命令仅回显，无其他效果。未来版本可能会添加更多命令。

### 5.8.3. UART 启动编程流程

1. 重置或关闭RP2350设备电源。
2. 驱动 CSn信号为低电平以选择BOOTSEL， SD1信号为高电平以选择UART。
3. 释放复位信号或为设备上电。
4. 等待启动画面字符串通过QSPI SD2 (TX) 传输。
5. 在QSPISD3 (RX) 上发送敲击序列 0x56、0xff、0x8b和0xe4。
6. 发送 'n' 无操作 (nop) 命令以确保接口已唤醒；若无响应，则重新发送敲击序列。
7. 持续发送 'w' 命令，直至整个写入负载传输完成。
8. (可选) 发送 'c' 清除命令以重置地址指针，随后发送 'r' 读取命令以回读并验证负载。
9. 发送 'x' 执行命令以尝试运行负载。

回显最终 'x' 命令后，UART启动程序无任何反馈。此时设备将重启，尝试对非安全UART引导加载程序加载的数据进行只读存储器映像引导。如果只读存储器映像引导失败，启动只读存储器 (bootrom) 将回落至下一个启动源，继续正常引导流程。保持 CSn拉低且SD1拉高将导致启动只读存储器第二次回落至UART引导，重新发送UART启动画面：这表明启动只读存储器未能识别UART引导二进制文件。

### 5.8.4. 恢复卡死的接口

GPIO上的噪声可能导致UART引导shell停止响应命令，例如其误以为主机正处于写入有效载荷的中途，而主机则认为不是。为重新同步至下一条命令的起始位置：

1. 等待1毫秒以使链路进入静止状态
2. 发送33个 'n' NOP命令 (最长命令的大小)
3. 等待1毫秒并清除接收缓存
4. 发送1个 'n' NOP命令，确认设备以回显NOP进行响应

若接口无法恢复，请重启设备后重试。故障可能由以下原因引起：

- GPIO引脚上的噪声（尤其是在长线路或导线上）
- 波特率匹配不正确
- XOSC XIN上的频率参考不稳定
- 电压等级不匹配（例如RP2350上的QSPI\_IOVDD为1.8 V，而主机IO电压为3.3 V）

## 5.8.5. Requirements for UART boot binaries

A UART boot binary is a normal RAM binary. It must have a valid `IMAGE_DEF` in order for the boot path to recognise it as a bootable binary. The search window for the `IMAGE_DEF` is the whole of SRAM, but it's recommended to place it close to the beginning, because the bootrom searches linearly forward for the beginning of the `IMAGE_DEF`.

The maximum size for a UART boot binary is the entirety of main SRAM: 520 kB, or 532 480 bytes.

UART boot only supports loading to the start of SRAM, so your binary must be linked to run at address `0x20000000`. Sparse loading is unsupported. Your program must load as a single flat binary image.

All security requirements relating to RAM image boot apply to UART boot too. If secure boot is enabled, your binary must be signed. Likewise, if OTP anti-rollback versioning is in effect, your binary's rollback version must be no lower than the version number stored in OTP.

## 5.9. Metadata block details

### 5.9.1. Blocks and block loops

Blocks consist of a fixed 32-bit header, one or more `items`, a 32-bit relative offset to the next block, and a fixed 32-bit footer. All multi-byte values within a block are little-endian. Blocks must start on a word-aligned boundary, and the total size is always an exact number of words (a multiple of four bytes).

The final item in a block must be of type `PICOBIN_BLOCK_ITEM_LAST`, which encodes the total word count of the block's items.

The 32-bit relative link forms a linked list of blocks. To be valid, this linked list must eventually link back to the first block in the list, forming a closed `block loop`; failure to close the loop results in the entire linked list being ignored. The loop rule is used to avoid treating orphaned blocks from partially overwritten images being treated as valid.

Due to RAM restrictions in the boot path, size of blocks is limited to 640 bytes for `PARTITION_TABLEs` and 384 bytes for `IMAGE_DEFs`. Blocks larger than this are ignored.

The format of a simple block with two items is shown:

Item	Word	Bytes	Value
HEADER	0	4	<code>0xffffded3</code>
ITEM 0	1	1	<code>size_flag:1</code> (0 means 1-byte size, 1 means 2-byte size), <code>item_type:7</code>
		1	<code>s0 % 256</code>
		1	<code>s0 / 256</code> if <code>size_flag == 1</code> or type-specific data for blocks that are never > 256 words
		1	Type-specific data
		...	...
ITEM 1	<code>1 + s0</code>	1	<code>size_flag:1</code> (0 means 1-byte size, 1 means 2-byte size), <code>item_type:7</code>
		1	<code>s1 % 256</code>
		1	<code>s1 / 256</code> if <code>size_flag == 1</code> or type-specific data for blocks that are never > 256 words
		1	Type-specific data
		...	...

## 5.8.5. UART 启动二进制文件要求

UART引导二进制文件为普通RAM二进制文件。必须具备有效的 `IMAGE_DEF`，启动路径才能识别其为可引导二进制文件。对 `IMAGE_DEF` 的搜索范围为整个SRAM，但建议将其放置于接近起始处位置，因为启动只读存储器会线性向前搜索 `IMAGE_DEF` 的起始点。

UART引导二进制文件最大尺寸为主SRAM全部容量：520 KB，即532,480字节。

UART引导仅支持加载至SRAM起始地址，故二进制文件必须链接为运行于地址 `0x2`。`0000000`。不支持稀疏加载。您的程序必须作为单一的平铺二进制映像加载。

所有与RAM映像启动相关的安全要求同样适用于UART启动。如启用安全启动，您的二进制文件必须经过签名。同样，若启用了OTP防回滚版本控制，您的二进制文件回滚版本不得低于OTP中存储的版本号。

## 5.9. 元数据块详细信息

### 5.9.1. 块及块循环

块由固定的32位头部、一个或多个条目、指向下一个块的32位相对偏移量及固定的32位尾部组成。块内所有多字节数值均采用小端格式。块必须从字对齐边界开始，且总大小始终为精确的字数（4字节的倍数）。

块中最后一个条目必须为类型 `PICOBIN_BLOCK_ITEM_LAST`，编码块内条目的总字数。

此32位相对链接构成块的链表。为保证链表有效，该链表最终必须回链至首个块，形成闭合块循环；未闭合循环将导致整个链表被忽略。循环规则用于防止将部分覆盖映像中的孤立块错误地视为有效块。

由于启动路径中RAM的限制，块大小被限制为 `PARTITION_TABLE` 为640字节，`IMAGE_DEF` 为384字节。超过此大小的块将被忽略。

下面展示了包含两个项的简单块格式：

项	字	字节	值
头部	0	4	<code>0xffffded3</code>
项 0	1	1	<code>size_flag:1</code> （0表示1字节大小，1表示2字节大小）， <code>item_type:7</code>
		1	<code>s0 % 256</code>
		1	<code>s0 / 256</code> 当 <code>size_flag==1</code> 时，或者对于绝不会超过256字的块的类型专用数据
		1	类型专用数据
		...	...
项 1	<code>1 + s0</code>	1	<code>size_flag:1</code> （0表示1字节大小，1表示2字节大小）， <code>item_type:7</code>
		1	<code>s1 % 256</code>
		1	<code>s1 / 256</code> 当 <code>size_flag==1</code> 时，或者对于绝不会超过256字的块的类型专用数据
		1	类型专用数据
		...	...

Item	Word	Bytes	Value
LAST_ITEM	$1 + s_0 + s_1$	1	<code>0xff</code> ( <code>size_flag == 1, item_type == BLOCK_ITEM_LAST</code> )
		2	$s_1 + s_2$ (other items' size)
		1	<code>0x00</code> (pad)
LINK	$2 + s_0 + s_1$	4	Relative position in bytes of next block HEADER relative to this block's HEADER. this forms a loop, so a single block loop has 0 here.
FOOTER	$3 + s_0 + s_1$	4	<code>0xab123579</code>

`IMAGE_DEF` and `PARTITION_TABLE` blocks are recognised by their first item being an `IMAGE_DEF` or `PARTITION_TABLE` item.

Constants describing blocks can be found in the SDK in `picobin.h` in the SDK.

## 5.9.2. Common block items

The following items might appear in a `IMAGE_DEF` or a `PARTITION_TABLE` block.

### 5.9.2.1. VERSION item

A major/minor version number for the binary, 32 bits total, plus optionally a 16-bit rollback version and a list of OTP rows which can be read to determine the (thermometer-coded) minimum major rollback version which this device will allow to be installed. The major and minor are always present, whereas the rollback version and OTP row list are generally only included if rollback protection is required.

#### NOTE

The rollback version and OTP row list are only valid for `IMAGE_DEF`s, and are ignored on a RP2350 that hasn't been secured.

If the number of OTP row entries is zero, there is no rollback version for this block.

Word	Bytes	Value
0	1	<code>0x48</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_VERSION</code> )
	1	$2 + ((\text{num\_otp\_row\_entries} != 0) + \text{num\_row\_entries} + 1) / 2$
	1	<code>0x00</code> (pad)
	1	<code>num_otp_row_entries</code>
1	2	Minor Version
	2	Major Version
(2)	(2)	Rollback version (if <code>num_otp_entries != 0</code> )
	(2)	First 16-bit OTP Row index (if <code>num_otp_entries != 0</code> )
...	...	Remaining 16-OTP Row indexes (padded with a zero to make a word boundary if necessary)

Each OTP row entry indicates the row number (1 through 4095 inclusive) of the first in a group of 3 OTP rows. The three OTP rows are each read as a 24 bit raw value, combined via a bitwise majority vote, and then the index of the most-significant 1 bit determines the version number. So, a single group of three rows can encode rollback versions from 0 to 23 inclusive, or, when all 24 bits are set, an indeterminate version of at least 24. Each additional OTP row index indicates a further group of 3 rows that increases the maximum version by 24.

There is no requirement for different OTP row entries to be contiguous in OTP. They should not overlap, though the

项	字	字节	值
LAST_ITEM	$1 + s0 + s1$	1	<code>0xff</code> ( <code>size_flag == 1, item_type == BLOCK_ITEM_LAST</code> )
		2	<code>s1 + s2</code> (其他项的大小)
		1	<code>0x00</code> (填充)
LINK	$2 + s0 + s1$	4	下一块 HEADER 相对于本块 HEADER 的字节偏移位置。此处构成循环，因此单块循环的该值为0。
FOOTER	$3 + s0 + s1$	4	<code>0xab123579</code>

IMAGE\_DEF 和 PARTITION\_TABLE 块通过其首项为 IMAGE\_DEF 或 PARTITION\_TABLE 项进行识别。

描述块的常量定义可在 SDK 的 picobin.h 文件中查阅。

## 5.9.2. 通用块项

以下项目可能出现在 IMAGE\_DEF 或 PARTITION\_TABLE 块中。

### 5.9.2.1. VERSION 项

二进制的主版本号和次版本号，共32位，外加可选的16位回退版本及OTP行列表，可用于读取以确定该设备允许安装的（温度计编码）最低主回退版本。主版本号和次版本号始终存在，而回滚版本号和OTP行列表一般仅在需要回滚保护时包含。

#### 注意

回滚版本号和OTP行列表仅对 IMAGE\_DEF 有效，对于未加固的 RP2350 则予以忽略。

如OTP行条目数为零，则该块无回滚版本号。

字	字节	值
0	1	<code>0x48</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_VERSION</code> )
	1	$2 + ((\text{num\_otp\_row\_entries} != 0) + \text{num\_row\_entries} + 1) / 2$
	1	<code>0x00</code> (填充)
	1	<code>num_otp_row_entries</code>
1	2	次版本号
	2	主版本号
(2)	(2)	回滚版本号 (当 <code>num_otp_entries != 0</code> 时)
	(2)	首个16位OTP行索引 (当 <code>num_otp_entries != 0</code> 时)
...	...	剩余的16位OTP行索引 (如有必要以零填充以满足字边界对齐)

每个OTP行条目表示一组三个OTP行中的第一个的行号（包含1至4095）。三个OTP行各自被读取为24位原始值，通过按位多数投票组合，然后最高有效 1 位的索引决定版本号。因此，单组三个OTP行可编码0到23（含）的回滚版本，或者当全部24位均被设置时，表示至少为24的不确定版本。每新增一个OTP行索引，表示增加一组三个OTP行，其最大版本号增加24。

不同的OTP行条目在OTP中无需连续，但不得重叠，尽管

bootrom doesn't need to check this (the boot signing tool may).

#### NOTE

For this entry to be considered valid, the number of available bits in the indicated OTP rows must be *strictly greater than* the rollback version. This means that it is always possible to determine that the device's minimum rollback version is greater than the rollback version indicated in this block, even if we don't know the full list of OTP rows used by later major versions.

The major/minor version are used to disambiguate which is newer out of two binaries with the same major rollback version. For example, to select which A/B image to boot from. When no major rollback version is specified, A/B comparisons will treat the missing major version as zero, but no rollback check will be performed.

### 5.9.2.2. HASH\_DEF item

Optional item with information about what how to hash:

Word	Bytes	Value
0	1	0x47 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_HASH_DEF)
	1	0x03 (size_lo)
	1	0x00 (pad)
	1	0x01 (PICOBIN_HASH_SHA-256)
1	2	Number of words of block hashed (not including HEADER word at the start of the block)
	2	0x0000 (pad)

`block_words_hashed` must include this item if using this item for a signature.

The most recent `LOAD_MAP` item (see [Section 5.9.3.2](#)) that defines *what* to hash.

### 5.9.2.3. HASH\_VALUE item

Optional item containing a hash value that can be used by the bootrom to verify the hash of an image or partition table when not using signatures.

Word	Bytes	Value
0	1	0x09 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_HASH_VALUE)
	1	0x01 + n where n is the number of hash words included (1-8)
	2	0x0000 (pad)
1	4	Hash Value (lowest significant 32 bits)
...	...	...
n	4	Hash Value (highest significant 32 bits)

bootrom无需对此进行检查（启动签名工具可能会检查）。

### 注意

为了使该条目有效，指定OTP行中可用位数必须严格大于回滚版本号。这表明即使我们不了解后续主版本所使用的全部OTP行，仍能确定设备的最小回滚版本高于该区块所指示的回滚版本。

主版本号和次版本号用于区分两个具有相同主回滚版本的二进制文件中哪个版本较新。例如，用于选择从哪个A/B镜像启动。当未指定主回滚版本时，A/B比较将缺失的主版本视为零，但不会执行回滚检查。

#### 5.9.2.2. HASH\_DEF 项

可选项，包含关于如何进行哈希的信息：

字	字节	值
0	1	<code>0x47</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_HASH_DEF</code> )
	1	<code>0x03</code> ( <code>size_lo</code> )
	1	<code>0x00</code> (填充)
	1	<code>0x01</code> ( <code>PICOBIN_HASH_SHA-256</code> )
1	2	被哈希块的字数（不包括块起始的HEADER字）
	2	<code>0x0000</code> (填充)

`block_words_hashed` 若将此项用于签名，必须包含该项。

最新的 `LOAD_MAP` 项（参见第5.9.3.2节），定义了需要哈希的内容。

#### 5.9.2.3. HASH\_VALUE 项

可选项，包含一个哈希值，该哈希值可由只读存储器用于在未使用签名的情况下验证映像或分区表的哈希。

字	字节	值
0	1	<code>0x09</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_HASH_VALUE</code> )
	1	<code>0x01 + n</code> 其中 <code>n</code> 为包含的哈希字数量（1-8）
	2	<code>0x0000</code> (填充)
1	4	哈希值（最低有效32位）
...	...	...
n	4	哈希值（最高有效32位）

 **TIP**

Whilst a SHA-256 hash is 8 words, you can include fewer (down to 1 word) to save space if you like, and only that many words will be compared against the full 8-word hash at runtime.

This `HASH_VALUE` item is paired with the most recent `HASH_DEF` item ([Section 5.9.2.2](#)) which defines what is being hashed.

#### 5.9.2.4. SIGNATURE item

Optional item containing cryptographic signature that can be used by the bootrom to signature check the hashed contents of an image or partition table.

Word	Bytes	Value
0	1	<code>0x4b</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_SIGNATURE</code> )
	1	<code>0x21</code> (Block size in words)
	1	<code>0x00</code> (pad)
	1	<code>0x01</code> ( <code>PICOBIN_SIGNATURE_SECP256K1</code> )
1	4	Public Key (lowest significant 32 bits)
...	...	...
16	4	Public Key (highest significant 32 bits)
17	4	Signature of hash (lowest significant 32 bits)
...	...	...
32	4	Signature of hash (highest significant 32 bits)

This `SIGNATURE` item is paired with the most recent `HASH_DEF` item ([Section 5.9.2.2](#)) which defines what the hash value whose signature is checked.

### 5.9.3. Image definition items

#### 5.9.3.1. IMAGE\_DEF item

The `IMAGE_DEF` item must be the first item within an Image Definition:

Word	Bytes	Value
0	1	<code>0x42</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_IMAGE_TYPE</code> )
	1	<code>0x01</code> (Block size in words)
	2	<code>image_type_flags</code>

The flags are defined in the SDK in [picobin.h in the SDK](#), but are summarised here:

Bits	Field	Values
0-3	Image Type	<ul style="list-style-type: none"> <li>0 <code>IMAGE_TYPE_INVALID</code></li> <li>1 <code>IMAGE_TYPE_EXE</code> : Image is executable</li> <li>2 <code>IMAGE_TYPE_DATA</code> : Image is valid, but is not intended to be executed</li> <li>3 reserved</li> </ul>

### 💡 提示

尽管 SHA-256 哈希包含 8 个字，您仍可选择包括较少的字（至少 1 个字）以节省空间，运行时仅比较包含的字数与完整的 8 字哈希。

该 **HASH\_VALUE** 项与最近的 **HASH\_DEF** 项（第 5.9.2.2 节）配对，后者定义了被哈希的数据。

#### 5.9.2.4. SIGNATURE 项

可选项，包含加密签名，可由只读存储器用于对映像或分区表的哈希内容进行签名校验。

字	字节	值
0	1	0x4b ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_SIGNATURE</code> )
	1	0x21 (块大小，单位为字)
	1	0x00 (填充)
	1	0x01 (PICOBIN_SIGNATURE_SECP256K1)
1	4	公钥（最低有效32位）
...	...	...
16	4	公钥（最高有效32位）
17	4	哈希签名（最低有效32位）
...	...	...
32	4	哈希签名（最高有效32位）

该 **SIGNATURE** 项与最近的 **HASH\_DEF** 项（第 5.9.2.2 节）配对，后者定义了所校验签名的哈希值。

### 5.9.3. 镜像定义项

#### 5.9.3.1. IMAGE\_DEF 项

**IMAGE\_DEF** 项必须为映像定义中的第一个项：

字	字节	值
0	1	0x42 ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_IMAGE_TYPE</code> )
	1	0x01 (块大小，单位为字)
	2	<i>image_type_flags</i>

这些标志在 SDK 的 `picobin.h` 中定义，现简要概述如下：

位	字段	数值
0-3	映像类型	0 IMAGE_TYPE_INVALID 1 IMAGE_TYPE_EXE：映像为可执行文件 2 IMAGE_TYPE_DATA：映像有效，但不用于执行 3 保留

Bits	Field	Values
The remaining bits are specific to the Image Type Values are only currently defined for the EXE Image Type:		
4-5	EXE Security	<ul style="list-style-type: none"> <li>0 EXE_SECURITY_UNSPECIFIED</li> <li>1 EXE_SECURITY_NS : Image runs in Non-secure mode</li> <li>2 EXE_SECURITY_S : Image runs in Secure mode</li> <li>3 reserved</li> </ul>
6-7	reserved	0
8-10	EXE CPU	<ul style="list-style-type: none"> <li>0 EXE_CPU_ARM : Image is for the Arm architecture</li> <li>1 EXE_CPU_RISCV : Image is for the RISC-V architecture</li> <li>2-7 reserved</li> </ul>
11	reserved	0
12-14	EXE CHIP	<ul style="list-style-type: none"> <li>0 EXE_CHIP_RP2040</li> <li>1 EXE_CHIP_RP2350</li> <li>2-7 reserved</li> </ul>
15	EXE TBYB	<ul style="list-style-type: none"> <li>0 not set</li> <li>1 EXE_TBYB : Image is flagged for "Try Before You Buy"</li> </ul>

### 5.9.3.2. LOAD\_MAP item

Optional item with a similar representation to the ELF program header. This is used both to define the content to hash, and also to "load" data before image execution. For example, a secure flash binary can be loaded into RAM prior to both signature check and execution.

The load map is a collection of runtime address, physical address, size and flags.

1. For a "packaged" binary, the information tells the bootrom where to load the code/data.
2. For a hashed or signed binary, the runtime addresses and size indicate code/data that must be included in the hash to be verified or signature checked.

#### **NOTE**

If the runtime\_address is in equal to the storage\_address, then data is never copied, it is just hashed in place.

Explanation of terms:

#### **physical address**

Where the data is stored in the logical address space of the image. For instance, the start of a flash image, even if stored in a partition, could have a physical address of **0x10000000**. The closest ELF concept is LMA.

#### **runtime address**

The address of the data at runtime. The closest ELF concept is VMA.

#### **storage address**

an absolute location where the data is stored in flash. Not necessarily the same as physical address for flash when partitions are in use.

RP2350 uses physical addresses in the **LOAD\_MAP**, not storage addresses, since this data is written by a tool working on the ELF which will not necessarily know where the binary will finally be stored in flash.

This serves several purposes:

位	字段	数值
剩余位专用于映像类型，目前仅对 EXE 类型定义数值：		
4-5	EXE 安全	0 EXE_SECURITY_UNSPECIFIED 1 EXE_SECURITY_NS：映像在非安全模式下运行 2 EXE_SECURITY_S：映像在安全模式下运行 3 保留
6-7	保留	0
8-10	EXE CPU	0 EXE_CPU_ARM：映像适用于 Arm 架构 1 EXE_CPU_RISCV：映像适用于 RISC-V 架构 2-7 保留
11	保留	0
12-14	EXE 芯片	0 EXE_CHIP_RP2040 1 EXE_CHIP_RP2350 2-7 保留
15	EXE TBYB	0 未设置 1 EXE_TBYB：映像标记为“先试用后购买”

### 5.9.3.2. LOAD\_MAP 条目

具有与 ELF 程序头类似表现形式的可选项。该项既用于定义哈希内容，也用于在映像执行前“加载”数据。例如，安全闪存二进制文件可以在签名校验和执行之前加载到 RAM 中。

加载映射是运行时地址、物理地址、大小及标志的集合。

- 对于“打包”二进制文件，该信息指示只读存储器应在哪里加载代码或数据。
- 对于已哈希或已签名的二进制文件，运行时地址和大小指明必须包含在哈希中以进行验证或签名校验的代码或数据。

#### i 注意

若 runtime\_address 等于 storage\_address，则数据不会被复制，而是在原位进行哈希。

术语说明：

#### 物理地址

数据在映像逻辑地址空间中的存储位置。例如，即使存储于分区中，闪存映像的起始处可能具有物理地址 `0x10000000`。ELF 中最接近的概念是 LMA。

#### 运行时地址

数据在运行时的地址。最接近的 ELF 概念是 VMA。

#### 存储地址

数据存储在闪存中的绝对位置。分区启用时，不一定与闪存的物理地址相同。

RP2350 在 `LOAD_MAP` 中使用物理地址，而非存储地址，因为该数据由处理 ELF 文件的工具编写，该工具不一定知道二进制文件最终存储在闪存中的具体位置。

此操作具备多项用途：

Word	Bytes	Value
0	1	<code>0x06</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP</code> )
	2	<code>1 + num_entries * 3</code> (Block size in words)
	1	<code>absolute:1, num_entries:7</code>
1-3	Load Map Entry 0	
	4	<ul style="list-style-type: none"> <li>if <code>absolute == 0</code>  <code>storage_start_address_rel</code> (storage start address relative to the address of this LOAD_MAP item)</li> <li>if <code>absolute == 1</code>  <code>storage_start_address</code> (absolute storage start address)</li> </ul> <p>Note: If this value is <code>0x00000000</code> irrespective of the value of the <code>absolute</code> flag, then the runtime address range is filled with zeros. In this case, the 32 bit size itself is hashed rather than size zero bytes.</p>
	4	<code>runtime_start_address</code> (absolute runtime start address)
	4	<ul style="list-style-type: none"> <li>if <code>absolute == 0</code>  <code>size</code> (of memory range in bytes)</li> <li>if <code>absolute == 1</code>  <code>storage_end_address</code> (absolute storage end address)</li> </ul>
	(4-6)	(Load Map Entry 1)  ...

All addresses must be word aligned, and sizes a multiple of 4. In RP2350 A3 and earlier, the bootrom allowed sizes which weren't multiples of 4 in some cases, but may not have functioned correctly.

#### 5.9.3.2.1. XIP pinning via LOAD\_MAP

Normally, when entering a binary, the XIP cache is un-pinned and flushed. This makes sense both for entering a flash binary, and for security purposes.

If, however, you have a non-flash binary with code or data in the XIP RAM address space, then you need to add a special `LOAD_MAP` entry to indicate to the bootrom that the XIP contents should be pinned.

Any load-map entry (with `storage_address == runtime_address`) and a valid size of greater than zero will suffice, as for example in this simple load map:

Word	Bytes	Value
0	1	<code>0x06</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP</code> )
	2	<code>0x04</code> (Block size in words)
	1	<code>0x81</code> ( <code>absolute == 1, num_entries == 1</code> )
1-3	Load Map Entry 0	
	4	<code>XIP_SRAM_BASE</code> ( <code>storage_start_address</code> )
	4	<code>XIP_SRAM_BASE</code> ( <code>runtime_start_address</code> )
	4	<code>0x04</code> (size in bytes)

字	字节	值
0	1	<code>0x06 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP)</code>
	2	<code>1 + num_entries * 3</code> (块大小, 单位字)
	1	<code>absolute:1, num_entries:7</code>
1-3	加载映射条目 0	
	4	<ul style="list-style-type: none"> <li>如果 <code>absolute == 0</code>  <code>storage_start_address_rel</code> (相对于该 LOAD_MAP 条目地址的存储起始地址)</li> <li>如果 <code>absolute == 1</code>  <code>storage_start_address</code> (绝对存储起始地址)</li> </ul> <p>注意：如果此值为 <code>0x00000000</code>无论 <code>absolute</code>标志的值为何，运行时地址范围均填充为零。在这种情况下，哈希的是32位的 size本身，而非size个零字节。</p>
	4	<code>runtime_start_address</code> (绝对运行时起始地址)
	4	<ul style="list-style-type: none"> <li>如果 <code>absolute == 0</code>  <code>size</code> (内存范围大小, 单位字节)</li> <li>如果 <code>absolute == 1</code>  <code>storage_end_address</code> (绝对存储结束地址)</li> </ul>
	(4-6)	(加载映射条目1)
	...	...

所有地址必须按字对齐，大小必须为4的倍数。在RP2350 A3及更早版本中，bootrom在某些情况下允许大小非4的倍数，但可能无法正常工作。

#### 5.9.3.2.1. 通过LOAD\_MAP实现XIP固定

通常，进入二进制文件时，XIP缓存会被解固定并刷新。这对于加载闪存二进制文件及安全目的均合理。

然而，如果您拥有一个非闪存二进制文件，其代码或数据位于XIP RAM地址空间，则需添加特殊的 LOAD\_MAP 条目用于向只读存储器指示应固定XIP内容。

任何load-map条目（其中`storage_address`等于 `runtime_address`）且大小有效且大于零均适用，例如以下简单的load map：

字	字节	值
0	1	<code>0x06 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP)</code>
	2	<code>0x04</code> (以字为单位的块大小)
	1	<code>0x81 (absolute == 1, num_entries == 1)</code>
1-3	加载映射条目 0	
	4	<code>XIP_SRAM_BASE (storage_start_address)</code>
	4	<code>XIP_SRAM_BASE (runtime_start_address)</code>
	4	<code>0x04</code> (以字节为单位的大小)

### 5.9.3.3. VECTOR\_TABLE item

Optional Arm only item for that specifies the location of the initial Arm vector table. The entry\_point/initial\_sp will be taken from here if present (unless there is also an `ENTRY_POINT` Item). If there is no `ENTRY_POINT` or `VECTOR_TABLE` Item, then the Arm vector table is assumed to be at the start of the image.

Word	Bytes	Value
0	1	<code>0x03</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_VECTOR_TABLE</code> )
	1	<code>0x02</code> (Block size in words)
	2	<code>0x0000</code> (pad)
1	4	Vector table (runtime) address

#### NOTE

The `VECTOR_TABLE` Item is ignored on RISC-V.

### 5.9.3.4. ENTRY\_POINT item

Optional item with info on initial PC, SP, and optionally the SP limit

Word	Bytes	Value
0	1	<code>0x44</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_ENTRY_POINT</code> )
	1	<code>0x03</code> or <code>0x04</code> (Block size in words)
	2	<code>0x0000</code> (pad)
1	4	Initial PC (runtime) address (aka entry point)
2	4	Initial SP address (aka stack pointer)
(3)	4	Optional SP limit address (aka stack limit)

### 5.9.3.5. ROLLING\_WINDOW\_DELTA item

Optional item that allow for binaries that aren't intended to be run at `0x10000000`. Note that this delta is in addition to the roll resulting from the binary being stored in a partition in flash.

Word	Bytes	Value
0	1	<code>0x05</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_ROLLING_WINDOW_DELTA</code> )
	1	<code>0x02</code> (Block size in words)
	2	<code>0x0000</code> (pad)
1	4	signed 32 bit delta

The delta is the number of bytes into the image that `0x10000000` should be mapped.

If positive, the delta must be a multiple of 4 kB, and allows for "skipping over" other data before the start of the binary. If negative, the delta must be a multiple of 4 MB, and allows for running flash binaries linked to run at `0x10400000`, `0x01080000` and `0x010c0000` as well as the standard `0x10000000`

### 5.9.3.3. VECTOR\_TABLE 项

仅适用于Arm的可选条目，用于指定初始Arm向量表的位置。如果存在，entry\_point/initial\_sp将从此处获取（除非同时存在ENTRY\_POINT条目）。若不存在ENTRY\_POINT或VECTOR\_TABLE条目，则假定Arm向量表位于映像起始处。

字	字节	值
0	1	0x03 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_VECTOR_TABLE)
	1	0x02 (块大小，单位为字)
	2	0x0000 (填充)
1	4	向量表（运行时）地址

#### 注意

在RISC-V架构上，VECTOR\_TABLE项被忽略。

### 5.9.3.4. ENTRY\_POINT 项

包含初始PC与SP信息的可选项，SP限制地址为可选

字	字节	值
0	1	0x44 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_ENTRY_POINT)
	1	0x03 或 0x04 (块大小，单位为字)
	2	0x0000 (填充)
1	4	初始PC（运行时）地址（即入口点）
2	4	初始SP地址（即栈指针）
(3)	4	可选的SP限制地址（即栈限制）

### 5.9.3.5. ROLLING\_WINDOW\_DELTA 项

允许二进制文件非在 0x1 地址运行的可选项 0000000。注意，该偏移量是相对于二进制文件存储在闪存分区中所引起的滚动偏移之外的增量。

字	字节	值
0	1	0x05 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_1BS_ROLLING_WINDOW_DELTA)
	1	0x02 (块大小，单位为字)
	2	0x0000 (填充)
1	4	有符号32位增量

该增量表示镜像中的字节偏移量，值为 0x1000000 应被映射。

如果为正数，增量必须是4 KB的整数倍，且允许在二进制起始位置之前“跳过”其他数据。如果为负数，增量必须是4 M B的整数倍，允许运行链接到 0x10400000、0x01080000 和 0x010c0000 以及标准 0x1 地址的闪存二进制文件。0000000

**NOTE**

The `ROLLING_WINDOW_DELTA` Item is ignored for non-flash binaries.

### 5.9.4. Partition table items

Partition tables allows dividing the 32 MB flash region ( $2 \times 16$  MB) into partitions. Permissions and other partition attributes may be specified for each partition, along with permissions for the un-partitioned space.

The permission specify read/write access for Secure code, Non-secure code, and "NSBoot" which refers to the boot loader (and PICOBOOT)

**NOTE**

These permissions are only advisory to Secure code, however they are respected by `flash_op()`, the PICOBOOT flash access commands, and UF2 downloads.

#### 5.9.4.1. PARTITION\_TABLE item

Word	Bytes	Value
0	1	<code>0x44</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_PARTITION_TABLE</code> )
	2	Block size in words
	1	<code>singleton_flag:1, pad:3, partition_count:4</code>
1	4	<code>unpartitioned_space_permissions_and_flags</code>
Partition 0		
2	4	<code>permissions_and_location</code> for partition 0
3	4	<code>permissions_and_flags</code> for partition 0
<i>if_partition_0_has_id:</i>		
3	4	<code>partition_0_ID_lo</code>
4	4	<code>partition_0_ID_hi</code>
one word per additional family ID (can be none):		
x	4	<code>partition_0_family_ID_0</code>
x + 1	4	<code>partition_0_family_ID_1</code>
...		
<i>if_partition_0_has_name:</i>		
y	1	<code>reserved:1 (0), name_len_bytes:7</code>
	1	<code>partition_0_name_byte_0</code>
	1	<code>partition_0_name_byte_1</code>
	1	<code>partition_0_name_byte_2</code>

**① 注意**

对于非闪存二进制文件，将忽略`ROLLING_WINDOW_DELTA`条目。

### 5.9.4. 分区表项

分区表允许将32 MB闪存区域（ $2 \times 16\text{ MB}$ ）划分为多个分区。每个分区可以指定权限及其他分区属性，同时也可为未分区空间设定权限。

权限用于指定安全代码、非安全代码及“NSBoot”（即引导加载程序及PICOBOOT）的读写访问权限。

**① 注意**

这些权限仅作为对Secure代码的建议，但`flash_op()`、PICOBOOT闪存访问命令以及UF2下载均予以遵守。

#### 5.9.4.1. PARTITION\_TABLE 项

字	字节	值
0	1	<code>0x44 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_PARTITION_TABLE)</code>
	2	块大小（单位：字）
	1	<code>singleton_flag:1, pad:3, partition_count:4</code>
1	4	未分区空间权限及标志
分区 0		
2	4	分区 0 的权限与位置
3	4	分区 0 的权限及标志
如果 <code>_partition_0_has_id</code> :		
3	4	<code>partition_0_ID_lo</code>
4	4	<code>partition_0_ID_hi</code>
每个额外的 <code>family ID</code> 占用一个字（可无）:		
x	4	<code>partition_0_family ID_0</code>
x + 1	4	<code>partition_0_family ID_1</code>
...		
如果 <code>_partition_0_has_name</code> :		
y	1	<code>reserved:1 (0), name_len_bytes:7</code>
	1	<code>partition_0_name_byte_0</code>
	1	<code>partition_0_name_byte_1</code>
	1	<code>partition_0_name_byte_2</code>

Word	Bytes	Value
y+1	1	partition_0_name_byte_3
	1	partition_0_name_byte_4
	1	partition_0_name_byte_5
	1	partition_0_name_byte_6
	...	...
	?	partition_0_name_byte_n_minus_x to partition_0_name_byte_n_minus_2
	1	partition_0_name_byte_n_minus_1
	?	(padding zero bytes to reach word alignment)
	...	...
(Partition 1)		
...	...	...

#### 5.9.4.2. Partition location, permissions, and flags

Two common words are stored in the partition table for both un-partitioned space and each partition. These common words describe the size/location, along with access permissions and various flags.

The permission fields are repeated in both words, hence the two words are `permissions_and_location` and `permissions_and_flags`.

Table 472. Permission Fields. '`P`' means the field applies to partitions, '`U`' means the field applies to un-partitioned space, however the word "partition" is always used in the description

Mask	AppliesTo	Description
0x04000000u	'P' 'U'	PERMISSION_S_R_BITS
		If set, the partition is readable by Secure code. See <a href="#">Section 5.1.3</a>
0x08000000u	'P' 'U'	PERMISSION_S_W_BITS
		If set, the partition is writable by Secure code. See <a href="#">Section 5.1.3</a>
0x10000000u	'P' 'U'	PERMISSION_NS_R_BITS
		If set, the partition is readable by Non-secure code. See <a href="#">Section 5.1.3</a>
0x20000000u	'P' 'U'	PERMISSION_NS_W_BITS
		If set, the partition is writable by Non-secure code. See <a href="#">Section 5.1.3</a>
0x40000000u	'P' 'U'	PERMISSION_NSBOOT_R_BITS
		If set, the partition is readable by NSBOOT (boot loader) Secure code. See <a href="#">Section 5.1.3</a>
0x80000000u	'P' 'U'	PERMISSION_NSBOOT_W_BITS
		If set, the partition is writable by NSBOOT (boot loader) Secure code. See <a href="#">Section 5.1.3</a>

Table 473. Location Fields. '`P`' means the field applies to partitions, '`U`' means the field applies to un-partitioned space, however the word "partition" is always used in the description

Mask	AppliesTo	Description
0x00001ffffu	'P' 'U'	LOCATION_FIRST_SECTOR_BITS
		The sector number (0-4095) of the first sector in the partition (a sector is 4 kB)
0x03ffe000u	'P' 'U'	LOCATION_LAST_SECTOR_BITS
		The sector number (0-4095) of the last sector in the partition (a sector is 4 kB)

字	字节	值
y+1	1	<i>partition_0_name_byte_3</i>
	1	<i>partition_0_name_byte_4</i>
	1	<i>partition_0_name_byte_5</i>
	1	<i>partition_0_name_byte_6</i>
	...	...
	?	<i>partition_0_name_byte_n_minus_x</i> 至 <i>partition_0_name_byte_n_minus_2</i>
	1	<i>partition_0_name_byte_n_minus_1</i>
(分区 1)		
...	...	...

#### 5.9.4.2. 分区位置、权限及标志

两个公共词存储于分区表中，分别对应未分区空间与各分区。这些公共词描述大小/位置，以及访问权限和各类标志。

权限字段在两个词中均重复出现，因此这两个词分别是permissions\_and\_location和 permissions\_and\_flags。

表472. 权限字段。  
'P'表示该字段适用于分区，'  
U'表示该字段适用于未分区空间，但描述中始终使用“partition”一词。

掩码	适用对象	描述
0x04000000u	'P' 'U'	PERMISSION_S_R_BITS
		若设置，本分区允许安全代码读取。详见第5.1.3节。
0x08000000u	'P' 'U'	PERMISSION_S_W_BITS
		若设置，本分区允许安全代码写入。详见第5.1.3节。
0x10000000u	'P' 'U'	PERMISSION_NS_R_BITS
		若设置，本分区允许非安全代码读取。详见第5.1.3节。
0x20000000u	'P' 'U'	PERMISSION_NS_W_BITS
		若设置，本分区允许非安全代码写入。详见第5.1.3节。
0x40000000u	'P' 'U'	PERMISSION_NSBOOT_R_BITS
		若设置，则该分区可被NSBOOT（引导加载程序）安全代码读取。详见第5.1.3节
0x80000000u	'P' 'U'	PERMISSION_NSBOOT_W_BITS
		若设置，则该分区可被NSBOOT（引导加载程序）安全代码写入。详见第5.1.3节

表473. 位置字段。  
'P'表示该字段适用于分区，'  
U'表示该字段适用于未分区空间，但描述中始终使用“分区”一词

掩码	适用对象	描述
0x00001ffffu	'P' 'U'	LOCATION_FIRST_SECTOR_BITS
		分区内第一个扇区的扇区号（0-4095）（每个扇区大小为4 kB）
0x03ffe000u	'P' 'U'	LOCATION_LAST_SECTOR_BITS
		分区内最后一个扇区的扇区号（0-4095）（每个扇区大小为4 kB）

Table 474. Flags Fields. 'P' means the field applies to partitions, 'U' means the field applies to un-partitioned space, however the word "partition" is always used in the description

Mask	AppliesTo	Description
0x00000001u	'P'	<b>FLAGS_HAS_ID_BITS</b> If set, the partition has a 64 bit identifier
0x00000006u	'P'	<b>FLAGS_LINK_TYPE_BITS</b> The type of link stored in the partition: <ul style="list-style-type: none"> <li>0x0 - None</li> <li>0x1 - A_PARTITION : This is a "B" partition, and The <b>LINK_VALUE</b> field stores the partition number of the corresponding "A" partition</li> <li>0x2 - OWNER : This is an "A" partition, and the <b>LINK_VALUE</b> field stores the partition number of the owning partition (which should also be an "A" partition).</li> </ul>
0x00000078u	'P'	<b>FLAGS_LINK_VALUE_BITS</b> If <b>LINK_TYPE</b> is non zero, then this field holds the partition number of the linked partition.
0x00000180u	'P'	<b>FLAGS_ACCEPTS_NUM_EXTRA_FAMILIES_BITS</b> 0-3 the number of extra non-standard UF2 family ids the partition accepts.
0x00000200u	'P'	<b>FLAGS_NOT_BOOTABLE_ARM_BITS</b> If set then this partition is marked non-bootable on Arm, and will be ignored during Arm boot. Setting this for non Arm bootable partitions can improve boot performance.
0x00000400u	'P'	<b>FLAGS_NOT_BOOTABLE_RISCV_BITS</b> If set then this partition is marked non-bootable on RISC-V, and will be ignored during RISC-V boot. Setting this for non RISC-V bootable partitions can improve boot performance.
0x00000800u	'P'	<b>FLAGS_UF2_DOWNLOAD_AB_NON_BOOTABLE_OWNER_AFFINITY</b>
0x00001000u	'P'	<b>FLAGS_HAS_NAME_BITS</b> If set, the partition has a name.
0x00002000u	'P' 'U'	<b>FLAGS_UF2_DOWNLOAD_NO_REBOOT_BITS</b> If set, the RP2350 will not reboot after dragging a UF2 into this partition.
0x00004000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2040_BITS</b> If set, a UF2 with the RP2040 family id <b>0xe48bff56</b> may be downloaded into this partition.
0x00008000u	'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_ABSOLUTE_BITS</b> If set for un-partitioned spaced, a UF2 with the <b>ABSOLUTE</b> family id <b>0xe48bff57</b> may be downloaded onto the RP2350 and will be written at the addresses specified in the UF2 without regard to partition locations. Partition-defined flash access permissions are still respected (the UF2 download will fail if it needs to write over a read-only region of flash).
0x00010000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_DATA_BITS</b> If set, a UF2 with the <b>DATA</b> family id <b>0xe48bff58</b> may be downloaded into this partition.
0x00020000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2350_ARM_S_BITS</b> If set, a UF2 with the <b>RP2350_ARM_S</b> family id <b>0xe48bff59</b> may be downloaded into this partition.
0x00040000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2350_RISCV_BITS</b> If set, a UF2 with the <b>RP2350_RISCV</b> family id <b>0xe48bff5a</b> may be downloaded into this partition.

表474. 标志字段。'P'表示该字段适用于分区，'U'表示该字段适用于未分区空间，但描述中始终使用“分区”一词

掩码	适用对象	描述
0x00000001u	'P'	<b>FLAGS_HAS_ID_BITS</b> 若设置，则该分区具有64位标识符。
0x00000006u	'P'	<b>FLAGS_LINK_TYPE_BITS</b> 存储在分区中的链接类型： <ul style="list-style-type: none"> <li>• 0x0 - 无</li> <li>• 0x1-A_PARTITION：这是一个“B”分区，<a href="#">LINK_VALUE</a>字段存储对应“A”分区的分区号。</li> <li>• 0x2-OWNER：这是一个“A”分区，<a href="#">LINK_VALUE</a>字段存储所属分区的分区号（该所属分区也应为“A”分区）。</li> </ul>
0x00000078u	'P'	<b>FLAGS_LINK_VALUE_BITS</b> 若 <a href="#">LINK_TYPE</a> 非零，则该字段保存链接分区的分区号。
0x00000180u	'P'	<b>FLAGS_ACCEPTS_NUM_EXTRA_FAMILIES_BITS</b> 0-3 表示分区接受的额外非标准UF2系列ID数量。
0x00000200u	'P'	<b>FLAGS_NOT_BOOTABLE_ARM_BITS</b> 若设置，则该分区在Arm架构上标记为不可启动，并将在Arm启动过程中被忽略。 为非Arm可启动分区设置此项可提升启动性能。
0x00000400u	'P'	<b>FLAGS_NOT_BOOTABLE_RISCV_BITS</b> 如果设置，此分区将在RISC-V上标记为不可启动，并在RISC-V启动时被忽略。对非RISC-V启动分区设置此项可提升启动性能。
0x00000800u	'P'	<b>FLAGS_UF2_DOWNLOAD_AB_NON_BOOTABLE_OWNER_AFFINITY</b>
0x00001000u	'P'	<b>FLAGS_HAS_NAME_BITS</b> 如果设置，分区将具有名称。
0x00002000u	'P' 'U'	<b>FLAGS_UF2_DOWNLOAD_NO_REBOOT_BITS</b> 如果设置，RP2350在将UF2文件拖入此分区后不会重新启动。
0x00004000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2040_BITS</b> 如果设置，具有 RP2040 系列 ID 0xe48bff56 的 UF2 可下载到该分区。
0x00008000u	'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_ABSOLUTE_BITS</b> 如果对未分区空间设置此项，具有 ABSOLUTE 系列 ID 0xe48bff57 的 UF2 可以下载到 RP2350，并会按照 UF2 中指定的地址写入，而不考虑分区位置。分区定义的闪存访问权限依然被严格遵守（若需写入只读闪存区域则 UF2 下载将会失败）。
0x00010000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_DATA_BITS</b> 若设置，带有 DATA 系列 ID 0xe48bff58 的 UF2 可下载至此分区。
0x00020000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2350_ARM_S_BITS</b> 若设置，带有 RP2350_ARM_S 系列 ID 0xe48bff59 的 UF2 可下载至此分区。
0x00040000u	'P' 'U'	<b>FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2350_RISCV_BITS</b> 若设置，带有 RP2350_RISCV_V 系列 ID 0xe48bff5a 的 UF2 可下载至此分区。

Mask	AppliesTo	Description
0x00080000u	'P' 'U'	FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2350_ARM_NS_BITS If set, a UF2 with the RP2350_ARM_NS family id 0xe48bff5b may be downloaded into this partition.
0x03f00000u	'P' 'U'	reserved; should be 0

### 5.9.5. Minimum viable image metadata

A minimum amount of metadata (a valid IMAGE\_DEF block) must be embedded in any binary for the bootrom to recognise it as a valid program image, as opposed to, for example, blank flash contents or a disconnected flash device. This must appear within the first 4 kB of a flash image, or anywhere in a RAM or OTP image.

Unlike RP2040, there is no requirement for flash binaries to have a checksummed "boot2" flash setup function at flash address 0. The RP2350 bootrom performs a simple best-effort XIP setup during flash scanning, and a flash-resident program can continue executing in this state, or can choose to reconfigure the QSPI interface at a later time for best performance.

#### 5.9.5.1. Minimum Arm IMAGE\_DEF

Assuming CRIT1.SECURE\_BOOT\_ENABLE is clear, the minimum valid IMAGE\_DEF is the following 20-byte sequence:

Word	LE Value	Bytes	Description
0	0xffffded3	4	PICOBIN_BLOCK_MARKER_START
1	0x10210142	1	0x42(item_type == PICOBIN_BLOCK_ITEM_1BS_IMAGE_TYPE)
		1	0x01 (Item is 1 word in size)
		2	0x1021 (PICOBIN_IMAGE_TYPE_IMAGE_TYPE_AS_BITS(EXE) PICOBIN_IMAGE_TYPE_EXE_SECURITY_AS_BITS(S) PICOBIN_IMAGE_TYPE_EXE_CPU_AS_BITS(Arm) PICOBIN_IMAGE_TYPE_EXE_CHIP_AS_BITS(RP23500))
2	0x000001ff	1	0xff(size_type == 1, item_type_ == PICOBIN_BLOCK_ITEM_2BS_LAST)
		2	0x0001 (size)
		1	0x00 (pad)
3	0x00000000	4	Relative pointer to next block in block loop - 0x00000000 means link to self (a loop containing just this block)
4	0xab123579	4	PICOBIN_BLOCK_MARKER_END

The LE Value column indicates a 32-bit little-endian value that should appear verbatim in your program image.

Since the above block does not specify an explicit entry point, the bootrom will assume the binary starts with a Cortex-M vector table, and enter via the reset handler and initial stack pointer specified in that table (offsets +4 and +0 bytes into the table). An explicit vector table pointer can be provided by a PICOBIN\_BLOCK\_ITEM\_1BS\_VECTOR\_TABLE item, or the entry point can be specified directly by a PICOBIN\_BLOCK\_ITEM\_1BS\_ENTRY\_POINT item.

#### 5.9.5.2. Minimum RISC-V IMAGE\_DEF

The minimum valid IMAGE\_DEF is the following 20-byte sequence:

掩码	适用对象	描述
0x00080000u	'P' 'U'	FLAGS_ACCEPTS_DEFAULT_FAMILY_RP2350_ARM_NS_BITS
		若设置，带有RP2350_ARM_NS系列ID 0xe48bff5b的UF2可下载至此分区。
0x03f00000u	'P' 'U'	保留；应设为0

### 5.9.5. 最小可用镜像元数据

任何二进制文件中必须嵌入最少量元数据（有效的 `IMAGE_DEF` 块），以便启动只读存储器能够识别其为有效程序映像，而非空白闪存内容或断开连接的闪存设备。该元数据必须出现在闪存映像的前4 KB内，或位于RAM或OTP映像的任意位置。

与RP2040不同，闪存二进制文件无需在闪存地址0处包含带校验和的“boot2”闪存初始化函数。RP2350启动只读存储器在扫描闪存时执行简单的尽力而为XIP设置，闪存驻留程序可在该状态下继续执行，或选择稍后重新配置QSPI接口以获得最佳性能。

#### 5.9.5.1 最小Arm `IMAGE_DEF`

假设CRIT1.SECURE\_BOOT\_ENABLE为清除状态，最小有效的 `IMAGE_DEF` 为以下20字节序列：

字	LE 值	字节	描述
0	0xffffded3	4	<code>PICOBIN_BLOCK_MARKER_START</code>
1	0x10210142	1	<code>0x42(item_type == PICOBIN_BLOCK_ITEM_1BS_IMAGE_TYPE)</code>
		1	<code>0x01</code> (项目大小为 1 字)
		2	<code>0x1021</code> <code>(PICOBIN_IMAGE_TYPE_IMAGE_TYPE_AS_BITS(EXE))</code> <code>PICOBIN_IMAGE_TYPE_EXE_SECURITY_AS_BITS(S))</code> <code>PICOBIN_IMAGE_TYPE_EXE_CPU_AS_BITS(Arm))</code> <code>PICOBIN_IMAGE_TYPE_EXE_CHIP_AS_BITS(RP23500))</code>
		2	<code>0xff(size_type == 1, item_type_ == PICOBIN_BLOCK_ITEM_2BS_LAST)</code>
2	0x000001ff	2	<code>0x0001</code> (size)
		1	<code>0x00</code> (pad)
		3	<code>0x00000000</code>
4	0xab123579	4	<code>PICOBIN_BLOCK_MARKER_END</code>

“LE 值”栏表示一个32位小端格式的数值，应准确无误地出现在您的程序镜像中。

由于上述区块未指定明确入口点，bootrom将假定二进制文件以Cortex-M向量表开始，并通过表中指定的复位处理程序及初始堆栈指针（表中+4和+0字节偏移）进入。可以通过 `PICOBIN_BLOCK_ITEM_1BS_VECTOR_TABLE` 项提供显式向量表指针，或通过 `PICOBIN_BLOCK_ITEM_1BS_ENTRY_POINT` 项直接指定入口点。

#### 5.9.5.2. 最小RISC-V `IMAGE_DEF`

最小有效的 `IMAGE_DEF` 为以下20字节序列：

Word	LE Value	Bytes	Description
0	0xffffded3	4	PICOBIN_BLOCK_MARKER_START
1	0x11010142	1	0x42(item_type == PICOBIN_BLOCK_ITEM_1BS_IMAGE_TYPE)
		1	0x01 (Item is 1 word in size)
		2	0x1101 (PICOBIN_IMAGE_TYPE_IMAGE_TYPE_AS_BITS(EXE) PICOBIN_IMAGE_TYPE_EXE_CPU_AS_BITS(RISCV) PICOBIN_IMAGE_TYPE_EXE_CHIP_AS_BITS(RP23500))
2	0x0000001ff	1	0xff(size_type == 1, item_type == PICOBIN_BLOCK_ITEM_2BS_LAST)
		2	0x0001 (size)
		1	0x00 (pad)
3	0x00000000	4	Relative pointer to next block in block loop - 0x00000000 means link to self (a loop containing just this block)
4	0xab123579	4	PICOBIN_BLOCK_MARKER_END

The *LE Value* column indicates a 32-bit little-endian value that should appear verbatim in your program image.

Since the above block does not specify an explicit entry point, the bootrom will enter the binary at its lowest address, which is the default behaviour on RISC-V. This default entry point can be overridden by a `PICOBIN_BLOCK_ITEM_1BS_ENTRY_POINT` item. Note that `PICOBIN_BLOCK_ITEM_1BS_VECTOR_TABLE` is not valid on RISC-V, as unlike Cortex-M the RISC-V vector table does not define the program entry point.

## 5.10. Example boot scenarios

This section describes the setup and configuration steps for various different boot scenarios.

### 5.10.1. Secure boot

To enable secure boot on RP2350, you must:

1. Set the SHA-256 hashes of the boot keys you will be using in `BOOTKEY0_0` onwards
2. Set bits in `BOOT_FLAGS1.KEY_VALID` for the keys you will be using
3. Optionally set bits in `BOOT_FLAGS1.KEY_INVALID` for all unused keys – this is recommended to prevent a malicious actor installing their own boot keys at a later date
4. Set `CRIT1.SECURE_BOOT_ENABLE` to turn on secure boot.

#### **i** NOTE

These steps are the minimum for enabling secure boot support *in the bootrom*. See Section 10.5 for additional steps you must take to fully secure your device, such as disabling hardware debug.

All of the above can be achieved with `picotool`. For example, when signing using `picotool seal` you can add an OTP JSON output file, to which it will add the relevant OTP field values to enable secure boot (`BOOTKEY0_0`, `BOOT_FLAGS1.KEY_VALID` and `CRIT1.SECURE_BOOT_ENABLE`):

字	LE 值	字节	描述
0	0xffffded3	4	PICOBIN_BLOCK_MARKER_START
1	0x11010142	1	0x42(item_type == PICOBIN_BLOCK_ITEM_1BS_IMAGE_TYPE)
		1	0x01(项目大小为1字)
		2	0x1101 (PICOBIN_IMAGE_TYPE_IMAGE_TYPE_AS_BITS(EXE) PICOBIN_IMAGE_TYPE_EXE_CPU_AS_BITS(RISCV) PICOBIN_IMAGE_TYPE_EXE_CHIP_AS_BITS(RP23500))
2	0x0000001ff	1	0xff(size_type == 1, item_type == PICOBIN_BLOCK_ITEM_2BS_LAST)
		2	0x0001(size)
		1	0x00(pad)
3	0x00000000	4	指向块循环中下一个块的相对指针 - 0x00000000 表示链接至自身（仅包含该块的循环）
4	0xab123579	4	PICOBIN_BLOCK_MARKER_END

“LE 值”栏表示一个 32 位小端格式的数值，应准确无误地出现在您的程序镜像中。

由于上述区块未指定明确入口点，bootrom 将从其最低地址进入二进制文件，此为 RISC-V 的默认行为。该默认入口点可通过 PICOBIN\_BLOCK\_ITEM\_1BS\_ENTRY\_POINT 项覆盖。请注意，PICOBIN\_BLOCK\_ITEM\_1BS\_VECTOR\_TABLE 在 RISC-V 上无效，因为与 Cortex-M 不同，RISC-V 的向量表不定义程序入口点。

## 5.10. 启动示例场景

本节描述各种不同启动场景的设置与配置步骤。

### 5.10.1. 安全启动

要在 RP2350 上启用安全启动，您必须：

1. 设置从 BOOTKEY0\_0 开始使用的启动密钥的 SHA-256 哈希值。
2. 在 BOOT\_FLAGS1.KEY\_VALID 中设置您将使用的密钥对应位。
3. 可选地，在 BOOT\_FLAGS1.KEY\_INVALID 中设置所有未使用密钥对应位——建议这样做以防止恶意行为者日后安装自己的启动密钥。
4. 设置 CRIT1.SECURE\_BOOT\_ENABLE 以启用安全启动。

#### 注意

以上步骤为启动只读存储器中启用安全启动支持的最低要求。有关完全保障设备安全所需采取的额外步骤，例如禁用硬件调试，请参见第 10.5 节。

以上所有操作均可通过 picotool 完成。例如，使用 picotool seal 进行签名时，可以添加一个 OTP JSON 输出文件，工具会在该文件中添加相关的 OTP 字段值，以启用安全启动 (BOOTKEY0\_0、BOOT\_FLAGS1.KEY\_VALID 和 CRIT1.SECURE\_BOOT\_ENABLE)：

```
$ picotool seal --sign unsigned.elf signed.elf private.pem /path/to/otp.json
```

To configure the SDK to output this OTP JSON file when signing, add the following command to your [CMakeLists.txt](#):

```
pico_set_otp_key_output_file(target_name /path/to/otp.json)
```

You can then issue the following command to write this OTP JSON file to the device, thus enabling secure boot:

```
$ picotool otp load /path/to/otp.json
```

Once secure boot is enabled, the bootrom verifies signatures of images from all supported media: flash, OTP, and images preloaded into SRAM via the UART and USB bootloaders. At this point you lose the ability to run unsigned images; during development you may find it more convenient to leave secure boot disabled. The next section describes the generation of **signed images** to run on a secure-boot-enabled device.

### 5.10.2. Signed images

 **TIP**

This section refers to the concepts of [block loops](#) and [image definitions](#) (and the associated [IMAGE\\_DEF](#) data structure) described in [Section 5.1](#). You should read the bootrom concepts section before this one.

An example of an image (and its block loop) produced by the SDK is shown below.

```
$ picotool seal --sign unsigned.elf signed.elf private.pem /path/to/otp.json
```

要配置 SDK 在签名时输出该 OTP JSON 文件，请在您的[CMakeLists.txt](#)中添加如下命令：

```
pico_set_otp_key_output_file(target_name /path/to/otp.json)
```

然后，您可以执行以下命令将该 OTP JSON 文件写入设备，从而启用安全启动：

```
$ picotool otp load /path/to/otp.json
```

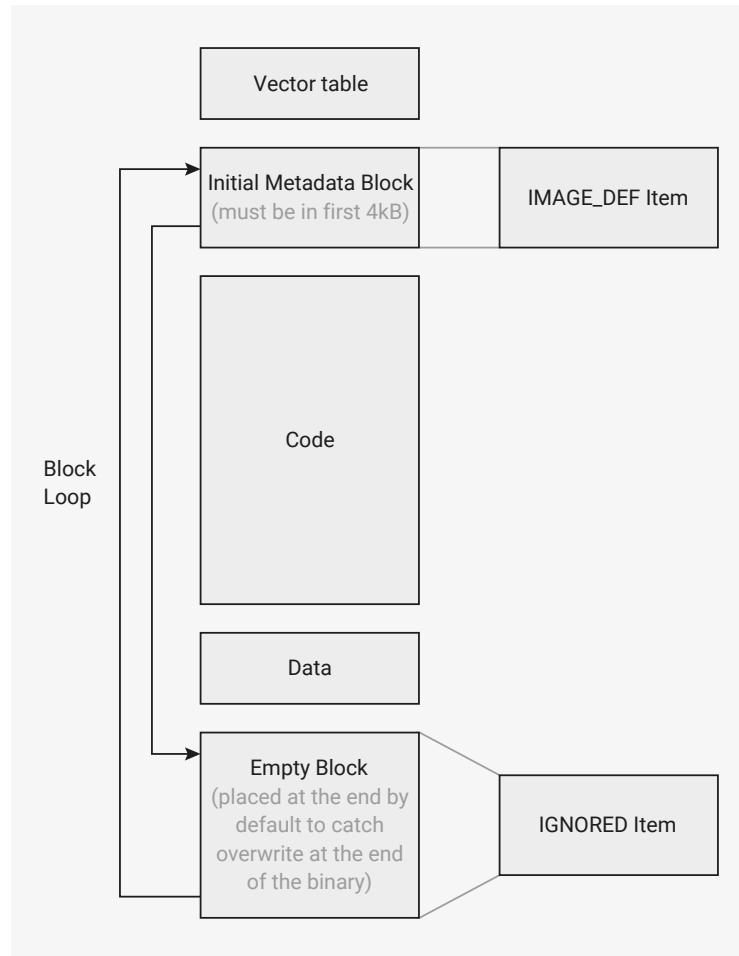

启用安全启动后，bootrom 将验证所有支持介质中镜像的签名：闪存、OTP 以及通过 UART 和 USB 启动加载器预加载至 SRAM 的镜像。此时，您将无法运行未签名的镜像；在开发过程中，您可能会发现禁用安全启动更为方便。下一节介绍了在启用安全启动的设备上运行的**signed images**的生成。

## 5.10.2. 签名映像

### 💡 提示

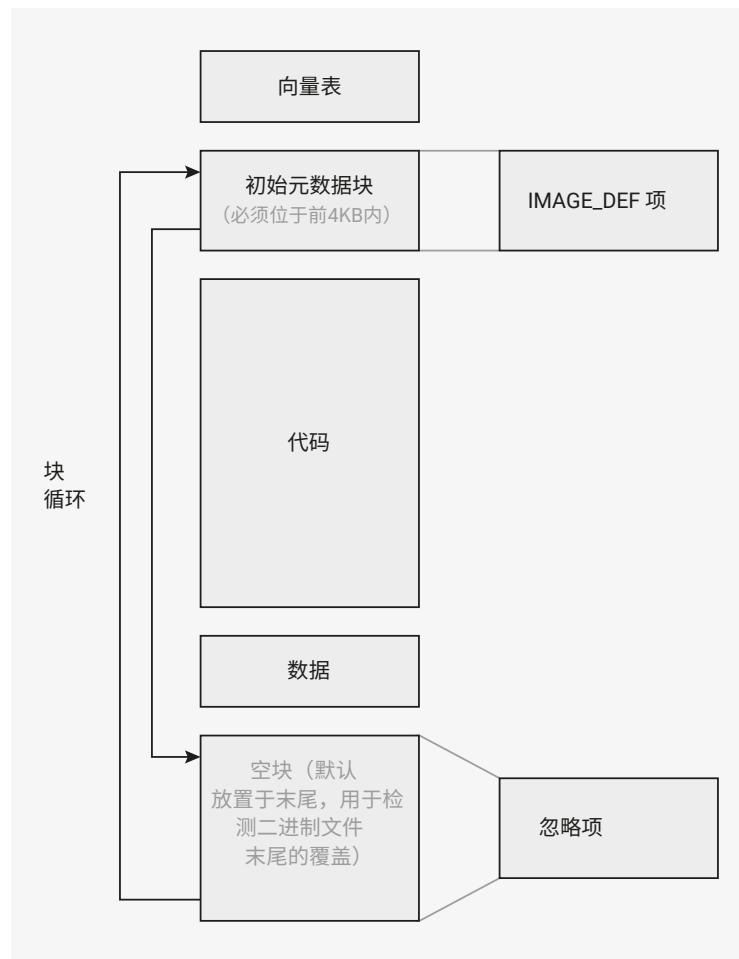

本节涉及第5.1节中描述的块循环和映像定义（及相关的 [IMAGE\\_DEF](#) 数据结构）概念。您应在阅读本节之前先阅读bootrom概念部分。

以下展示了由SDK生成的一个映像（及其块循环）示例。

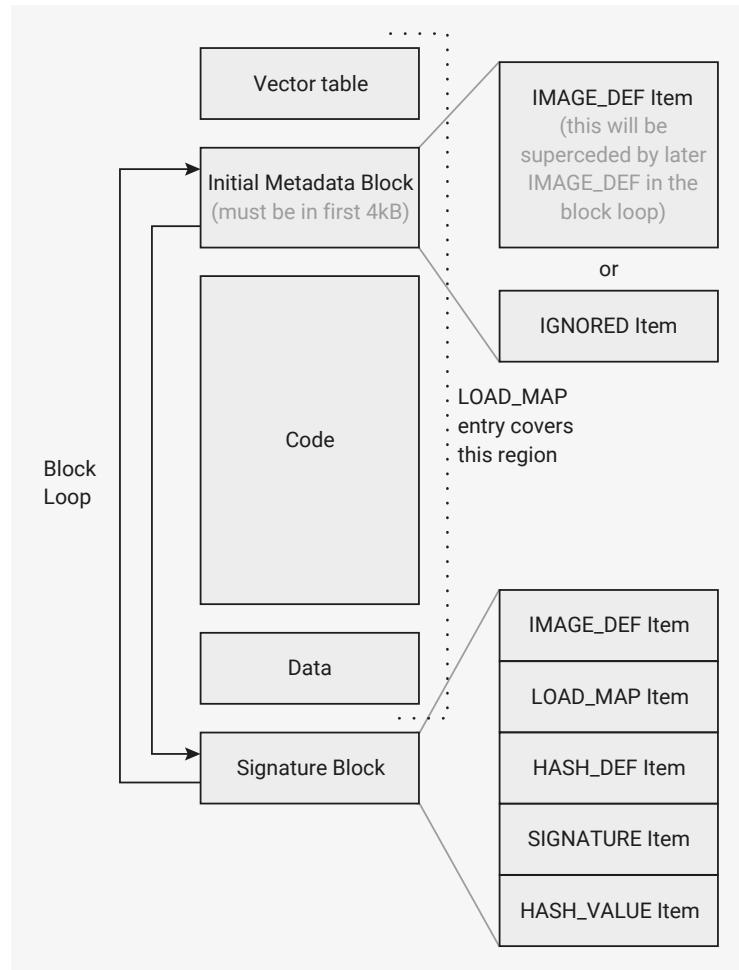

The first block must be within the first 4 kB of the image, and is an [IMAGE\\_DEF](#) block describing the image. This block is linking to an empty block at the end of the image, that is included in the block loop to help detect partially written binaries. If the end of the image is missing or overwritten, then the block loop not be properly closed and will be considered invalid.

[picotool](#) can be used to sign a binary, in which case it modifies the image as follows:

第一个块必须位于映像的前4KB内，且是描述该映像的 IMAGE\_DEF 块。该块链接到映像末尾的一个空块，空块包含在块循环中，用于帮助检测部分写入的二进制文件。如果映像末尾缺失或被覆盖，则块循环无法正确闭合，视为无效。

`picotool` 可用于对二进制文件进行签名，在此情况下会按照以下方式修改映像：

Note that the marker block at the end of the image has been replaced with a new `IMAGE_DEF` block including the first block's information along with additional new information. The new information includes the signature (or hash value if hashing only), along with a `LOAD_MAP` entry indicating the regions of the image that are signed or hashed.

At runtime, the bootrom will pick the last valid `IMAGE_DEF` in the block loop as the one to boot.

Signing requires a SHA-256 hash of the data specified in the `LOAD_MAP`, along with the words of the block specified by the `HASH_VALUE` Item (which must include the first word of the `SIGNATURE` Item). This hash is then signed with an ECDSA secp256k1 private key, to produce the 64 byte signature stored in the `SIGNATURE` Item.

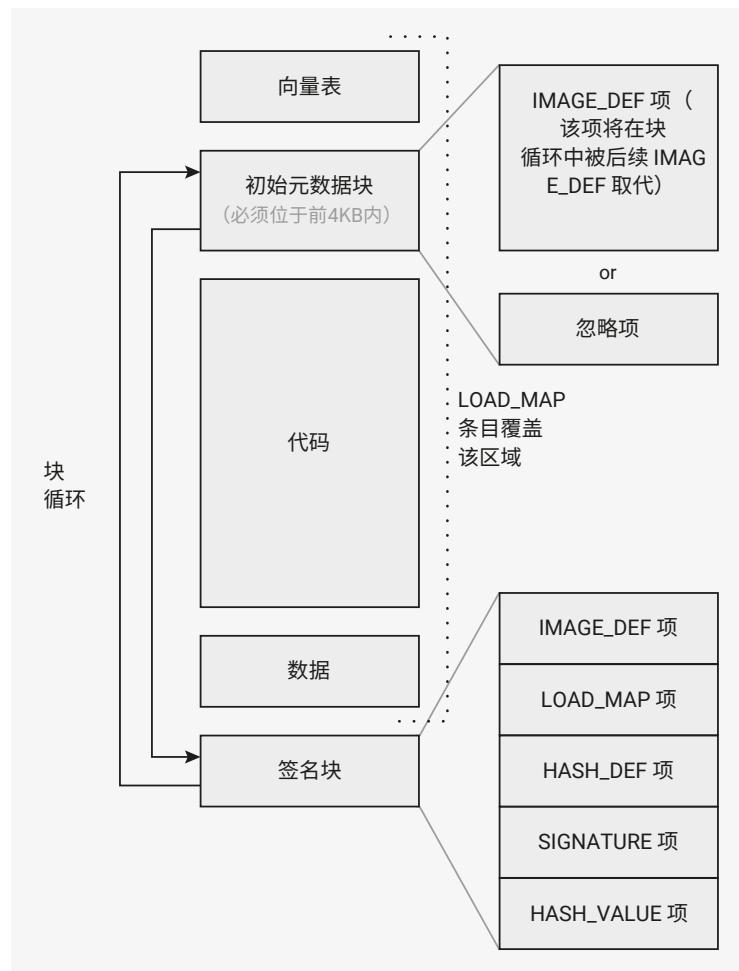

For secure boot, it is recommended to use packaged SRAM binaries instead of flash binaries, as the signature check is only performed during boot, so a malicious actor with physical access could replace the data on the external flash after the signature check to run unsigned code.

To sign and/or hash a binary in the SDK, you can add the following functions to your CMakeLists.txt file:

```
pico_sign_binary(target_name /path/to/keyfile.pem)
pico_hash_binary(target_name)
```

This will invoke the `picotool seal` command to sign and/or hash your binary when you call `pico_add_extra_outputs`. You can manually invoke `picotool seal` to sign and/or hash a binary using:

```
$ picotool seal --sign --hash unsigned.elf signed.elf private.pem
```

请注意，镜像末尾的标记块已被新的 **IMAGE\_DEF** 块替换，该块包含首块的信息及附加的新信息。新信息包括签名（或仅进行散列时的散列值），以及一条 **LOAD\_MAP** 条目，指明被签名或散列的镜像区域。

运行时，bootrom 将选择块循环中最后一个有效的 **IMAGE\_DEF** 作为启动项。

签名要求对 **LOAD\_MAP** 中指定的数据进行 **SHA-256** 散列，并对 **HASH\_VALUE** 项指定块的字（必须包括 **SIGNATURE** 项的首字）进行散列。此散列随后使用 **ECDSA secp256k1** 私钥签名，生成存储于 **SIGNATURE** 项中的64字节签名。

为实现安全启动，建议使用封装后的SRAM二进制文件代替闪存二进制文件，因签名校验只在启动阶段执行，若攻击者获得物理访问权限，可能在签名校验后替换外部闪存中的数据，从而运行未签名代码。

在SDK中对二进制文件进行签名和/或哈希处理时，您可将以下函数添加至CMakeLists.txt文件：

```
pico_sign_binary(target_name /path/to/keyfile.pem)
pico_hash_binary(target_name)
```

调用 **pico\_add\_extra\_outputs** 时，此操作将触发 **picotool seal** 命令，对二进制文件执行签名和/或哈希处理。也可通过手动执行以下命令调用 **picotool seal**，对二进制文件进行签名和/或哈希处理：

```
$ picotool seal --sign --hash unsigned.elf signed.elf private.pem
```

### 5.10.3. Packaged binaries

A packaged binary is an SRAM/XIP RAM-only binary that has been post-processed for storage in flash. To create a packaged SRAM binary, you can take a binary compiled to run in SRAM (`no_flash` binary in the SDK) and add a relative `LOAD_MAP` Item into the `IMAGE_DEF` block, with the runtime address(es) in SRAM. The subsequent binary can then be run normally from RAM, or stored in flash to be loaded into RAM by the bootrom. This `LOAD_MAP` item will be added to all binaries when using `picotool seal`.

To package binaries in the SDK, add the following to your `CMakeLists.txt` file. This will target the `UF2` file to the start of flash when dragged and dropped, and will invoke `picotool seal` to add an appropriate `LOAD_MAP`.

```
pico_package_uf2_output(target_name 0x10000000)
```

Alternatively, you can use an absolute `LOAD_MAP`, with the `storage_address` in flash and the `runtime_address` in SRAM. However, these binaries can only run after storing in flash and can't be booted directly in SRAM for debugging.

For example, if you have a binary compiled to run at `0x2000000` of length `0x8000`, and a metadata block at the end of the binary containing the `LOAD_MAP` as the second Item (after the `IMAGE_DEF`, which means the `LOAD_MAP` is 8 bytes into the block), then the relative `LOAD_MAP` would be:

Word	Bytes	Value
0	1	<code>0x06</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP</code> )
	2	<code>0x04</code> (Block size in words)
	1	<code>0x01</code> ( <code>absolute == 0, num_entries == 1</code> )
1-3	Load Map Entry 0	
	4	<code>-0x8008 = 0xFFFF7FF8</code> ( <code>storage_start_address_rel</code> )
	4	<code>0x20000000</code> ( <code>runtime_start_address</code> )
	4	<code>0x8000</code> ( <code>size in bytes</code> )

The absolute `LOAD_MAP` would be:

Word	Bytes	Value
0	1	<code>0x06</code> ( <code>size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP</code> )
	2	<code>0x04</code> (Block size in words)
	1	<code>0x81</code> ( <code>absolute == 1, num_entries == 1</code> )
1-3	Load Map Entry 0	
	4	<code>0x10000000</code> ( <code>storage_start_address</code> )
	4	<code>0x20000000</code> ( <code>runtime_start_address</code> )
	4	<code>0x20008000</code> ( <code>runtime_end_address</code> )

### 5.10.4. A/B booting

This is a common boot scenario, to be able to update the software without overwriting it. A simple partition layout would be:

### 5.10.3. 打包二进制文件

封装二进制文件为仅限SRAM/XIP RAM使用的二进制文件，已进行后期处理以便存储于闪存中。创建封装SRAM二进制文件时，可将已编译可在SRAM中运行的二进制文件（SDK中的`no_flash`二进制文件）添加相对`LOAD_MAP`项于`IMAGE_DEF`块中，指定SRAM的运行时地址。生成的二进制文件可正常在RAM中运行，或存储于闪存，由启动只读存储器加载至RAM。此`LOAD_MAP`项将在使用`picotool seal`时添加至所有二进制文件。

要在SDK中封装二进制文件，请将以下内容添加到您的CMakeLists.txt文件中。这将使UF2文件定位于闪存起始位置，拖放时自动调用`picotool seal`以添加相应的`LOAD_MAP`。

```
pico_package_uf2_output(target_name 0x10000000)
```

或者，您可以使用绝对的`LOAD_MAP`，其中`storage_address`位于闪存，`runtime_address`位于SRAM。但这些二进制文件仅能在写入闪存后运行，无法直接在SRAM中启动以进行调试。

例如，假设您有一个编译为运行在`0x20000000`且长度为`0x8000`的二进制文件，文件末尾包含一个元数据块，作为第二项（紧随`IMAGE_DEF`之后，即`LOAD_MAP`在该块内偏移8字节）的`LOAD_MAP`，则相对的`LOAD_MAP`内容为：

字	字节	值
0	1	<code>0x06 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP)</code>
	2	<code>0x04</code> （以字为单位的块大小）
	1	<code>0x01 (absolute == 0, num_entries == 1)</code>
1-3	加载映射条目 0	
	4	<code>-0x8008 = 0xFFFF7FF8 (storage_start_address_rel)</code>
	4	<code>0x20000000 (runtime_start_address)</code>
	4	<code>0x8000</code> （以字节为单位的大小）

绝对`LOAD_MAP`为：

字	字节	值
0	1	<code>0x06 (size_flag == 0, item_type == PICOBIN_BLOCK_ITEM_LOAD_MAP)</code>
	2	<code>0x04</code> （以字为单位的块大小）
	1	<code>0x81 (absolute == 1, num_entries == 1)</code>
1-3	加载映射条目 0	
	4	<code>0x10000000 (storage_start_address)</code>
	4	<code>0x20000000 (runtime_start_address)</code>
	4	<code>0x2008000 (runtime_end_address)</code>

### 5.10.4. A/B 启动

这是常见的启动场景，允许在不覆盖软件的情况下进行软件更新。一个简单的分区布局如下：

```

Partition 0
 Accepts UF2 Families: rp2350-arm-s, rp2350-riscv
Partition 1
 Accepts UF2 Families: rp2350-arm-s, rp2350-riscv
 Link Type: "A"
 Link Value: 0

```

This is a partition table with 2 partitions, where partition 0 is the A partition of partition 1 (which is thus the B partition).

**i NOTE**

To avoid confusion, it is a recommended best practice to have the same permissions for both partitions, and for both partitions to accept the same UF2 families. The bootrom will only look at the UF2 families from the A partition when deciding if a given A/B pair accepts a particular family, and will not allow download to partition A even if it is writable if partition B isn't.

When dragging a UF2 to the device, it will target whichever partition is not currently booting. The bootrom will then perform a `FLASH_UPDATE` boot into the new binary (see [Section 5.1.16](#))

**i NOTE**

When starting with blank A/B partitions, the first download actually goes into partition B.

To create the partition table above with `picotool partition create`, the following json could be used:

```
{
 "version": [1, 0],
 "unpartitioned": {
 "families": ["absolute"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 "partitions": [
 {
 "name": "Example A",
 "id": 0,
 "size": "2044K",
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 {
 "name": "Example B",
 "id": 1,
 "size": "2044K",
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["a", 0]
 }
]
}
```

分区 0  
支持的UF2系列：rp2350-arm-s, rp2350-riscv  
分区 1  
支持的UF2系列：rp2350-arm-s, rp2350-riscv  
链接类型：“A”  
链接值：0

这是一个包含两个分区的分区表，其中分区0是分区1的A分区（因此分区1是B分区）。

### *i* 注意

为避免混淆，建议采用最佳实践，使两个分区权限一致且均支持相同的UF2系列。bootrom 仅会检查 A 分区中的 UF2 系列，以确定某个 A/B 组合是否接受特定系列，即使分区 B 不可写，也不会允许向分区 A 下载。

将 UF2 文件拖拽到设备时，系统将定位当前未启动的分区。然后，bootrom 将执行FLASH\_UPDATE操作，启动进入新的二进制文件（详见第 5.1.16 节）。

### *i* 注意

在空白的 A/B 分区状态下，首次下载实际写入分区 B。

使用picotool partition create创建上述分区表时，可采用以下 json：

```
{
 "version": [1, 0],
 "unpartitioned": {
 "families": ["absolute"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 "partitions": [
 {
 "name": "Example A",
 "id": 0,
 "size": "2044K",
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 {
 "name": "示例 B",
 "id": 1,
 "size": "2044K",
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["a", 0]
 }
]
}
```

```

 }
]
}

```

This can then be installed onto the device using `picotool load`, or UF2 drag and drop if you output the partition table as a UF2 file.

### 5.10.5. A/B booting with owned partitions

The concept of [owned partitions](#) applies when:

- you require separate data partitions (which generally won't contain a [block loop](#)), but
- you would like these to be associated with a specific boot partition in an A/B pair

An example partition table for this scenario would be:

```

Partition 0
 Accepts Families: rp2350-arm-s, rp2350-riscv
Partition 1
 Accepts Families: rp2350-arm-s, rp2350-riscv
 Link Type: "A"
 Link Value: 0
Partition 2
 Accepts Families: data
 Link Type: "Owner"
 Link Value: 0
 ignored_during_arm_boot: true
 ignored_during_riscv_boot: true
Partition 3
 Accepts Families: data
 Link Type: "A"
 Link Value: 2
 ignored_during_arm_boot: true
 ignored_during_riscv_boot: true

```

This is a partition table with 4 partitions. As before, partition 0 is the A partition of partition 1 (which is thus a B partition). Additionally, partition 2 is the A partition of partition 3 (which is thus a B partition). Finally, partition 0 is the "owner" partition of partition 2.

As a result partitions 2 and 3 "belong to" partitions 0 and 1.

When downloading a UF2 into an owned partition, the bootloader will select which partition out of 2/3 it goes to target based on which partition out of 0/1 is currently booting. For example, if partition 1 is currently booting (due to having a higher version than partition 0), then any UF2 downloads with the data family ID will target partition 3.

 **TIP**

There is a flag in each partition that you can use to swap the "affinity", for example, to have the data family ID target partition 2 instead of partition 3 in the scenario above.

```

 }
]
}

```

然后可以使用`picotool load`将其安装到设备上，或者如果您将分区表导出为 UF2 文件，则可以通过 UF2 拖放方式安装。

### 5.10.5. 具所有权分区的 A/B 启动

拥有分区的概念适用于以下情形：

- 您需要单独的数据分区（通常不包含块循环），但
- 您希望将这些分区与 A/B 配对中的特定引导分区关联

此场景下的示例分区表如下：

```

分区 0
接受系列: rp2350-arm-s, rp2350-riscv, 分区1

接受系列: rp2350-arm-s, rp2350-riscv
链接类型: "A"
链接值: 0 分区2
接受类别: da
ta 链接类型: "Owner" 链
接值: 0

ignored_during_arm_boot: true
ignored_during_riscv_boot: true

分区3
接受类别: data
链接类型: "A"
链接值: 2
ignored_during_arm_boot: true
ignored_during_riscv_boot: true

```

这是一个包含4个分区的分区表。如前所述，分区0是分区1的A分区（因此分区1为B分区）。此外，分区2是分区3的A分区（因此分区3为B分区）。最后，分区0是分区2的“所有者”分区。

因此，分区2和3“属于”分区0和1。

当向被拥有的分区下载UF2文件时，引导加载程序会根据当前启动的分区0或1，选择目标分区2或3。例如，若当前启动的为分区1（因其版本高于分区0），则所有带有数据家族ID的UF2下载将定位至分区3。

#### 提示

每个分区中均设有标志，可用于切换“affinity”，例如，在上述情形中使数据家族ID定位至分区2而非分区3。

**NOTE**

Only the `get_uf2_target_partition()` bootrom function considers owner partitions. The `pick_ab_partition()` function always pick solely based on the A/B partition it is passed, in other words if passed partition 2, it would not look at partitions 0 and 1.

To create this partition table using `picotool partition create`, the following JSON could be used:

```
{
 "version": [1, 0],
 "unpartitioned": {
 "families": ["absolute"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 "partitions": [
 {
 "name": "Example A",
 "id": 0,
 "size": 128k,
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 {
 "name": "Example B",
 "id": 1,
 "size": 128k,
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["a", 0]
 },
 {
 "name": "Example a",
 "id": 2,
 "size": 20k,
 "families": ["data"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["owner", 0],
 "ignored_during_arm_boot": true,
 "ignored_during_riscv_boot": true
 },
 {
 "name": "Example b",
 "id": 3,
 "size": 20k,
 "families": ["data"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 }
]
}
```

### ⓘ 注意

仅有get\_uf2\_target\_partition() bootrom函数会考虑所有者分区。pick\_ab\_partition()函数始终仅基于传入的A/B分区进行选择，换言之，若传入分区2，则不会查看分区0与1。

使用picotool partition create创建此分区表时，可采用以下JSON：

```
{
 "version": [1, 0],
 "unpartitioned": {
 "families": ["absolute"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 "partitions": [
 {
 "name": "示例A",
 "id": 0,
 "size": 128k,
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 }
 },
 {
 "name": "示例B",
 "id": 1,
 "size": 128k,
 "families": ["rp2350-arm-s", "rp2350-riscv"],
 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["a", 0]
 },
 {
 "name": "示例a", "id": 2, "size": 20k, "families": ["data"], "permissions": {
 "secure": "rw", "nonsecure": "rw", "bootloader": "rw"
 },
 "link": ["owner", 0],
 "ignored_during_arm_boot": true,
 "ignored_during_riscv_boot": true
 },
 {
 "name": "示例b", "id": 3, "size": 20k, "families": ["data"],
```

```

 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["a", 2],
 "ignored_during_arm_boot": true,
 "ignored_during_riscv_boot": true
}
]
}

```

This can then be installed onto the device using `picotool load`, or UF2 drag and drop if you output the partition table as a UF2 file.

### 5.10.6. Custom bootloader

In this scenario, a bootloader is run before booting into an image. This could perform additional validation, or set up peripherals for use by the image. For this to work, the block loop must contain both an `IMAGE_DEF` for the bootloader and a `PARTITION_TABLE` to define the flash layout.

In this example, we want to have A / B versions of the bootloader, so we use both slot 0 and slot 1. See [Section 5.1.15](#) for more details of this, as you may well need to increase the size of slot 0 in order to fit the bootloader.

 **WARNING**

Making a slot size change is not reversible, so feel free to leave out slot 1 if you try this in practice.

An example flash layout might resemble the following:

```

Slot 0 (0x00000000-0x00008000)
Bootloader Image 0
Partition Table 0
Slot 1 (0x00008000-0x00010000)
Bootloader Image 1
Partition Table 1
Partition 0 (0x00010000-0x00020000)
Binary A
Partition 1 (0x00020000-0x00030000)
Link Type: "A"
Link Value: 0
Binary B

```

The block loop with both `IMAGE_DEF` and `PARTITION_TABLE` might look like this (after signing in this case):

```

 "permissions": {
 "secure": "rw",
 "nonsecure": "rw",
 "bootloader": "rw"
 },
 "link": ["a", 2],
 "ignored_during_arm_boot": true,
 "ignored_during_riscv_boot": true
}
]
}

```

然后可以使用`picotool load`将其安装到设备上，或者如果您将分区表导出为 UF2 文件，则可以通过 UF2 拖放方式安装。

### 5.10.6. 自定义引导加载程序

在此情形下，bootloader 会在启动镜像之前运行。该过程可能执行额外的验证，或配置供镜像使用的外设。为了使其生效，块循环必须同时包含引导加载程序的 `IMAGE_DEF` 以及定义闪存布局的 `PARTITION_TABLE`。

在本例中，我们希望引导加载程序存在 A/B 两个版本，因此使用槽 0 和槽 1。有关详细信息，请参见第 5.1.15 节，您可能需要增大槽 0 的大小以容纳引导加载程序。

 **警告**

槽大小的更改不可逆，因此若您在实际操作中尝试，可选择省略槽 1。

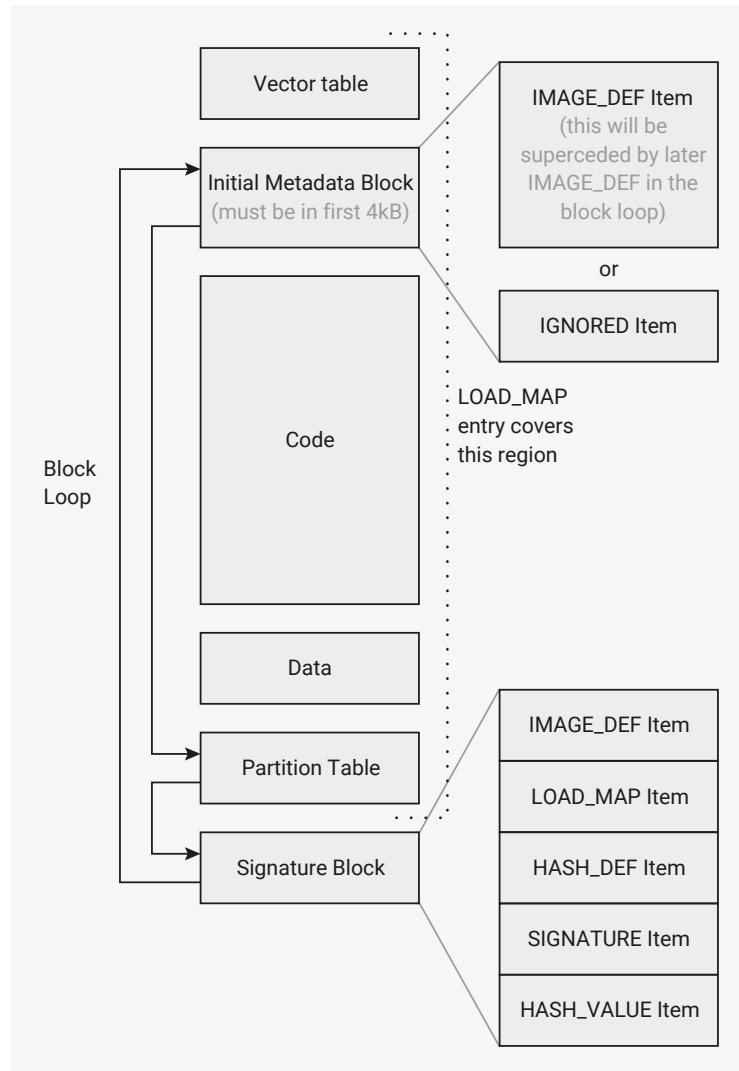

一个示例闪存布局可能如下所示：

```

槽0 (0x00000000-0x00008000)
引导加载程序映像0
分区表0
槽1 (0x00008000-0x00010000)
引导加载程序映像1
分区表1
分区0 (0x00010000-0x00020000)
二进制A
分区1 (0x00020000-0x00030000)
链接类型："A"
链接值：0
二进制 B

```

包含 `IMAGE_DEF` 和 `PARTITION_TABLE` 的块循环在此情况下（签名后）可能如下所示：

Note the 3 blocks in the block loop:

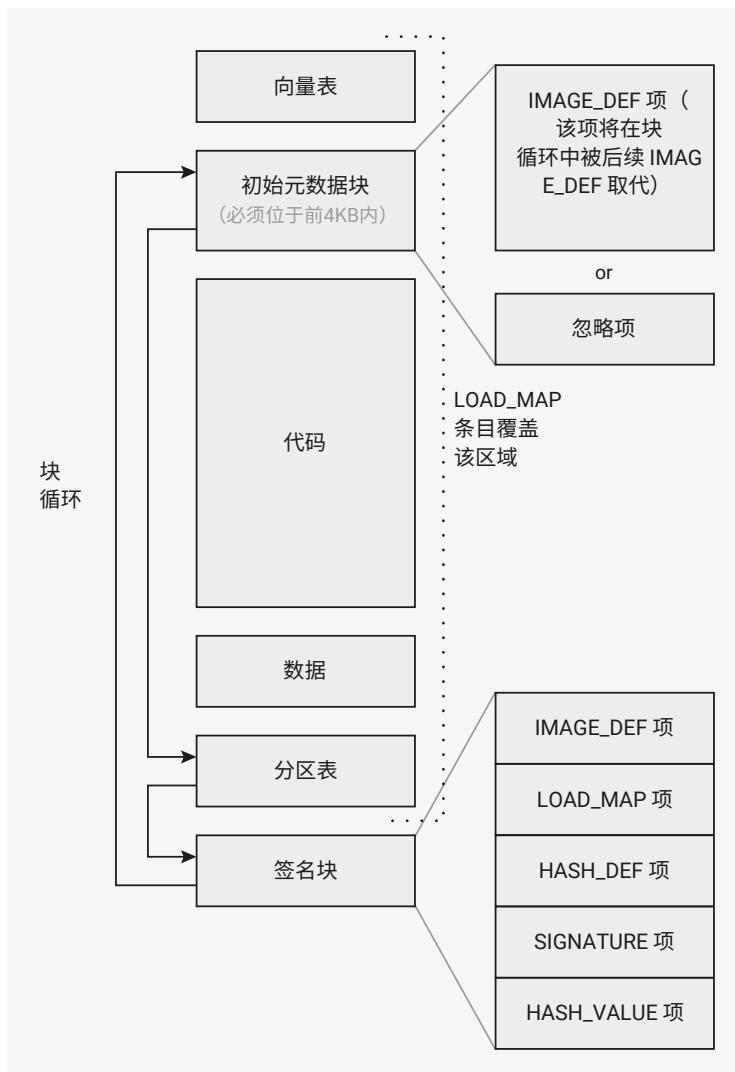

1. Original block in first 4 kB (contents doesn't matter, as it will be superseded by the later IMAGE\_DEF)
2. **PARTITION\_TABLE** at end of binary
3. Signed IMAGE\_DEF

#### **NOTE**

It is possible to sign both the **PARTITION\_TABLE** and the **IMAGE\_DEF** separately, however for the fastest boot speed, the bootrom also allows you to use a "covering" **LOAD\_MAP** in the **IMAGE\_DEF**. As long as the **LOAD\_MAP** defined area to be hashed/signed includes the entirety of the **PARTITION\_TABLE** block, the "covering" signature is used to validate the **PARTITION\_TABLE** too.

For the bootloader to find and launch a new image, it may wish to utilise various bootrom methods:

- [get\\_partition\\_table\\_info\(\)](#) to get the full partition information.
- or [get\\_partition\\_table\\_info\(\)](#) with **SINGLE\_PARTITION**, the chosen partition number, and **PARTITION\_LOCATION\_AND\_FLAGS**, to get the address of a single partition

请注意块循环中的三个块：

1. 前 4 kB 内的原始块（内容无关紧要，因稍后的 **IMAGE\_DEF** 将覆盖其内容）
2. 二进制文件末尾的 **PARTITION\_TABLE**
3. 已签名的 **IMAGE\_DEF**

#### **注意**

可以分别对 **PARTITION\_TABLE** 和 **IMAGE\_DEF** 进行签名，然而为实现最快启动速度，bootrom 允许在 **IMAGE\_DEF** 中使用“覆盖型” **LOAD\_MAP**。只要 **LOAD\_MAP** 中定义的进行哈希/签名的区域涵盖整个 **PARTITION\_TABLE** 块，“覆盖”签名即可用于验证该 **PARTITION\_TABLE**。

为了使引导加载程序找到并启动新的映像，可能需要利用各种 bootrom 方法：

- **get\_partition\_table\_info()** 用于获取完整的分区信息。
- 或者调用 **get\_partition\_table\_info()**，传入 **SINGLE\_PARTITION**、所选分区号及 **PARTITION\_LOCATION\_AND\_FLAGS**，以获取单个分区的地址。

```

uint32_t partition_info[3];
get_partition_table_info(partition_info, 3, PT_INFO_PARTITION_LOCATION_AND_FLAGS
 | PT_INFO_SINGLE_PARTITION | (boot_partition << 24));
uint16_t first_sector_number = (partition_info[1]
 & PICOBIN_PARTITION_LOCATION_FIRST_SECTOR_BITS)
 >> PICOBIN_PARTITION_LOCATION_FIRST_SECTOR_LSB;
uint16_t last_sector_number = (partition_info[1]
 & PICOBIN_PARTITION_LOCATION_LAST_SECTOR_BITS)
 >> PICOBIN_PARTITION_LOCATION_LAST_SECTOR_LSB;
uint32_t data_start_addr = first_sector_number * 0x1000;
uint32_t data_end_addr = (last_sector_number + 1) * 0x1000;
uint32_t data_size = data_end_addr - data_start_addr;

```

- `get_sys_info()` with `BOOT_INFO`, to get the `flash_update_boot_window_base` if any:

```

uint32_t sys_info[5];
get_sys_info(sys_info, 5*4, SYS_INFO_BOOT_INFO);
uint32_t flash_update_boot_window_base = sys_info[3];

```

- `pick_ab_partition()` to pick the boot partition between A/B partitions if desired:

```

uint8_t boot_partition = pick_ab_partition(workarea, 0xC00, 0,
 flash_update_boot_window_base);

```

- or `get_b_partition()` to find the other partition directly.
- `chain_image()` with `data_start_addr` and `data_size`, to boot a chosen image:

```

// note a negative 3rd parameter indicates to chain_image that the image is being chained as
// part of a "flash update" boot, so TBYB and/or version downgrade may be in play
chain_image(workarea,
 0xC00,
 (XIP_BASE + data_start_addr) * (info.boot_type == BOOT_TYPE_FLASH_UPDATE ? -1 :
 1),
 data_size
);

```

#### NOTE

The `workarea` used must not overlap the image being chained into, so beware SRAM or packaged binaries. If the binary overlaps the `workarea`, the results are undefined, but hardly likely to be good.

### 5.10.7. OTP bootloader

This is similar to the custom bootloader scenario, but it will be stored in the OTP and will run in SRAM.

One possible use case could place decryption code into OTP which decrypts an executable image from a flash partition into RAM.

The entire bootloader will need to fit in the OTP rows from `0x0C0` to `0xF48` to avoid interfering with other reserved OTP functionality, giving a maximum size of 7440 bytes (2 bytes per ECC row). If some boot keys and OTP keys are unused, this region can extend slightly on either end.

```

uint32_t partition_info[3];
get_partition_table_info(partition_info, 3, PT_INFO_PARTITION_LOCATION_AND_FLAGS
 | PT_INFO_SINGLE_PARTITION | (boot_partition << 24));
uint16_t first_sector_number = (partition_info[1]
 & PICOBIN_PARTITION_LOCATION_FIRST_SECTOR_BITS)
 >> PICOBIN_PARTITION_LOCATION_FIRST_SECTOR_LSB;
uint16_t last_sector_number = (partition_info[1]
 & PICOBIN_PARTITION_LOCATION_LAST_SECTOR_BITS)
 >> PICOBIN_PARTITION_LOCATION_LAST_SECTOR_LSB;
uint32_t data_start_addr = first_sector_number * 0x1000;
uint32_t data_end_addr = (last_sector_number + 1) * 0x1000;
uint32_t data_size = data_end_addr - data_start_addr;

```

- 使用 `get_sys_info()` 携带 `BOOT_INFO` 参数以获取 `flash_update_boot_window_base` (如有) :

```

uint32_t sys_info[5];
get_sys_info(sys_info, 5*4, SYS_INFO_BOOT_INFO);
uint32_t flash_update_boot_window_base = sys_info[3];

```

- 使用 `pick_ab_partition()` 在 A/B 分区间选择启动分区 (如需要) :

```

uint8_t boot_partition = pick_ab_partition(workarea, 0xC00, 0,
 flash_update_boot_window_base);

```

- 或者使用 `get_b_partition()` 直接定位另一个分区。
- 使用 `chain_image()` 携带 `data_start_addr` 和 `data_size` 参数以启动所选映像:

```

// 注意, 第三个参数为负数表示告知 chain_image 该映像作为“闪存更新”启动流程的一部分被链式调用,
// 且不能直接从 SRAM 启动

(XIP_BASE + data_start_addr) * (info.boot_type == BOOT_TYPE_FLASH_UPDATE ? -1 :
1),
data_size
);

```

### 注意

所使用的 `workarea` 不得与被链入的映像重叠, 因此须注意 SRAM 或封装的二进制文件。若二进制文件与 `workarea` 重叠, 结果不可预测, 但极有可能是不良后果。

## 5.10.7. OTP 引导加载程序

此情形类似于自定义引导加载程序, 但程序将存储于 OTP 并在 SRAM 中运行。

一种可能的应用是将解密代码置于 OTP, 从而将闪存分区的可执行映像解密至 RAM 中。

整个引导加载程序必须位于 OTP 行范围 `0x0C0` 至 `0xF48` 内, 以避免干扰其他保留 OTP 功能, 最大尺寸为 7440 字节 (每个 ECC 行 2 字节)。若部分引导密钥及 OTP 密钥未被使用, 该区域可在任一端适度延伸。

The OTP bootloader itself should be stored in ECC format, starting from the row set in `OTPBOOT_SRC` with size set in `OTPBOOT_LEN`. When booting, it will be loaded into the address specified in `OTPBOOT_DST0` and `OTPBOOT_DST1`, which must be in the main SRAM. The bootloader must fulfil the same criteria as a standard image: it must include an `IMAGE_DEF`, which must be signed if secure boot is enabled.

Once the OTP bootloader has been written to OTP, and the `OTPBOOT_SRC`, `OTPBOOT_LEN`, `OTPBOOT_DST0` and `OTPBOOT_DST1` set, OTP booting can be enabled by setting `BOOT_FLAGS0.ENABLE OTP_BOOT`. If the OTP image fails the bootrom's launch checks, then, by default, boot continues along the normal flash boot path. You can prevent this by setting `BOOT_FLAGS0.DISABLE_FLASH_BOOT`.

 **WARNING**

Take extreme care when writing an OTP bootloader. Once the ECC rows are written, they *cannot* be modified.

### 5.10.8. Rollback versions and bootloaders

 **WARNING**

Ignoring the advice in this section could render your device unable to boot.

For bootloaders that need to chain into executable images with rollback versions on a secured RP2350, you *must* use separate OTP rows for:

- The bootloader rollback version
- The chained executable image's rollback version

Otherwise, bumping the version of the chained executable image renders the OTP bootloader and your device unable to boot.

You must also make sure that *both* the bootloader and the executable image have non-zero rollback versions, as the OTP flags relating to requiring rollback versions are global. Failure to do so will render your device unable to boot.

We recommend using the `DEFAULT_BOOT_VERSION0` and `DEFAULT_BOOT_VERSION1` rows for the binary's rollback version, and selecting some other unused rows in the OTP for the bootloader's rollback version.

OTP引导加载程序须以ECC格式存储，起始于OTPBOOT\_SRC指定的行，大小由OTPBOOT\_LEN确定。启动时，将加载至OTPBOOT\_DST0和OTPBOOT\_DST1指定的地址，且该地址必须位于主SRAM内。引导加载程序必须符合标准映像的条件：必须包含IMAGE\_DEF，且启用安全启动时必须签名。

一旦OTP引导加载程序写入OTP，并且设置了OTPBOOT\_SRC、OTPBOOT\_LEN、OTPBOOT\_DST0和OTPBOOT\_DST1，即可通过设置BOOT\_FLAGS0.ENABLE OTP\_BOOT启用OTP引导。如果OTP映像未通过bootrom的启动检查，默认情况下，引导将继续走正常的闪存引导路径。您可以通过设置BOOT\_FLAGS0.DISABLE\_FLASH\_BOOT来阻止此情况发生。

#### ● 警告

编写OTP引导加载程序时务必极为谨慎。ECC行一经写入，将无法修改。

### 5.10.8. 回滚版本及引导加载程序

#### ● 警告

忽视本节建议可能导致您的设备无法启动。

对于需链入带回滚版本的可执行映像的安全RP2350引导加载程序，您必须使用单独的OTP行分别用于：

- 引导加载程序的回滚版本
- 链入的可执行映像的回滚版本

否则，提升链入可执行映像版本将导致OTP引导加载程序及设备无法启动。

您还必须确保引导加载程序和可执行映像的回滚版本均为非零，因为相关要求回滚版本的OTP标志是全局性的。未遵守将导致设备无法启动。

我们建议使用DEFAULT\_BOOT\_VERSION0和DEFAULT\_BOOT\_VERSION1行作为二进制文件的回滚版本，并在OTP中选择其他未使用的行作为引导程序的回滚版本。

# Chapter 6. Power

## 6.1. Power supplies

RP2350 requires five separate power supplies. However, in most applications, several of these can be combined and connected to a single power source. Typical applications only require a single 3.3 V supply. See [Figure 19](#).

The power supplies and a number of potential power supply schemes are described in the following sections. Detailed power supply parameters are provided in [Section 14.9.5](#).

### 6.1.1. Digital IO supply (`IOVDD`)

`IOVDD` provides the IO supply for the chip's GPIO, and should be powered at a nominal voltage between 1.8 V and 3.3 V. The supply voltage sets the external signal level for the digital IO, and should be chosen based on the level required, see [Section 14.9](#) for details. All GPIOs share the same power supply and operate at the same signal level.

If the digital IO is powered at a nominal 1.8 V, the IO input thresholds should be adjusted by setting the `VOLTAGE_SELECT` register to 1. `VOLTAGE_SELECT` is set to 0 by default, which results in input thresholds that are valid for a nominal IO voltage between 2.5 V and 3.3 V. See [Chapter 9](#) for details.

#### ⚠ CAUTION

Powering the `IOVDD` at 1.8 V with input thresholds set for a 2.5 V to 3.3 V supply is a safe operating mode, but will result in input thresholds that do not meet specification. Powering the IO at voltages greater than 1.8 V with input thresholds set for a 1.8 V supply may result in damage to the chip.

### 6.1.2. QSPI IO supply (`QSPI_IOVDD`)

`QSPI_IOVDD` provides the IO supply for the chip's QSPI interface, and should be powered at a nominal voltage between 1.8 V and 3.3 V. The supply voltage sets the external signal level for the QSPI interface, and should be chosen based on the level required, see [Section 14.9](#) for details. In most applications the QSPI interface will be connected to an external flash device, which will determine the required signal level.

If the QSPI interface is powered at a nominal 1.8 V, the IO input thresholds should be adjusted by setting the `VOLTAGE_SELECT` register to 1. `VOLTAGE_SELECT` is set to 0 by default, which results in input thresholds that are valid for a nominal IO voltage between 2.5 V and 3.3 V. See [Chapter 9](#) for details.

#### ⚠ CAUTION

Powering the `IOVDD` at 1.8 V with input thresholds set for a 2.5 V to 3.3 V supply is a safe operating mode, but will result in input thresholds that do not meet specification. Powering the IO at voltages greater than 1.8 V with input thresholds set for a 1.8 V supply may result in damage to the chip.

### 6.1.3. Digital core supply (`DVDD`)

The chip's core digital logic is powered by `DVDD`, which should be at a nominal 1.1 V. A dedicated on-chip core voltage regulator allows `DVDD` to be generated from a 2.7 V to 5.5 V input supply. See [Section 6.3](#) for details. Alternatively, `DVDD` can be supplied directly from an off-chip power source.

If the on-chip core voltage regulator is used, the two `DVDD` pins closest to the regulator should be decoupled with a 100nF capacitor close to the pins. The `DVDD` pin furthest from the regulator should be decoupled with a 4.7μF capacitor close to

# 第6章 电源

## 6.1. 电源供应

RP2350 需要五个独立的电源供应。但在大多数应用中，可以将其中几个合并接入单一电源。典型应用通常只需要单一的 3.3 V 电源。见图19。

以下章节描述了电源供应及若干潜在的电源供应方案。详细的电源供应参数见第14.9.5节。

### 6.1.1. 数字 IO 电源 ( IOVDD )

**IOVDD** 为芯片GPIO提供IO电源，标称电压应为1.8 V至3.3 V之间。

供电电压决定数字IO的外部信号电平，应根据所需电平选择，详见第14.9节。所有GPIO共用同一电源，并以相同信号电平工作。

若数字IO以标称1.8 V供电，输入阈值应通过将VOLTAGE\_SELECT寄存器设置为 1 进行调整。VOLTAGE\_SELECT默认设置为 0，此时输入阈值适用于标称IO电压介于2.5 V至3.3 V之间。详见第9章。

#### ⚠ 警告

IOVDD以1.8 V供电且输入阈值设定为2.5 V至3.3 V的供电范围，此为安全操作模式，但输入阈值不符合规范要求。若IO以高于1.8 V的电压供电，且输入阈值设定为1.8 V供电范围，可能导致芯片损坏。

### 6.1.2. QSPI IO 电源 ( QSPI\_IOVDD )

**QSPI\_IOVDD** 为芯片的QSPI接口提供IO电源，供电电压应为标称1.8 V至3.3 V之间。该供电电压决定QSPI接口的外部信号电平，应根据所需电平选取，详见第14.9节。在大多数应用中，QSPI接口将连接至外部闪存设备，该设备决定所需的信号电平。

若QSPI接口标称供电为1.8 V，应通过将VOLTAGE\_SELECT寄存器设置为 1 以调整IO输入阈值。VOLTAGE\_SELECT默认设置为 0，此时输入阈值适用于标称IO电压介于2.5 V至3.3 V之间。详见第9章。

#### ⚠ 警告

IOVDD以1.8 V供电且输入阈值设定为2.5 V至3.3 V的供电范围，此为安全操作模式，但输入阈值不符合规范要求。若IO以高于1.8 V的电压供电，且输入阈值设定为1.8 V供电范围，可能导致芯片损坏。

### 6.1.3. 数字核心电源 ( DVDD )

芯片核心数字逻辑由 **DVDD** 供电，标称电压为1.1 V。片内专用核心电压调节器允许将2.7 V至5.5 V的输入电源转换为 **DVDD**。详见第6.3节。另可由片外电源直接供给 **DVDD**。

若使用片内核心电压调节器，靠近调节器的两引脚 **DVDD** 应使用100nF电容器靠近引脚去耦。距离调节器最远的 **DVDD** 引脚应使用4.7μF电容器靠近引脚去耦。

the pin.

#### 6.1.4. USB PHY and OTP supply (`USB_OTP_VDD`)

`USB_OTP_VDD` supplies the chip's USB PHY and OTP memory, and should be powered at a nominal 3.3 V. To reduce the number of external power supplies, `USB_OTP_VDD` can use the same power source as the core voltage regulator analogue supply (`VREG_AVDD`), or digital IO supply (`IOVDD`), assuming `IOVDD` is also powered at 3.3 V. This supply must always be provided, even in applications where the USB PHY is never used.

`USB_OTP_VDD` should be decoupled with a 100nF capacitor close to the chip's `USB_OTP_VDD` pin.

#### 6.1.5. ADC supply (`ADC_AVDD`)

`ADC_AVDD` supplies the chip's Analogue to Digital Converter (ADC). It can be powered at a nominal voltage between 1.8 V and 3.3 V, but the performance of the ADC will be compromised at voltages below 2.97 V. To reduce the number of external power supplies, `ADC_AVDD` can use the same power source as the core voltage regulator analogue supply (`VREG_AVDD`) or digital IO supply (`IOVDD`).

**NOTE**

It is safe to supply `ADC_AVDD` at a higher or lower voltage than `IOVDD`, e.g. to power the ADC at 3.3 V, for optimum performance, while supporting 1.8 V signal levels on the digital IO. But the voltage on the ADC analogue inputs must not exceed `IOVDD`, e.g. if `IOVDD` is powered at 1.8 V, the voltage on the ADC inputs should be limited to 1.8 V. Voltages greater than `IOVDD` will result in leakage currents through the ESD protection diodes. See [Section 14.9](#) for details.

`ADC_AVDD` should be decoupled with a 100nF capacitor close to the chip's `ADC_AVDD` pin.

#### 6.1.6. Core voltage regulator input supply (`VREG_VIN`)

`VREG_VIN` is the input supply for the on-chip core voltage regulator, and should be in the range 2.7 V to 5.5 V. To reduce the number of external power supplies, `VREG_VIN` can use the same power source as the voltage regulator analogue supply (`VREG_AVDD`), or digital IO supply (`IOVDD`). Though care should be taken to minimise the noise on `VREG_AVDD`.

A 4.7 $\mu$ F capacitor should be connected between `VREG_VIN` and ground close to the chip's `VREG_VIN` pin.

For more details on the on-chip voltage regulator see [Section 6.3](#).

#### 6.1.7. On-chip voltage regulator analogue supply (`VREG_AVDD`)

`VREG_AVDD` supplies the on chip voltage regulator's analogue control circuits, and should be powered at a nominal 3.3 V. To reduce the number of external power supplies, `VREG_AVDD` can use the same power source as the voltage regulator input supply (`VREG_VIN`), or the digital IO supply (`IOVDD`). Though care should be taken to minimise the noise on `VREG_AVDD`. A passive low pass filter may be required, see [Section 6.3.7](#) for details.

**NOTE**

`VREG_AVDD` also powers the chip's power-on reset and brownout detection blocks, so it must be powered even if the on-chip voltage regulator is not used.

引脚。

#### 6.1.4. USB PHY 与 OTP 电源 (USB\_OTP\_VDD)

USB\_OTP\_VDD为芯片的USB PHY及OTP只读存储器供电，应以标称3.3 V供电。为减少外部电源数量，USB\_OTP\_VDD可与核心电压调节器的模拟电源(VREG\_AVDD)或数字IO电源(IOVDD)共用同一电源，前提是IOVDD同样为3.3 V供电。该电源必须始终提供，即便在USB PHY未使用的应用中亦然。

USB\_OTP\_VDD应在芯片的USB\_OTP\_VDD引脚附近通过100nF电容进行去耦。

#### 6.1.5. ADC 电源 (ADC\_AVDD)

ADC\_AVDD为芯片的模数转换器(ADC)供电。其标称供电电压范围为1.8 V至3.3 V，但电压低于2.97 V时，ADC性能将受影响。为减少外部电源数量，ADC\_AVDD可与核心电压调节器的模拟电源共用同一电源。

(VREG\_AVDD) 或数字IO电源(IOVDD)。

##### ① 注意

向ADC\_AVDD供电时，电压高于或低于IOVDD是安全的，例如，为实现最佳性能，可以以3.3 V为ADC供电，同时支持数字IO的1.8 V信号电平。但ADC模拟输入端的电压不得超过IOVDD，例如若IOVDD为1.8 V，ADC输入端电压应限制在1.8 V以内。超过IOVDD的电压将导致通过ESD保护二极管的漏电流发生。详情请参见第14.9节。

应在芯片的ADC\_AVDD引脚附近使用一个100nF电容对ADC\_AVDD进行去耦。

#### 6.1.6. 核心电压稳压器输入电源 (VREG\_VIN)

VREG\_VIN为片上核心电压调节器的输入电源，电压范围应为2.7 V至5.5 V。为减少外部电源数量，VREG\_VIN可与电压调节器模拟电源(VREG\_AVDD)或数字IO电源(IOVDD)共用同一电源。应注意尽量减少VREG\_AVDD上的噪声。

应在VREG\_VIN与地之间连接一个4.7 μF电容，且该电容应靠近芯片的VREG\_VIN引脚。

有关片上电压调节器的更多详情，请参见第6.3节。

#### 6.1.7. 芯片内电压稳压器模拟电源 (VREG\_AVDD)

VREG\_AVDD为片上电压调节器的模拟控制电路供电，额定供电电压应为3.3 V。

为减少外部电源数量，VREG\_AVDD可使用与电压调节器输入电源(VREG\_VIN)或数字IO电源(IOVDD)相同的电源。应注意尽量减少VREG\_AVDD上的噪声。

可能需要被动低通滤波器，详情请参见第6.3.7节。

##### ① 注意

VREG\_AVDD还为芯片的上电复位和欠压检测模块供电，因此即使不使用片上电压调节器，也必须为其供电。

### 6.1.8. Power supply sequencing

With the exception of the two voltage regulator supplies ([VREG\\_VIN](#) and [VREG\\_AVDD](#)), which should be powered up together, RP2350's power supplies may be powered up or down in any order. However, small transient currents may flow in the ADC supply ([ADC\\_AVDD](#)) if it is powered up before, or powered down after, the digital core supply (DVDD). This will not damage the chip, but can be avoided by powering up DVDD before or at the same time as [ADC\\_AVDD](#), and powering down DVDD after or at the same time as [ADC\\_AVDD](#). In the most common power supply scheme, where the chip is powered from a single 3.3 V supply, DVDD will be powered up shortly after [ADC\\_AVDD](#) due to the startup time of the on-chip voltage regulator. This is acceptable behaviour.

## 6.2. Power management

RP2350 retains the power control features of RP2040, but extends them by splitting the chip's digital core into a number of power domains, which can be selectively powered off. This allows significant power saving in applications where the chip is not continuously active. This section describes the core power domains and how they are controlled. The legacy RP2040 power control features still offer useful power savings, and are described in [Section 6.5](#).

Power domains, and transitions between power states, are controlled by a Power manager. The Power manager runs from either an internal low power oscillator [lposc](#), or the reference clock [clk\\_ref](#). The device may be configured to power down under software control and can wakeup on a GPIO or timer event. Configuration of the power manager is via the [POWMAN](#) registers in [Section 6.4](#).

### 6.2.1. Core power domains

RP2350's core logic is divided into five power domains. With some restrictions, these domains can be selectively powered off to reduce the chip's power consumption. The five domains are:

- **AON** - Always On - a small amount of logic that is always powered on when chip's core supply ([DVDD](#)) is available
- **SWCORE** - Switched Core - the remaining core logic functions, including processors, bus fabric, peripherals, etc.
- **XIP** - XIP cache SRAM and Boot RAM
- **SRAM0** - SRAM Power Domain 0 - the lower half of the large SRAM banks
- **SRAM1** - SRAM Power Domain 1 - the upper half of the large SRAM banks, and the scratch SRAMs

Logic in the AON domain controls the power state of the other power domains, which can be powered on or off independently. The only exception is the XIP domain, which must always be powered when the SWCORE domain is powered. SRAMs that are powered on retain their contents when the switched core is powered off.

[Figure 18](#) gives an overview of the core power domains.

### 6.1.8. 电源供应顺序

除两个电压调节器供电输入（**VREG\_VIN**和**VREG\_AVDD**）应同时上电外，RP2350的电源可按任意顺序上电或断电。但是，如果ADC电源（**ADC\_AVDD**）在数字核心电源（DVDD）之前上电，或在数字核心电源之后断电，可能会有小的瞬态电流流动。这不会损坏芯片，但可通过先于或同时为**ADC\_AVDD**供电后再为DVDD供电，以及在断开**ADC\_AVDD**电源时，同时或随后断开DVDD电源来避免。在最常见的电源方案中，当芯片由单一3.3 V电源供电时，由于片上电压稳压器的启动时间，DVDD的上电时间会稍晚于**ADC\_AVDD**。此行为属可接受情况。

## 6.2. 电源管理

RP2350保留了RP2040的电源控制功能，并通过将芯片的数字核心划分为多个可选择性断电的电源域加以扩展，从而在芯片非持续激活的应用场景中实现显著的功耗节约。本节描述核心电源域及其控制方式。传统的RP2040电源控制功能仍提供有效的节能效果，详见第6.5节。

电源域及电源状态之间的切换由电源管理器控制。电源管理器运行于内部低功耗振荡器 **lposc** 或参考时钟 **clk\_ref**。设备可通过软件控制配置以关闭电源，并可通过GPIO或定时器事件唤醒。电源管理器的配置通过第6.4节中的**POWMAN**寄存器完成。

### 6.2.1. 核心电源域

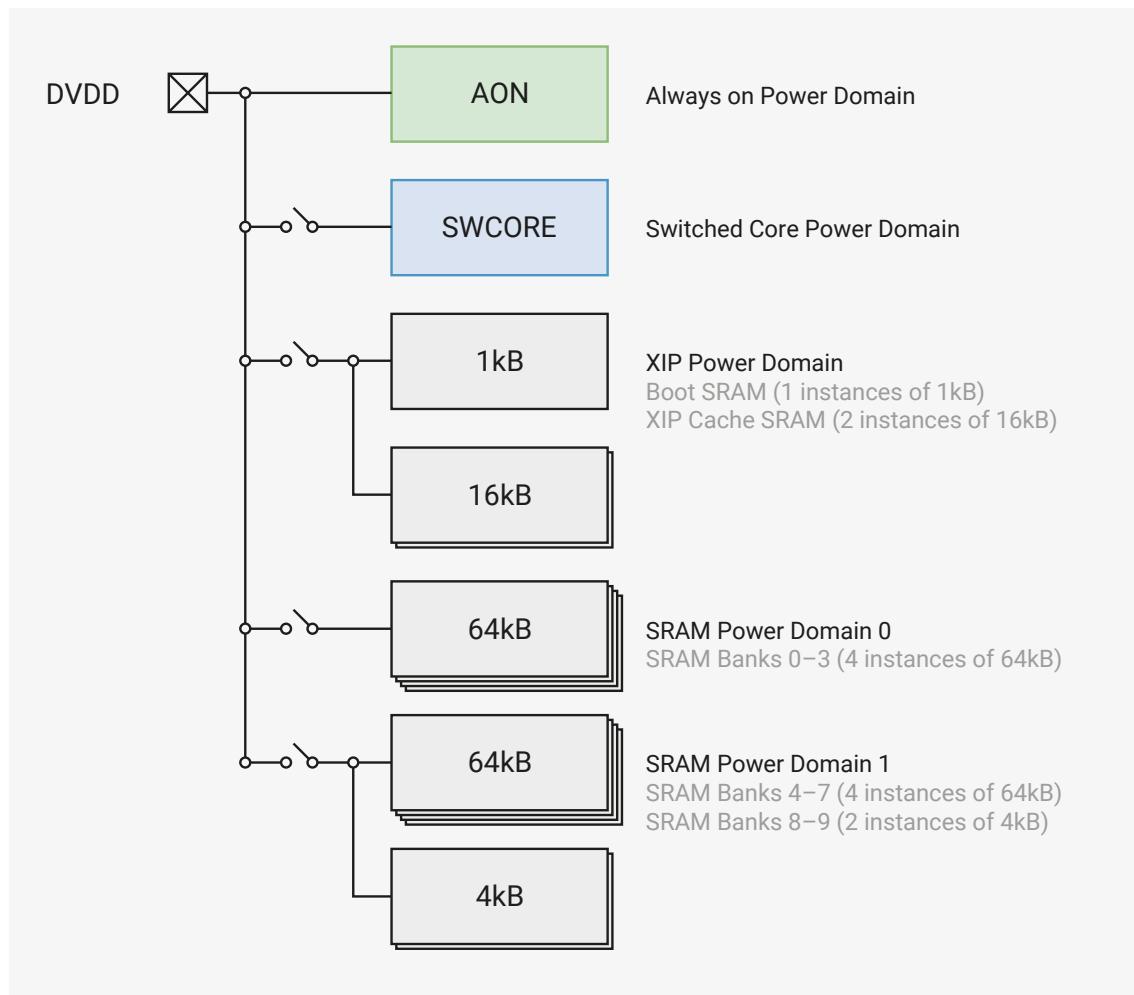

RP2350的核心逻辑划分为五个电源域。在某些限制条件下，这些电源域可以选择性关闭，以降低芯片功耗。五个电源域为：

- **AON** - 始终开启 - 芯片核心供电（**DVDD**）可用时始终保持供电的小部分逻辑
- **SWCORE** - 切换核心 - 其余核心逻辑功能，包括处理器、总线结构、外设等。
- **XIP** - XIP 缓存 SRAM 及启动 RAM
- **SRAM0** - SRAM 电源域 0 — 大型 SRAM 存储区的下半部分
- **SRAM1** - SRAM 电源域 1 — 大型 SRAM 存储区的上半部分及临时 SRAM

始终开启（AON）域中的逻辑控制其他电源域的供电状态，这些电源域可独立开关电源。唯一例外为 XIP 域，当 SWCORE 域通电时，XIP 域必须始终保持供电。被供电的 SRAM 在开关核心断电时内容将被保留。

图 18 概述了核心电源域架构。

Figure 18. core power domains

### 6.2.2. Power states

RP2350 can operate in a number of power states, depending on which domains are powered on or off. Power states have names in the form **Pc.m** where:

- **c** indicates the state of the switched core (SWCORE) domain: **0** = on / **1** = off
- **m** is a 3 bit binary representation of the memory power domains, in the order XIP, SRAM0, SRAM1

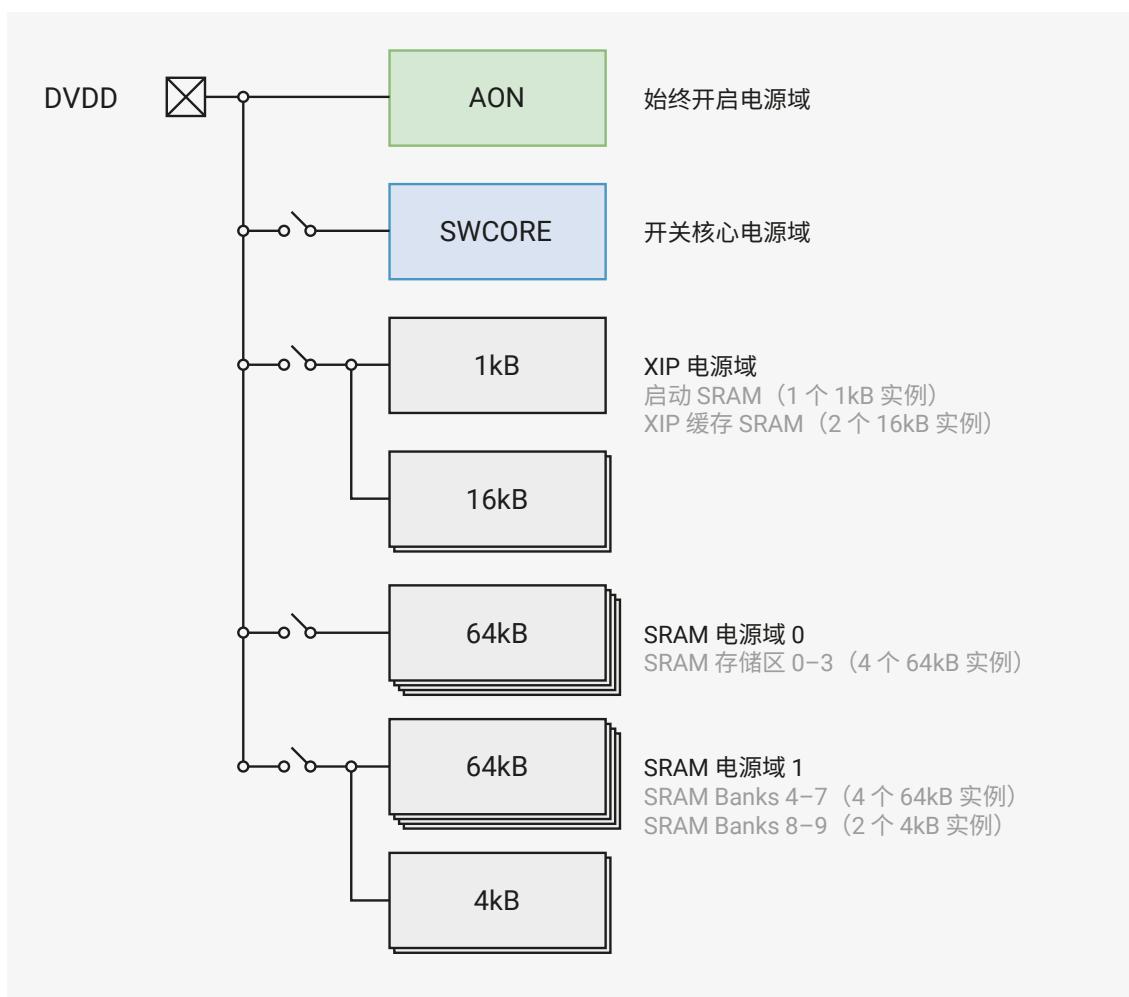

**P0.m** states, where the switched core is powered on, are *Normal Operating* states. **P1.m** states, where the switched core is powered off, are *Low Power* states

Table 475 shows the available power states.

Table 475. supported power states

Power State	Description	AON	SWCORE	XIP	SRAM0	SRAM1
<b>P0.0</b>	Normal Operation	on	on	on	on	on
<b>P0.1</b>	Normal Operation (SRAM1 off)	on	on	on	on	off
<b>P0.2</b>	Normal Operation (SRAM0 off)	on	on	on	off	on
<b>P0.3</b>	Normal Operation (SRAM0 & SRAM1 off)	on	on	on	off	off
<b>P1.0</b>	Low Power	on	off	on	on	on
<b>P1.1</b>	Low Power (SRAM1 off)	on	off	on	on	off
<b>P1.2</b>	Low Power (SRAM0 off)	on	off	on	off	on

图 18. 核心电源域

### 6.2.2. 电源状态

RP2350 可根据各电源域的开启或关闭状态处于多个电源状态。电源状态的命名格式为 **Pc.m**，其中：

- **c** 表示切换核心 (SWCORE) 电源域的状态：**0**= 开启 / **1**= 关闭
- **m** 为内存电源域的 3 位二进制表示，顺序为 XIP、SRAM0、SRAM1

**P0.m** 状态表示切换核心处于开启状态，为正常操作状态。**P1.m** 状态表示切换核心处于关闭状态，为低功耗状态。

表 475 显示了所有可用电源状态。

表475. 支持的电源状态

电源状态	描述	AON	SWCORE	XIP	SRAM0	SRAM1
P0.0	正常操作	开启	开启	开启	开启	开启
P0.1	正常操作 (SRAM1 关闭)	开启	开启	开启	开启	关闭
P0.2	正常操作 (SRAM0 关闭)	开启	开启	开启	关闭	开启
P0.3	正常操作 (SRAM0 和 SRAM1 关闭)	开启	开启	开启	关闭	关闭
P1.0	低功耗	开启	关闭	开启	开启	开启
P1.1	低功耗 (SRAM1 关闭)	开启	关闭	开启	开启	关闭
P1.2	低功耗 (SRAM0 关闭)	开启	关闭	开启	关闭	开启

Power State	Description	AON	SWCORE	XIP	SRAM0	SRAM1
P1.3	Low Power (SRAM0 & SRAM1 off)	on	off	on	off	off
P1.4	Low Power (XIP off)	on	off	off	on	on
P1.5	Low Power (XIP & SRAM1 off)	on	off	off	on	off
P1.6	Low Power (XIP & SRAM0 off)	on	off	off	off	on
P1.7	Low Power (XIP & SRAM0 & SRAM1 off)	on	off	off	off	off
OFF	Not Powered	off	off	off	off	off

In the **OFF** state, the chip has no external power and all domains are unpowered. The chip moves from **OFF** to **P0.0** automatically as soon as external power is applied.

To determine the current power state, read the **STATE.CURRENT** field. **CURRENT** is a 4 bit field representing the power state of the switched core and memory power domains.

### 6.2.3. Power state transitions

Transitions between power states can be initiated by software, hardware, or via the chip's debug subsystem. After initiation, transitions are managed by autonomous power sequencers in the chip's AON power domain. The power sequencers can be configured, in a limited way, via the **SEQ\_CFG** register. The sequencers can also be observed and controlled, again in a limited way, via the RP-AP registers in the chip's debug subsystem. These registers are described in [Section 3.5.10](#).

Valid power state transitions are as follows:

- all transitions from one **P0.m** state (switched core powered on) to another **P0.m** state (switched core powered on), if they increase or decrease the number of SRAM domains that are powered on
- all transitions from a **P0.m** state (switched core powered on) to a **P1.m** state (switched core powered off), except transitions that would result in a powered off SRAM domain becoming powered on
- all transitions from a **P1.m** state (switched core powered off) to a **P0.m** state (switched core powered on), except transitions that would result in a powered on SRAM domain becoming powered off

Transitions from one **P1.m** state (switched core powered off) to another **P1.m** state (switched core powered off) are not supported, and will be prevented by the hardware.

Valid transitions are shown in the table below.

Table 476. valid power state transitions

From	To	P0.1	P0.2	P0.3	P1.0	P1.1	P1.2	P1.3	P1.4	P1.5	P1.6	P1.7
<b>P0.0</b>												
<b>P0.1</b>	<b>P0.0</b>			<b>P0.3</b>		<b>P1.1</b>		<b>P1.3</b>		<b>P1.5</b>		<b>P1.7</b>
<b>P0.2</b>	<b>P0.0</b>			<b>P0.3</b>			<b>P1.2</b>	<b>P1.3</b>			<b>P1.6</b>	<b>P1.7</b>
<b>P0.3</b>	<b>P0.0</b>	<b>P0.1</b>	<b>P0.2</b>					<b>P1.3</b>				<b>P1.7</b>
<b>P1.0</b>	<b>P0.0</b>											
<b>P1.1</b>	<b>P0.0</b>	<b>P0.1</b>										
<b>P1.2</b>	<b>P0.0</b>		<b>P0.2</b>									
<b>P1.3</b>	<b>P0.0</b>	<b>P0.1</b>	<b>P0.2</b>	<b>P0.3</b>								
<b>P1.4</b>	<b>P0.0</b>											
<b>P1.5</b>	<b>P0.0</b>	<b>P0.1</b>										

电源状态	描述	AON	SWCORE	XIP	SRAM0	SRAM1
P1.3	低功耗 (SRAM0 和 SRAM1 关闭)	开启	关闭	开启	关闭	关闭
P1.4	低功耗 (XIP 关闭)	开启	关闭	关闭	开启	开启
P1.5	低功耗 (XIP 和 SRAM1 关闭)	开启	关闭	关闭	开启	关闭
P1.6	低功耗 (XIP 和 SRAM0 关闭)	开启	关闭	关闭	关闭	开启
P1.7	低功耗 (XIP、SRAM0 和 SRAM1 关闭)	开启	关闭	关闭	关闭	关闭
关闭	无电源	关闭	关闭	关闭	关闭	关闭

在关闭状态下，芯片无外部电源且所有域均无电。芯片在接通外部电源后，会自动从关闭状态切换至 P0.0 状态。

要确定当前电源状态，请读取 STATE.CURRENT 字段。 CURRENT 是一个 4 位字段，表示切换核心和内存电源域的电源状态。

### 6.2.3. 电源状态转换

功率状态之间的转换可由软件、硬件或通过芯片的调试子系统发起。启动后，转换由芯片 AON 功率域内的自主功率序列器管理。功率序列器可通过 SEQ\_CFG 寄存器进行有限配置。同样，可通过芯片调试子系统中的 RP\_AP 寄存器对序列器进行有限观察和控制。这些寄存器详述于第 3.5.10 节。

有效的功率状态转换如下：

- 所有从一个 P0.m 状态（已开启切换核心）到另一个 P0.m 状态（已开启切换核心）的转换，若该转换增加或减少了开启的 SRAM 域数量
- 所有从 P0.m 状态（已开启切换核心）到 P1.m 状态（已关闭切换核心）的转换，除非该转换导致已关闭的 SRAM 域被开启
- 所有从 P1.m 状态（切换核心电源关闭）向 P0.m 状态（切换核心电源开启）的转换，除导致开启的 SRAM 域变为关闭的转换

从一个 P1.m 状态（切换核心电源关闭）转换至另一个 P1.m 状态（切换核心电源关闭）的操作不被支持，且硬件将禁止此类转换。

有效转换如下表所示。

表476。有效电源状态转换

起始状态	目标状态

### 6.2.3.1. Transitions from Normal Operating (P0.m) states

Transitions from a Normal Operating ( $P0.m$ ) state to either a Low Power ( $P1.m$ ) state, or another Normal Operating ( $P0.m$ ) state, are initiated by writing to the `STATE.REQ` field. `REQ` is a 4-bit field representing the requested power state of the switched core and memory power domains. The `STATE.WAITING` field will be set immediately, followed by the `STATE.CHANGING` field, after the actual state change starts. If a transition to a Low Power ( $P1.m$ ) state is requested, `WAITING` will remain set until the processors have gone into a low power state (via `_wfi()`). In the `WAITING` state, writing to the `STATE.REQ` field can change or cancel the initial request. The requested state can't be changed when in the `CHANGING` state.

A request to move to an unsupported state, or a state that would result in an invalid transition, causes the `STATE.BAD_SW_REQ` field to be set.

If a hardware power up request is received while in the `WAITING` state, the transition requested via `STATE.REQ` will be halted and the power up request completed. The `STATE.PWRUP WHILE_WAITING` and `STATE.REQ IGNORED` fields will be set.

On writing to `STATE.REQ`:

- If there is a pending power up request, `STATE.REQ IGNORED` is set and no further action is taken
- If the requested state is invalid, `STATE.BAD_SW_REQ` is set and no further action is taken
- If the switched core is being powered off, `STATE.WAITING` is set until both processors enter `_wfi()`. After which `STATE.CHANGING` will be set, but no processors will be powered up to read the flag at this time
  - If there is a power up request while in `STATE.WAITING`, `STATE.PWRUP WHILE_WAITING` is set, which can also raise an interrupt to bring the processors out of `_wfi()`. No further action is taken
  - You can get out of the `WAITING` state by writing a new request to `STATE.REQ` before both processors have gone into `_wfi()`
- Any state request that isn't powering down the switched core, such as powering up or down SRAM domain 0 or 1 starts immediately. Software should wait until `STATE.CHANGING` has cleared to know the power down sequence. After the `STATE.CHANGING` flag is cleared `STATE.CURRENT` is updated.
- If powering up, software should also wait for `STATE.CHANGING` to make sure everything is powered up before continuing. In practice this is handled by the RP2350 bootrom.

Invalid state transitions are:

- any combination of power up and power down requests
- any request which would result in power down of XIP/bootRAM and power up of SWCORE

If XIP, boot RAM, sram0, or sram1 remain powered while SWCORE is powered off, the sram will automatically switch to a low power state. Stored data will be retained.

Before transitioning to a switched-core power down state ( $P1.m$ ), software needs to configure:

- the GPIO wakeup conditions if required
- the wakeup alarm if required
- the return state of the SRAM0 & SRAM1 domains

起始状态	目标状态										
P1.6	P0.0		P0.2								
P1.7	P0.0	P0.1	P0.2	P0.3							

### 6.2.3.1. 从正常运行 (P0.m) 状态的转换

从正常运行状态 ( $P0.m$ ) 向低功耗状态 ( $P1.m$ ) 或另一个正常运行状态 ( $P0.m$ ) 的转换，需通过写入STATE.REQ字段来触发。REQ为4位字段，表示切换核心及存储电源域所请求的电源状态。STATE.WAITING字段将被立即设置，随后在实际状态变更开始时设置STATE.CHANGING字段。如果请求切换到低功耗 ( $P1.m$ ) 状态，WAITING字段将保持设置，直到处理器通过 `_wfi()` 进入低功耗状态。在 WAITING状态下，写入 STATE.REQ 字段可更改或取消初始请求。在 CHANGING 状态时，无法更改请求的状态。

请求切换到不支持的状态或导致无效转换的状态时，STATE.BAD\_SW\_REQ 字段将被设置。

如果在 WAITING状态下接收到硬件上电请求，则通过 STATE.REQ 请求的转换将被中止，硬件上电请求将被完成。STATE.PWRUP WHILE\_WAITING 和 STATE.REQ IGNORED 字段将被设置。

写入 STATE.REQ 时：

- 若存在待处理的上电请求，则设置STATE.REQ IGNORED，且不采取后续操作。
- 若请求的状态无效，则设置STATE.BAD\_SW\_REQ，且不采取后续操作。
- 若被切换的核正处于断电状态，则设置STATE.WAITING，直至两个处理器均进入 `_wfi()` 状态。随后将设置STATE.CHANGING，然而此时不会对任何处理器进行上电以读取该标志。
  - 若在STATE.WAITING期间出现上电请求，则设置STATE.PWRUP WHILE\_WAITING，该状态亦可触发中断以使处理器退出 `_wfi()` 状态。不采取任何后续操作。
  - 在两个处理器进入 `_wfi()` 之前，通过向STATE.REQ写入新请求，可使系统退出WAITING状态。
- 任何非断电切换核的状态请求，如对SRAM域0或1进行上电或断电，将立即启动。软件应等待直到 STATE.CHANGING 标志清除，以了解断电顺序。  
在 STATE.CHANGING 标志清除后，STATE.CURRENT 会被更新。
- 如果是上电，软件也应等待 STATE.CHANGING 标志，以确保所有部分均已上电，然后再继续。在实际操作中，该过程由 RP2350 bootrom 处理。

无效的状态转换包括：

- 任何上电与断电请求的组合
- 任何导致 XIP/bootRAM 断电且 SWCORE 上电的请求

若 XIP、boot RAM、sram0 或 sram1 在 SWCORE 断电时仍保持上电，sram 会自动切换至低功耗状态。存储的数据将被保留。

在切换至切换核心断电状态 ( $P1.m$ ) 之前，软件需配置：

- 如有需要，配置 GPIO 唤醒条件
- 如有需要，配置唤醒闹钟
- SRAM0 和 SRAM1 区域的返回状态

### 6.2.3.2. Transitions from Low Power (P1.m) states

Transitions from P1.m to P0.m states are initiated by GPIO events or the timer alarm.

There are up to 5 wakeup sources:

- up to 4 GPIO wakeups (level high/low or falling edge/rising edge)
- 1 alarm wakeup

GPIO wakeups are configured by the [PWRUP0-PWRUP3](#) registers. The wakeups are not enabled until the power sequencer completes the power down operation.

The alarm wakeup is configured by writing to the [ALARM\\_TIME\\_15T00-ALARM\\_TIME\\_63T048](#) registers. The alarm wakeup has a resolution of 1ms. Once set, the alarm wakeup is armed by writing a 1 to both [TIMER.PWRUP\\_ON\\_ALARM](#) and [TIMER.ALARM\\_ENAB](#). If the alarm fires during the power down sequence, a power up sequence will start when the power down sequence completes.

The [LAST\\_SWCORE\\_PWRUP](#) register indicates which event caused the most recent power up.

### 6.2.3.3. Debugger-initiated power state transitions

The debugger can be used to trigger a power up sequence via the [CSYSPWRUPREQ](#) output from the [SW-DP CTRL/STAT](#) register. This powers all domains (i.e. returns to state [P0.0](#)) and also inhibits any further software initiated power state transitions.

When [CSYSPWRUPREQ](#) is asserted, the power sequencer will:

- complete any power state transitions that are in progress
- return to power state [P0.0](#)
- assert [CSYSPWRUPACK](#) to signal completion to the debug host

If [CSYSPWRUPREQ](#) is de-asserted then software initiated power transitions will be able to resume. The user can detect when a software requested transition is ignored because of [CSYSPWRUPREQ](#) using the following hints:

- Getting a [STATE.REQ\\_IGNORED](#) after a write to [STATE.REQ](#)
- [CURRENT\\_PWRUP\\_REQ](#) will have bit 5 (coresight) set
- Either:
  - Get the debugger to de-assert [CSYSPWRUPREQ](#) or
  - Mask out [CSYSPWRUPREQ](#) by setting [DBG\\_PWRCFG.IGNORE](#)

#### **NOTE**

[DBG\\_PWRCFG.IGNORE](#) is useful to test going to sleep with a debugger attached or ignoring [CSYSPWRUPREQ](#). A debugger will likely leave [CSYSPWRUPREQ](#) set when disconnecting. It would be impossible to go to sleep after this without [DBG\\_PWRCFG.IGNORE](#).

### 6.2.3.4. Power-mode-aware GPIO control

The power manager sequencer is able to switch the state of two GPIO outputs on entry to and exit from a P1.m state, i.e. one where the switched core is powered down. This allows external devices to be power-aware. The GPIOs switch to indicate the low power state *after* the core is powered down and switch to indicate the high power state *before* the core is powered up. This ensures the high power state of the external components always overlaps the high power state of the core. The GPIOs are configured by the [EXT\\_CTRL0](#) and [EXT\\_CTRL1](#) registers.

### 6.2.3.2. 从低功耗 (P1.m) 状态的转换

从 P1.m 状态切换到 P0.m 状态由 GPIO 事件或定时器警报触发。

最多有 5 个唤醒源：

- 最多 4 个 GPIO 唤醒（高电平/低电平或下降沿/上升沿）
- 1 个警报唤醒

GPIO 唤醒通过 PWRUP0-PWRUP3 寄存器进行配置。在电源序列器完成关机操作之前，唤醒功能不会启用。

警报唤醒通过写入 ALARM\_TIME\_15T00 至 ALARM\_TIME\_63T048 寄存器进行配置。警报唤醒的时间分辨率为 1 毫秒。设置完成后，警报唤醒通过同时向 TIMER.PWRUP\_ON\_ALARM 和 TIMER.ALARM\_ENAB 写入 1 来启动。如果在关机序列期间警报触发，电源上电序列将在关机序列完成后启动。

LAST\_SWCORE\_PWRUP 寄存器指示最近一次上电的触发事件。

### 6.2.3.3. 调试器启动的电源状态转换

调试器可通过 SW-DP CTRL/STAT 寄存器的 CSYSPWRUPREQ 输出触发上电序列。

此操作将为所有域供电（即返回至状态 P0.0），并禁止任何进一步的软件发起的电源状态转换。

当 CSYSPWRUPREQ 被置位时，电源序列控制器将执行以下操作：

- 完成任何正在进行的电源状态转换。
- 返回至电源状态 P0.0。
- 置位 CSYSPWRUPACK 以向调试主机发送完成信号。

如果 CSYSPWRUPREQ 被取消置位，则允许软件发起的电源转换恢复。用户可以通过以下提示检测因 CSYSPWRUPREQ 导致的软件请求转换被忽略的情况：

- 写入 STATE.REQ 后出现 STATE.REQ\_IGNORED。
- CURRENT\_PWRUP\_REQ 的第 5 位（coresight）被置位。
- 以下任一情况：
  - 使调试器取消置位 CSYSPWRUPREQ，或
  - 通过设置 DBG\_PWRCFG.IGNORE 屏蔽 CSYSPWRUPREQ

#### **注意**

DBG\_PWRCFG.IGNORE 对于测试连接调试器时进入休眠或忽略 CSYSPWRUPREQ 非常有用。调试器断开时，通常会保持 CSYSPWRUPREQ 为设定状态。若无 DBG\_PWRCFG.IGNORE，之后无法进入休眠。

### 6.2.3.4 电源模式感知 GPIO 控制

电源管理序列器能够在进入及退出 P1.m 状态时切换两个 GPIO 输出的状态，即切换核心处于断电状态时。该功能使外部设备能够感知电源状态。核心断电后，GPIO 切换以指示低功耗状态；核心通电前，GPIO 切换以指示高功耗状态，确保外部组件的高功耗状态始终与核心的高功耗状态重叠。GPIO 由 EXT\_CTRL0 和 EXT\_CTRL1 寄存器配置。

### 6.2.3.5. Isolation

When powering down SWCORE, the pad control and data signals are latched and isolated from the IO logic. This avoids transitions on pads which could potentially corrupt external components. On SWCORE power up, the isolation is not released automatically. The user releases the isolation by clearing the ISO field of the pad control register (for example [GPIO0.ISO](#)) after the IO logic has been configured.

## 6.3. Core voltage regulator

RP2350 provides an on-chip voltage regulator for its digital core supply ([DVDD](#)). The regulator requires a 2.7 V to 5.5 V input supply ([VREG\\_VIN](#)), allowing DVDD to be generated directly from a single lithium ion cell, or a USB power supply. A separate, nominally 3.3 V, low noise supply ([VREG\\_AVDD](#)) is required for the regulator's analogue control circuits. The regulator supports both switching and linear modes of regulation, allowing efficient operation at both high and low loads.

To allow the chip to start up, the regulator is enabled by default, and will power up as soon as its supplies are available. The regulator starts in switching mode, with a nominal 1.1 V output, but its operating mode and output voltage can be changed once the chip is out of reset. The output voltage can be set in the range 0.55 V to 3.30 V, and the regulator can supply up to 200mA.

Although intended for the chip's digital core supply ([DVDD](#)), the regulator can be used for other purposes if DVDD is powered directly from an external power supply.

### 6.3.1. Operating modes

The regulator has the following three modes of operation.

#### 6.3.1.1. Normal mode

In normal mode, the regulator operates in a switching mode, and can supply up to 200mA. Normal mode is used for [P0.x](#) power states, when the chip's switched core is powered on. The regulator must be in normal mode *before* the core supply current is allowed to exceed 1mA. The regulator starts up in normal mode when its input supplies are first applied.

#### 6.3.1.2. Low-power mode

In low-power mode, the regulator operates in a linear mode, and can only supply up to 1mA. Low-power mode can be used for [P1.x](#) power states, where the chip's switched core is powered off. The core supply current must be less than 1mA *before* the regulator is moved to low-power mode. The regulator's output voltage is limited to 1.3 V in low-power mode.

#### CAUTION

In low-power mode, the output of the regulator is directly connected to [DVDD](#). It isn't possible to disconnect the regulator from [DVDD](#) in this mode. Don't put the regulator into low-power mode if [DVDD](#) is being powered from an external supply.

#### 6.3.1.3. High-impedance mode

In high-impedance mode, the regulator is disabled, its power consumption is minimised, and its outputs are set to a high-impedance state. This mode should only be used if the digital core supply (DVDD) is provided by an external

### 6.2.3.5. 隔离

关闭 SWCORE 电源时，垫片控制信号和数据信号将被锁存并与 IO 逻辑隔离。此举可避免垫片产生可能损坏外部元件的信号切换。SWCORE 加电时，隔离不会自动解除。用户须在配置 IO 逻辑后，通过清除垫片控制寄存器（例如 `GPIO0.ISO`）中的 ISO 字段以解除隔离。

## 6.3. 核心电压调节器

RP2350 为其实数核心供电 (`DVDD`) 提供片上电压调节器。该调节器要求输入电压为 2.7 V 至 5.5 V (`VREG_VIN`)，可直接由单节锂离子电池或 USB 电源产生 `DVDD`。调节器的模拟控制电路需要单独的标称 3.3 V 低噪声电源 (`VREG_AVDD`)。该调节器支持开关和线性两种调节模式，确保在高负载和低负载状态下均能高效工作。

为使芯片启动，调节器默认启用，并将在其电源可用时立即供电。

调节器以开关模式启动，标称输出电压为 1.1 V，但芯片复位解除后，其工作模式和输出电压可被更改。输出电压可设置在 0.55 V 至 3.30 V 范围内，调节器最大供应电流为 200mA。

虽然调节器设计用于芯片数字核心电源 (`DVDD`)，但若 `DVDD` 由外部电源直接供电，调节器亦可用于其他用途。

### 6.3.1. 运行模式

调节器具备以下三种工作模式。

#### 6.3.1.1. 正常模式

在正常模式下，调节器以开关模式运行，最大供应电流为 200mA。正常模式用于 `P0.x` 电源状态，即芯片切换核心电源开启时。调节器必须在允许核心电源电流超过 1mA 之前处于正常模式。当调节器的输入电源首次接通时，调节器以正常模式启动。

#### 6.3.1.2. 低功耗模式

在低功耗模式下，调节器以线性模式工作，最大输出电流仅为 1mA。低功耗模式适用于 `P1.x` 电源状态，此时芯片的切换核心处于断电状态。调节器进入低功耗模式前，核心供电电流必须低于 1mA。调节器在低功耗模式下的输出电压限制为 1.3 V。

#### ⚠ 警告

在低功耗模式下，调节器的输出直接连接至 `DVDD`。在此模式下，无法将调节器从 `DVDD` 断开。如果 `DVDD` 由外部电源供电，则不得将调节器置于低功耗模式。

#### 6.3.1.3. 高阻抗模式

在高阻抗模式下，调节器被禁用，功耗降至最低，输出端置于高阻抗状态。仅当数字核心电源 (`DVDD`) 由外部调节器供电时，才应使用此模式。

regulator. If the on-chip regulator is supplying DVDD, entering high-impedance mode causes a reset event, returning the on-chip regulator to Normal mode.

### 6.3.2. Software control

#### ⚠️ WARNING

The regulator can't be relocked after it's been unlocked. Avoid accidental writes to the VREG register.

The regulator can be directly controlled by software, but must first be unlocked by writing a 1 to the [UNLOCK](#) field in the [VREG\\_CTRL](#) register. Once unlocked, the regulator can be controlled via the [VREG](#) register.

The regulator's operating mode defaults to Normal, at initial power up or after a reset event, but can be switched to high impedance by writing a 1 to the [VREG](#) register's [HIZ](#) field. The regulator's output voltage can be set by writing to the register's [VSEL](#) field, see the [VREG](#) register description for details on available settings. To prevent accidental over-voltage, the output voltage is limited to 1.3 V unless the [DISABLE\\_VOLTAGE\\_LIMIT](#) field in the [VREG\\_CTRL](#) is set. The output voltage defaults to 1.1 V at initial power-on or after a reset event.

The [UPDATE\\_IN\\_PROGRESS](#) field in the [VREG](#) register is set while the regulator's operating mode or output voltage are being updated. When [UPDATE\\_IN\\_PROGRESS](#) is set, writes to the register are ignored.

It isn't possible to place the regulator in low-power mode under software control because the load current will exceed 1mA when software is running.

#### ⚠️ CAUTION

The regulator's output voltage can be varied between 0.55 V and 3.3 V, but RP2350 might not operate reliably with its digital core supply ([DVDD](#)) at a voltage other than 1.1 V.

### 6.3.3. Power Manager control

The regulator's operating mode and output voltage can also be controlled by the Power Manager. Power Manager control is typically used when the chip enters or exits a low-power ([P1.x](#)) state, when software might not be running.

In addition to normal and high-impedance modes, Power Manager control allows the regulator to be placed in low-power mode. By default, the regulator switches to low-power mode when entering a low-power ([P1.x](#)) state, and returns to Normal mode when returning to a normal ([P0.x](#)) state.

The operating mode and output voltage in the low-power state are set by the values in the [VREG\\_LP\\_ENTRY](#) register. And the operating mode and output voltage to be used when the chip has returned to a normal state are set by values in the [VREG\\_LP\\_EXIT](#) register. The registers contain an additional [MODE](#) field that allows low-power mode to be selected.

The values in the registers must be written by software before requesting a transition to a low-power state because software won't be running during or after the transition. The actual transitions to and from the low-power state are handled by the Power Manager. Once the chip has returned to a normal state, software can be run and the regulator controlled directly. The values in the [VREG](#) register reflect the regulator's current operating mode and output voltage once the chip has returned to a normal state.

调节器。如果片内调节器向DVDD供电，进入高阻抗模式将触发复位事件，使片内调节器恢复到正常模式。

### 6.3.2. 软件控制

#### ● 警告

调节器解锁后不可重新上锁。避免对VREG寄存器的误写操作。

调节器可由软件直接控制，但须先向VREG\_CTRL寄存器的UNLOCK字段写入1以完成解锁。解锁后，可通过VREG寄存器对调节器进行控制。

调节器的工作模式在初次上电或复位后默认为正常模式，但可通过向VREG寄存器的HIZ字段写入1切换至高阻抗模式。调节器的输出电压可通过写入寄存器的VSEL字段进行设置，具体可用设置详见VREG寄存器说明。为防止意外过压，输出电压被限制在1.3 V，除非VREG\_CTRL中的DISABLE\_VOLTAGE\_LIMIT字段被设置。输出电压在初次上电或复位事件后默认为1.1 V。

当调节器的工作模式或输出电压正在更新时，VREG寄存器中的UPDATE\_IN\_PROGRESS字段将被设置。当UPDATE\_IN\_PROGRESS字段被设置时，对寄存器的写入操作将被忽略。

由于软件运行时负载电流将超过1mA，因此无法通过软件控制将调节器置于低功耗模式。

#### ⚠ 警告

调节器的输出电压可在0.55 V至3.3 V之间调节，但RP2350的数字核心电源（DVDD）在非1.1 V电压下可能无法可靠运行。

### 6.3.3. 电源管理器控制

调节器的工作模式和输出电压也可以由电源管理器控制。电源管理器控制通常应用于芯片进入或退出低功耗（P1.x）状态且软件可能未运行的情况。

除正常模式和高阻抗模式外，电源管理器控制还允许调节器进入低功耗模式。默认情况下，调节器在进入低功耗（P1.x）状态时切换至低功耗模式，返回正常（P0.x）状态时切换回正常模式。

低功耗状态下的工作模式和输出电压由VREG\_LP\_ENTRY寄存器中的值设定。

芯片返回正常状态时所采用的工作模式和输出电压由VREG\_LP\_EXIT寄存器中的值设定。寄存器中包含一个额外的MODE字段，用以选择低功耗模式。

必须在请求转换至低功耗状态之前由软件写入寄存器值，因为转换期间及之后软件将不运行。实际的低功耗状态转换由电源管理器负责处理。芯片恢复到正常状态后，软件即可运行并直接控制调节器。VREG寄存器的数值反映了芯片恢复正常状态后，稳压器当前的工作模式和输出电压。

### **⚠ CAUTION**

Low-power mode should only be used when the regulator is providing the chip's digital core supply (**DVDD**) because the regulator's low-power output is connected to **DVDD** on chip.

#### 6.3.4. Status

To determine the status of the regulator, read the **VREG\_STS** register, which contains two fields:

- **VOUT\_OK** indicates whether the voltage regulator's output is being correctly regulated. At power-on, **VOUT\_OK** remains low until the regulator has started up and the output voltage reaches the **VOUT\_OK** assertion threshold (**VOUT\_OK<sub>TH,ASSERT</sub>**). It then remains high until the voltage drops below the **VOUT\_OK** de-assertion threshold (**VOUT\_OK<sub>TH,DEASSERT</sub>**), remaining low until the output voltage is above the assertion threshold again. **VOUT\_OK<sub>TH,ASSERT</sub>** is nominally 90% of the selected output voltage, 0.99 V if the selected output voltage is 1.1 V, and **VOUT\_OK<sub>TH,DEASSERT</sub>** is nominally 87% of the selected output voltage, 0.957 V if the selected output voltage is 1.1 V. See [Section 14.9.6](#) for details.
- **STARTUP** is high when the regulator is starting up, and remains high until the regulator's operating mode or output voltage are changed, either by software or the Power Manager

Adjusting the output voltage to a higher voltage will cause **VOUT\_OK** to go low until the assertion threshold for the higher voltage is reached. **VOUT\_OK** will also go low if the regulator is placed in high-impedance mode.

#### 6.3.5. Current limit

The voltage regulator includes a current limit to prevent the load current exceeding the maximum rated value. The output voltage won't be regulated and will drop below the selected value when the current limit is active. See [Section 14.9.6](#) for details.

#### 6.3.6. Over temperature protection

The voltage regulator will terminate regulation and disable its power transistors, if the transistor junction temperature rises above a threshold set by the **HT\_TH** field in the **VREG\_CTRL** register. The regulator will restart regulation when the transistor junction temperature drops to approximately 20°C below the temperature threshold.

#### 6.3.7. Application circuit

The regulator requires two external power supplies, the input supply (**VREG\_VIN**), and a separate low noise supply for its analogue control circuits (**VREG\_AVDD**). **VREG\_VIN** must be in the range 2.7 V to 5.5 V, and **VREG\_AVDD** must be in the range 3.135 V to 3.63 V.

If **VREG\_VIN** is limited to the range 3.135 V to 3.63 V, a single combined supply can be used for both **VREG\_VIN** and **VREG\_AVDD**. This approach is shown in [Figure 19](#). Take care to minimise noise on **VREG\_AVDD**.

### ⚠ 警告

低功耗模式应仅在稳压器为芯片数字核心电源（**DVDD**）供电时使用，因为稳压器的低功耗输出连接至芯片上的 **DVDD** 端。

### 6.3.4. 状态

要确定稳压器的状态，请读取包含两个字段的VREG\_STS寄存器：

- **VOUT\_OK**指示电压稳压器的输出电压是否被正确调节。上电时，**VOUT\_OK**保持低电平，直到稳压器启动且输出电压达到**VOUT\_OK**断言阈值（**VOUT\_OK<sub>TH.ASSERT</sub>**）。随后，**VOUT\_OK**保持高电平，直到电压降至**VOUT\_OK**取消断言阈值（**VOUT\_OK TH.DEASSERT**）以下，此后保持低电平，直到输出电压再次超过断言阈值。**VOUT\_OK TH.ASSERT**名义值为所选输出电压的90%；若所选输出电压为1.1 V，则该值为0.99 V。**VOUT\_OK<sub>TH.DEASSERT</sub>**名义值为所选输出电压的87%；若所选输出电压为1.1 V，则为0.957 V。详见第14.9.6节。
- 当稳压器启动时，**STARTUP**信号为高电平，并保持高电平，直到通过软件或电源管理器更改稳压器的工作模式或输出电压。

将输出电压调整至更高电压时，**VOUT\_OK**信号将变为低电平，直至达到该更高电压的断言阈值。如果稳压器处于高阻抗模式，**VOUT\_OK**信号同样会变为低电平。

### 6.3.5. 电流限制

电压稳压器包含电流限制功能，以防止负载电流超过最大额定值。当电流限制启动时，输出电压将失去调节并低于所选值。详见第14.9.6节。

### 6.3.6. 过温保护

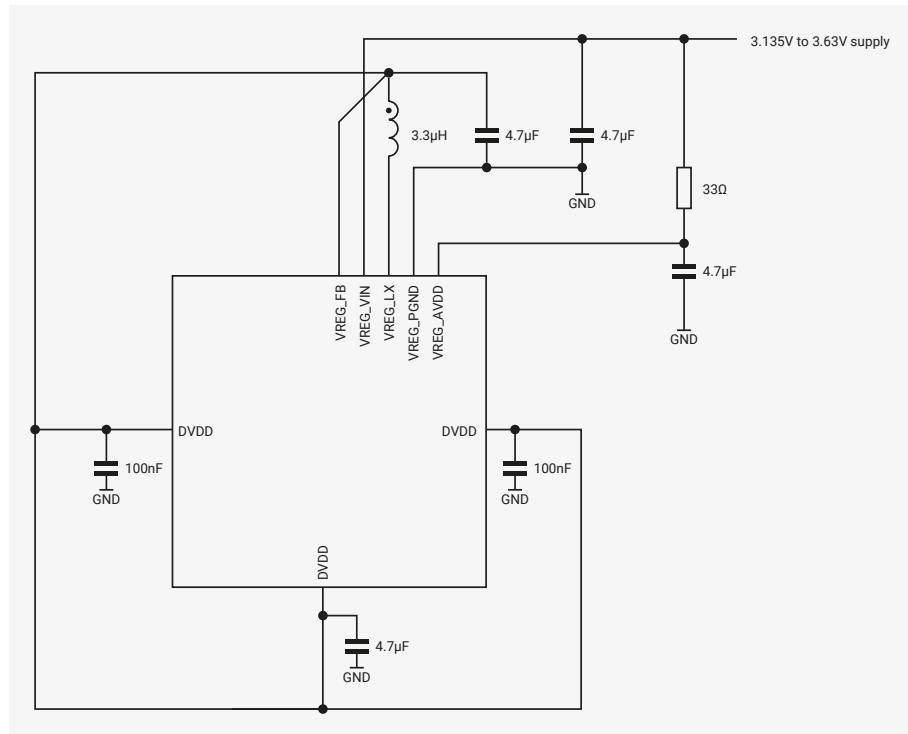

若晶体管结温超过VREG\_CTRL寄存器中 **HT\_TH** 字段设定的阈值，稳压器将终止调节并关闭其功率晶体管。当晶体管结温下降至该温度阈值以下约20°C时，稳压器将恢复调节。

### 6.3.7. 应用电路

稳压器需要两个外部电源，输入电源（**VREG\_VIN**）和供模拟控制电路的独立低噪声电源（**VREG\_AVDD**）。**VREG\_VIN**必须在2.7 V至5.5 V范围内，且**VREG\_AVDD**必须在3.135 V至3.63 V范围内。

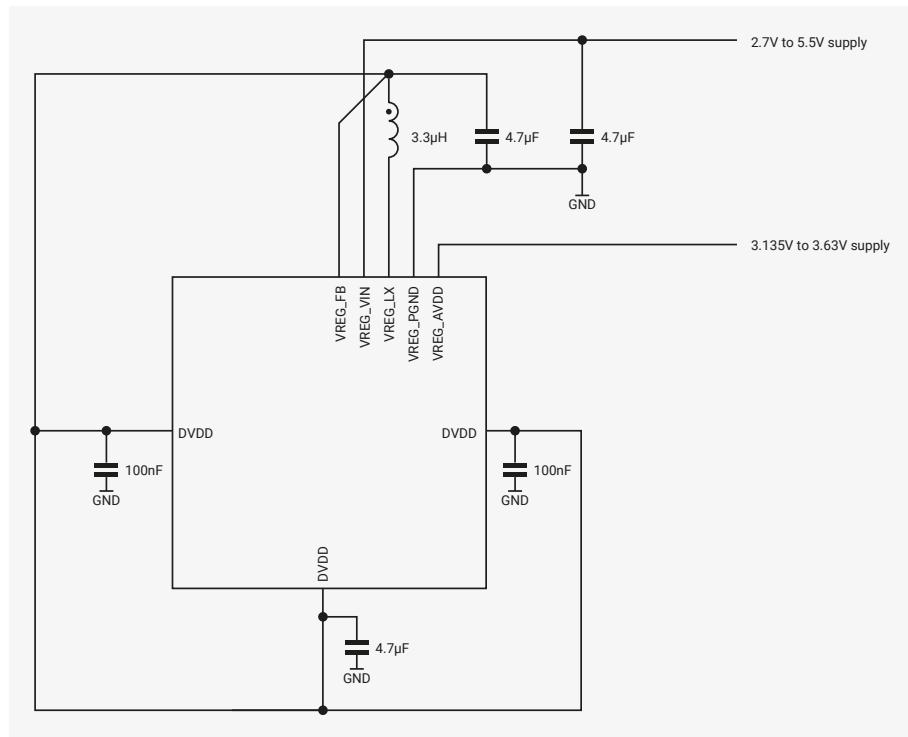

如果 **VREG\_VIN** 被限制在3.135 V至3.63 V范围内，则可以使用单一组合电源为**VREG\_VIN**和**VREG\_AVDD**供电。该方案如图19所示。请注意最大限度地减少 **VREG\_AVDD** 上的噪声。

Figure 19. Core voltage regulator with combined supplies

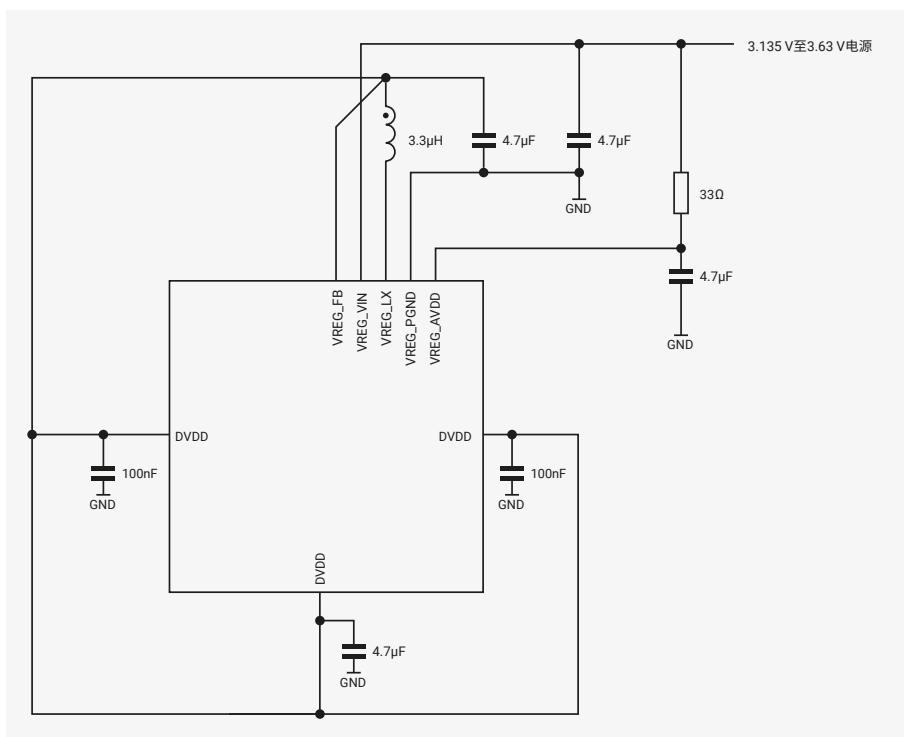

Alternatively, to support input voltages above 3.63 V, **VREG\_VIN** and **VREG\_AVDD** can be powered separately. This is shown in Figure 20.

Figure 20. Core voltage regulator with separate supplies

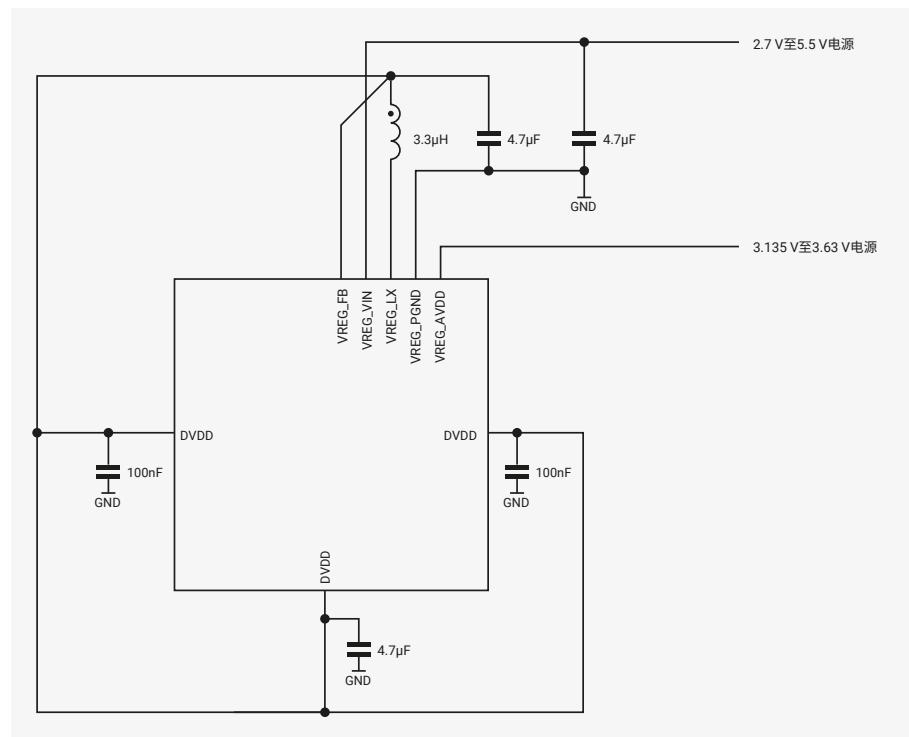

If the digital core supply (DVDD) is powered from an external 1.1V supply, the on-chip regulator can be disabled and the application circuit simplified. Power must still be provided on the regulator's analogue supply (**VREG\_AVDD**) and input supply (**VREG\_VIN**) to power the chip's power-on reset and brown-out detection blocks. But the inductor can be omitted and only a single input capacitor is required. Connect **VREG\_FB** directly to ground. This is shown in Figure 21.

图19 带组合  
电源的核心电压调  
节器

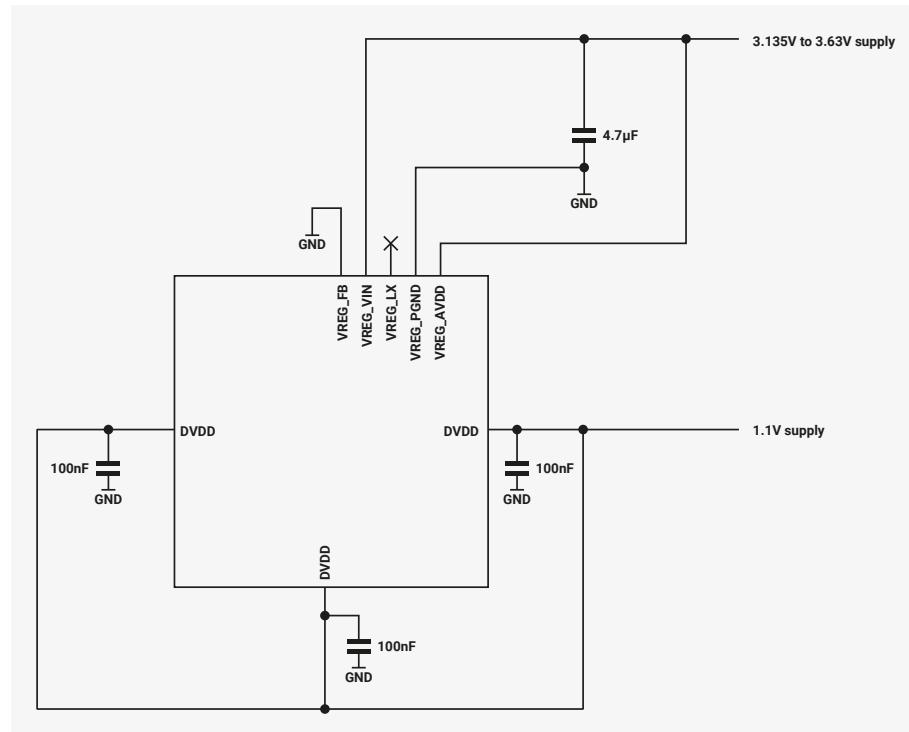

或者，为支持高于3.63 V的输入电压，**VREG\_VIN**和**VREG\_AVDD**可分别供电。如图20所示。

图20。带独  
立电源的核心电压  
调节器

若数字核心供电（DVDD）由外部1.1V电源提供，片上调节器可被禁用，从而简化应用电路。但仍需为调节器的模拟电源（**VREG\_AVDD**）及输入电源（**VREG\_VIN**）供电，以驱动芯片的上电复位和欠压检测电路。电感器可省略，仅需一个输入电容。将**VREG\_FB**直接接地。如图21所示。

Figure 21. External core supply with on-chip regulator disabled.

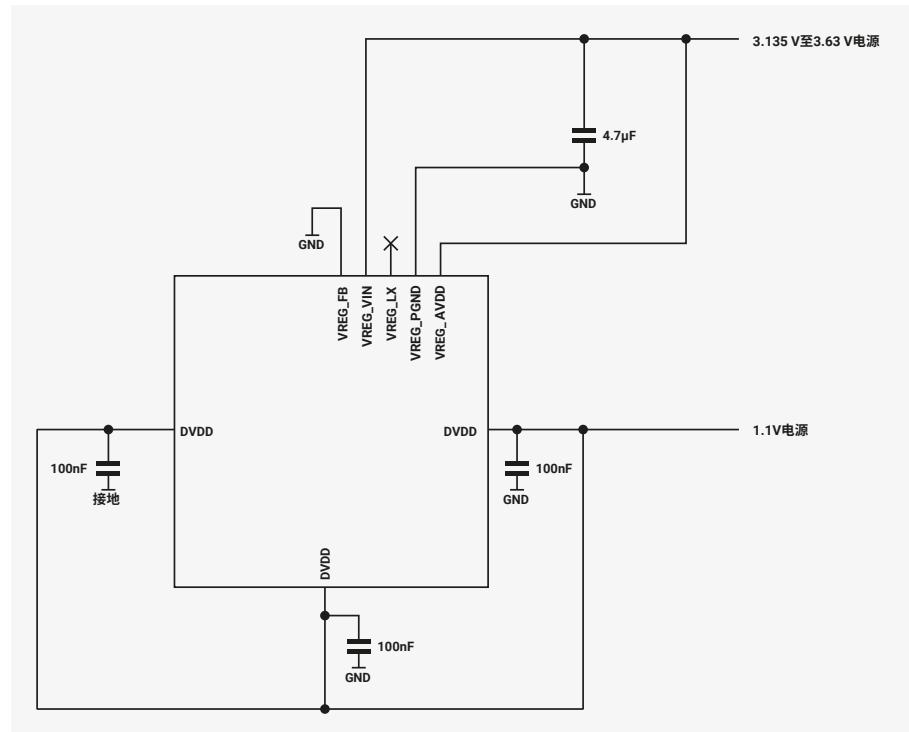

The on-chip regulator will still power on as soon as `VREG_VIN` and `VREG_AVDD` are available, but can be shut down under software control after the chip is out of reset. This is a safe mode of operation, though the regulator will consume approximately 400  $\mu$ A until it's shut down. The regulator should be shut down by writing a 1 to the `VREG` register's HIZ field.

### 6.3.8. External components and PCB layout requirements

The most critical part of an RP2350 PCB layout is the core voltage regulator. This should be placed first on any board design and these guidelines must be strictly followed.

图21。禁用片上  
调节器的外部核  
心供电。

只要 `VREG_VIN` 和 `VREG_AVDD` 可用，片上调节器将自动上电；但芯片复位完成后，可通过软件控制关闭其工作。这是安全的操作模式，但稳压器在关闭之前将消耗大约  $400 \mu\text{A}$  的电流。应通过向 `VREG` 寄存器的 `HIZ` 字段写入 1 来关闭稳压器。

### 6.3.8. 外部元件及PCB布局要求

RP2350 PCB 布局中最关键的部分是核心电压稳压器。该部分应优先放置于任何电路板设计中，且必须严格遵守相关指导原则。

Figure 22. Regulator section of the Raspberry Pi Pico 2 schematic. The nets highlighted in bold show the high switching current paths

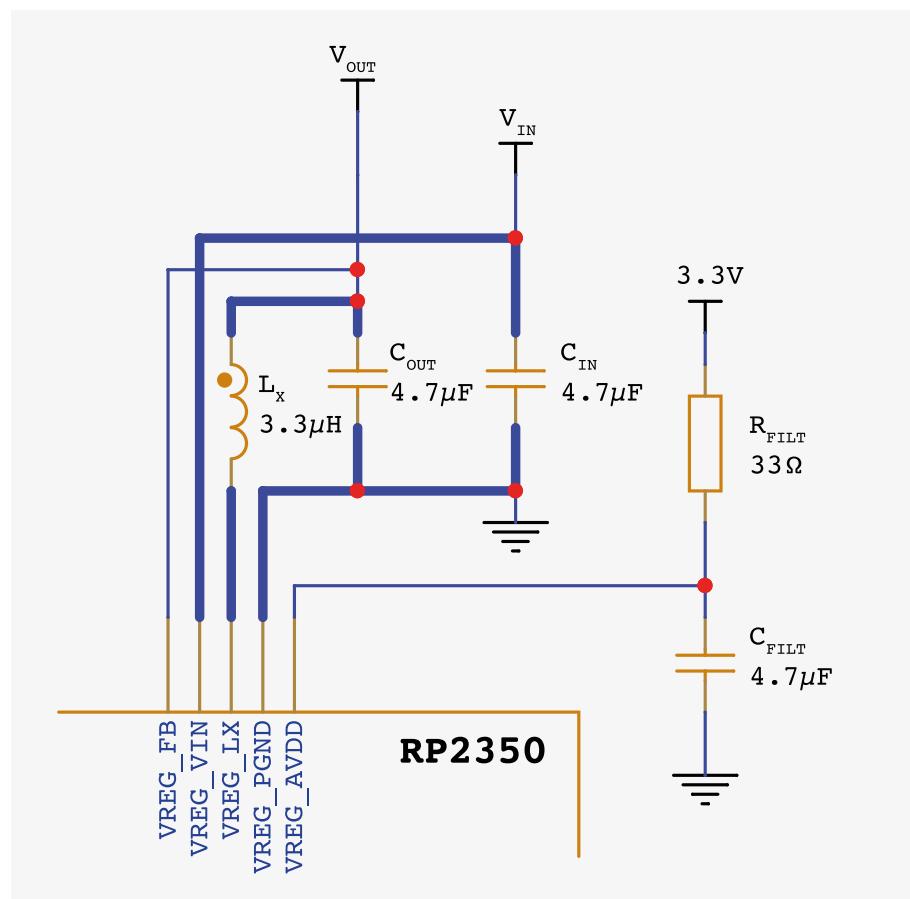

图 22。Raspberry  
Pi Pico 2 原  
理图中的稳压器  
部分。加粗显示

。

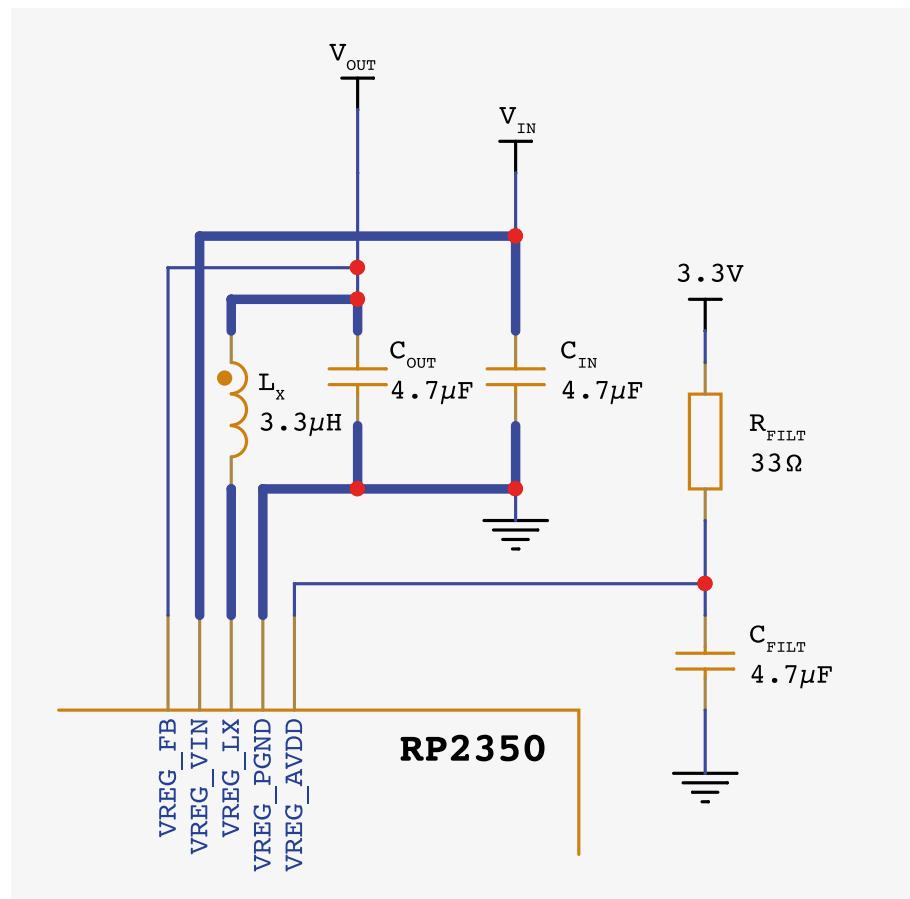

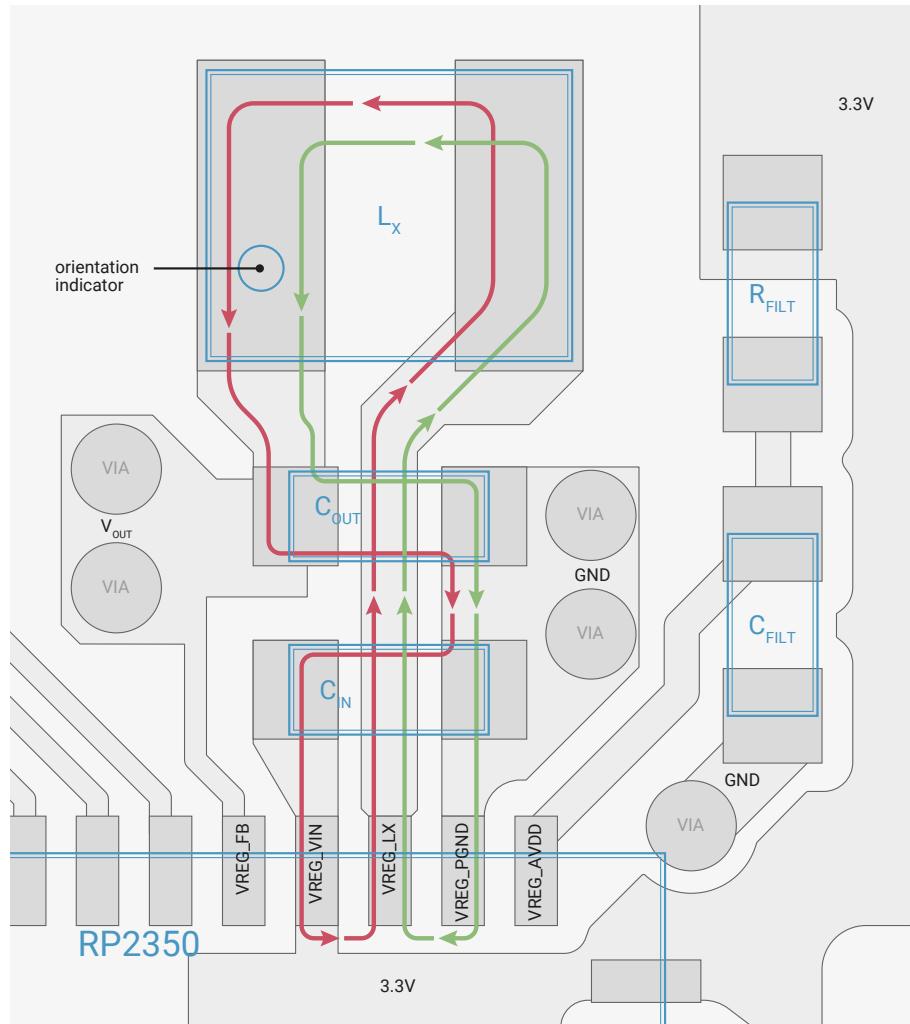

Figure 23. Regulator section of the Raspberry Pi Pico 2 PCB layout showing the high current paths for each of the regulator's switching phases. The AOTA-B201610S3R3-101-T inductor's case size is 0806 (2016 metric), the resistor and capacitors are 0402 (1005 metric)

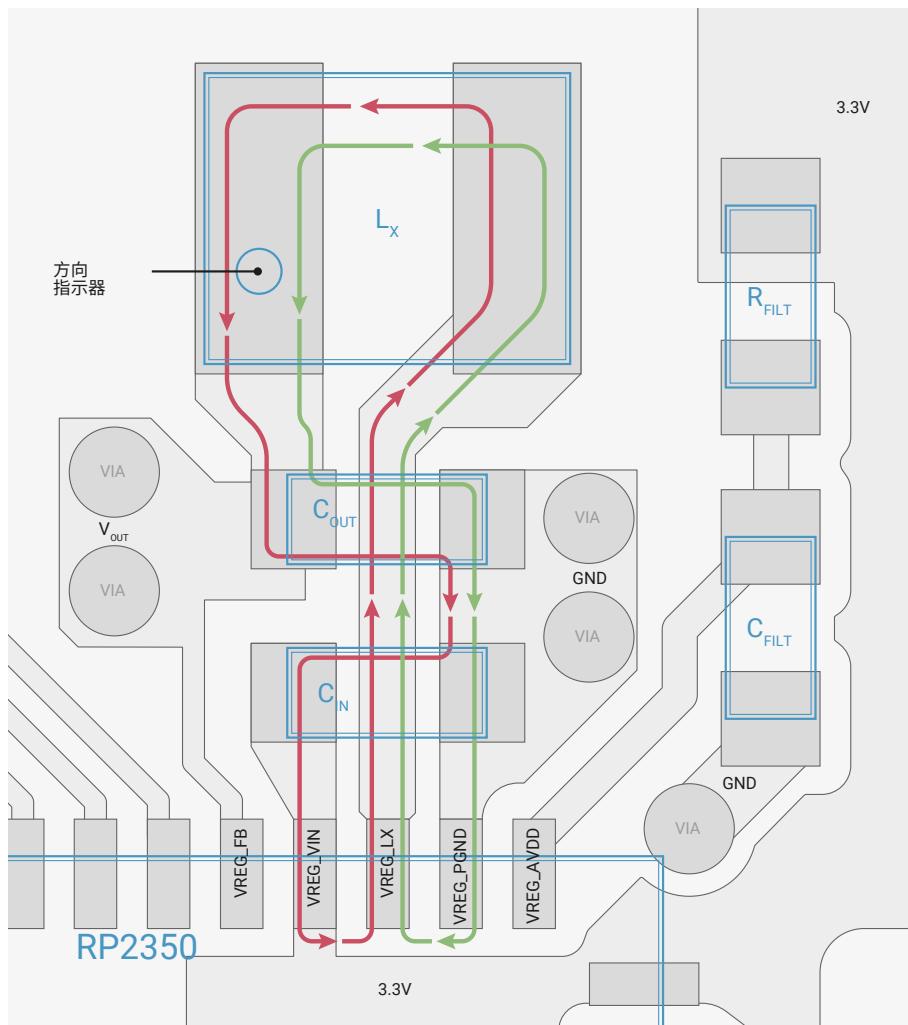

Designers should follow the above schematic [Figure 22](#) and layout [Figure 23](#) as closely as possible as this has had the most verification and is considered our best practice layout. This circuit design is present on the Raspberry Pi Pico 2 and RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#)) and both of these designs are made available in either Cadence Allegro or Kicad formats respectively. [Figure 23](#) shows the regulator layout on the top layer of the Raspberry Pi Pico 2 PCB. The bottom layer under the regulator is a ground plane that connects to the QFN GND central pad.

### 6.3.8.1. Layout recommendations

- [VREG\\_AVDD](#) is a noise sensitive signal and must be RC filtered as per [Figure 22](#).
  - Avoid doing anything that might couple noise into [VREG\\_AVDD](#).
  - $C_{IN}$  needs its own separate GND via / low impedance path back to the RP2350 GND pad.
- The red and green arrows in [Figure 23](#) show the high current paths for each of the regulator's switching phases. It is critical keep the loop area of these current paths as small and low-impedance as possible, while also keeping them isolated (i.e. only connect to main GND at one point).
  - Follow this layout as closely as possibly.
  - Don't place any of  $C_{IN}/L_x/C_{OUT}$  on the opposite side of the PCB.
- Reduce parasitics on the [VREG\\_LX](#) node.
- On the top layer make sure to cut away any extra copper underneath the inductor, cut back copper near the [VREG\\_LX](#) trace where possible.

图 23。Raspberry Pi Pico 2 PCB  
布局中的稳压器部分，显示了稳压器各开关相的高电流路径。A

101电感的封装  
尺寸为0806 (201  
6公制)，电阻和电  
容封装为0402 (1  
005公制)

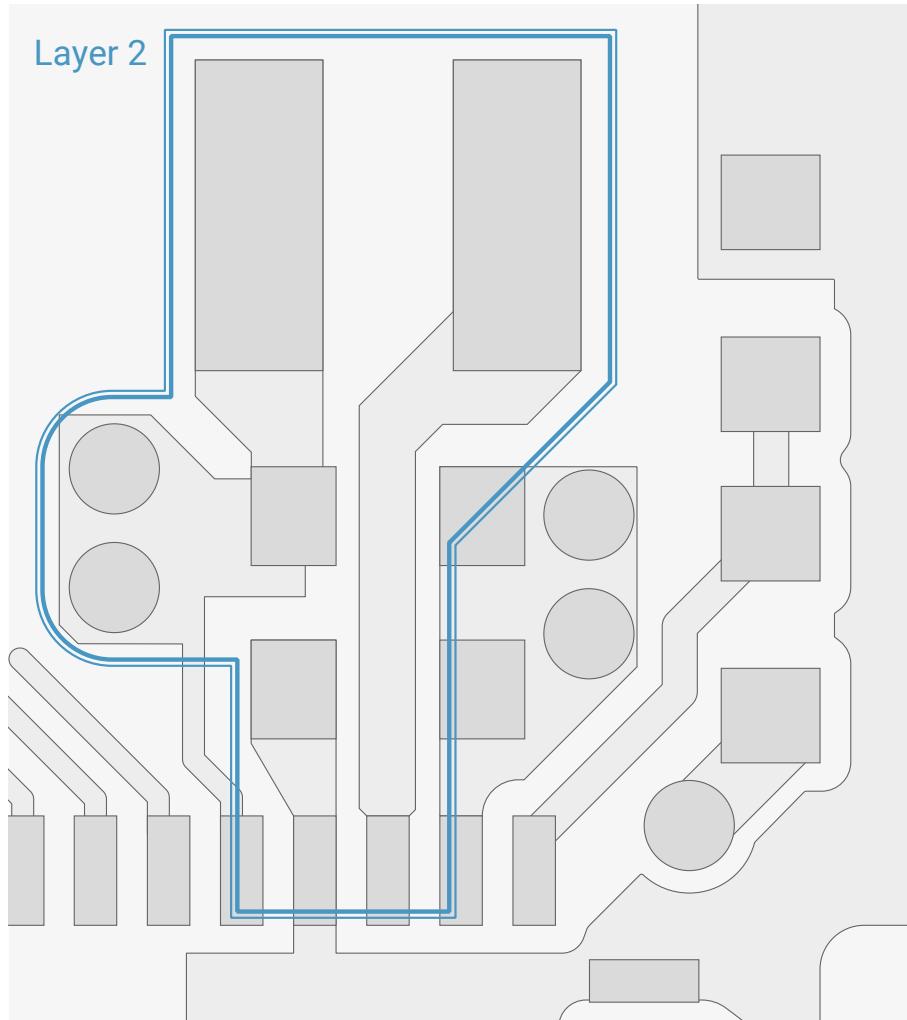

设计人员应尽可能严格遵循上述示意图图22及布局图23，因为这些图经过最充分的验证，且被视为我们的最佳实践布局方案。本电路设计应用于Raspberry Pi Pico 2及RP2350参考设计（详见RP2350硬件设计，极简设计示例），这两种设计分别以Cadence Allegro与Kicad格式提供。图23展示了Raspberry Pi Pico 2 PCB顶层的稳压器布局。稳压器下方的底层为接地平面，连接至QFN封装的GND中心焊盘。

### 6.3.8.1. 布局建议

- VREG\_AVDD 为噪声敏感信号，必须按照图22进行RC滤波。
  - 避免做任何可能将噪声耦合至 VREG\_AVDD 的行为。
  - C<sub>IN</sub> 需设有独立的接地通孔或低阻抗路径，直接连接至RP2350接地焊盘。
- 图23中红色和绿色箭头标示了各稳压器开关阶段的高电流路径。务必保持这些电流路径的回路面积尽可能小且低阻抗，且保持隔离（即仅在单一节点连接至主接地）。
  - 请尽可能严格遵循此布局。
  - 请勿将任何C<sub>IN</sub>/L<sub>x</sub>/C<sub>OUT</sub>元件安置于PCB背面。
- 降低 VREG\_LX 节点上的寄生效应。
- 在顶层，务必切除电感器下方多余铜箔，并尽可能切除靠近 VREG\_LX 走线的铜箔。

- For a multi-layer board (4 or more layers) please cut away any copper immediately underneath  $L_x/VREG\_LX$  node. For example, [Figure 24](#) illustrates this.
- The GND via placement is critical.
  - There must be a short-as-possible, low impedance GND path back to the Raspberry Pi Pico 2 QFN GND pad from the high-current GND at one single point (using 2 adjacent vias to reduce the impedance).
  - $C_{FILT}$  must also have a low impedance and short-as-possible path back to the QFN GND pad (don't share any GND vias with the  $C_{IN}/C_{OUT}$  high current GND).
- The VREG\_FB pin should be fed from the output of  $C_{OUT}$ , avoiding routing directly underneath  $L_x$ .
- $C_{OUT}$  is critical for regulator performance and EMI. It must be placed between  $VREG\_VIN$  and  $VREG\_PGND$  as close to the pins as practically possible.
  - In addition to  $C_{OUT}$ , for best performance we recommend a second 4.7 $\mu$ F capacitor is used on the  $V_{OUT}$  net, located on the bottom edge of the package (DVDD pin 23 on the QFN-60). Don't place this near  $L_x/C_{OUT}$ .

*Figure 24. Cut-out beneath LX/VREG\_LX net on layer 2 of 4 (or more) layer PCBs*

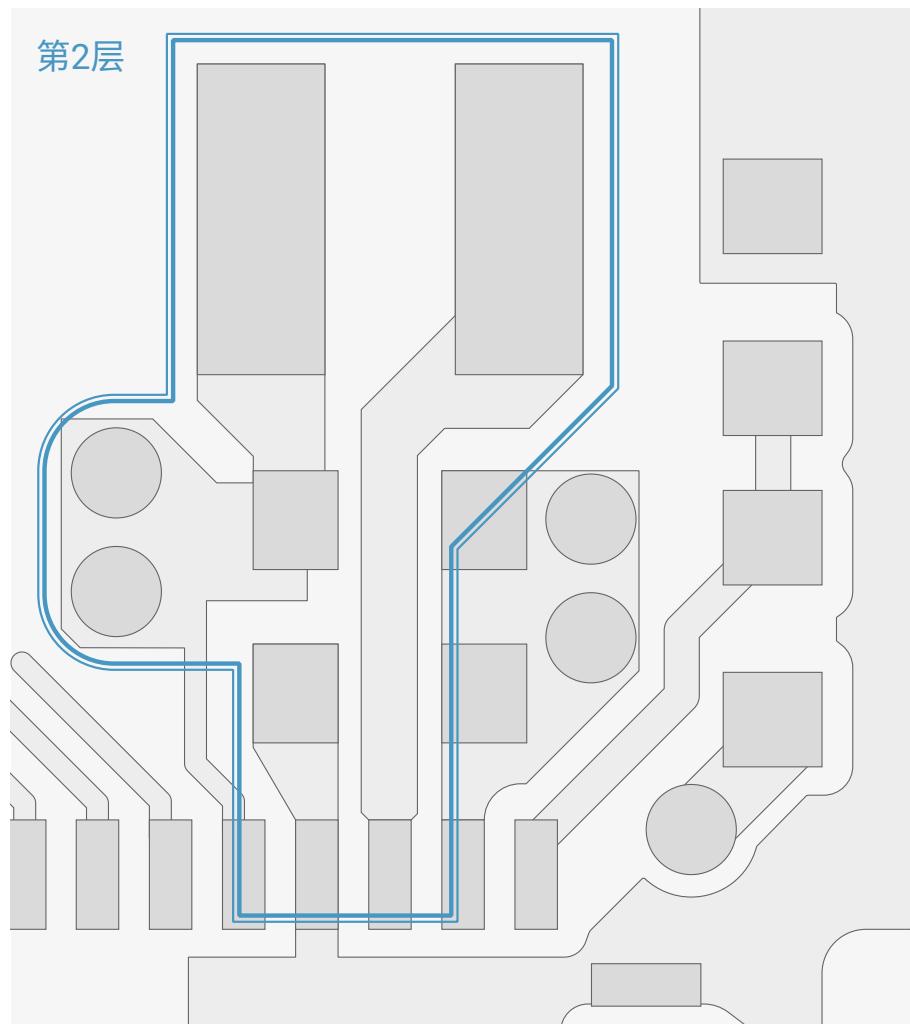

### 6.3.8.2. Component values

- $C_{IN}$  should be at least 4.7 $\mu$ F and have a maximum parasitic resistance of 50m $\Omega$ .
- $C_{OUT}$  must be 4.7 $\mu$ F  $\pm$ 20% with a maximum parasitic resistance of 250m $\Omega$  and a maximum inductance of 6nH.
- $L_x$  must be fully shielded, 3.3 $\mu$ H  $\pm$ 20% and with a maximum DC resistance of 250m $\Omega$ . Saturation current should be at least 1.5A. The inductor must be marked for polarity (see [Figure 25](#)) and placed on the layout as indicated in [Figure 23](#). As discussed below, we recommend the [AOTA-B201610S3R3-101-T](#).

- 对于四层及以上多层板，请切除 $L_x/VREG\_LX$ 节点正下方的所有铜箔。例如，图24展示了这一点。
- 接地过孔的位置至关重要。
  - 必须确保从高电流接地点到Raspberry Pi Pico 2 QFN接地焊盘的接地路径尽可能短且低阻抗（采用两个相邻的过孔以降低阻抗）。
  - 滤波电容 $C_{FILT}$ 也必须有低阻抗且尽可能短的回流路径至QFN接地焊盘（不得与高电流输入/输出电容 $C_{IN}/C_{OUT}$ 共用任何接地过孔）。
- $VREG\_FB$ 引脚应从 $C_{OUT}$ 的输出端供电，避免布线直接经过 $L_x$ 下方。
- $C_{OUT}$ 对稳压器性能和电磁干扰控制至关重要，应置于 $VREG\_VIN$ 与 $VREG\_PGND$ 之间，并尽可能靠近引脚。
  - 除 $C_{OUT}$ 外，为获得最佳性能，我们建议在 $V_{OUT}$ 线上再使用一个 $4.7\mu F$ 的电容。位于封装底部边缘（QFN-60封装上的DVDD引脚23）。请勿将此处置于 $L_x/C_{OUT}$ 附近。

图24。四层（或更多层）PCB的第2层 $L_x/VREG\_LX$ 网络下方的开槽

### 6.3.8.2. 元件数值

- $C_{IN}$  应不少于 $4.7\mu F$ ，且最大寄生电阻不得超过 $50m\Omega$ 。
- $C_{OUT}$  必须为 $4.7\mu F \pm 20\%$ ，最大寄生电阻不超过 $250m\Omega$ ，最大电感不超过 $6nH$ 。
- $L_x$ 必须完全屏蔽，电感值为 $3.3\mu H \pm 20\%$ ，最大直流电阻不超过 $250m\Omega$ 。饱和电流应至少为 $1.5A$ 。电感须标注极性（见图25），并按图23所示进行布局。如以下所述，我们推荐AOTA-B201610S3R3-101-T型号。

### 6.3.8.3. Regulator sensitivities

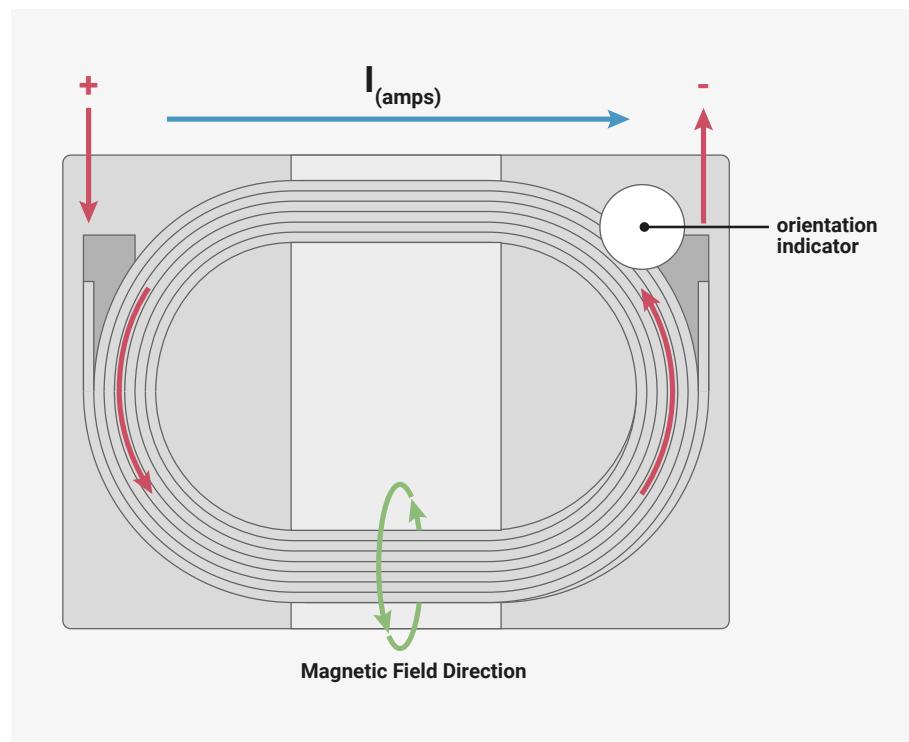

The RP2350 regulator has a few sensitivities:

- The **VREG\_AVDD** supply is noise sensitive.
- Efficiency is quite sensitive to inductance roll-off with inductor current, so an inductor with low roll-off is required for best operation (generally the higher saturation current the better).
- Even with nominally fully shielded inductors, leakage magnetic field coupling into the loop formed by the output **VREG\_LX** node through the inductor and output capacitor ( $C_{OUT}$ ) seems to affect the regulator control loop and output voltage. Field orientation (and hence inductor orientation) matters - the inductor has to be the right way around to make sure the regulator operates properly especially at higher output currents and for higher load transients. This necessitates an inductor with marked polarity.

To meet the above requirements, Raspberry Pi have worked with Abracor to create a custom 2.0×1.6mm 3.3 $\mu$ H polarity-marked inductor, part number [AOTA-B201610S3R3-101-T](#) (see [Figure 25](#) and [Figure 25](#)). These will be available in general distribution in time, but for now please contact Raspberry Pi to request samples / production volumes.

Raspberry Pi is still working with the regulator IP vendor to fully verify and qualify the regulator and custom inductor.

*Figure 25. AOTA-B201610S3R3-101-T inductor with orientation marking, showing current and magnetic field directions*

### 6.3.8.3. 稳压器灵敏度

RP2350 稳压器具有若干灵敏之处：

- **VREG\_AVDD** 电源对噪声极为敏感。
- 效率对电感电流引起的电感衰减非常敏感，因此需选用低衰减的电感。  
以确保最佳运行效果（通常饱和电流越高效果越佳）。
- 即使使用标称完全屏蔽的电感，泄漏磁场通过电感和输出电容（COUT）形成的输出节点**VREG\_LX**回路耦合，仍可能影响稳压器的控制回路及输出电压。磁场方向（因此电感方向）至关重要——电感必须正确安装，才能确保稳压器在较高输出电流和较大负载瞬变下正常工作。这要求电感具有明确的极性标识。

为满足上述要求，Raspberry Pi 与 Abraccon 合作，开发了一款定制的 $2.0 \times 1.6\text{mm}$   $3.3\mu\text{H}$ 带极性标记电感，型号为AOTA-B2 01610S3R3-101-T（见图25）。这些产品将在适当时间普遍发行，但目前请联系 Raspberry Pi 以申请样品或批量生产。

Raspberry Pi 仍在与稳压器 IP 供应商合作，全面验证并鉴定稳压器及定制电感器。

### 6.3.9. List of registers

The voltage regulator shares a register address space with other power management subsystems in the always-on domain. This address space is referred to as **POWMAN** elsewhere in this document, and a complete list of **POWMAN** registers is provided in [Section 6.4](#). For reference information on **POWMAN** registers associated with the voltage regulator is repeated here.

The **POWMAN** registers start at a base address of **0x40100000** (defined as **POWMAN\_BASE** in the SDK).

- [VREG\\_CTRL](#)
- [VREG\\_STS](#)
- [VREG](#)
- [VREG\\_LP\\_ENTRY](#)
- [VREG\\_LP\\_EXIT](#)

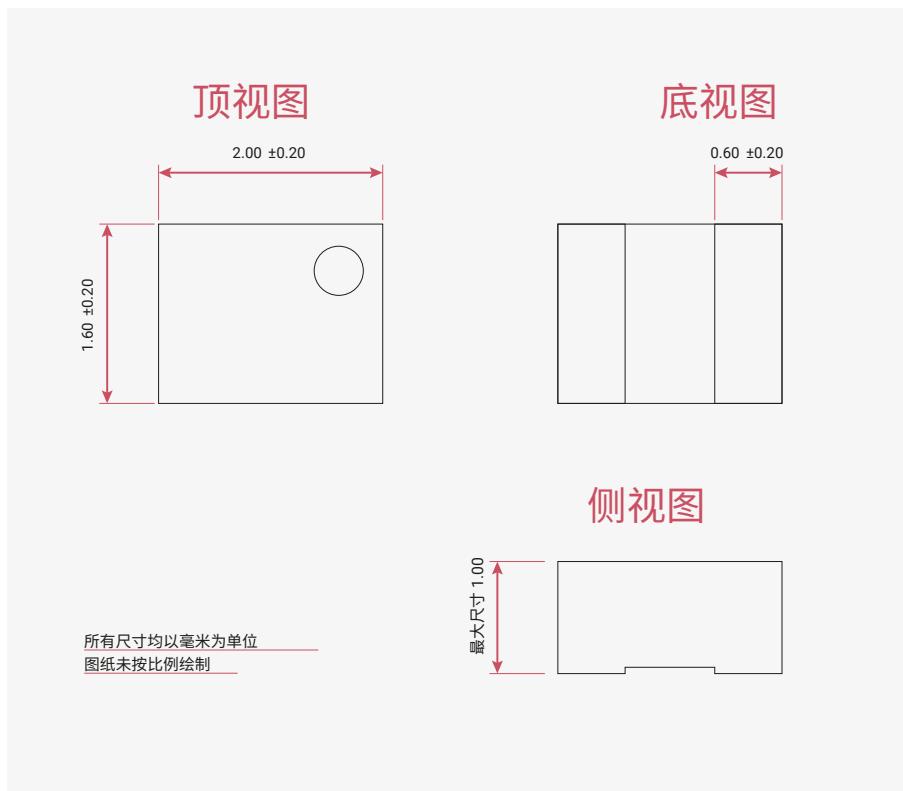

## 6.4. Power management (POWMAN) registers

Password-protected POWMAN registers require a password (**0x5AFE**) to be written to the top 16 bits to enable the write operation. This protects against accidental writes that could crash the chip untraceably. Writes to protected registers that don't include the password are ignored, setting a flag in the **BADPASSWD** register. Reads from protected registers don't return the password, to protect against erroneous read-modify-write operations.

Protected registers obviously don't have writeable fields in the top 16 bits, however they may have read-only fields in that range.

All registers with address offsets up to and including **0x000000ac** are password protected. Therefore, the following writeable registers are unprotected and have 32-bit write access:

### 6.3.9. 寄存器列表

稳压器与始终通电域内其他电源管理子系统共享寄存器地址空间。该地址空间在本文件其他部分称为 **POWMAN**，**POWMAN** 寄存器完整列表详见第 6.4 节。此处重复列出与稳压器相关的 **POWMAN** 寄存器参考信息。

**POWMAN** 寄存器的基址起始于 0x40100000（在 SDK 中定义为 **POWMAN\_BASE**）。

- [VREG\\_CTRL](#)
- [VREG\\_STS](#)
- [VREG](#)
- [VREG\\_LP\\_ENTRY](#)
- [VREG\\_LP\\_EXIT](#)

## 6.4. 电源管理（POWMAN）寄存器

受密码保护的 **POWMAN** 寄存器要求在高 16 位写入密码（0x5AFE）以启用写操作。此措施防止意外写入导致芯片无迹崩溃。对未包含密码的受保护寄存器的写操作将被忽略，并在 **BADPASSWD** 寄存器中置位标志。对受保护寄存器的读取不会返回密码，防止错误的读-改-写操作。

受保护寄存器在高 16 位显然无可写字段，但该范围内可能存在只读字段。

所有地址偏移量最高达且包括 0x000000ac 的寄存器均受密码保护。因此，以下可写寄存器不受保护，支持 32 位写访问：

- POWMAN\_SCRATCH0 → POWMAN\_SCRATCH7
- POWMAN\_BOOT0 → POWMAN\_BOOT3
- POWMAN\_INTR
- POWMAN\_INTE
- POWMAN\_INTF

Table 477. List of POWMAN registers

Offset	Name	Info
0x00	BADPASSWD	Indicates a bad password has been used
0x04	VREG_CTRL	Voltage Regulator Control
0x08	VREG_STS	Voltage Regulator Status
0x0c	VREG	Voltage Regulator Settings
0x10	VREG_LP_ENTRY	Voltage Regulator Low Power Entry Settings
0x14	VREG_LP_EXIT	Voltage Regulator Low Power Exit Settings
0x18	BOD_CTRL	Brown-out Detection Control
0x1c	BOD	Brown-out Detection Settings
0x20	BOD_LP_ENTRY	Brown-out Detection Low Power Entry Settings
0x24	BOD_LP_EXIT	Brown-out Detection Low Power Exit Settings
0x28	LPOSC	Low power oscillator control register.
0x2c	CHIP_RESET	Chip reset control and status
0x30	WDSEL	Allows a watchdog reset to reset the internal state of powman in addition to the power-on state machine (PSM). Note that powman ignores watchdog resets that do not select at least the CLOCKS stage or earlier stages in the PSM. If using these bits, it's recommended to set PSM_WDSEL to all-ones in addition to the desired bits in this register. Failing to select CLOCKS or earlier will result in the POWMAN_WDSEL register having no effect.
0x34	SEQ_CFG	For configuration of the power sequencer Writes are ignored while POWMAN_STATE_CHANGING=1

- POWMAN\_SCRATCH0 → POWMAN\_SCRATCH7
- POWMAN\_BOOT0 → POWMAN\_BOOT3
- POWMAN\_INTR
- POWMAN\_INTE
- POWMAN\_INTF

表477. POWMAN  
寄存器列表

偏移量	名称	说明
0x00	BADPASSWD	表示密码错误
0x04	VREG_CTRL	电压调节器控制
0x08	VREG_STS	电压调节器状态
0x0c	VREG	电压调节器设置
0x10	VREG_LP_ENTRY	电压调节器低功耗进入设置
0x14	VREG_LP_EXIT	电压调节器低功耗退出设置
0x18	BOD_CTRL	欠压检测控制
0x1c	BOD	欠压检测设置
0x20	BOD_LP_ENTRY	欠压检测低功耗进入设置
0x24	BOD_LP_EXIT	欠压检测低功耗退出设置
0x28	LPOSC	低功耗振荡器控制寄存器
0x2c	CHIP_RESET	芯片复位控制与状态
0x30	WDSEL	允许看门狗复位在电源开机状态机（PSM）之外，也复位powman的内部状态。 请注意，powman会忽略未至少选择PSM中CLOCKS阶段或更早阶段的看门狗复位。使用这些位时，建议将PSM_WDSEL设置为全1，并在该寄存器中设置所需位。如果未选择CLOCKS或更早阶段，POWMAN_WDSEL寄存器将不起作用。
0x34	SEQ_CFG	用于配置电源时序器 当POWMAN_STATE_CHANGING=1时，写入操作将被忽略。

Offset	Name	Info
0x38	STATE	<p>This register controls the power state of the 4 power domains. The current power state is indicated in POWMAN_STATE_CURRENT which is read-only.</p> <p>To change the state, write to POWMAN_STATE_REQ.</p> <p>The coding of POWMAN_STATE_CURRENT &amp; POWMAN_STATE_REQ corresponds to the power states defined in the datasheet:</p> <ul style="list-style-type: none"> <li>bit 3 = SWCORE</li> <li>bit 2 = XIP cache</li> <li>bit 1 = SRAM0</li> <li>bit 0 = SRAM1</li> <li>0 = powered up</li> <li>1 = powered down</li> </ul> <p>When POWMAN_STATE_REQ is written, the POWMAN_STATE_WAITING flag is set while the Power Manager determines what is required. If an invalid transition is requested the Power Manager will still register the request in POWMAN_STATE_REQ but will also set the POWMAN_BAD_REQ flag. It will then implement the power-up requests and ignore the power down requests. To do nothing would risk entering an unrecoverable lock-up state. Invalid requests are: any combination of power up and power down requests any request that results in swcore being powered and xip unpowered If the request is to power down the switched-core domain then POWMAN_STATE_WAITING stays active until the processors halt. During this time the POWMAN_STATE_REQ field can be re-written to change or cancel the request. When the power state transition begins the POWMAN_STATE_WAITING_flag is cleared, the POWMAN_STATE_CHANGING flag is set and POWMAN register writes are ignored until the transition completes.</p>
0x3c	POW_FASTDIV	
0x40	POW_DELAY	power state machine delays
0x44	EXT_CTRL0	Configures a gpio as a power mode aware control output
0x48	EXT_CTRL1	Configures a gpio as a power mode aware control output
0x4c	EXT_TIME_REF	Select a GPIO to use as a time reference, the source can be used to drive the low power clock at 32kHz, or to provide a 1ms tick to the timer, or provide a 1Hz tick to the timer. The tick selection is controlled by the POWMAN_TIMER register.
0x50	LPOSC_FREQ_KHZ_INT	Informs the AON Timer of the integer component of the clock frequency when running off the LPOSC.
0x54	LPOSC_FREQ_KHZ_FRAC	Informs the AON Timer of the fractional component of the clock frequency when running off the LPOSC.
0x58	XOSC_FREQ_KHZ_INT	Informs the AON Timer of the integer component of the clock frequency when running off the XOSC.
0x5c	XOSC_FREQ_KHZ_FRAC	Informs the AON Timer of the fractional component of the clock frequency when running off the XOSC.
0x60	SET_TIME_63T048	
0x64	SET_TIME_47T032	

偏移量	名称	说明
0x38	状态	<p>该寄存器控制4个电源域的电源状态。 当前电源状态显示在只读的POWMAN_STATE_CURRENT寄存器中。 要更改状态，请写入POWMAN_STATE_REQ寄存器。 POWMAN_STATE_CURRENT和POWMAN_STATE_REQ的编码对应数据手册中定义的电源状态：</p> <p>bit 3 = SWCORE bit 2 = XIP cache bit 1 = SRAM0 bit 0 = SRAM1 0 = 已加电 1 = 已断电 写入 POWMAN_STATE_REQ 后， POWMAN_STATE_WAITING 标志被设置，电源管理器开始确定所需操作。若请求无效转换，电源管理器仍会在 POWMAN_STATE_REQ 中登记该请求，同时设置 POWMAN_BAD_REQ 标志。随后执行加电请求，忽略断电请求。无动作将导致进入不可恢复的死锁状态。无效请求包括：任何加电与断电请求的组合；任何导致 swcore 加电且 xip 断电的请求；若请求断电交换核心域，则 POWMAN_STATE_WAITING 保持激活，直至处理器停止。此期间，POWMAN_STATE_REQ 字段可被重写以更改或取消请求。当电源状态转换开始时，POWMAN_STATE_WAITING 标志将被清除，POWMAN_STATE_CHANGING 标志被置位，且在转换完成前，POWMAN 寄存器的写入操作将被忽略。</p>
0x3c	POW_FASTDIV	
0x40	POW_DELAY	电源状态机延时
0x44	EXT_CTRL0	将 GPIO 配置为电源模式感知的控制输出
0x48	EXT_CTRL1	将 GPIO 配置为电源模式感知的控制输出
0x4c	EXT_TIME_REF	选择一个 GPIO 作为时间参考源，该源可用于驱动 32kHz 的低功耗时钟，或为定时器提供 1ms 的滴答信号，或为定时器提供 1Hz 的滴答信号。滴答信号的选择由 POWMAN_TIMER 寄存器控制。
0x50	LPOSC_FREQ_KHZ_INT	在使用 LPOSC 作为时钟源运行时，通知 AON 定时器时钟频率的整数部分。
0x54	LPOSC_FREQ_KHZ_FRAC	在使用 LPOSC 作为时钟源运行时，通知 AON 定时器时钟频率的小数部分。
0x58	XOSC_FREQ_KHZ_INT	在使用 XOSC 作为时钟源运行时，通知 AON 定时器时钟频率的整数部分。
0x5c	XOSC_FREQ_KHZ_FRAC	当系统由XOSC供电时，向AON定时器报告时钟频率的小数部分。

## POWMAN: WDSEL Register

Offset: 0x30

### Description

Allows a watchdog reset to reset the internal state of powman in addition to the power-on state machine (PSM).

Note that powman ignores watchdog resets that do not select at least the CLOCKS stage or earlier stages in the PSM. If using these bits, it's recommended to set PSM\_WDSEL to all-ones in addition to the desired bits in this register. Failing to select CLOCKS or earlier will result in the POWMAN\_WDSEL register having no effect.

Table 490. WDSEL Register

Bits	Description	Type	Reset
31:13	Reserved.	-	-
12	<b>RESET_PSM:</b> If set to 1, a watchdog reset will run the full power-on state machine (PSM) sequence From a user perspective it is the same as setting RSM_WDSEL_PROC_COLD From a hardware debug perspective it has the same effect as a reset from a glitch detector	RW	0x0

## POWMAN: WDSEL 寄存器

偏移量: 0x30

### 描述

允许看门狗复位在电源开机状态机（PSM）之外，也复位powman的内部状态。

请注意，powman会忽略未至少选择PSM中CLOCKS阶段或更早阶段的看门狗复位。使用这些位时，建议将PSM\_WDSEL设置为全1，并在该寄存器中设置所需位。如果未选择CLOCKS或更早阶段，POWMAN\_WDSEL寄存器将不起作用。

## POWMAN: STATE Register

Offset: 0x38

### Description

This register controls the power state of the 4 power domains.

The current power state is indicated in POWMAN\_STATE\_CURRENT which is read-only.

To change the state, write to POWMAN\_STATE\_REQ.

The coding of POWMAN\_STATE\_CURRENT & POWMAN\_STATE\_REQ corresponds to the power states defined in the datasheet:

bit 3 = SWCORE

bit 2 = XIP cache

bit 1 = SRAM0

bit 0 = SRAM1

0 = powered up

1 = powered down

When POWMAN\_STATE\_REQ is written, the POWMAN\_STATE\_WAITING flag is set while the Power Manager determines what is required. If an invalid transition is requested the Power Manager will still register the request in POWMAN\_STATE\_REQ but will also set the POWMAN\_BAD\_REQ flag. It will then implement the power-up requests and ignore the power down requests. To do nothing would risk entering an unrecoverable lock-up state. Invalid requests are: any combination of power up and power down requests any request that results in swcore being powered and xip unpowered If the request is to power down the switched-core domain then POWMAN\_STATE\_WAITING stays active until the processors halt. During this time the POWMAN\_STATE\_REQ field can be re-written to change or cancel the request. When the power state transition begins the POWMAN\_STATE\_WAITING\_flag is cleared, the POWMAN\_STATE\_CHANGING flag is set and POWMAN register writes are ignored until the transition completes.

位	描述	类型	复位

0	<b>HW_PWRUP_SRAM1</b> : 指定切换核从低功耗状态 (P1.xxx) 上电至高功耗状态 (P0.0xx) 时, SRAM1的电源状态。 0=上电 1=保持不变	读写	0x0

## POWMAN: 状态寄存器

偏移量: 0x38

### 描述

该寄存器控制4个电源域的电源状态。

当前电源状态显示在只读的POWMAN\_STATE\_CURRENT寄存器中。

要更改状态, 请写入POWMAN\_STATE\_REQ寄存器。

POWMAN\_STATE\_CURRENT和POWMAN\_STATE\_REQ的编码对应数据手册中定义的电源状态:

```

bit 3 = SWCORE
bit 2 = XIP cache
bit 1 = SRAM0
bit 0 = SRAM1
0 = 已加电
1 = 已断电

```

当写入POWMAN\_STATE\_REQ时, POWMAN\_STATE\_WAITING标志被置位, 电源管理器开始确定所需状态。若请求无效转换, 电源管理器仍会在POWMAN\_STATE\_REQ中登记该请求, 同时设置POWMAN\_BAD\_REQ标志。随后执行加电请求, 忽略断电请求。无动作将导致进入不可恢复的死锁状态。无效请求包括: 任何加电与断电请求的组合; 任何导致swcore加电且xip断电的请求; 若请求断电交换核心域, 则POWMAN\_STATE\_WAITING保持激活, 直至处理器停止。在此期间, POWMAN\_STATE\_REQ字段可以被重新写入以更改或取消请求。当电源状态转换开始时, POWMAN\_STATE\_WAITING标志将被清除, POWMAN\_STATE\_CHANGING标志被置位, 且在转换完成前, POWMAN寄存器的写入操作将被忽略。

## POWMAN: TIMER Register

Offset: 0x88

Table 512. TIMER  
Register

Bits	Description	Type	Reset
31:20	Reserved.	-	-
19	<b>USING_GPIO_1HZ</b> : Timer is synchronised to a 1hz gpio source	RO	0x0
18	<b>USING_GPIO_1KHZ</b> : Timer is running from a 1khz gpio source	RO	0x0
17	<b>USING_LPOSC</b> : Timer is running from lposc	RO	0x0
16	<b>USING_XOSC</b> : Timer is running from xosc	RO	0x0
15:14	Reserved.	-	-
13	<b>USE_GPIO_1HZ</b> : Selects the gpio source as the reference for the sec counter. The msec counter will continue to use the lposc or xosc reference.	RW	0x0
12:11	Reserved.	-	-
10	<b>USE_GPIO_1KHZ</b> : switch to gpio as the source of the 1kHz timer tick	SC	0x0
9	<b>USE_XOSC</b> : switch to xosc as the source of the 1kHz timer tick	SC	0x0
8	<b>USE_LPOSC</b> : Switch to lposc as the source of the 1kHz timer tick	SC	0x0
7	Reserved.	-	-
6	<b>ALARM</b> : Alarm has fired. Write to 1 to clear the alarm.	WC	0x0
5	<b>PWRUP_ON_ALARM</b> : Alarm wakes the chip from low power mode	RW	0x0
4	<b>ALARM_ENAB</b> : Enables the alarm. The alarm must be disabled while writing the alarm time.	RW	0x0
3	Reserved.	-	-
2	<b>CLEAR</b> : Clears the timer, does not disable the timer and does not affect the alarm. This control can be written at any time.	SC	0x0
1	<b>RUN</b> : Timer enable. Setting this bit causes the timer to begin counting up from its current value. Clearing this bit stops the timer from counting.  Before enabling the timer, set the POWMAN_LPOSC_FREQ* and POWMAN_XOSC_FREQ* registers to configure the count rate, and initialise the current time by writing to SET_TIME_63TO48 through SET_TIME_15TO0. You must not write to the SET_TIME_x registers when the timer is running.  Once configured, start the timer by setting POWMAN_TIMER_RUN=1. This will start the timer running from the LPOSC. When the XOSC is available switch the reference clock to XOSC then select it as the timer clock by setting POWMAN_TIMER_USE_XOSC=1	RW	0x0
0	<b>NONSEC_WRITE</b> : Control whether Non-secure software can write to the timer registers. All other registers are hardwired to be inaccessible to Non-secure.	RW	0x0

## POWMAN: PWRUP0 Register

表 511。  
ALARM\_TIME\_15T00  
寄存器

## POWMAN：TIMER 寄存器

偏移: 0x88

表 512。TIMER  
寄存器

位	描述	类型	复位
31:20	保留。	-	-
19	<b>USING_GPIO_1HZ</b> : 定时器同步至 1Hz GPIO 源	只读	0x0
18	<b>USING_GPIO_1KHZ</b> : 定时器运行于 1kHz GPIO 源	只读	0x0
17	<b>USING_LPOSC</b> : 定时器运行于 LPOSC	只读	0x0
16	<b>USING_XOSC</b> : 定时器运行于 XOSC	只读	0x0
15:14	保留。	-	-
13	<b>USE_GPIO_1HZ</b> : 选择 gpio 作为秒计数器的参考源。 毫秒计数器将继续使用 lposc 或 xosc 作为参考源。	读写	0x0
12:11	保留。	-	-
10	<b>USE_GPIO_1KHZ</b> : 切换至 gpio 作为 1kHz 定时器节拍源。	SC	0x0
9	<b>USE_XOSC</b> : 切换至 xosc 作为 1kHz 定时器节拍源。	SC	0x0
8	<b>USE_LPOSC</b> : 切换至 lposc 作为 1kHz 定时器节拍源。	SC	0x0
7	保留。	-	-
6	<b>ALARM</b> : 闹钟已触发。写入 1 以清除闹钟标志。	WC	0x0
5	<b>PWRUP_ON_ALARM</b> : 闹钟将芯片从低功耗模式唤醒。	读写	0x0
4	<b>ALARM_ENAB</b> : 启用闹钟功能。设置闹钟时间时，必须先禁用闹钟。	读写	0x0
3	保留。	-	-
2	<b>CLEAR</b> : 清除定时器计数，不禁用定时器且不影响闹钟状态。此控制位可随时写入。	SC	0x0
1	<b>RUN</b> : 定时器使能位。设置此位后，定时器将从当前计数值开始递增计数。清除此位将停止计时器计数。  在启用计时器之前，须设置 POWMAN_LPOSC_FREQ* 和 POWMAN_XOSC_FREQ* 寄存器以配置计数速率，并通过写入 SET_TIME_63T048 至 SET_TIME_15T00 寄存器初始化当前时间。计时器运行时，严禁写入 SET_TIME_X 寄存器。  配置完成后，通过设置 POWMAN_TIMER_RUN=1 启动计时器，使计时器自 LPOSC 开始计数。当 XOSC 可用时，将参考时钟切换至 XOSC，随后通过设置 POWMAN_TIMER_USE_XOSC=1 选择其为计时器时钟。	读写	0x0
0	<b>NONSEC_WRITE</b> : 控制非安全软件是否允许写入计时器寄存器。所有其他寄存器均被硬连线设定为非安全不可访问。	读写	0x0

## POWMAN：PWRUPO 寄存器

**Offset:** 0x8c**Description**

4 GPIO powerup events can be configured to wake the chip up from a low power state.

The pwrups are level/edge sensitive and can be set to trigger on a high/rising or low/falling event

The number of gpios available depends on the package option. An invalid selection will be ignored  
source = 0 selects gpio0

1. +

2. + source = 47 selects gpio47

**POWMAN: PWRUP1 寄存器**

偏移: 0x90

**描述**

可配置4个GPIO上电事件，用于从低功耗状态唤醒芯片。

上电事件对电平或边缘敏感，可设置为在高电平/上升沿或低电平/下降沿时触发。

GPIO 的数量取决于封装选项。无效选择将被忽略

source = 0 选择 gpio0

1. +

2. + source = 47 selects gpio47  
source = 48 selects qspi\_ss  
source = 49 selects qspi\_sd0  
source = 50 selects qspi\_sd1  
source = 51 selects qspi\_sd2  
source = 52 selects qspi\_sd3  
source = 53 selects qspi\_sclk  
level = 0 triggers the pwrup when the source is low  
level = 1 triggers the pwrup when the source is high

## POWMAN: BOOTDIS Register

Offset: 0xa8

### Description

Tell the bootrom to ignore the BOOT0..3 registers following the next RSM reset (e.g. the next core power down/up).

If an early boot stage has soft-locked some OTP pages in order to protect their contents from later stages, there is a risk that Secure code running at a later stage can unlock the pages by powering the core up and down.

This register can be used to ensure that the bootloader runs as normal on the next power up, preventing Secure code at a later stage from accessing OTP in its unlocked state.

Should be used in conjunction with the OTP BOOTDIS register.

Table 520. BOOTDIS  
Register

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>NEXT:</b> This flag always ORs writes into its current contents. It can be set but not cleared by software.  The BOOTDIS_NEXT bit is OR'd into the BOOTDIS_NOW bit when the core is powered down. Simultaneously, the BOOTDIS_NEXT bit is cleared. Setting this bit means that the BOOT0..3 registers will be ignored following the next reset of the RSM by powman.  This flag should be set by an early boot stage that has soft-locked OTP pages, to prevent later stages from unlocking it by power cycling.	RW	0x0

## POWMAN: BOOTDIS 寄存器

偏移: 0xa8

### 描述

告知只读存储器忽略下一个 RSM 复位（例如，下一个核心断电/上电）后 BOOT0..3 寄存器的内容。

如果早期启动阶段已软锁定部分 OTP 页面以保护其内容免受后续阶段访问，存在安全代码在后续阶段通过断电重启核心来解锁这些页面的风险。

该寄存器可用于确保引导加载程序在下一次上电时正常运行，从而防止后续阶段的安全代码访问处于未锁定状态的OTP。

应与OTP BOOTDIS寄存器配合使用。

表520. BOOTDIS  
寄存器

位	描述	类型	复位
31:2	保留。	-	-
1	<b>NEXT:</b> 该标志写入操作总是与其当前内容做按位或（OR）操作。软件可以设置该位，但不能清除此位。  当核心断电时，BOOTDIS_NEXT 位会按位或（OR）进 BOOTDIS_NOW 位。 同时，BOOTDIS_NEXT 位会被清零。设置此位表示，在powman对 RSM 进行下一次复位后，BOOT0..3 寄存器将被忽略。  此标志应由具备软锁OTP页面功能的早期引导阶段设置，以防止后续阶段通过断电重启进行解锁。	读写	0x0

Bits	Description	Type	Reset
0	<b>NOW:</b> When powman resets the RSM, the current value of BOOTDIS_NEXT is OR'd into BOOTDIS_NOW, and BOOTDIS_NEXT is cleared.  The bootrom checks this flag before reading the BOOT0..3 registers. If it is set, the bootrom clears it, and ignores the BOOT registers. This prevents Secure software from diverting the boot path before a bootloader has had the chance to soft lock OTP pages containing sensitive data.	WC	0x0

## 6.5. Power reduction strategies

RP2350 retains the SLEEP and DORMANT states for dynamic power control from RP2040. It extends these states by introducing power domains ([Section 6.2.1](#)), which allow power to be removed from various components on chip, virtually eliminating the leakage currents, and allowing lower power modes to be supported.

**6.5. 电源降低策略**

RP2350 保留了 RP2040 用于动态功耗控制的睡眠 (SLEEP) 和休眠 (DORMANT) 状态，并通过引入电源域（第 6.2.1 节）对其进行了扩展，允许对芯片上的各个组件断电，几乎消除泄漏电流，从而支持更低功耗模式。

### 6.5.1. Top-level clock gates

Each clock domain (for example, the system clock) may drive a large number of distinct hardware blocks, not all of which might be required at once. To avoid unnecessary power dissipation, each individual endpoint of each clock (for example, the UART system clock input) may be disabled at any time.

Enabling and disabling a clock gate is glitch-free. If a peripheral clock is temporarily disabled, and subsequently re-enabled, the peripheral will be in the same state as prior to the clock being disabled. No reset or reinitialisation should be required.

Clock gates are controlled by two sets of registers: the `WAKE_ENx` registers (starting at `WAKE_EN0`) and `SLEEP_ENx` registers (starting at `SLEEP_EN0`). These two sets of registers are identical at the bit level, each possessing a flag to control each clock endpoint. The `WAKE_EN` registers specify which clocks are enabled whilst the system is awake, and the `SLEEP_EN` registers select which clocks are enabled while the processor is in the SLEEP state (Section 6.5.2).

The two processors do not have externally-controllable clock gates. Instead, the processors gate the clocks of their subsystems autonomously, based on execution of `WFI`/`WFE` instructions, and external Event and IRQ signals.

### 6.5.2. SLEEP state

RP2350 enters the SLEEP state when all of the following are true:

- Both processors are asleep (e.g. in a `WFE` or `WFI` instruction)
- The system DMA has no outstanding transfers on any channel

RP2350 exits the SLEEP state when either processor is awoken by an interrupt.

When in the SLEEP state, the top-level clock gates are masked by the `SLEEP_ENx` registers (starting at `SLEEP_EN0`), rather than the `WAKE_ENx` registers (starting at `WAKE_EN0`). This permits more aggressive pruning of the clock tree when the processors are asleep.

#### NOTE

Though it is possible for a clock to be enabled during SLEEP and disabled outside of SLEEP, this is generally not useful.

For example, if the system is sleeping until a character interrupt from a UART, the entire system except for the UART can be clock-gated (`SLEEP_ENx` = all-zeroes except for `CLK_SYS_UART0` and `CLK_PERI_UART0`). This includes system infrastructure such as the bus fabric.

When the UART asserts its interrupt and wakes a processor, RP2350 leaves SLEEP mode and switches back to the `WAKE_ENx` clock mask. At the minimum, this should include the bus fabric and the memory devices containing the processor's stack and interrupt vectors.

A system-level clock request handshake holds the processors off the bus until the clocks are re-enabled.

### 6.5.3. DORMANT state

The DORMANT state is a true zero-dynamic-power sleep state, where all clocks (and all oscillators) are disabled. The system can awake from the DORMANT state upon a GPIO event (high/low level or rising/falling edge), or an AON Timer alarm: this restarts one of the oscillators (either ring oscillator or crystal oscillator) and ungates the oscillator output after it is stable. System state is retained, so code execution resumes immediately upon leaving the DORMANT state.

If relying on the AON Timer (Section 12.10) to wake from the DORMANT state, the AON Timer must run from the LPOSC or an external clock source. The AON Timer accepts clock frequencies as low as 1Hz.

DORMANT does not halt PLLs. To avoid unnecessary power dissipation, software should power down PLLs before entering the DORMANT state, and power up and reconfigure the PLLs again after exiting.

### 6.5.1. 顶层时钟门控

每个时钟域（例如系统时钟）可能驱动大量不同的硬件模块，且并非所有模块都需要同时启用。为避免不必要的功耗，每个时钟的各个端点（例如 UART 系统时钟输入）均可随时被禁用。

时钟门控的启用和禁用过程无毛刺现象。若外设时钟被临时禁用，随后重新启用，外设将恢复到禁用前的状态。不应需要复位或重新初始化。

时钟门控由两组寄存器控制：[WAKE\\_ENx](#)寄存器（从 WAKE\_EN0 开始）和 [SLEEP\\_ENx](#)寄存器（从 SLEEP\_EN0 开始）。这两组寄存器在位级上完全相同，均包含用于控制各时钟端点的标志位。[WAKE\\_EN](#)寄存器指定系统处于唤醒状态时启用的时钟，[SLEEP\\_ENx](#)寄存器则选择处理器处于 [SLEEP](#) 状态时启用的时钟（参见第6.5.2节）。

两个处理器均无外部可控的时钟门控功能。处理器基于执行 [WFI](#)/[WFE](#)指令以及外部事件和中断信号，自主对其子系统的时钟进行门控。

### 6.5.2. 睡眠状态

当满足下列所有条件时，RP2350 进入 SLEEP 状态：

- 两个处理器均处于睡眠状态（例如执行 [WFE](#) 或 [WFI](#) 指令时）
- 系统DMA在任何通道上均无未完成的传输。

当任一处理器被中断唤醒时，RP2350退出SLEEP状态。

在SLEEP状态下，顶层时钟门控由 [SLEEP\\_ENx](#)寄存器（从SLEEP\_EN0起）控制掩码，而非 [WAKE\\_ENx](#)寄存器（从WAKE\_EN0起）。这使得在处理器休眠时能够更积极地裁剪时钟树。

#### 注意

尽管时钟可以在SLEEP期间启用而在非SLEEP期间禁用，但这通常无实际意义。

例如，若系统休眠直至UART字符中断，则除UART外，整个系统均可进行时钟门控控制（[SLEEP\\_ENx](#) = 全部为零，唯独 [CLK\\_SYS\\_UART0](#) 和 [CLK\\_PERI\\_UART0](#)例外）。这包括诸如总线结构等系统基础设施。

当UART触发中断并唤醒处理器时，RP2350退出SLEEP模式并切换回[WAKE\\_ENx](#)时钟掩码。至少应包括总线结构和包含处理器堆栈及中断向量的存储器设备。

系统级时钟请求握手将在时钟重新启用之前，令处理器停用总线。

### 6.5.3. 休眠状态

休眠状态（DORMANT）为真正的零动态功耗睡眠状态，其中所有时钟（包括所有振荡器）均被禁用。系统可通过GPIO事件（高/低电平或上升/下降沿）或AON定时器警报唤醒：这将重新启动一个振荡器（环振荡器或晶体振荡器），并在振荡器稳定后开启振荡器输出门控。系统状态得以保留，退出休眠状态（DORMANT）后代码执行立即恢复。

若依赖AON定时器（第12.10节）从休眠状态唤醒，AON定时器必须由LPOSC或外部时钟源驱动。AON定时器支持低至1 Hz的时钟频率。

DORMANT 状态不会停止锁相环（PLL）。为避免不必要的功耗，软件应在进入 DORMANT 状态前关闭 PLL，退出后重新开启并重新配置 PLL。

If you halt the crystal oscillator (XOSC), you must also halt the PLLs to prevent them losing lock when their input reference clock stops. The PLL VCO may behave erratically when the frequency reference is lost, such as increasing to a very high frequency. Reconfigure and re-enable the PLLs after the XOSC starts again. Do not attempt to run clocks from the PLLs while the XOSC is stopped.

The DORMANT state is entered by writing a keyword to the DORMANT register in whichever oscillator is active: ring oscillator ([Section 8.3](#)) or crystal oscillator ([Section 8.2](#)). If both are active, the one providing the processor clock must be stopped last because it will stop software from executing.

#### 6.5.3.1. Waking from the DORMANT state

The system exits the DORMANT state on any of the following events:

- an alarm from the AON Timer which causes `TIMER.ALARM` to assert
- the assertion of an interrupt from GPIO Bank 0 to the `DORMANT_WAKE` interrupt destination
- the assertion of an interrupt from GPIO Bank 1 to the `DORMANT_WAKE` interrupt destination

When waking from the AON Timer you do not have to enable the IRQ output from POWMAN. It is sufficient for the timer to fire, without being mapped to an interrupt output. Any AON Timer alarm comparison event which causes `TIMER.ALARM` to assert causes the system to exit the DORMANT state. It is the actual alarm event which causes the exit, not the `TIMER.ALARM` status; if you enter the DORMANT state with the `TIMER.ALARM` status set to 1, but the timer alarm comparison logic disabled by `TIMER.ALARM_ENAB`, you will not exit the DORMANT state.

The GPIO Bank registers have interrupt enable registers for interrupts targeting the DORMANT mode wake logic, such as `DORMANT_WAKE_INTE0`. These are identical to the interrupt enable registers for interrupts targeting the processors, such as `PROCO_INTE0`.

Waking from the DORMANT state restarts the oscillator which was disabled by entry to the DORMANT state. It does not restart any other oscillators, or change any system-level clock configuration.

#### 6.5.4. Memory periphery power down

The main system memories (`SRAM0` → `SRAM9`, mapped to bus addresses 0x20000000 to 0x20081fff), as well as the USB DPRAM, can be partially powered down via the `MEMPOWERDOWN` register in the SYSCFG registers (see [Section 12.15.2](#)). This powers down the analogue circuitry used to access the SRAM storage array (the **periphery** of the SRAM) but the storage array itself remains powered. Memories retain their current contents, but cannot be accessed. Static power is reduced.

##### CAUTION

Memories must not be accessed when powered down. Doing so can corrupt memory contents.

When powering a memory back up, a 20ns delay is required before accessing the memory again.

The XIP cache (see [Section 4.4](#)) can also be powered down, with `CTRL.POWER_DOWN`. The XIP hardware will not generate cache accesses whilst the cache is powered down. Note that this is unlikely to produce a net power savings if code continues to execute from XIP, due to the comparatively high voltages and switching capacitances of the external QSPI bus.

#### 6.5.5. Full memory power down

RP2350 can completely power down its internal SRAM. Unlike the memory periphery power down described in [Section 6.5.4](#), this completely disconnects the SRAM from the power supply, reducing static power to near zero.

Contents are lost when fully powering down memories. When you power memories up again following a power down,

如果停止晶振（XOSC），必须同时停止PLL，以防其输入参考时钟停止时PLL失锁。当频率参考丢失时，PLL的电压控制振荡器（VCO）可能表现异常，例如频率升至异常高值。XOSC重新启动后，应重新配置并启用PLL。XOSC停止期间，不得尝试由PLL供时钟运行。

DORMANT状态通过向当前活动的任一振荡器（环振荡器（见第8.3节）或晶振（见第8.2节））的DORMANT寄存器写入关键字来进入。若两者均处于活动状态，必须最后停止为处理器供时的振荡器，因为其停止将阻止软件执行。

### 6.5.3.1. 从 DORMANT 状态唤醒

系统在以下任一事件发生时退出休眠（DORMANT）状态：

- 来自AON计时器的报警，导致TIMER.ALARM被置位
- 来自GPIO银行0的中断被断言至DORMANT\_WAKE中断目标
- 来自GPIO银行1的中断被断言至DORMANT\_WAKE中断目标

从AON计时器唤醒时，**无需启用POWMAN的IRQ输出。计时器触发即可，无需映射至中断输出。任何导致TIMER.ALARM置位的AON计时器报警比较事件，均会使系统退出休眠状态。真正导致退出的是报警事件本身，而非TIMER.ALARM状态；若进入休眠状态时TIMER.ALARM状态为1，但计时器报警比较逻辑被TIMER.ALARM\_ENAB禁用，系统将不会退出休眠状态。**

GPIO银行寄存器设有针对休眠模式唤醒逻辑的中断使能寄存器，如DORMANT\_WAKE\_INTE0。其与针对处理器的中断使能寄存器（如PROCO\_INTE0）完全相同。

从DORMANT（休眠）状态唤醒将重新启动因进入DORMANT状态而被禁用的振荡器。此操作不会重新启动任何其他振荡器，也不会更改系统级时钟配置。

### 6.5.4. 内存外围断电

主系统内存（SRAM0至SRAM9，映射至总线地址0x20000000至0x20081fff）及USB DPRAM，均可通过SYSCFG寄存器中的MEMPOWERDOWN寄存器实现部分断电（详见第12.15.2节）。该操作关闭了用于访问SRAM存储阵列的模拟电路（即SRAM的外围电路），但存储阵列本身保持供电。内存内容保持不变，但无法访问。静态功耗有所降低。

#### ⚠ 警告

内存断电状态下严禁访问。否则可能导致内存内容损坏。

对内存重新供电后，必须延迟至少20纳秒后方可访问内存。

XIP缓存（详见第4.4节）亦可通过CTRL.POWER\_DOWN断电。缓存断电期间，XIP硬件不会生成缓存访问请求。请注意，由于外部QSPI总线的较高电压和开关电容，如果代码继续从XIP执行，通常不会带来净功率节约。

### 6.5.5. 全内存断电

RP2350能够完全关闭其内部SRAM。与第6.5.4节中描述的存储外围电源关闭不同，此操作完全断开SRAM电源，使静态功率降至近乎零。

存储器在完全断电时，其内容将全部丢失。当您在断电后重新为存储器供电时，

the contents is completely undefined.

There are three distinct SRAM power domains:

#### SRAM0

Contains main system SRAM for addresses `0x20000000` through `0x2003ffff` (SRAM banks 0 through 3).

#### SRAM1

Contains main system SRAM for addresses `0x20040000` through `0x20081fff` (SRAM banks 4 through 9).

#### XIP

Contains the XIP cache and the boot RAM.

The XIP power domain is always powered when the switched core domain is powered. The switched core domain is the domain which includes all core logic, such as processors, bus fabric and peripherals. This means the memories in this domain are always powered whenever software is running.

Besides powering memory down to save power, you can also leave memories powered *up* whilst powering down the switched core domain. This retains program state in SRAM while eliminating static power dissipation in core logic.

For more information see:

- [Chapter 4](#) for a list of RP2350 memory resources, including main system SRAM, the XIP cache and boot RAM
- [Section 6.2.1](#) for the definition of core power domains, including the memory power domains enumerated above
- [Section 6.2.2](#) for the list of supported memory power states
- [Section 6.2.3](#) for information on initiating power state transitions to power memories up or down
- [Section 14.9.7.2](#) for typical power consumption in low-power states including memory power down

## 6.5.6. Programmer's model

### 6.5.6.1. Sleep

The `hello_sleep` example ([hello\\_sleep\\_aon.c](#) in the [pico-playground GitHub repository](#)) demonstrates sleep mode. The `hello_sleep` application (and underlying functions) takes the following steps:

1. Switches all clocks in the system to run from XOSC.
2. Configures an alarm in the AON Timer for 10 seconds in the future.
3. Sets the AON Timer clock as the only clock running in sleep mode using the `SLEEP_ENx` registers (see [SLEEP\\_EN0](#)).
4. Enables deep sleep in the processor.
5. Calls `_wfi` on processor, which will put the processor into deep sleep until woken by the AON Timer interrupt.
6. After 10 seconds, the AON Timer interrupt clears the alarm and then calls a user supplied callback function.
7. The callback function ends the example application.

#### NOTE

To enter sleep mode, you must enable deep sleep on both proc0 and proc1, call `_wfi`, and ensure the DMA is stopped.

`hello_sleep` makes use of functions in `pico_sleep` of the [Pico Extras](#). In particular, `sleep_goto_sleep_until` puts the processor to sleep until woken up by an AON Timer time assumed to be in the future.

其内容是完全未定义的。

SRAM具有三个独立的电源域：

#### SRAM0

包含主系统SRAM，地址范围为 `0x20000000` 至 `0x2003ffff` (SRAM银行0至3)。

#### SRAM1

包含主系统SRAM，地址范围为 `0x20040000` 至 `0x20081fff` (SRAM银行4至9)。

#### XIP

包含XIP缓存及启动RAM。

当切换核心域通电时，XIP电源域始终保持供电。切换核心域指包括所有核心逻辑的域，如处理器、总线结构和外设。这意味着该域内的存储器在软件运行时始终保持通电。

除了关闭存储器以节省功耗外，还可以在关闭切换核心域的同时保持存储器通电。此举在保留SRAM中程序状态的同时，消除了核心逻辑的静态功耗。

更多信息请参见：

- [第4章 — RP2350存储资源列表，包括主系统SRAM、XIP缓存和启动RAM](#)
- [第6.2.1节 — 核心电源域定义，包括上述列举的存储电源域](#)
- [第6.2.2节 — 支持的存储电源状态列表](#)
- [第6.2.3节 — 启动存储电源状态切换以实现存储通电或断电的信息](#)
- [第14.9.7.2节 — 包括存储断电在内的典型低功耗状态功耗](#)

## 6.5.6. 程序员模型

### 6.5.6.1 睡眠

`hello_sleep`示例（位于[pico-playground GitHub仓库](#)的`hello_sleep_aon.c`中）演示了睡眠模式。`hello_sleep`应用程序（及其底层函数）执行以下步骤：

1. 将系统中所有时钟切换为由XOSC驱动。
2. 在AON定时器中设置一个10秒后的闹钟。
3. 使用`SLEEP_ENx`寄存器（参见`SLEEP_EN0`）将AON定时器时钟设置为睡眠模式下唯一运行的时钟。
4. 启用处理器的深度睡眠。
5. 调用处理器上的`_wfi`，处理器将进入深度睡眠，直至被AON定时器中断唤醒。
6. 10秒后，AON定时器中断清除闹钟，并调用用户提供的回调函数。
7. 该回调函数结束示例应用程序的执行。

#### 注意

要进入睡眠模式，必须在proc0和proc1上启用深度睡眠，调用`_wfi`，并确保DMA已停止。

`hello_sleep`调用了Pico Extras中`pico_sleep`的函数。尤其是，`sleep_goto_sleep_until`使处理器进入睡眠状态，直到被假定在未来的AON定时器时间唤醒。

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/pico\\_sleep/sleep.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/pico_sleep/sleep.c) Lines 159 - 183

```

159 void sleep_goto_sleep_until(struct timespec *ts, aon_timer_alarm_handler_t callback)
160 {
161
162 // We should have already called the sleep_run_from_dormant_source function
163 // This is only needed for dormancy although it saves power running from xosc while
164 // sleeping
165 //assert(dormant_source_valid(_dormant_source));
166
167 clocks_hw->sleep_en0 = CLOCKS_SLEEP_EN0_CLK_REF_POWMAN_BITS;
168 clocks_hw->sleep_en1 = 0x8;
169
170 aon_timer_enable_alarm(ts, callback, false);
171
172 stdio_flush();
173
174 // Enable deep sleep at the proc
175 processor_deep_sleep();
176
177 // Go to sleep
178 __wfi();
179 }
```

### 6.5.6.2. DORMANT

The `hello_dormant` example, `hello_dormant_gpio.c` in the [pico-playground GitHub repository](#), demonstrates the DORMANT state. The example takes the following steps:

1. Switches all clocks in the system to run from XOSC.
2. Configures a GPIO interrupt for the `dormant_wake` hardware, which can wake both the ROSC and XOSC from dormant mode.
3. Puts the XOSC into dormant mode, which stops all processor execution (and all other clocked logic on the chip) immediately.
4. When GPIO 10 goes high, the XOSC restarts and program execution continues.

`hello_dormant` uses `sleep_goto_dormant_until_pin` under the hood:

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/pico\\_sleep/sleep.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/pico_sleep/sleep.c) Lines 258 - 282

```

258 void sleep_goto_dormant_until_pin(uint gpio_pin, bool edge, bool high) {
259 bool low = !high;
260 bool level = !edge;
261
262 // Configure the appropriate IRQ at IO bank 0
263 assert(gpio_pin < NUM_BANK0_GPIOS);
264
265 uint32_t event = 0;
266
267 if (level && low) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_LEVEL_LOW_BITS;
268 if (level && high) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_LEVEL_HIGH_BITS;
269 if (edge && high) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_EDGE_HIGH_BITS;
270 if (edge && low) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_EDGE_LOW_BITS;
271
272 gpio_init(gpio_pin);
273 gpio_set_input_enabled(gpio_pin, true);
274 gpio_set_dormant_irq_enabled(gpio_pin, event, true);
275 }
```

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/pico\\_sleep/sleep.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/pico_sleep/sleep.c) 第159至183行

```

159 void sleep_goto_sleep_until(struct timespec *ts, aon_timer_alarm_handler_t callback)
160 {
161
162 // 我们应已调用 sleep_run_from_dormant_source 函数
163 // 该函数仅在休眠模式下需要，尽管它节省了休眠时使用 xosc 运行的功耗
164
165 //assert(dormant_source_valid(_dormant_source));
166
167 clocks_hw->sleep_en0 = CLOCKS_SLEEP_EN0_CLK_REF_POWMAN_BITS;
168 clocks_hw->sleep_en1 = 0x0;
169
170 aon_timer_enable_alarm(ts, callback, false);
171
172 stdio_flush();
173
174 // 启用处理器深度睡眠
175 processor_deep_sleep();
176
177 // 进入睡眠状态
178 __wfi();
179 }
```

### 6.5.6.2. 休眠状态

pico-playground GitHub 仓库中的 `hello_dormant` 示例 (`hello_dormant_gpio.c`) 演示了 DORMANT 状态。该示例执行以下步骤：

1. 将系统中所有时钟切换为由XOSC驱动。
2. 为 `dormant_wake` 硬件配置 GPIO 中断，该硬件可以唤醒处于休眠状态的 ROSC 和 XOSC。
3. 将 XOSC 置于休眠模式，立即停止所有处理器执行及芯片上的所有其他时钟逻辑。
4. 当 GPIO 10 变为高电平时，XOSC 重新启动，程序执行继续。

`hello_dormant` 底层使用了 `sleep_goto_dormant_until_pin`:

Pico 补充资料: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/pico\\_sleep/sleep.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/pico_sleep/sleep.c) 第 258 至 282 行

```

258 void sleep_goto_dormant_until_pin(uint gpio_pin, bool edge, bool high) {
259 bool low = !high;
260 bool level = !edge;
261
262 // 在 IO bank 0 配置相应的中断请求 (IRQ)
263 assert(gpio_pin < NUM_BANK0_GPIOS);
264
265 uint32_t event = 0;
266
267 if (level && low) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_LEVEL_LOW_BITS;
268 if (level && high) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_LEVEL_HIGH_BITS;
269 if (edge && high) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_EDGE_HIGH_BITS;
270 if (edge && low) event = IO_BANK0_DORMANT_WAKE_INTE0_GPIO0_EDGE_LOW_BITS;
271
272 gpio_init(gpio_pin);
273 gpio_set_input_enabled(gpio_pin, true);
274 gpio_set_dormant_irq_enabled(gpio_pin, event, true);
275 }
```

```
276 _go_dormant();
277 // Execution stops here until woken up
278
279 // Clear the irq so we can go back to dormant mode again if we want
280 gpio_acknowledge_irq(gpio_pin, event);
281 gpio_set_input_enabled(gpio_pin, false);
282 }
```

```
276 _go_dormant();
277 // 执行在此处停止，直到被唤醒
278
279 // 清除中断，以便我们可以根据需要重新进入休眠模式
280 gpio_acknowledge_irq(gpio_pin, event);
281 gpio_set_input_enabled(gpio_pin, false);
282 }
```

# Chapter 7. Resets

## 7.1. Overview

Resets are divided into three categories, each of which applies to a subset of RP2350:

### Chip-level resets

apply to the entire chip. Used to put the entire chip into a default state. These are initiated by hardware events, the watchdog, or the debugger. When all chip level resets are de-asserted, the system resets are released and the processors boot.

### System resets

apply to components essential to processor operation. System components have interdependencies, therefore their resets are de-asserted in sequence by the Power-on State Machine (PSM). The full PSM sequence is triggered by deassertion of chip-level resets. A full or partial sequence can be triggered by the watchdog or debugger. The sequence culminates in processor boot.

### Subsystem resets

apply to components *not* essential for operation of the processors. The resets can be independently asserted by writing to the **RESETS** registers and de-asserted by software, the watchdog, or the debugger.

The watchdog can be programmed to trigger any of the above categories.

## 7.2. Changes from RP2040

RP2350 retains all RP2040 chip-level reset features.

RP2350 adds the following features:

- new chip reset sources:
  - glitch detector
  - watchdog
  - debugger
- new destinations:
  - new power management components

RP2350 makes the following modifications to existing features:

- Modified the **CHIP\_RESET** register, which records the source of the last chip level reset. In RP2040, **CHIP\_RESET** was stored in the **LDO\_POR** register block. In RP2350, **CHIP\_RESET** was extended and moved to the **POWMAN** register block, which is in the new always-on power domain (**AON**).
- Renamed the brownout reset (**BOR**) registers to brownout detect (**BOD**), added functionality, and moved them to the new **POWLMAN** register block.
- Added more system reset stages. To support this, added additional Power-on State Machine fields and rearranged the existing fields.
- Added additional **RESETS** registers and rearranged the existing fields.
- Extended watchdog options to enable triggers for new resets.

# 第7章 重置

## 7.1. 概述

重置分为三种类别，分别适用于RP2350的不同子集：

### 芯片级重置

适用于整个芯片。用于将整个芯片恢复到默认状态。此类重置由硬件事件、看门狗或调试器触发。当所有芯片级重置解除断言后，系统重置被释放，处理器开始启动。

### 系统重置

适用于对处理器操作至关重要的组件。系统组件之间存在相互依赖性，因此它们的重置由上电状态机（PSM）按顺序解除断言。完整的PSM序列由芯片级复位的取消断言触发。完整或部分序列可以由看门狗或调试器触发。该序列以处理器启动为终点。

### 子系统复位

适用于非处理器正常运行所必需的组件。这些复位可通过写入RESETS寄存器独立断言，并由软件、看门狗或调试器取消断言。

看门狗可编程以触发上述任意类别。

## 7.2. 与 RP2040 的变更

RP2350保留所有RP2040芯片级复位功能。

RP2350新增以下功能：

- 新的芯片复位源：
  - 毛刺检测器
  - 看门狗
  - 调试器
- 新的复位目标：
  - 新的电源管理组件

RP2350对现有功能作出以下修改：

- 修改了CHIP\_RESET寄存器，该寄存器记录最后一次芯片级复位的来源。在RP2040中，CHIP\_RESET存储于LDO\_POR寄存器块内。在RP2350中，CHIP\_RESET被扩展并移至POWMAN寄存器块，该寄存器块位于新的始终开启电源域（AON）中。
- 将棕断电复位（BOR）寄存器重命名为棕断电检测（BOD），增加了功能，并移至新的POWMAN寄存器块。
- 增加了更多的系统复位阶段。为支持该功能，新增了电源上电状态机字段，并重新排列了现有字段。
- 新增了更多RESETS寄存器，并重新排列了现有字段。
- 扩展了看门狗选项，以支持新的复位触发。

**NOTE**

Watchdog scratch registers are not preserved when the watchdog triggers a chip-level reset. However, watchdog scratch registers are preserved after a system or subsystem reset. For general purpose scratch registers that do not reset after a chip-level reset, see the [POWMAN](#) register block [Section 6.4, “Power management \(POWMAN\) registers”](#).

## 7.3. Chip-level resets

Chip-level resets put the entire chip into a default state. These resets are only initiated by hardware events, the debugger, or a watchdog timeout.

### 7.3.1. Chip-level reset table

[Table 528, “List of chip-level reset causes”](#) shows the components reset by each of the chip-level reset sources. A dash (–) indicates no change caused by this source.

*Table 528. List of chip-level reset causes*

Reset Source	SW-DP	AON Scratch	POWMAN	Power State	Double Tap	Rescue
POR	reset	reset	hard reset	→ P0.0	reset	reset
BOR	reset	reset	hard reset	→ P0.0	reset	reset
EXTERNAL RESET (RUN)	reset	reset	hard reset	→ P0.0	–	reset
DEBUGGER RESET REQ	–	–	hard reset	→ P0.0	–	reset
DEBUGGER RESCUE	–	–	hard reset	→ P0.0	–	set
WATCHDOG POWMAN ASYNC RESET	–	–	hard reset	→ P0.0	–	–
WATCHDOG POWMAN RESET	–	–	soft reset	→ P0.0	–	–
WATCHDOG SWCORE RESET	–	–	–	→ P0.0	–	–
SWCORE POWERDOWN	–	–	–	→ P0.x	–	–
GLITCH_DETECTOR	–	–	–	–	–	–
WATCHDOG RESET PSM	–	–	–	–	–	–

All chip-level resets sources in the table also reset the Power-on State Machine (PSM). This asserts all of the system resets downstream of the PSM. System resets includes low-level chip infrastructure like the system-level clock generators, as well as the processor cold and warm reset domains.

All chip-level reset sources in the table also reset the system watchdog peripheral. This includes watchdog scratch registers [SCRATCH0](#) → [SCRATCH7](#).

You can interpret the table columns as follows:

#### Reset Source

Indicates which of the events listed in [Chip-level Reset Sources](#) is responsible for this chip-level reset.

#### SW-DP

Indicates the SWD Debug Port and the RP-AP ([Section 3.5.10, “RP-AP”](#)) are reset.

#### AON Scratch

Indicates scratch register state in POWMAN [SCRATCH0](#) → [SCRATCH7](#) and [BOOT0](#) → [BOOT3](#) registers is lost. These registers are always-on, meaning they are preserved across power-down of the switched core domain.

### ⓘ 注意

当看门狗触发芯片级复位时，看门狗临时寄存器不会被保留。然而，在系统或子系统复位后，看门狗临时寄存器会被保留。有关不会在芯片级复位后复位的一般用途临时寄存器，请参阅第6.4节“电源管理（POWMAN）寄存器”中POWMAN寄存器块的说明。

## 7.3. 芯片级复位

芯片级复位会将整个芯片恢复到默认状态。这些复位仅由硬件事件、调试器或看门狗超时触发。

### 7.3.1. 芯片级复位表

表528，“芯片级复位原因列表”展示了各芯片级复位源所复位的组件。破折号（–）表示该源未引起任何变化。

表528。芯片级复位原因列表

复位源	SW-DP	AON 暂存区	POWMAN	电源状态	快速双击	救援
POR	复位	复位	硬件复位	→ P0.0	复位	复位
BOR	复位	复位	硬件复位	→ P0.0	复位	复位
外部复位（运行）	复位	复位	硬件复位	→ P0.0	–	复位
调试器复位请求	–	–	硬件复位	→ P0.0	–	复位
调试器救援	–	–	硬件复位	→ P0.0	–	已设置
看门狗电源管理异步复位	–	–	硬件复位	→ P0.0	–	–
看门狗 POWMAN 复位	–	–	软复位	→ P0.0	–	–
看门狗 SWCORE 复位	–	–	–	→ P0.0	–	–
SWCORE 断电	–	–	–	→ P0.x	–	–
GLITCH_DETECTOR	–	–	–	–	–	–
看门狗复位 PSM	–	–	–	–	–	–

表中所有芯片级复位源亦会复位上电状态机（PSM）。此操作会断言所有下游的系统复位信号。系统复位包括系统级时钟发生器等低层芯片基础设施，以及处理器的冷复位和热复位域。

表中所有芯片级复位源亦会复位系统看门狗外围设备，包括看门狗擦写寄存器 SCRATCH0 → SCRATCH7。

您可按以下方式解读表格列：

#### 复位源

指示“芯片级复位源”中所列事件中，哪个事件导致该芯片级复位。

#### SW-DP

指示软件调试端口（SWD）和 RP-AP（第 3.5.10 节，“RP-AP”）被复位。

#### AON 暂存区

指示 POWMAN 寄存器 SCRATCH0 → SCRATCH7 和 BOOT0 → BOOT3 的擦写寄存器状态已丢失。

这些寄存器始终通电，意味着在切换核心域断电时其状态得以保留。

**POWMAN**

Indicates some or all of the register state of the power manager (POWMAN) is reset.

**Power State**

Indicates a change to the powered/unpowered status of core voltage domains.

**Double Tap**

Indicates the [CHIP\\_RESET.DOUBLE\\_TAP](#) bit is reset.

**Rescue**

Indicates changes to the [CHIP\\_RESET.RESCUE\\_FLAG](#) bit.

### 7.3.2. Chip-level reset destinations

Chip-level resets apply to the following primary components:

- the SW-DP and RP-AP debug components
- power manager scratch and boot registers
- power manager including the always-on timer
- power state (restored to state [P0.0](#), in which all domains are powered, see [Section 6.2.2, “Power states”](#))
- system resets (any chip-level reset triggers the PSM (power-on state machine), which sequences the system resets, see [Section 7.4, “System resets \(Power-on State Machine\)”](#))
- watchdog (reset by any chip-level reset, including one triggered by the watchdog)

Chip-level resets also reset the following two [CHIP\\_RESET](#) register flags:

- [CHIP\\_RESET.DOUBLE\\_TAP](#): the bootrom can use this flag to detect a double-press of a button connected to the RUN pin, and enter the USB or UART bootloader. See the [BOOT\\_FLAGS1.DOUBLE\\_TAP](#) OTP flag.
- [CHIP\\_RESET.RESCUE\\_FLAG](#): this flag instructs the bootrom to halt the boot process. The bootrom clears the flag to acknowledge. You can use this to perform a full-system reset from almost any state (particularly ones where all system clocks are stopped), and catch the processors before they re-run the code that caused the bad state.

**NOTE**

When the SW-DP and RP-AP are out of reset, you can use them to perform low-level debug operations like a rescue reset or a forced power-up over SWD. However accessing any other debug hardware, such as the Mem-APs, requires the system clock to be running.

**NOTE**

These flags are located in located in the [CHIP\\_RESET](#) register in the POWMAN register space, so they are included in the always-on (AON) power domain.

### 7.3.3. Chip-level reset sources

In order of severity, the following events can trigger a chip-level reset:

**Power-On Reset (POR)**

The power-on reset ensures the chip starts up cleanly when power is first applied by holding it in reset until the digital core supply (DVDD) reaches a voltage high enough to reliably power the chip's core logic. The POR component is described in detail in [Section 7.6.1, “Power-on reset \(POR\)”](#).

**POWMAN**

表示电源管理器（POWMAN）部分或全部寄存器状态已复位。

**电源状态**

指示核心电压域的通电/断电状态发生变化。

**快速双击**

指示 CHIP\_RESET.DOUBLE\_TAP 位被复位。

**救援**

指示 CHIP\_RESET.RESCUE\_FLAG 位发生变化。

### 7.3.2. 芯片级复位目标

芯片级复位适用于以下主要组件：

- SW-DP 和 RP-AP 调试组件
- 电源管理器的临时寄存器和启动寄存器
- 包括常通电计时器在内的电源管理器
- 电源状态（恢复到状态 **P0.0**，所有域均通电，详见第6.2.2节“电源状态”）
- 系统复位（任何芯片级复位都会触发 PSM（上电状态机），该状态机负责系统复位的序列，详见第7.4节“系统复位（上电状态机）”）
- 看门狗（由任何芯片级复位触发，包括看门狗本身触发的复位）

芯片级复位同时复位以下两个 CHIP\_RESET 寄存器标志：

- **CHIP\_RESET.DOUBLE\_TAP**：引导只读存储器（bootrom）可利用该标志检测连接至 RUN 引脚的按钮的双击操作，并进入 USB 或 UART 引导加载程序。参见 BOOT\_FLAGS1.DOUBLE\_TAP OTP 标志。
- **CHIP\_RESET.RESCUE\_FLAG**：该标志指示引导只读存储器暂停启动流程。引导只读存储器清除此标志以示确认。您可利用此功能在几乎任何状态下执行全系统复位（特别是所有系统时钟停止的状态），并在处理器重新执行导致异常状态的代码之前捕获处理器。

**i 注意**

当 SW-DP 与 RP-AP 解除复位后，您可使用它们执行低级调试操作，如救援复位或通过 SWD 强制上电。但访问其它调试硬件，如 Mem-AP，需要系统时钟保持运行。

**i 注意**

这些标志位于 POWMAN 寄存器空间的 CHIP\_RESET 寄存器内，因此包含于常时供电（AON）电源域。

### 7.3.3. 芯片级复位源

按照严重程度，以下事件可能触发芯片级复位：

**上电复位（POR）**

上电复位确保芯片在首次通电时能干净启动，通过将芯片保持在复位状态，直到数字核心电源（DVDD）达到足以可靠驱动核心逻辑的电压水平。POR 组件详见第 7.6.1 节，“上电复位（POR）”。

### Brownout Detection (BOD)

The brownout detector prevents unreliable operation when the digital core supply (DVDD) drops below a safe operating level. The BOD component is described in detail in [Section 7.6.2, “Brownout detection \(BOD\)”](#). The reset asserted by the BOD is referred to as the brownout reset, or BOR.

### External Reset

The chip can be reset by taking the `RUN` pin low. This holds the chip in reset irrespective of the state of the core power supply (DVDD), the power-on reset block, and brownout detection block. `RUN` can be used to extend the initial power-on reset, or can be driven from an external source to start and stop the chip as required. If `RUN` is not used, it should be tied high. Double-tapping the `RUN` low will set `CHIP_RESET.DOUBLE_TAP`. Boot code reads this flag and selects an alternate boot sequence if the flag is set.

### Debugger Reset Request

The debugger is able to initiate a chip-level reset using the `CDBG_PWRUPREQ` control. For more information, see [Section 3.5, “Debug”](#).

### Rescue Debug Port Reset

The chip can also be reset via the Rescue Debug Port. This allows the chip to be recovered from a locked-up state. In addition to resetting the chip, a Rescue Debug Port reset also sets `CHIP_RESET.RESCUE_FLAG`. This is checked by boot code at startup, causing it to enter a safe state if the bit is set. See [Section 3.5.8, “Rescue reset”](#) for more information.

### Watchdog

The watchdog can trigger various levels of chip-level reset by setting appropriate bits in the `WDSEL` register. A chip-level reset triggered by a watchdog reset will reset the watchdog and the watchdog scratch registers. Additional general purpose scratch registers are available in `POWMAN`. These are not reset by a chip-level reset triggered by the watchdog.

### SWCORE Powerdown

For a list of operations that power down the switched-core power domain (SWCORE) and trigger this reset, see [Section 6.2, “Power management”](#).

### Glitch Detector

This reset fires if a glitch is detected in SWCORE power supply. For more information, see [Section 10.9, “Glitch detector”](#).

### RISC-V Non-Debug-Module Reset

The `dmcontrol.ndmreset` bit in the RISC-V Debug Module resets all RISC-V harts in the system. It resets no other hardware. However, it is recorded as a chip-level reset reason in `CHIP_RESET.HAD_HZD_SYS_RESET_REQ`. See [Section 3.5.3, “RISC-V debug”](#) for details of the RISC-V debug subsystem.

The source of the last chip-level reset is recorded in the `CHIP_RESET` register.

A complete list of `POWMAN` registers is provided in [Section 6.4, “Power management \(POWMAN\) registers”](#).

## 7.4. System resets (Power-on State Machine)

## 欠压检测（BOD）

欠压检测器防止数字核心电源（DVDD）降至不安全工作水平以下而导致不可靠操作。BOD 组件详见第 7.6.2 节，“欠压检测（BOD）”。由 BOD 断言的复位称为欠压复位，简称 BOR。

### 外部复位

将 **RUN** 引脚拉低可复位芯片。此操作无论核心电源（DVDD）、上电复位模块或欠压检测模块状态如何，均能保持芯片处于复位状态。**RUN** 可用于延长初始上电复位时间，或由外部信号驱动，以根据需要启动和停止芯片。若未使用 **RUN** 信号，应将其拉高。双击将 **RUN** 设为低电平会设置 CHIP\_RESET.DOUBLE\_TAP 标志。引导代码读取该标志，若被设置则选择备用启动序列。

### 调试器复位请求

调试器可通过 **CDBGWRUPREQ** 控制发起芯片级复位。详情请参见第 3.5 节，“调试”。

### 救援调试端口复位

芯片也可通过救援调试端口复位，从而实现从死锁状态恢复。

救援调试端口复位不仅会复位芯片，还会设置 CHIP\_RESET.RESCUE\_FLAG。启动代码在启动时检查该标志，若被设置则进入安全状态。详见第 3.5.8 节，“救援复位”。

### 看门狗

看门狗通过在 WDSEL 寄存器中设置相应位，可触发不同级别的芯片级复位。由看门狗复位触发的芯片级复位将重置看门狗及看门狗擦写寄存器。POWMAN 中提供了额外的通用擦写寄存器。这些寄存器不会因看门狗触发的芯片级复位而被重置。

### SWCORE 电源关闭

有关关闭切换核心电源域（SWCORE）并触发此复位的操作列表，请参见  
第 6.2 节，“电源管理”。

### 瞬态故障检测器

若检测到 SWCORE 电源供应中的瞬态故障，将触发此复位。详情请参见第 10.9 节，“瞬态故障检测器”。

### RISC-V 非调试模块复位

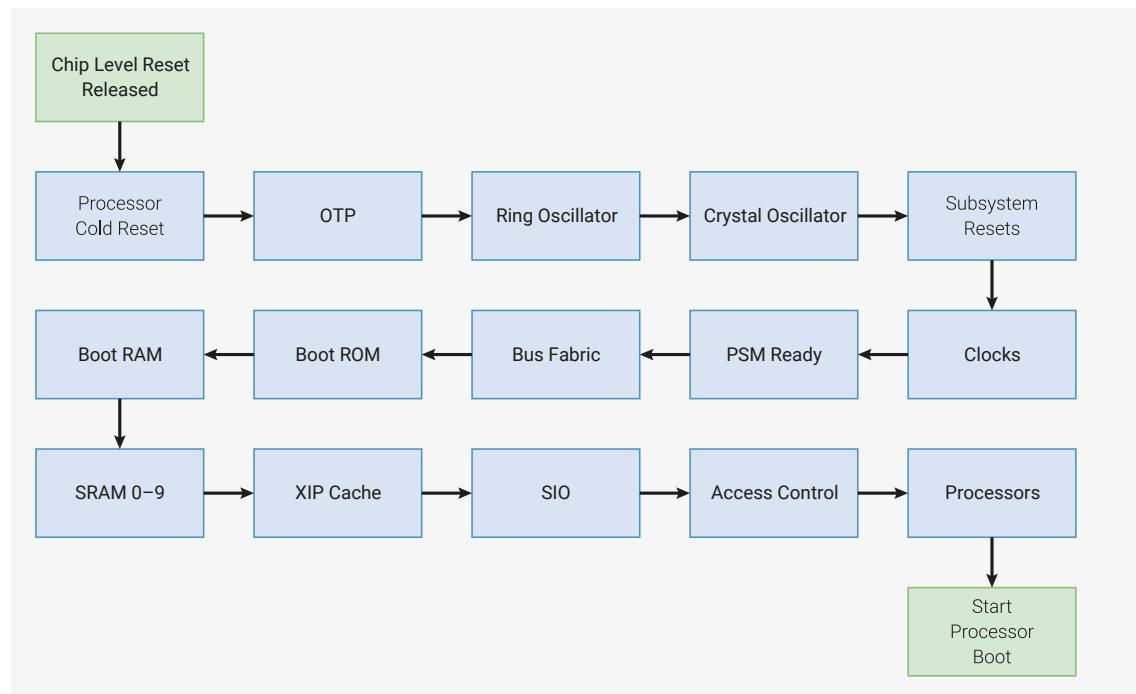

RISC-V 调试模块中的 **dmcontrol.ndmreset** 位会复位系统中所有 RISC-V hart。该操作不会复位其他硬件。但它会作为芯片级复位原因记录于 CHIP\_RESET.HAD\_HZD\_SYS\_RESET\_REQ 中。有关 RISC-V 调试子系统的详细信息，请参见第 3.5.3 节，“RISC-V 调试”。

最后一次芯片级复位的来源记录于 CHIP\_RESET 寄存器。

完整的 POWMAN 寄存器列表详见第 6.4 节，“电源管理（POWMAN）寄存器”。

## 7.4. 系统复位（上电状态机）

Figure 27. Power-on State Machine Sequence

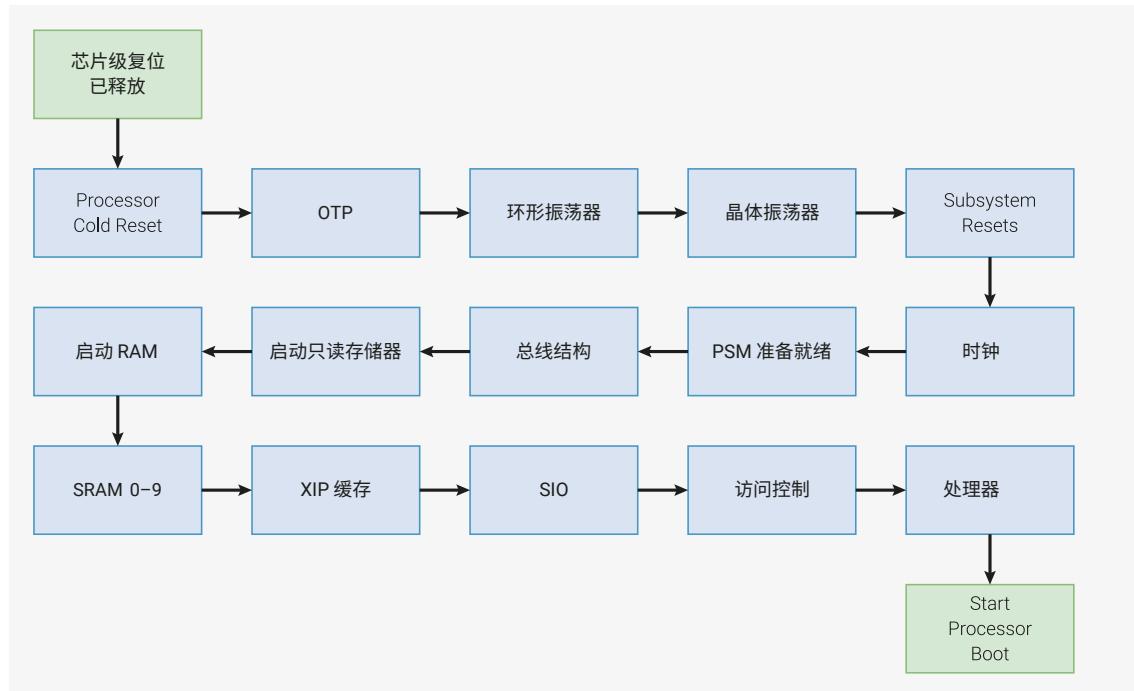

System Resets apply to components essential to processor operation. System components have interdependencies, therefore their resets are de-asserted in sequence by the Power-on State Machine (PSM). Each stage of the sequencer outputs a reset done signal when complete, `rst_done`, which releases the reset input to the next stage. A partial sequence runs after a write to the `FRCE_OFF` register or a watchdog timeout. Note that the `FRCE_ON` register is intended for internal use only and is disabled in production devices.

The Power-on State Machine sequences system-level reset release following a power-up of the switched core power domain. It is distinct from the power manager (POWMAN) which controls power domain switching, see [Section 6.2, "Power management"](#).

#### 7.4.1. Reset sequence

Following a chip-level reset, the Power-on State Machine (PSM):

1. Removes cold reset to processors.
2. Takes OTP out of reset. OTP reads any content required to boot and asserts `rst_done`.
3. Starts the Ring Oscillator. Asserts `rst_done` once the oscillator output is stable.
4. Removes Crystal Oscillator (XOSC) controller reset. The XOSC does not start yet, so `rst_done` is asserted immediately.
5. Deasserts the master subsystem reset, but does not remove individual subsystem resets.
6. Starts the `clk_ref` and `clk_sys` clock generators. In the initial configuration, `clk_ref` runs from the ring oscillator with no divider and `clk_sys` runs from `clk_ref`.
7. The PSM confirms the clocks are active.
8. Removes Bus Fabric reset and initialises logic.
9. Removes various memory controllers' resets and initialises logic.
10. Removes Single-cycle IO subsystem (SIO) reset and initialises logic.
11. Removes Access Controller reset and initialises logic.
12. Deasserts Processor Complex reset. Both core 0 and core 1 start executing the boot code from ROM. The boot code reads the core id and core 1 sleeps, leaving core 0 to continue bootrom execution.

图27。上电  
状态机  
序列

系统复位适用于处理器运行所必需的组件。系统组件之间存在相互依赖性，因此它们的重置由上电状态机（PSM）按顺序解除断言。每个序列器阶段完成时会输出复位完成信号 `rst_done`，并释放下一阶段的复位输入。部分序列将在写入 `FRCE_OFF` 寄存器或看门狗超时后执行。请注意，`FRCE_ON` 寄存器仅供内部使用，且在生产设备中已被禁用。

上电状态机在切换核心电源域上电后，按顺序释放系统级复位。其不同于控制电源域切换的电源管理器（POWMAN），详见第6.2节“电源管理”。

### 7.4.1. 复位序列

芯片级复位后，上电状态机（PSM）执行以下操作：

1. 解除处理器的冷复位。
2. 解除OTP复位。OTP读取启动所需的所有内容并断言 `rst_done`。
3. 启动环形振荡器。一旦振荡器输出稳定，断言 `rst_done`。
4. 解除晶体振荡器（XOSC）控制器复位。XOSC尚未启动，因此立即断言 `rst_done`。
5. 撤销主子系统复位，但不解除各子系统复位。
6. 启动 `clk_ref` 和 `clk_sys` 时钟生成器。在初始配置中，`clk_ref` 由无分频环形振荡器驱动，`clk_sys` 由 `clk_ref` 驱动。
7. PSM确认时钟处于激活状态。
8. 取消总线结构复位并初始化逻辑。
9. 取消各类内存控制器复位并初始化逻辑。
10. 取取消单周期IO子系统（SIO）复位并初始化逻辑。
11. 取消访问控制器复位并初始化逻辑。
12. 释放处理器复合体复位信号。核0和核1均从只读存储器（ROM）执行启动代码。启动代码读取核ID，核1进入休眠，核0继续执行引导程序。

Following a watchdog reset trigger, the PSM restarts from a point selected by the PSM [WDSEL](#) register.

### 7.4.2. Register control

The PSM is a fully automated piece of hardware: it requires no input from the user to work. The debugger can trigger a full or partial sequence by writing to the [FRCE\\_OFF](#) register. The [FRCE\\_ON](#) register is a development feature that does nothing in production devices.

### 7.4.3. Interaction with watchdog

The watchdog can trigger a full or partial sequence by writing to the [WDSEL](#) register.

### 7.4.4. List of registers

The PSM registers start at a base address of [0x40018000](#) (defined as [PSM\\_BASE](#) in SDK).

*Table 529. List of PSM registers*

Offset	Name	Info
0x0	<a href="#">FRCE_ON</a>	Force block out of reset (i.e. power it on)
0x4	<a href="#">FRCE_OFF</a>	Force into reset (i.e. power it off)
0x8	<a href="#">WDSEL</a>	Set to 1 if the watchdog should reset this
0xc	<a href="#">DONE</a>	Is the subsystem ready?

## PSM: FRCE\_ON Register

**Offset:** 0x0

### Description

Force block out of reset (i.e. power it on)

*Table 530. FRCE\_ON Register*

Bits	Description	Type	Reset
31:25	Reserved.	-	-
24	<b>PROC1</b>	RW	0x0
23	<b>PROC0</b>	RW	0x0
22	<b>ACCESSCTRL</b>	RW	0x0

14	<b>SRAM4</b>	RW	0x0
13	<b>SRAM3</b>	RW	0x0
12	<b>SRAM2</b>	RW	0x0

看门狗复位触发后，PSM从PSM WDSEL寄存器指定的位置重新启动。

### 7.4.2. 寄存器控制

PSM是完全自动化的硬件组件：无需用户输入即可工作。调试器可通过写入 **FRCE\_ON** 寄存器触发完整或部分序列。**FRCE\_OFF** 寄存器为开发特性，生产设备中无效。

### 7.4.3. 与看门狗的交互

看门狗可通过写入 **WDSEL** 寄存器触发完整或部分序列。

### 7.4.4. 寄存器列表

PSM 寄存器起始地址为 **0x40018000**（在 SDK 中定义为 PSM\_BASE）。

表 529. PSM 寄存器列表

偏移量	名称	说明
0x0	<b>FRCE_ON</b>	强制解除复位（即开启电源）
0x4	<b>FRCE_OFF</b>	强制进入复位（即关闭电源）
0x8	<b>WDSEL</b>	如果看门狗需重置此项，则置为 1
0xc	<b>完成</b>	子系统是否已就绪？

### PSM: FRCE\_ON 寄存器

偏移：0x0

## 7.5. Subsystem resets

### 7.5.1. Overview

The reset controller allows software to reset non-critical components in RP2350. The reset controller can reset the following components:

- USB Controller
- PIO
- Peripherals, including UART, I2C, SPI, PWM, Timer, ADC
- PLLs
- IO and Pad registers

For a full list of components that can be reset using the reset controller, see the register descriptions ([Section 7.5.3, "List of Registers"](#)).

When reset, components are held in reset at power-up. To use the component, software must deassert the reset.

#### NOTE

The SDK automatically deasserts some components after a reset.

### 7.5.2. Programmer's model

The SDK uses the following struct to represent the resets registers:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/resets.h) Lines 63 - 159

```

63 typedef struct {
64 _REG_(RESETS_RESET_0_OFFSET) // RESETS_RESET
65 // 0x10000000 [28] USBCTRL (1)
66 // 0x08000000 [27] UART1 (1)
67 // 0x04000000 [26] UART0 (1)
68 // 0x02000000 [25] TRNG (1)
69 // 0x01000000 [24] TIMER1 (1)
70 // 0x00800000 [23] TIMER0 (1)
71 // 0x00400000 [22] TBMAN (1)
72 // 0x00200000 [21] SYSINFO (1)
73 // 0x00100000 [20] SYSCFG (1)
74 // 0x00080000 [19] SPI1 (1)
75 // 0x00040000 [18] SPI0 (1)
76 // 0x00020000 [17] SHA256 (1)
77 // 0x00010000 [16] PWM (1)
78 // 0x00008000 [15] PLL_USB (1)
79 // 0x00004000 [14] PLL_SYS (1)
80 // 0x00002000 [13] PIO2 (1)
81 // 0x00001000 [12] PIO1 (1)

90 // 0x00000008 [3] HSTX (1)

```

## 7.5. 子系统复位

### 7.5.1. 概述

复位控制器允许软件重置 RP2350 中的非关键组件。复位控制器可重置以下组件：

- USB 控制器
- 可编程输入输出端口
- 外围设备，包括 UART、I2C、SPI、PWM、定时器及 ADC
- PLLs
- IO和引脚寄存器

有关可通过复位控制器复位的所有组件完整列表，请参阅寄存器说明（第7.5.3节，“[寄存器列表](#)”）。

组件在复位时会于上电时保持复位状态。要使用该组件，软件必须撤销复位信号的断言。

#### 注意

SDK在复位后会自动撤销部分组件的复位断言。

### 7.5.2. 程序员模型

SDK使用以下结构体表示复位寄存器：

SDK链接：[https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/resets.h) 第63至159行

```

63 typedef struct {
64 _REG_(RESETS_RESET_OFFSET) // RESETS_RESET
65 // 0x10000000 [28] USBCTRL (1)
66 // 0x08000000 [27] UART1 (1)
67 // 0x04000000 [26] UART0 (1)
68 // 0x02000000 [25] TRNG (1)

147 // 0x00000400 [10] PADS_QSPI (0)
148 // 0x00000200 [9] PADS_BANK0 (0)
149 // 0x00000100 [8] JTAG (0)
150 // 0x00000080 [7] IO_QSPI (0)
151 // 0x00000040 [6] IO_BANK0 (0)
152 // 0x00000020 [5] I2C1 (0)
153 // 0x00000010 [4] I2C0 (0)
154 // 0x00000008 [3] HSTX (0)

```

```

155 // 0x00000004 [2] DMA (0)
156 // 0x00000002 [1] BUSCTRL (0)
157 // 0x00000001 [0] ADC (0)
158 io_ro_32 reset_done;
159 } resets_hw_t;

```

This struct defines the following registers:

- **reset**: This register contains a bit for each component that can be reset. When set to 1, the reset is asserted. If the bit is cleared, the reset is deasserted.
- **wdsel**: This register contains a bit for each component that can be reset. When set to 1, this component will reset if the watchdog fires. If you reset the power-on state machine, the entire reset controller will reset, which includes every component.
- **reset\_done**: This register contains a bit for each component that is automatically set when the component is out of reset. This allows software to wait for this status bit in case the component requires initialisation before use.

The SDK defines reset functions as follows:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_resets/include/hardware/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_resets/include/hardware/resets.h) Lines 159 - 161

```

159 static __force_inline void reset_block(uint32_t bits) {
160 reset_block_mask(bits);
161 }

```

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_resets/include/hardware/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_resets/include/hardware/resets.h) Lines 163 - 165

```

163 static __force_inline void unreset_block(uint32_t bits) {
164 unreset_block_mask(bits);
165 }

```

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_resets/include/hardware/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_resets/include/hardware/resets.h) Lines 167 - 169

```

167 static __force_inline void unreset_block_wait(uint32_t bits) {
168 return unreset_block_mask_wait_blocking(bits);
169 }

```

One example use of reset functions is the UART driver, which defines a **uart\_reset** function that selects a different bit of the reset register depending on the UART specified:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_uart/uart.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_uart/uart.c) Lines 32 - 38

```

32 static inline void uart_reset(uart_inst_t *uart) {
33 reset_block_num(uart_get_reset_num(uart));
34 }
35
36 static inline void uart_unreset(uart_inst_t *uart) {
37 unreset_block_num_wait_blocking(uart_get_reset_num(uart));
38 }

```

### 7.5.3. List of Registers

The reset controller registers start at a base address of **0x40020000** (defined as **RESETS\_BASE** in SDK).

```

155 // 0x00000004 [2] DMA (0)
156 // 0x00000002 [1] BUSCTRL (0)
157 // 0x00000001 [0] ADC (0)
158 io_ro_32 reset_done;
159 } resets_hw_t;

```

该结构体定义以下寄存器：

- **reset**: 该寄存器包含每个可复位组件的对应位。设置为 1 时，复位信号被置位。若该位清零，复位信号撤销。
- **wdsel**: 该寄存器包含每个可复位组件的对应位。设置为 1 时，当看门狗触发，此组件将被复位。若复位上电状态机，则整个复位控制器（包括所有组件）将被复位。
- **reset\_done**: 该寄存器包含每个组件在退出复位后自动置位的状态位。软件可以通过等待该状态位来确保组件在使用前完成初始化。

SDK 定义了以下复位函数：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_resets/include/hardware/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_resets/include/hardware/resets.h) 第159至161行

```

159 static __force_inline void reset_block(uint32_t bits) {
160 reset_block_mask(bits);
161 }

```

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_resets/include/hardware/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_resets/include/hardware/resets.h) 第163至165行

```

163 static __force_inline void unreset_block(uint32_t bits) {
164 unreset_block_mask(bits);
165 }

```

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_resets/include/hardware/resets.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_resets/include/hardware/resets.h) 第167至169行

```

167 static __force_inline void unreset_block_wait(uint32_t bits) {
168 return unreset_block_mask_wait_blocking(bits);
169 }

```

重置函数的一个示例用法是UART驱动程序，该驱动程序定义了一个 **uart\_reset** 函数，根据指定的UART选择重置寄存器的不同位：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_uart/uart.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_uart/uart.c) 第32至38行

```

32 static inline void uart_reset(uart_inst_t *uart) {
33 reset_block_num(uart_get_reset_num(uart));
34 }
35
36 static inline void uart_unreset(uart_inst_t *uart) {
37 unreset_block_num_wait_blocking(uart_get_reset_num(uart));
38 }

```

### 7.5.3. 寄存器列表

重置控制器寄存器的基址为 **0x40020000**（在SDK中定义为RESETS\_BASE）。

## 7.6. 上电复位与欠压检测

### 7.6.1. Power-on reset (POR)

The power-on reset block ensures the chip starts up cleanly when power is first applied. It accomplishes this by holding the chip in reset until the digital core supply ( $DVDD$ ) reaches a voltage high enough to reliably power the chip's core logic. The block holds its `por_n` output low until  $DVDD$  exceeds the **power-on reset threshold** ( $DVDD_{TH.POR}$ ) for a period greater than the **power-on reset assertion delay** ( $t_{POR ASSERT}$ ). Once high, `por_n` remains high even if  $DVDD$  subsequently falls below  $DVDD_{TH.POR}$ . The behaviour of `por_n` when power is applied is shown in Figure 28, "A power-on reset cycle".

Figure 28. A power-on reset cycle

$DVDD_{TH.POR}$  is fixed at a nominal 0.957V, which should result in a threshold between 0.924V and 0.99V. The threshold assumes a nominal  $DVDD$  of 1.1V at initial power-on, and `por_n` may never go high if a lower voltage is used. Once the chip is out of reset,  $DVDD$  can be reduced without `por_n` going low.

#### 7.6.1.1. Detailed specifications

Table 538. Power-on Reset Parameters

Parameter	Description	Min	Typ	Max	Units
$DVDD_{TH.POR}$	power-on reset threshold	0.924	0.957	0.99	V
$t_{POR ASSERT}$	power-on reset assertion delay		3	10	$\mu s$

### 7.6.2. Brownout detection (BOD)

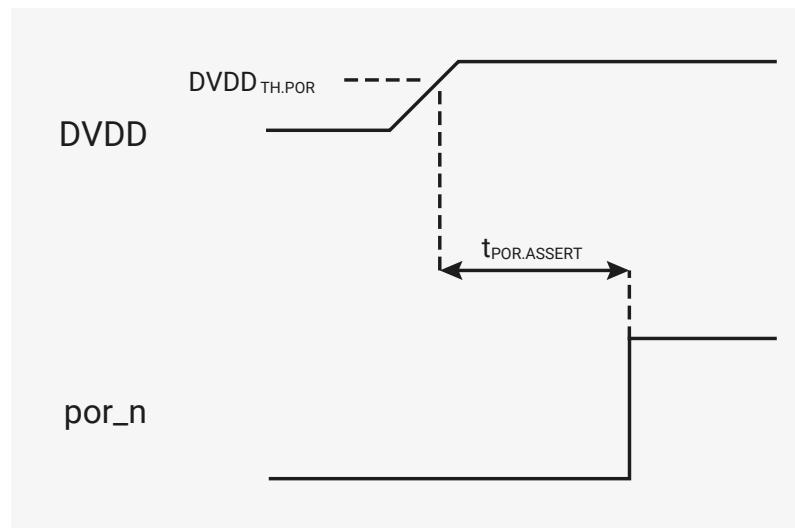

The brownout detection block prevents unreliable operation when the digital core supply ( $DVDD$ ) drops below a safe operating level. If enabled, the block resets the chip by taking its `bor_n` output low when  $DVDD$  drops below the **brownout detection assertion threshold** ( $DVDD_{TH.BOD ASSERT}$ ) for a period greater than the **brownout detection assertion delay** ( $t_{BOD ASSERT}$ ). If  $DVDD$  subsequently rises above the **brownout detection de-assertion threshold** ( $DVDD_{TH.BOD DEASSERT}$ ) for a period greater than the **brownout detection de-assertion delay** ( $t_{BOD DEASSERT}$ ), the block releases reset by taking `bor_n` high. A brownout, followed by supply recovery, is shown in Figure 29, "A brownout detection cycle".

### 7.6.1. 上电复位 (POR)

上电复位模块确保芯片在首次加电时能够稳定启动。该模块通过保持芯片处于复位状态，直到数字核供电 ( $DVDD$ ) 达到足以可靠驱动芯片核心逻辑的电压水平来实现此目的。

该模块将其  $por\_n$  输出维持在低电平，直到  $DVDD$  超过上电复位阈值( $DVDD_{TH.POR}$ )，且持续时间超过上电复位断言延迟( $t_{POR ASSERT}$ )。一旦 $por\_n$ 变为高电平，即使 $DVDD$ 随后降至低于 $DVDD_{TH.POR}$ ，也会保持高电平。 $por\_n$ 在加电过程中的行为如图28所示，“一次上电复位周期”。

图28. 上电  
复位周期

$DVDD_{TH.POR}$ 固定为标称0.957V，阈值应介于0.924V与0.99V之间。该阈值假设  $DVDD$ 在初始上电时为标称1.1V，若使用较低电压， $por\_n$ 可能永远不会变为高电平。芯片脱离复位后， $DVDD$ 可以降低，而  $por\_n$ 不会变为低电平。

#### 7.6.1.1. 详细规格

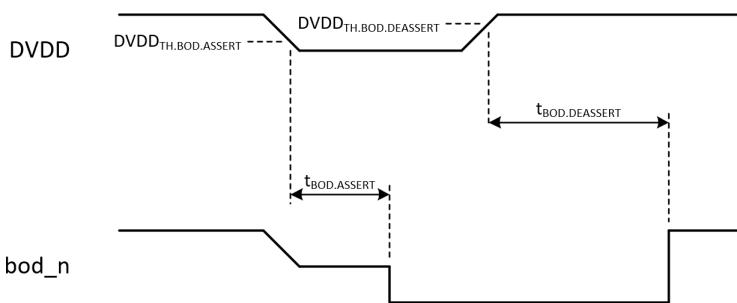

表538. 上电  
复位参数

参数	描述	最小值	典型值	最大值	单位
$DVDD_{TH.POR}$	上电复位 阈值	0.924	0.957	0.99	V
$t_{POR ASSERT}$	上电复位 断言延时		3	10	$\mu s$

### 7.6.2. 欠压检测 (BOD)

欠压检测模块防止数字核心电源 ( $DVDD$ ) 降至安全工作电压以下时发生不可靠操作。若启用，当  $DVDD$ 降至欠压检测断言阈值( $DVDD_{TH.BOD ASSERT}$ )以下，并持续时间超过欠压检测断言延时 ( $t_{BOD ASSERT}$ )时，模块通过将 $bod\_n$ 输出拉低来复位芯片。如果  $DVDD$ 随后上升超过棕褐色检测取消断言阈值 ( $DVDD_{TH.BOD DEASSERT}$ )且持续时间超过棕褐色检测取消断言延迟 ( $t_{BOD DEASSERT}$ )，该模块通过将 $bod\_n$ 拉高来释放复位。图29，“棕褐色检测周期”展示了一次棕褐色及其供电恢复过程。

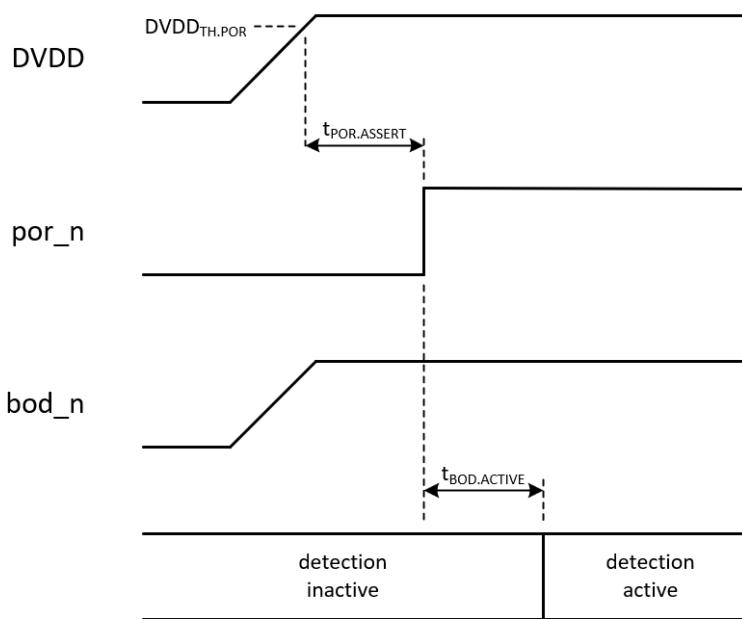

Figure 29. A brownout detection cycle

### 7.6.2.1. Detection enable

Brownout detection is always enabled at initial power-on. There is, however, a short delay, the **brownout detection activation delay** ( $t_{BOD.ACTIVE}$ ), between `por_n` going high and detection becoming active. This is shown in Figure 30, "Activation of brownout detection at initial power-on and following a brownout event".

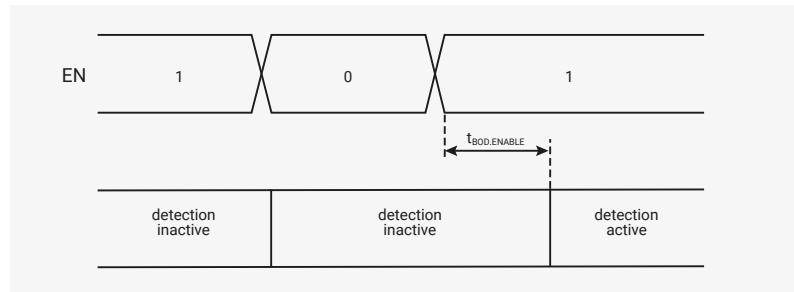

Figure 30. Activation of brownout detection at initial power-on and following a brownout event.

Once the chip is out of reset, detection can be disabled under software control. This saves a small amount of power. If detection is subsequently re-enabled, there will be another short delay, the **brownout detection enable delay** ( $t_{BOD.ENABLE}$ ), before it becomes active again. This is shown in Figure 31, "Disabling and enabling brownout detection".

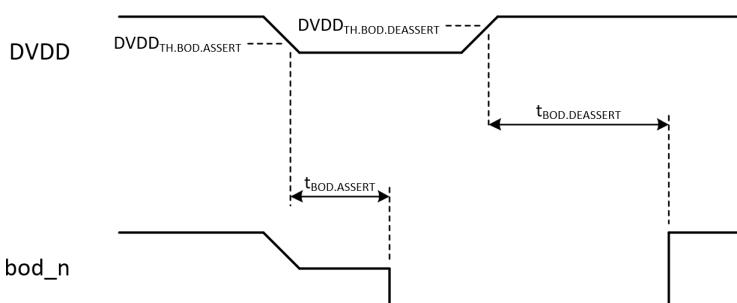

Detection is disabled by writing a `0` to the `EN` field in the `BOD` register and is re-enabled by writing a `1` to the same field. The block's `bod_n` output is high when detection is disabled.

Figure 31. Disabling and enabling brownout detection

Detection is re-enabled if the BOD register is reset, as this sets the register's `EN` field to `1`. Again, detection will become

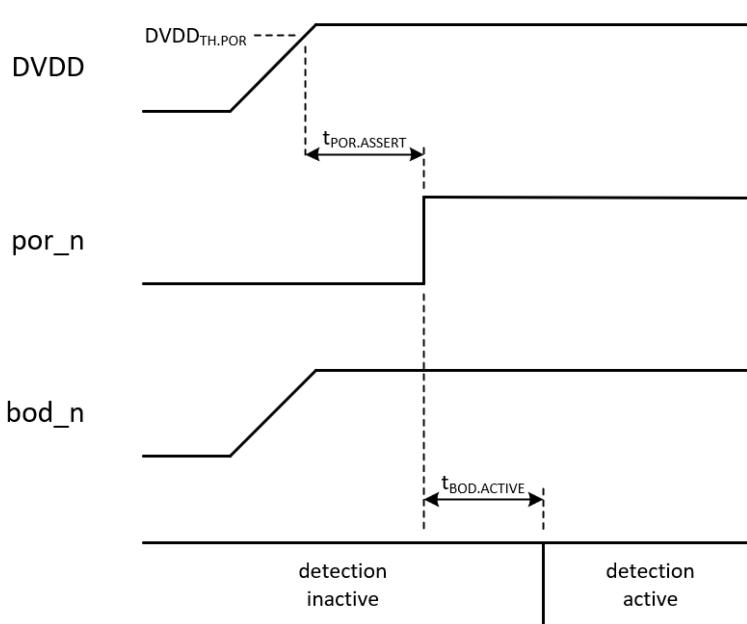

图29。棕褐色检测周期

### 7.6.2.1. 检测启用

棕褐色检测在设备初次上电时始终启用。但在por\_n拉高与检测激活之间存在一个短暂延迟，即棕褐色检测激活延迟 (t<sub>BOD ACTIVE</sub>)。如图30，“设备初次上电及棕褐色事件后棕褐色检测的激活”所示。

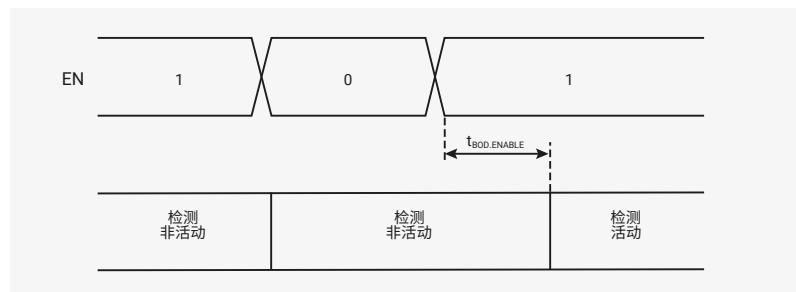

图30。设备初次上电及棕褐色事件后棕褐色检测的激活

芯片一旦解除复位，检测即可通过软件控制被禁用。此举可节省少量功耗。如果随后重新启用检测，将有一次短暂延迟，即棕色断电检测启用延迟 (t<sub>BOD ENABLE</sub>)，之后检测方会重新生效。该过程如图31所示，“禁用与启用棕色断电检测”。

通过向BOD寄存器的 EN字段写入0可禁用检测，写入 1则可重新启用检测。检测被禁用时，模块的 bod\_n输出为高电平。

图31。禁用与启用棕色断电检测

若BOD寄存器被复位，检测将重新启用，因为寄存器的 EN字段会被设置为 1。检测将

active after a delay equal to the brownout detection enable delay ( $t_{BOD,ENABLE}$ ).

**NOTE**

If the **BOD** register is reset by a power-on or brownout-initiated reset, the delay between the register being reset and brownout detection becoming active will be equal to the brownout detection activation delay ( $t_{BOD,ACTIVE}$ ). The delay will be equal to the brownout detection enable delay ( $t_{BOD,ENABLE}$ ) for all other reset sources.

### 7.6.2.2. Adjusting the detection threshold

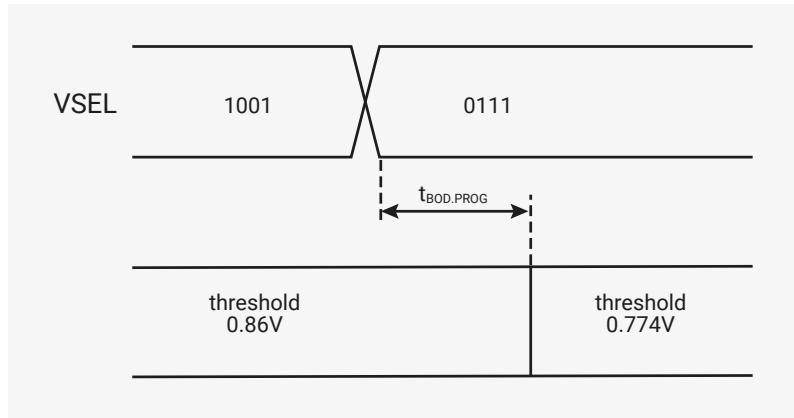

The **brownout detection threshold** ( $DVDD_{TH,BOD}$ ) has a nominal value of 0.946V at initial power-on or after a reset event. This should result in a detection threshold between 0.913V and 0.979V. Once out of reset, the threshold can be adjusted under software control. The new detection threshold will take effect after the **brownout detection programming delay** ( $(t_{BOD,PROG})$ ). An example of this is shown in [Figure 32, "Adjusting the brownout detection threshold"](#).

The threshold is adjusted by writing to the **VSEL** field in the **BOD** register. See the **BOD** register description for details.

**NOTE**

The nominal supply voltage for DVDD is 1.1 V. You should not increase the brownout detection threshold above the nominal supply voltage.

Figure 32. Adjusting the brownout detection threshold

### 7.6.2.3. Detailed specifications

Table 539. Brownout Detection Parameters

Parameter	Description	Min	Typ	Max	Units
$DVDD_{TH,BOD,ASSERT}$	brownout detection assertion threshold	96.5	100	103.5	% of selected threshold voltage
$DVDD_{TH,BOD,DEASSERT}$	brownout detection de-assertion threshold	97.4	101	105	% of selected threshold voltage
$t_{BOD,ACTIVE}$	brownout detection activation delay		55	80	$\mu s$
$t_{BOD,ASSERT}$	brownout detection assertion delay		3	10	$\mu s$

在等于棕色断电检测启用延迟 ( $t_{BOD.ENABLE}$ ) 的时间后重新生效。

#### **i 注意**

若 BOD 寄存器因上电或低电压复位触发而重置，寄存器重置与棕色断电检测激活之间的延迟将等于棕色断电检测激活延迟 ( $t_{BOD.ACTIVE}$ )。对于所有其他复位源，该延迟将等于棕色断电检测使能延迟 ( $t_{BOD.ENABLE}$ )。

### 7.6.2.2. 调整检测阈值

棕色断电检测阈值(DVDDTH.BOD) 在初次上电或复位事件后具有标称值0.946V。

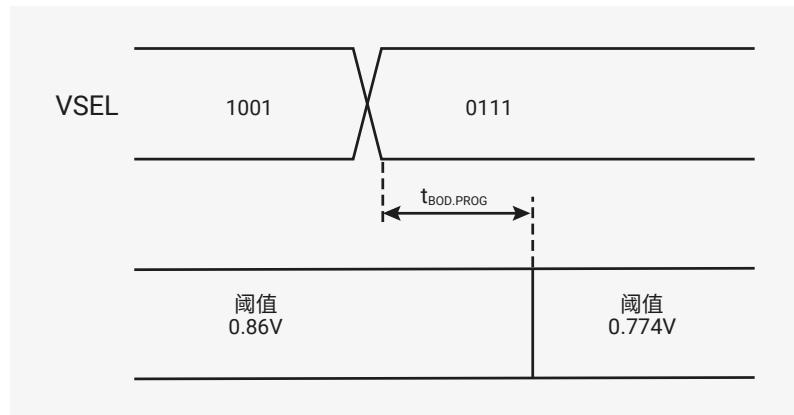

该值对应的检测阈值应在0.913V至0.979V之间。复位结束后，阈值可通过软件进行调整。新的检测阈值将在**棕色断电检测编程延迟** ( $t_{BOD.PROG}$ ) 后生效。示例见图32，“调整棕色断电检测阈值”。

通过向 BOD 寄存器中的 VSEL 字段写入数据调整阈值。详见 BOD 寄存器说明。

#### **i 注意**

DVDD的额定供电电压为1.1 V。请勿将欠压检测阈值设置高于额定供电电压。

图32。调整  
欠压检测  
阈值

### 7.6.2.3. 详细规格

表539。欠压检测参数

参数	描述	最小值	典型值	最大值	单位
$DVDD_{TH.BOD ASSERT}$	欠压检测断言阈值	96.5	100	103.5	所选阈值电压的百分比
$DVDD_{TH.BOD DEASSERT}$	欠压检测取消断言阈值	97.4	101	105	所选阈值电压的百分比
$t_{BOD.ACTIVE}$	欠电压检测激活延迟		55	80	μs
$t_{BOD ASSERT}$	欠电压检测断言延迟		3	10	μs

Parameter	Description	Min	Typ	Max	Units
$t_{BOD.DEASSERT}$	brownout detection de-assertion delay		55	80	μs
$t_{BOD.ENABLE}$	brownout detection enable delay		35	55	μs
$t_{BOD.PROG}$	brownout detection programming delay		20	30	μs

### 7.6.3. Supply monitor

The power-on and brownout reset blocks are powered by the core voltage regulator's analogue supply (**VREG\_AVDD**). The blocks are initialised when power is first applied, but may not be reliably re-initialised if power is removed and then reapplied before **VREG\_AVDD** has dropped to a sufficiently low level. To prevent this happening, **VREG\_AVDD** is monitored and the power-on reset block is re-initialised if it drops below the **VREG\_AVDD activation threshold** ( $VREG_AVDD_{TH.ACTIVE}$ ).  $VREG_AVDD_{TH.ACTIVE}$  is fixed at a nominal 1.1V, which should result in a threshold between 0.87V and 1.26V. This threshold does not represent a safe operating voltage. Instead, it represents the voltage that **VREG\_AVDD** must drop below to reliably re-initialise the power-on reset block. For safe operation, **VREG\_AVDD** must be at a nominal voltage of 3.3V. See Table 1441, "Power Supply Specifications".

#### 7.6.3.1. Detailed specifications

Table 540. Voltage Regulator Input Supply Monitor Parameters

Parameter	Description	Min	Typ	Max	Units
$VREG_{VIN}_{TH.ACTIVE}$	<b>VREG_VIN</b> activation threshold	0.87	1.1	1.26	V

### 7.6.4. List of registers

The chip-level reset subsystem shares a register address space with other power management subsystems in the always-on domain. The address space is referred to as **POWMAN** elsewhere in this document. A complete list of **POWMAN** registers is provided in Section 6.4, "Power management (POWMAN) registers", but information on registers associated with the brownout detector are repeated here.

The **POWMAN** registers start at a base address of **0x40100000** (defined as **POWMAN\_BASE** in SDK).

- **BOD\_CTRL**
- **BOD**
- **BOD\_LP\_ENTRY**
- **BOD\_LP\_EXIT**

参数	描述	最小值	典型值	最大值	单位
$t_{BOD.DEASSERT}$	欠电压 检测解除断言 延迟		55	80	μs
$t_{BOD.ENABLE}$	欠电压 检测启用 延迟		35	55	μs
$t_{BOD.PROG}$	欠电压 检测 编程 延迟		20	30	μs

### 7.6.3. 电源监控器

上电和欠电压复位模块由核心电压调节器的模拟电源（VREG\_AVDD）供电。模块在首次加电时完成初始化，但若 VREG\_AVDD 未降至足够低的水平即断电再重新加电，可能无法可靠地重新初始化。为防止此类情况发生，监测 VREG\_AVDD，并在其低于**VREG\_AVDD激活阈值**（VREG\_AVDD<sub>TH\_ACTIVE</sub>）时重新初始化上电复位模块。

VREG\_AVDD<sub>TH\_ACTIVE</sub>固定为标称1.1V，阈值范围应为0.87V至1.26V。该阈值不表示安全工作电压。此电压表示 VREG\_AVDD 必须下降到的阈值以下，以可靠地重新初始化上电复位模块。为确保安全运行，**VREG\_AVDD的标称电压应为3.3V**。详见表144 1，“电源规格”。

#### 7.6.3.1. 详细规格

表540。电压  
稳压器输入供电  
监测参数

参数	描述	最小值	典型值	最大值	单位
VREG_VIN <sub>TH_ACTIVE</sub>	<b>VREG_VIN</b> 激活阈值	0.87	1.1	1.26	V

### 7.6.4. 寄存器列表

芯片级复位子系统与常通电域内其他电源管理子系统共享寄存器地址空间。该地址空间在本文档中称为 **POWMAN**。**POWMAN** 寄存器完整列表见第6.4节“电源管理（POWMAN）寄存器”，但与棕断检测器相关的寄存器信息在此重复列出。

**POWMAN**寄存器基址为0x40100000（在SDK中定义为POWMAN\_BASE）。

# Chapter 8. Clocks

## 8.1. Overview

The clocks block provides independent clocks to on-chip and external components. It takes inputs from a variety of clock sources, allowing the user to trade off performance against cost, board area and power consumption. From these sources it uses multiple clock generators to provide the required clocks. This architecture allows the user flexibility to start and stop clocks independently and to vary some clock frequencies whilst maintaining others at their optimum frequencies.

Figure 33. Clocks overview

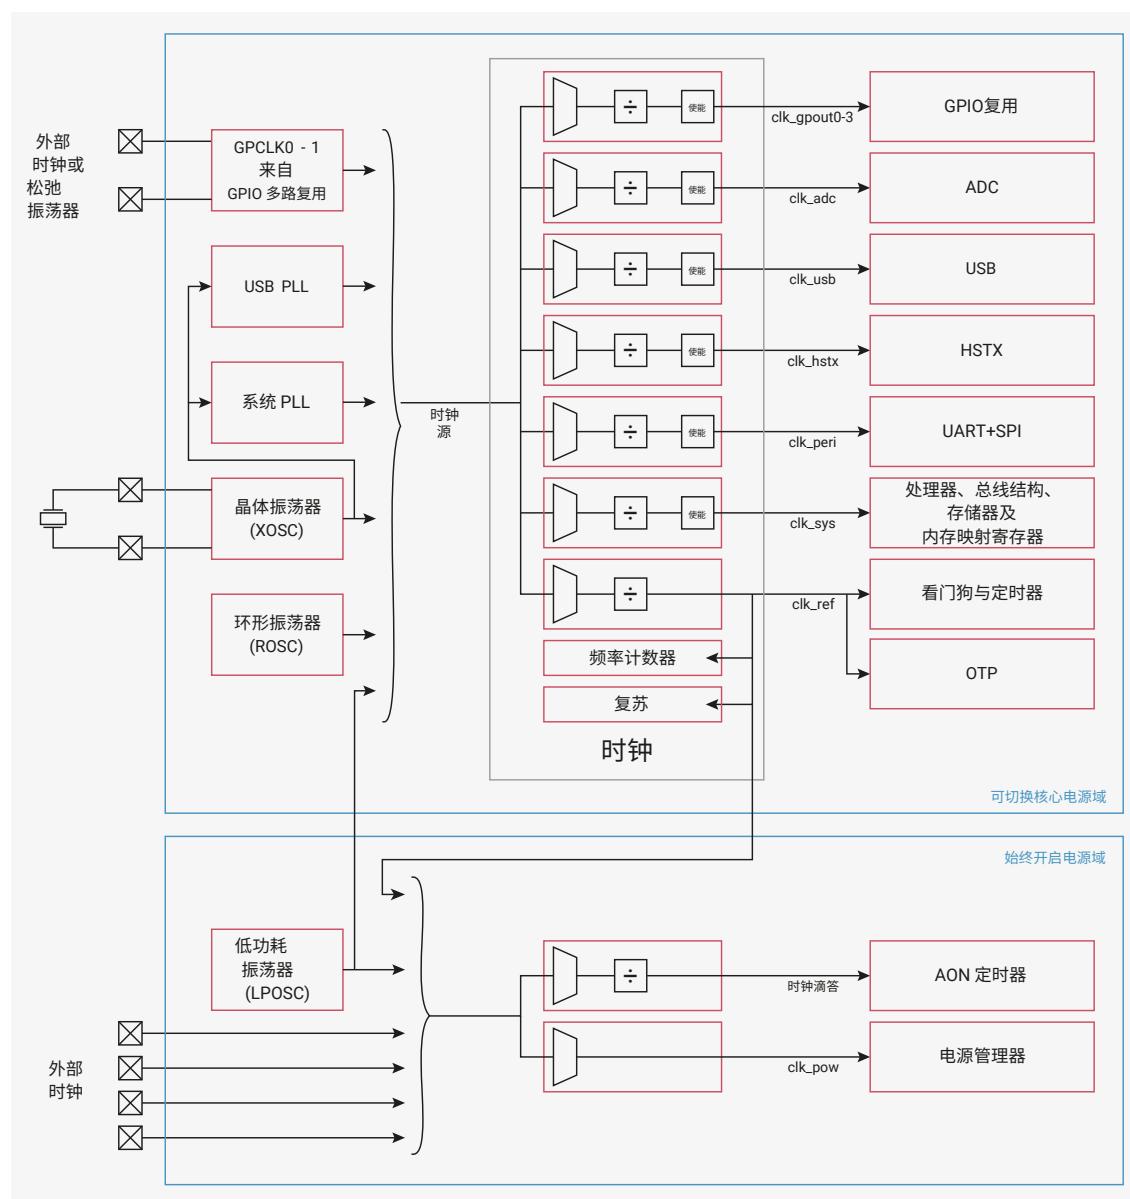

The crystal oscillator (XOSC) provides a reference to two PLLs, which provide high precision clocks to the processors and peripherals. These are slow to start when waking from the various low-power modes, so the on-chip ring oscillator (ROSC) is provided to boot the device until they are available. When the switched-core is powered down or the device is in DORMANT mode (see [Section 6.5.3, “DORMANT state”](#)) the on-chip 32kHz low-power oscillator (LPOSC) provides a clock to the power manager and a tick to the Always-on Timer (AON Timer).

# 第8章 时钟

## 8.1. 概述

时钟模块为片上及外部组件提供独立时钟。其接收多种时钟源输入，使用户能够在性能、成本、板载面积及功耗之间进行权衡。该模块利用多个时钟发生器，从这些时钟源中产生所需时钟。该架构允许用户灵活地独立启动和停止时钟，并在保持部分时钟于最优频率的同时调整其他时钟频率。

图33. 时钟概览

晶体振荡器 (XOSC) 为两个锁相环 (PLL) 提供参考，这些PLL为处理器和外设提供高精度时钟。在从各种低功耗模式唤醒时，这些时钟启动较慢，因此片上环形振荡器 (ROSC) 用于启动设备，直到它们可用为止。当切换核心断电或设备处于DORMANT模式（参见第6.5.3节“DORMANT状态”）时，片上32kHz低功耗振荡器 (LPOSC) 为电源管理器提供时钟，并为始终开启定时器 (AON定时器) 提供滴答信号。

The clock generators select from the clock sources and optionally divide the selected clock before outputting through enable logic that provides automatic clock gating in sleep mode (see [Section 8.1.3.5.2, "System sleep mode"](#)).

An on-chip frequency counter facilitates debugging of the clock setup and also allows measurement of the frequencies of LPOSC, ROSC and external clocks. If the system clock stops accidentally, the on-chip `resus` (short for `resuscitate`) component restarts it from a known good clock. This allows the software debugger to access registers and debug the problem.

When the switched-core is powered, the power manager clock automatically switches to the reference clock (`clk_ref`). The user can optionally switch the AON Timer tick, though we recommend waiting until `clk_ref` is running from the XOSC, because the ROSC frequency is imprecise.

You can substitute the clock sources with up to 2 GPIO clock inputs. This helps avoid adding a second crystal into systems that already have an accurate clock source and enables replacement of the ROSC and LPOSC with more accurate external sources.

You can also output up to 4 generated clocks to GPIOs at up to 50MHz. This enables you to supply clocks to external devices, reducing the need for additional clock components that consume power and board area.

### 8.1.1. Changes between RP2350 revisions

RP2350 A3 changes the reset values of:

- `CLK_SYS_CTRL.SRC` from `0` to `1` (select AUX source).
- `CLK_SYS_CTRL.AUXSRC` from `0` to `2` (select ROSC as AUX source).

See [Hardware changes](#) for information about related changes made to the ROSC configuration at reset. See [Bootrom changes](#) for related changes made in the A3 boot ROM.

### 8.1.2. Clock sources

RP2350 can use a variety of clock sources. This flexibility allows the user to optimise the clock setup for performance, cost, board area and power consumption. RP2350 supports the following potential clock sources:

- On-chip 32kHz low-power oscillator ([Section 8.4, "Low Power oscillator \(LPOSC\)"](#))
- On-chip ring oscillator ([Section 8.3, "Ring oscillator \(ROSC\)"](#))
- Crystal oscillator ([Section 8.2, "Crystal oscillator \(XOSC\)"](#))
- External clocks from GPIOs ([Section 8.1.6.4, "Configuring a GPIO input clock"](#)) and PLLs ([Section 8.6, "PLL"](#))

The list of clock sources is different per clock generator and can be found as enumerated values in the `CTRL` register. See `CLK_SYS_CTRL` as an example.

#### 8.1.2.1. Low-power oscillator

The on-chip 32kHz low-power oscillator ([Section 8.4, "Low Power oscillator \(LPOSC\)"](#)) requires no external components. It starts automatically when the always-on domain is powered, providing a clock for the power manager and a tick for the Always-on Timer (AON Timer) when the switched-core power domain is powered off.

The LPOSC can be tuned to 1% accuracy, and the divider in the AON Timer tick generator can further tune the 1ms tick. However, the LPOSC frequency varies with voltage and temperature, so fine-tuning is only useful in systems with stable voltage and temperature.

When the switched-core is powered, the LPOSC clock can drive the reference clock (`clk_ref`), which in turn can drive the system clock (`clk_sys`). This allows another low-power mode where the processors remain powered but, unlike the SLEEP and DORMANT modes, clocks are running. The LPOSC clock can also be sent to the frequency counter for calibration or output to a GPIO.

时钟发生器从时钟源中选择，并可选择性地对选中的时钟进行分频，随后通过使能逻辑输出，该逻辑在睡眠模式下实现自动时钟门控（参见第8.1.3.5.2节“系统睡眠模式”）。

片上频率计有助于调试时钟设置，同时允许测量LPOSC、ROSC及外部时钟的频率。若系统时钟意外停止，片上重启(resume，意为复苏)模块将从已知的正常时钟重新启动系统时钟。此功能使软件调试器能够访问寄存器并排查问题。

切换核供电时，电源管理时钟会自动切换至参考时钟（`clk_ref`）。

用户可选择切换AON定时器计时，但建议等待 `clk_ref`由XOSC驱动稳定后再切换，因ROSC频率存在不精确性。

您可使用最多两个GPIO时钟输入替代默认时钟源。此举有助于避免在已有精确时钟源的系统中增加第二晶体，并能用更准确的外部时钟替代ROSC和LPOSC。

您还可以将最多4个生成时钟以最高50MHz频率输出至GPIO。此功能使您能够向外部设备提供时钟信号，减少对额外时钟组件的需求，从而降低功耗和电路板面积。

### 8.1.1. RP2350 版本间的变更

RP2350 A3更改了以下复位值：

- `CLK_SYS_CTRL.SRC` 从 0 变更为 1（选择AUX源）。
- `CLK_SYS_CTRL.AUXSRC` 从 0 变更为 2（选择ROSC作为AUX源）。

有关复位时对ROSC配置所做相关更改的信息，请参见硬件更改一节。有关A3版Boot ROM中相关更改的信息，请参见Boot ROM更改一节。

### 8.1.2. 时钟源

RP2350支持多种时钟源。该灵活性允许用户针对性能、成本、电路板面积及功耗优化时钟配置。RP2350支持以下潜在的时钟源：

- 片上32kHz低功耗振荡器（第8.4节，“低功耗振荡器（LPOSC）”）
- 片上环形振荡器（第8.3节，“环形振荡器（ROSC）”）
- 晶体振荡器（第8.2节，“晶体振荡器（XOSC）”）
- 来自GPIO（第8.1.6.4节，“配置GPIO输入时钟”）和PLL（第8.6节，“PLL”）的外部时钟

时钟源列表因时钟发生器不同而异，可在 `CTRL` 寄存器中以枚举值形式查阅。

以`CLK_SYS_CTRL`为例。

#### 8.1.2.1. 低功耗振荡器

片上32kHz低功耗振荡器（第8.4节，“低功耗振荡器（LPOSC）”）无需任何外部元件。

当始终通电域通电时，振荡器自动启动，为电源管理器提供时钟信号，并在切换核心电源域关闭时为始终通电定时器（AON定时器）提供计时脉冲。

该LPOSC频率可调至1%精度，且AON定时器计时脉冲发生器中的分频器可对1ms计时脉冲进行进一步微调。但由于LPOSC频率随电压和温度变化，故细调仅适用于电压和温度相对稳定的系统。

当切换核心通电时，LPOSC时钟可驱动参考时钟（`clk_ref`），进而驱动系统时钟（`clk_sys`）。这允许另一种低功耗模式，在该模式下处理器保持通电，但与SLEEP和DORMANT模式不同，时钟继续运行。LPOSC时钟亦可送至频率计进行校准，或输出至GPIO。

### 8.1.2.2. Ring oscillator

The on-chip ring oscillator ([Section 8.3, “Ring oscillator \(ROSC\)”](#)) requires no external components. It starts automatically when the switched-core domain is powered and is used to clock the chip during the initial boot stages. During boot, the ROSC runs at a nominal 11MHz, but varies with PVT (Process, Voltage, and Temperature). The ROSC frequency is guaranteed to be in the range 4.6MHz to 19.6MHz.

For low-cost applications where frequency accuracy is unimportant, the chip can continue to run from the ROSC. If your application requires greater performance, the frequency can be increased by programming the registers as described in [Section 8.3, “Ring oscillator \(ROSC\)”](#). Because the frequency varies with PVT (Process, Voltage, and Temperature), the user must take care to avoid exceeding the maximum frequencies described in the clock generators section. For information about reducing this variation when running the ROSC at frequencies close to the maximum, see [Section 8.1.2.2.1, “Mitigate ROSC frequency variation due to process”](#). Alternatively, use an external clock or the XOSC to provide a stable reference clock and use the PLLs to generate higher frequencies. However, this approach requires external components, which will cost board area and increase power consumption.

When using an external clock or the XOSC, you can stop the ROSC to save power. Before stopping the ROSC, you must switch the reference clock generator and the system clock generator to an alternate source.

The ROSC is unpowered when the switched-core domain is powered down, but starts immediately when the switched-core powers up. It is not affected by sleep mode. To save power, reduce the frequency before entering sleep mode. When entering DORMANT mode, the ROSC is automatically stopped. When exiting DORMANT mode, the ROSC restarts in the same configuration. If you drive clocks at close to their maximum frequencies with the ROSC, drop the frequency before entering SLEEP or DORMANT mode. This allows for frequency variation due to changes in environmental conditions during SLEEP or DORMANT mode.

To use ROSC clock externally, output it to a GPIO pin using one of the `clk_gpc1k0-3` generators.

The following sections describe techniques for mitigating PVT variation of the ROSC frequency. They also provide some interesting design challenges for use in teaching both the effects of PVT and writing software to control real time functions.

 **TIP**

Because the ROSC frequency varies with PVT (Process, Voltage, and Temperature), you can use the ROSC frequency to measure any one of the three PVT variables as long as you know the other two variables.

#### 8.1.2.2.1. Mitigate ROSC frequency variation due to process

Process varies for the following reasons:

- Chips leave the factory with a spread of process parameters. This causes variation in the ROSC frequency across chips.
- Process parameters vary slightly as the chip ages. This is only observable over many thousands of hours of operation.

To mitigate process variation, the user can characterise individual chips and program the ROSC frequency accordingly. This is an adequate solution for small numbers of chips, but does not scale well to volume production. For high-volume applications, consider using [automatic mitigation](#).

#### 8.1.2.2.2. Mitigate ROSC frequency variation due to voltage

Supply voltage varies for the following reasons:

- The power supply itself can vary.
- As chip activity varies, on-chip IR varies.

To mitigate voltage variation, calibrate for the minimum performance target of your application, then adjust the ROSC

### 8.1.2.2. 环形振荡器

片上环形振荡器（第 8.3 节，“[环形振荡器（ROSC）](#)”）无需外部元件。当切换核心域通电时，环形振荡器自动启动，并用于芯片初始启动阶段的时钟驱动。

启动期间，ROSC 以标称 11MHz 频率运行，但会随 PVT（工艺、电压和温度）变化。ROSC 频率保证处于 4.6MHz 至 19.6MHz 范围内。

对于频率精度不重要的低成本应用，芯片可继续由 ROSC 运行。若您的应用需更高性能，可通过对寄存器编程提升频率，详见第 8.3 节“[环形振荡器（ROSC）](#)”。因频率随 PVT（工艺、电压及温度）变化，用户务必避免超过时钟发生器章节中规定的最大频率。关于在接近最大频率运行 ROSC 时减少频率波动的措施，请参阅第 8.1.2.2.1 节“[缓解工艺引起的 ROSC 频率变化](#)”。或者，可采用外部时钟或 XOSC 提供稳定参考时钟，并利用 PLL 生成更高频率。但此方案需要外部组件，会增加电路板面积并提高功耗。

使用外部时钟或 XOSC 时，可停止 ROSC 以节省功耗。停止 ROSC 前，必须将参考时钟发生器及系统时钟发生器切换至备用时钟源。

当切换核心域断电时，ROSC 处于无电状态，但切换核心上电时会立即启动。其运行不受睡眠模式影响。为节约功耗，请在进入睡眠模式前降低频率。

进入 DORMANT 模式时，ROSC 会自动停止。退出 DORMANT 模式时，ROSC 将以相同配置重新启动。若驱动 ROSC 时钟频率接近最大值，须在进入 SLEEP 或 DORMANT 模式前降低频率。此举可补偿 SLEEP 或 DORMANT 模式期间因环境条件变化引起的频率波动。

欲外部使用 ROSC 时钟，请通过 [clk\\_gpcclk0-3](#) 生成器将其输出至 GPIO 引脚。

下列章节阐述缓解 ROSC 频率 PVT 变化的技术方案。同时，这些内容为教学 PVT 效应及编写实时控制软件提供了重要的设计挑战。

#### 提示

由于 ROSC 频率随 PVT（工艺、电压和温度）变化，只要已知其中任意两个变量，便可利用 ROSC 频率测量第三个变量。

#### 8.1.2.2.1. 缓解因工艺造成的 ROSC 频率变化

工艺变化的原因如下：

- 芯片出厂时存在一定范围的工艺参数差异。这导致芯片间 ROSC 频率存在差异。
- 芯片随着老化，工艺参数会发生轻微变化。这一现象仅在运行数千小时后才可观测到。

为缓解工艺变异，用户可对单个芯片进行特性描述并相应编程 ROSC 频率。

此方法适用于少量芯片，但不适合大规模生产。对于大批量应用，应考虑采用自动缓解机制。

#### 8.1.2.2.2. 缓解因电压引起的 ROSC 频率变化

电源电压变化的原因如下：

- 电源本身可能存在波动。
- 由于芯片活动的变化，片上 IR 也随之变化。

为减轻电压变化，应校准应用的最低性能目标，然后调整 ROSC

frequency to always exceed that minimum.

#### 8.1.2.2.3. Mitigate ROSC frequency variation due to temperature

Temperature varies for the following reasons:

- The ambient temperature can vary.
- The chip temperature varies as chip activity varies due to self-heating.

To mitigate temperature variations, stabilise the temperature. You can use a temperature controlled environment, passive cooling, or active cooling. Alternatively, track the temperature using the on-chip temperature sensor and adjust the ROSC frequency so it remains within the required bounds.

#### 8.1.2.2.4. Automatic mitigation of ROSC frequency variation due to PVT

Techniques for automatic ROSC frequency control avoid the need to calibrate individual chips, but require periodic access to a clock reference or to a time reference.

If a clock reference is available, you can use it to periodically measure the ROSC frequency and adjust accordingly. The on-chip XOSC is one potential clock reference. You can even run the XOSC intermittently to save power for very low-power application where it is too costly to run the XOSC continuously or use the PLLs to achieve high frequencies.

If a time reference is available, you can clock the on-chip AON Timer from the ROSC and periodically compare it against the time reference, adjusting the ROSC frequency as necessary. Using these techniques, the ROSC frequency still drifts due to voltage and temperature variation. As a result, you should also implement mitigations for voltage and temperature to ensure that variations do not allow the ROSC frequency to drift out of the acceptable range.

#### 8.1.2.2.5. Automatic overclocking using the ROSC

The datasheet maximum frequencies for any digital device are quoted for worst case PVT. Most chips in most normal environments can run significantly faster than the quoted maximum, and therefore support overclocking. When RP2350 runs from the ROSC, PVT affects both the ROSC and the digital components. As the ROSC gets faster, the processors can also run faster. This means the user can overclock from the ROSC, then rely on the ROSC frequency tracking with PVT variations. The tracking of ROSC frequency and the processor capability is not perfect, and currently there is insufficient data to specify a safe ROSC setting for this mode of operation, so some experimentation is required.

This mode of operation maximises processor performance, but causes variations in the time taken to complete a task. Only use overclocking for applications where this variation is acceptable. If your application uses frequency sensitive interfaces such as USB or UART, you must use the XOSC and PLL to provide a precise clock for those components.

#### 8.1.2.3. Crystal oscillator

The Crystal Oscillator ([Section 8.2, "Crystal oscillator \(XOSC\)"](#)) provides a precise, stable clock reference and should be used where accurate timing is required and no suitable external clocks are available. The XOSC requires an external crystal component. The external crystal determines the frequency. RP2350 supports 1MHz to 50MHz crystals and the RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#)) uses a 12MHz crystal. Using the XOSC and the PLLs, you can run on-chip components at their maximum frequencies. Appropriate margin is built into the design to tolerate up to 1000ppm variation in the XOSC frequency.

The XOSC is unpowered when the switched-core domain is powered down. It remains inactive when the switched-core is powered up. If required, you must enable it in software. XOSC startup takes several milliseconds, and software must wait for the `XOSC_STABLE` flag to be set before starting the PLLs and changing any clock generators. Before the XOSC completes startup, output might be non-existent or exhibit very short pulse widths; this will corrupt logic if used. When XOSC startup is complete, the reference clock (`clk_ref`) and the system clock (`clk_sys`) can run from the XOSC. If you

频率，以始终超过该最低值。

#### 8.1.2.2.3. 缓解因温度引起的ROSC频率变化

温度变化的原因包括：

- 环境温度可能发生变化。
- 由于芯片活动引起的自我发热，芯片温度也会变化。

为减轻温度变化，应保持温度稳定。您可以采用温控环境、被动散热或主动散热。或者，利用片上温度传感器监测温度，并调整ROSC频率，使其保持在所需范围内。

#### 8.1.2.2.4. 基于PVT的ROSC频率变化自动缓解

自动ROSC频率控制技术避免了单个芯片校准的需要，但需定期访问时钟参考或时间参考。

如果有时钟参考，可利用其周期性测量ROSC频率并进行相应调整。片上XOSC是一种潜在的时钟参考源。对于极低功耗应用，您甚至可以间歇性启动XOSC以节省功耗，因为持续运行XOSC或使用PLL来实现高频率的代价过高。

如果具备时间参考，您可以使用ROSC为片上AON定时器提供时钟，并定期将其与时间参考进行比较，必要时调整ROSC频率。采用这些技术后，ROSC频率仍会因电压和温度变化而发生漂移。因此，您还应针对电压和温度变化实施缓解措施，以确保ROSC频率的漂移不会超出可接受范围。

#### 8.1.2.2.5. 利用ROSC的自动超频

任何数字设备的数据手册中标注的最大频率均为最恶劣PVT条件下的数值。大多数芯片在大多数正常环境中能够显著超过该最大频率运行，从而支持超频。当RP2350工作于ROSC时，PVT因素同时影响ROSC与数字组件。随着ROSC频率的提升，处理器亦可运行得更快。这意味着用户可以通过ROSC进行超频，然后依赖ROSC频率随着PVT变化进行追踪。ROSC频率与处理器性能的追踪并非完美，且目前缺乏足够数据以确定该工作模式下的安全ROSC设置，因此需要进行适当实验。

该工作模式最大化处理器性能，但会导致完成任务所需时间出现波动。

仅在该时间波动可接受的应用场景中使用超频。如您的应用涉及频率敏感接口（如USB或UART），必须采用XOSC和PLL为相关组件提供精确时钟。

#### 8.1.2.3. 晶体振荡器

晶体振荡器（见第8.2节“晶体振荡器（XOSC）”）提供精确且稳定的时钟参考，当需要精准定时且无合适外部时钟时应予以采用。XOSC需要外部晶体元件。外部晶体决定振荡频率。RP2350 支持 1MHz 至 50MHz 的晶体，且 RP2350 参考设计（参见 RP2350 硬件设计与最小设计示例）采用 12MHz 晶体。利用 XOSC 与 PLL，可使片上组件达到其最大工作频率。设计中预留了适当裕度，以容忍 XOSC 频率最高达 1000ppm 的偏差。

当切换核心域断电时，XOSC 不供电。切换核心上电时，XOSC 仍保持非活动状态。如需启用，必须通过软件激活。XOSC 启动需数毫秒，软件必须等待 `XOSC_STABLE` 标志置位后，方可启动 PLL 并调整任何时钟发生器。在 XOSC 启动完成前，输出信号可能不存在或仅呈现极短脉冲；若此时使用输出信号，将导致逻辑损坏。当 XOSC 启动完成后，参考时钟 (`clk_ref`) 和系统时钟 (`clk_sys`) 可由 XOSC 驱动运行。如果您

switch the system and reference clocks to run from the XOSC, you can stop the ROSC to save power.

The XOSC is not affected by sleep mode. It automatically stops and restarts in the same configuration when entering and exiting DORMANT mode.

To use the XOSC clock externally, output it to a GPIO pin using one of the [clk\\_gpclk0-clk\\_gpclk03](#) generators. You cannot take XOSC output directly from the XIN (XI) or XOUT (XO) pins.

#### 8.1.2.4. External clocks

If external clocks exist in the hardware design, you can use them to clock RP2350. You can use clocks individually or in conjunction with the other (internal or external) clock sources. Use XIN and one of GPIN0-GPIN1 to input external clocks.

If you drive an external clock into XIN, you don't need an external crystal. When driving an external clock into XIN, you must configure the XOSC to pass through the XIN signal. When the switched-core powers down, this configuration will be lost, but the configuration is unaffected by SLEEP and DORMANT modes. The input is limited to 50MHz, but the on-chip PLLs can synthesise higher frequencies from the XIN input if required.

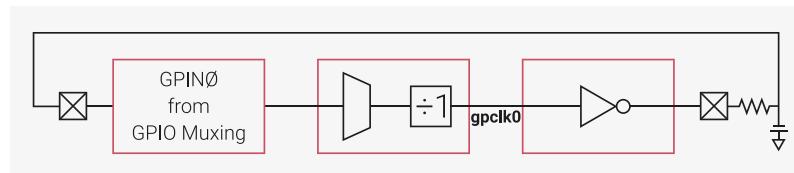

GPIN0-GPIN1 can provide system and peripherals clocks, but is limited to 50MHz. This can potentially save power and allows components on RP2350 to run synchronously with external components, which simplifies data transfer between chips. If the frequency accuracy of the external clocks is poorer than 1000ppm, the generated clocks should not run at their maximum frequencies since they could exceed their design margins. Once the external clocks begin to run, the reference clock ([clk\\_ref](#)) and the system clock ([clk\\_sys](#)) can run from the external clocks and you can stop the ROSC to save power. When the switched-core powers down, GPIN0-GPIN1 configuration will be lost, but the configuration is unaffected by SLEEP and DORMANT modes.

To provide a more accurate tick to the AON Timer, use one of the GPIN0-GPIN3 inputs to replace the clock from the LPOSC. These inputs are limited to 29MHz. GPIN0-GPIN3 configuration is unaffected by switched-core power down, sleep mode, and DORMANT mode.

#### 8.1.2.5. Relaxation oscillators

If there is no appropriate clock available, but you still want to replace or supplement external clocks with another clock source, you can construct one or two relaxation oscillators from external passive components. Send the clock source (GPIN0-GPIN1) to one of the [clk\\_gpclk0-clk\\_gpclk03](#) generators, invert it through the GPIO inverter [OUTOVER](#), and connect back to the clock source input via an RC circuit:

Figure 34. Simple relaxation oscillator example

The frequency of clocks generated from relaxation oscillators depend on the delay through the chip and the drive current from the GPIO output, both of which vary with PVT. The frequency and frequency accuracy depend on the quality and accuracy of the external components. More elaborate external components such as ceramic resonators, can improve performance, but also increase cost and complexity. Such an oscillator will not achieve 1000ppm, so they cannot drive internal clocks at their maximum frequencies. To drive internal clocks at the maximum possible frequency, use the XOSC.

The configuration of the relaxation oscillators will be lost when the switched-core powers down, but is not affected by sleep mode or DORMANT mode.

将系统和参考时钟切换为由XOSC驱动运行，可以停止ROSC以节省功耗。

XOSC不受睡眠模式影响。进入和退出休眠模式时，它会自动在相同配置下停止并重新启动。

若要将XOSC时钟输出到外部，需使用 `clk_gpclk0` 至 `clk_gpclk03` 生成器之一，将其输出至GPIO引脚。不可直接从XIN (XI) 或XOUT (XO) 引脚获取XOSC输出。

#### 8.1.2.4. 外部时钟

如果硬件设计中存在外部时钟，可用于为RP2350提供时钟。时钟可单独使用，也可与其他（内部或外部）时钟源联合使用。使用XIN及GPIN0至GPIN1之一输入外部时钟。

如果您向 XIN 输入外部时钟，则无需外部晶体。在向 XIN 输入外部时钟时，必须配置 XOSC 以透传 XIN 信号。当切换核心断电时，该配置将会丢失，但该配置不受 SLEEP 和 DORMANT 模式的影响。输入信号限制为 50MHz，但片内 PLL 可根据需要从 XIN 输入合成更高频率。

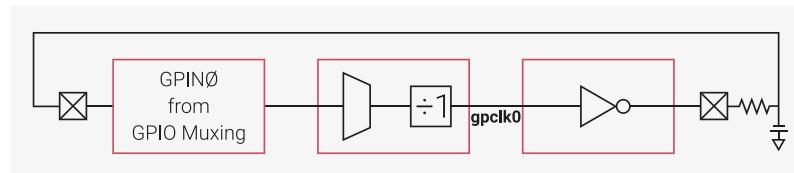

GPIN0-GPIN1 可提供系统和外设时钟，但频率限于 50MHz。这有助于节省功耗，并允许 RP2350 上的组件与外部组件同步运行，从而简化芯片间的数据传输。若外部时钟的频率精度低于 1000ppm，生成的时钟不应在最大频率下运行，否则可能超出其设计裕度。一旦外部时钟开始运行，参考时钟 (`clk_ref`) 和系统时钟 (`clk_sys`) 即可由外部时钟驱动，您可以关闭 ROSC 以节省功耗。当切换核心断电时，GPIN0-GPIN1 的配置将丢失，但该配置不受 SLEEP 与 DORMANT 模式的影响。

为了为 AON 计时器提供更精确的时钟，可以使用 GPIN0-GPIN3 中的任一输入替代 LPOSC 时钟。此类输入频率限制为 29 MHz。GPIN0-GPIN3 的配置不受切换核心断电、睡眠模式及 DORMANT 模式的影响。

#### 8.1.2.5. 松弛振荡器

若无合适的时钟源，但仍需用其他时钟替代或补充外部时钟，则可使用外部无源元件构建一至两个松弛振荡器。将时钟源 (GPIN0-GPIN1) 发送至 `clk_gpclk0` 至 `clk_gpclk03` 生成器之一，通过 GPIO 反相器 OUTOVER 反向，并通过 RC 电路连接回时钟源输入：

图34。简单  
松弛振荡器  
示例

由松弛振荡器产生的时钟频率取决于芯片的延迟和GPIO输出的驱动电流，这两者均受工艺、压、温 (PVT) 变化的影响。频率和频率准确度则依赖于外部元件的质量和精度。更复杂的外部元件，如陶瓷谐振器，可提升性能，但同时增加成本和系统复杂性。此类振荡器无法达到1000ppm的精度，因此无法以最大频率驱动内部时钟。若需以最高可能频率驱动内部时钟，请使用XOSC。

松弛振荡器的配置在切换核心断电时将丢失，但不受睡眠模式或休眠模式 (DORMANT模式) 影响。

### 8.1.2.6. PLLs

The PLLs ([Section 8.6, “PLL”](#)) are used to provide fast clocks when running from the XOSC or an external clock source driven into the XIN pin. In a fully-featured application, the USB PLL provides a fixed 48MHz clock to the ADC and USB while `clk_ref` is driven from the XOSC or external clock source. This allows the user to drive `clk_sys` from the system PLL and vary the frequency according to demand to save power without having to change the setups of the other clocks. `clk_peri` can be driven either from the fixed frequency USB PLL or from the variable frequency system PLL. If `clk_sys` never needs to exceed 48MHz, one PLL can be used and the divider in the `clk_sys` clock generator can scale the `clk_sys` frequency according to demand.

When a PLL starts, you cannot use the output until the PLL locks as indicated by the `LOCK` bit in the `STATUS` register. As a result, the PLL output cannot be used during changes to the reference clock divider, the output dividers or the bypass mode. The output can be used during feedback divisor changes, though the output frequency might overshoot or undershoot during large changes to the feedback divisor. For more information, see [Section 8.6, “PLL”](#).

The PLLs can drive clocks at their maximum frequency as long as the reference clock is accurate to 1000ppm, since this keeps the frequency of the generated clocks within design margins.

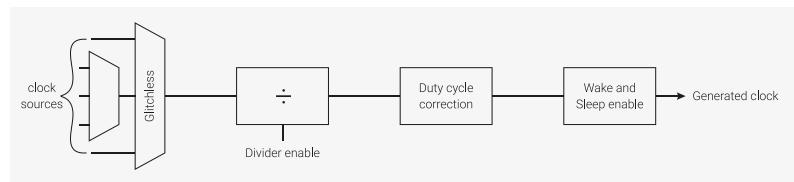

The PLLs are not affected by sleep mode. To save power in sleep mode, switch all clock generators away from the PLLs stop them in software before entering sleep mode.

The PLLs do not stop and restart automatically when entering and exiting DORMANT mode. If the PLLs are running when entering DORMANT mode, they will be corrupted because the reference clock in the XOSC stops. This generates out-of-control clocks that consume power unnecessarily. Before entering DORMANT mode, always switch all clock generators away from the PLLs and stop the PLLs in software.

### 8.1.3. Clock generators

The clock generators are built on a standard design that incorporates clock source multiplexing, division, duty cycle correction, and sleep mode enabling. To save chip area and power, some individual clock generators omit certain features.

Figure 35. A generic clock generator

#### 8.1.3.1. Instances

RP2350 has several clock generators, which are listed below.

Table 541. RP2350 clock generators

Clock	Description	Nominal Frequency
<code>clk_gpout0</code>	Clock output to GPIO. Can be used to clock external devices or debug on chip clocks with a logic analyser or oscilloscope.	N/A
<code>clk_gpout1</code>		
<code>clk_gpout2</code>		
<code>clk_gpout3</code>		
<code>clk_ref</code>	Reference clock that is always running unless in DORMANT mode. Runs from ring oscillator (ROSC) at power-up but can be switched to crystal oscillator (XOSC) for more accuracy.	6 - 12MHz

### 8.1.2.6. PLL

锁相环（PLL，章节8.6，“PLL”）用于在使用XOSC或外部时钟源驱动至XIN引脚时提供高速时钟。在完整功能的应用中，USB PLL为ADC和USB提供固定的48MHz时钟，同时 `clk_ref`由XOSC或外部时钟源驱动。这允许用户通过系统PLL驱动`clk_sys`，并可根据需求调整频率以节省功耗，无需更改其他时钟的设置。

`clk_peri`可由固定频率的USB PLL或可变频率的系统PLL驱动。如`clk_sys`无需超过48MHz，则可仅使用一套PLL，且`clk_sys`时钟生成器中的分频器可根据需求调整`clk_sys`的频率。

PLL启动后，必须等待锁定，锁定状态由 `STATUS`寄存器中的`LOCK`位指示，在此之前不得使用PLL输出。因此，在更改参考时钟分频器、输出分频器或旁路模式期间，PLL输出不可用。反馈分频器更改时，输出可以继续使用，但在大幅调整反馈分频器时，输出频率可能会出现超调或欠调现象。详见第8.6节，“PLL”，以获取更多信息。

只要参考时钟精度达到1000ppm，PLL即可驱动时钟达到最大频率，确保生成时钟频率保持在设计容差范围内。

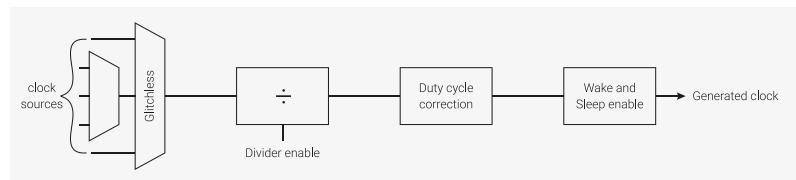

PLL不受睡眠模式影响。为节省睡眠模式下功耗，请将所有时钟发生器切换远离PLL，并在进入睡眠模式前通过软件停止PLL。

PLL在进入及退出休眠模式时不会自动停止或重启。若PLL在进入休眠模式时仍运行，因XOSC中的参考时钟停止，PLL将受到损坏。这会产生失控时钟，造成不必要的功耗。进入休眠模式前，须将所有时钟发生器切换远离PLL，并通过软件停止PLL。

### 8.1.3. 时钟发生器

时钟发生器采用标准设计，包含时钟源多路复用、分频、占空比校正及睡眠模式启用功能。为节省芯片面积与功耗，部分时钟发生器省略某些功能。

图35. 通用时钟发生器

#### 8.1.3.1. 实例

RP2350配置了多个时钟发生器，详列如下。

表541. RP2350  
时钟发生器

时钟	描述	标称频率
<code>clk_gpout0</code>	时钟输出至GPIO。可用于为外部设备提供时钟，或使用逻辑分析仪或示波器对芯片时钟进行调试。	不适用
<code>clk_gpout1</code>		
<code>clk_gpout2</code>		
<code>clk_gpout3</code>		
<code>clk_ref</code>	参考时钟，除非处于休眠模式（DORMANT），否则持续运行。上电时由环形振荡器（ROSC）驱动，但可切换至晶体振荡器（XOSC）以获得更高精度。	6 - 12MHz

Clock	Description	Nominal Frequency
<code>clk_sys</code>	System clock that is always running unless in DORMANT mode. Runs from <code>clk_ref</code> at power-up, but is typically switched to a PLL.	150MHz
<code>clk_peri</code>	Peripheral clock. Typically runs from <code>clk_sys</code> but allows peripherals to run at a consistent speed if <code>clk_sys</code> is changed by software.	12 - 150MHz
<code>clk_usb</code>	USB reference clock. Must be 48MHz.	48MHz
<code>clk_adc</code>	ADC reference clock. Must be 48MHz.	48MHz
<code>clk_hstx</code>	HSTX clock.	150MHz

For a full list of clock sources for each clock generator, see the appropriate `CTRL` register. For example, [CLK\\_SYS\\_CTRL](#).

### 8.1.3.2. Multiplexers

All clock generators have a multiplexer referred to as the auxiliary (aux) mux. This mux has a conventional design whose output will glitch when changing the select control. The reference clock (`clk_ref`) and the system clock (`clk_sys`) have an additional multiplexer referred to as the **glitchless mux**. The glitchless mux can switch between clock sources without generating a glitch on the output.

Before switching the clock source of an auxiliary mux you must either:

- Temporarily switch the glitchless mux away from aux (if a glitchless mux is available).
- Temporarily disable the clock generator using its `CTRL_ENABLE` bit.
- Hold the destination in reset so that a potential clock glitch doesn't cause undefined operation.

Failure to do at least one of the above can cause a glitch on the clock input of all hardware currently clocked by this clock generator. Avoid clock glitches at all costs; they can corrupt the logic running from the clock.

Clock generators require two cycles of the source clock to stop the output and two cycles of the new source to restart the output. Wait for the generator to stop before changing the auxiliary mux. When the destination clock is much slower than the system clock, there is a danger that software changes the aux mux source before the clock generator has come to a safe halt. Avoid this by polling the clock generator's `CTRL_ENABLED` status until it matches the value of `CTRL_ENABLE`.

The glitchless mux is only implemented for always-on clocks. On RP2350, the always-on clocks are the reference clock (`clk_ref`) and the system clock (`clk_sys`). Such clocks must run continuously unless the chip is in DORMANT mode. The glitchless mux has a status output (`SELECTED`) that indicates which source is selected. You can read this status output from software to confirm that a change of clock source has completed.

The recommended control sequences are as follows.

To switch between clock sources for the glitchless mux:

1. Switch the glitchless mux to an alternate source.
2. Poll the `SELECTED` register until the switch completes.

To switch between clock sources for the aux mux when the generator has a glitchless mux:

1. Switch the glitchless mux to a source that isn't the aux mux.
2. Poll the `SELECTED` register until the switch completes.
3. Change the auxiliary mux select control.

时钟	描述	标称频率
<code>clk_sys</code>	系统时钟，除非处于休眠模式（DORMANT），否则持续运行。上电时由 <code>clk_ref</code> 驱动，通常切换为PLL。	150MHz
<code>clk_peri</code>	外设时钟。通常由 <code>clk_sys</code> 驱动，但当 <code>clk_sys</code> 经软件更改时，允许外设保持恒定速度运行。	12 - 150MHz
<code>clk_usb</code>	USB参考时钟，必须为48MHz。	48MHz
<code>clk_adc</code>	ADC参考时钟，必须为48MHz。	48MHz
<code>clk_hstx</code>	HSTX时钟。	150MHz

有关各时钟发生器所有时钟源的完整列表，请参阅相应的CTRL寄存器。例如，`CLK_SYS_CTRL`。

### 8.1.3.2. 复用器

所有时钟发生器均配备一个称为辅助（aux）复用器的复用器。该复用器采用传统设计，切换选择控制时输出会产生毛刺。参考时钟（`clk_ref`）和系统时钟（`clk_sys`）具有额外的复用器，称为无毛刺复用器（glitchless mux）。无毛刺复用器可在不产生输出毛刺的情况下切换时钟源。

切换辅助复用器的时钟源之前，必须执行以下任一操作：

- 临时将无毛刺复用器切换离开aux（若无毛刺复用器可用）。
- 临时通过其`CTRL_ENABLE`位禁用时钟发生器。
- 保持目的模块处于复位状态，以防止潜在时钟毛刺导致未定义操作。

未执行上述任一操作，可能导致该时钟发生器当前所有时钟输入出现毛刺。务必避免时钟毛刺；它们可能会破坏时钟运行的逻辑。

时钟发生器需要两个源时钟周期来停止输出，并需要两个新源时钟周期来重新启动输出。在更改辅助复用器之前，请等待发生器停止。当目标时钟比系统时钟慢得多时，存在软件在时钟发生器安全停止前修改辅助复用器源的风险。通过轮询时钟发生器的`CTRL_ENABLED`状态，直至其与`CTRL_ENABLE`的值匹配，以避免此类情况。

无毛刺复用器仅适用于始终开启的时钟。在RP2350上，始终开启的时钟是参考时钟（`clk_ref`）和系统时钟（`clk_sys`）。此类时钟必须持续运行，除非芯片处于休眠（DORMANT）模式。无毛刺复用器具有状态输出（`SELECTED`），用于指示所选时钟源。您可通过软件读取该状态输出，以确认时钟源切换已完成。

推荐的控制序列如下：

切换无毛刺多路复用器的时钟源：

- 将无毛刺多路复用器切换至备用源。
- 轮询 `SELECTED` 寄存器，直至切换完成。

当发生器配备无毛刺多路复用器时，切换辅助多路复用器的时钟源：

- 将无毛刺多路复用器切换至非辅助多路复用器的时钟源。
- 轮询 `SELECTED` 寄存器，直至切换完成。
- 更改辅助多路复用器的选择控制。

4. Switch the glitchless mux back to the aux mux.
5. If required, poll the **SELECTED** register until the switch completes.

To switch between clock sources for the aux mux when the generator does *not* have a glitchless mux:

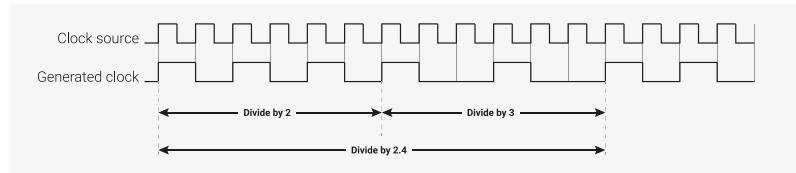

1. Disable the clock divider.
2. Wait for the generated clock to stop (two cycles of the clock source).
3. Change the auxiliary mux select control.
4. Enable the clock divider.
5. If required, wait for the clock generator to restart (two cycles of the clock source).

See [Section 8.1.6.1, “Configuring a clock generator”](#) for a code example of this.

### 8.1.3.3. Divider

A fully featured divider divides by a fractional number in the range 1.0 to  $2^{16}$ . Fractional division is achieved by toggling between 2 integer divisors; this yields a jittery clock that might be unsuitable for some applications. For example, when dividing by 2.4, the divider divides by 2 for 3 cycles and by 3 for 2 cycles. For divisors with large integer components, the jitter will be much smaller and less critical.

Figure 36. An example of fractional division.

All dividers support **on-the-fly divisor changes**: the output clock can switch cleanly from one divisor to another. The clock generator does not need to be stopped during clock divisor changes, because the dividers synchronise the divisor change to the end of the clock cycle. Similarly, dividers synchronise the enable to the end of the clock cycle to avoid glitches when the clock generator is enabled or disabled. Clock generators for always-on clocks are permanently enabled and therefore do not have an enable control.

In the event that a clock generator locks up and never completes the current clock cycle, it can be forced to stop using the **KILL** control. This can result in an output glitch, which can corrupt the logic driven by the clock. Always reset the destination logic before using the **KILL** control. Clock generators for always-on clocks are permanently active and therefore do not have a **KILL** control.

**i** **NOTE**

This clock generator design has been used in numerous chips and has never been known to lock up. The **KILL** control is inelegant and unnecessary and should not be used as an alternative to the enable.

### 8.1.3.4. Duty cycle correction

The divider operates on the rising edge of the input clock, so it does not generate an even duty cycle clock when dividing by odd numbers. For example, divide by 3 gives a duty cycle of 33.3%, and divide by 5 gives a duty cycle of 40%.

If enabled, duty cycle correction logic will shift the falling edge of the output clock to the falling edge of the input clock and restore a 50% duty cycle. The duty cycle correction can be enabled and disabled while the clock is running. It doesn't operate when dividing by an even number.

4. 将无毛刺多路复用器切换回辅助多路复用器。

5. 如有必要，轮询 **SELECTED** 寄存器，直至切换完成。

当发生器未配备无毛刺多路复用器时，切换辅助多路复用器的时钟源：

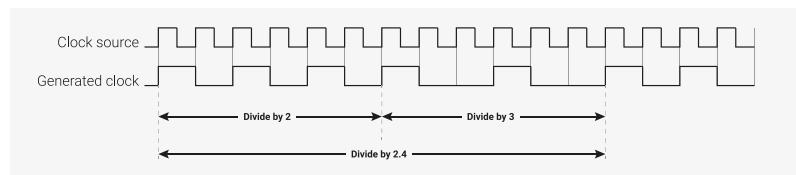

1. 禁用时钟分频器。
2. 等待生成的时钟停止（时钟源的两个周期）。
3. 更改辅助多路复用器的选择控制。
4. 启用时钟分频器。
5. 如有必要，等待时钟发生器重启（时钟源的两个周期）。

代码示例请参见第8.1.6.1节，“配置时钟发生器”。

### 8.1.3.3 分频器

功能齐全的分频器可对范围在1.0至 $2^{16}$ 之间的分数进行除法运算。分数除法通过在两个整数除数之间切换实现；这将产生抖动的时钟信号，可能不适用于某些应用。例如，当除以2.4时，分频器对三个周期使用除数2，对两个周期使用除数3。对于整数部分较大的除数，抖动将显著减小且影响较小。

图36. 分数除法的一个示例。

所有分频器均支持**动态除数切换**：输出时钟可实现从一个除数向另一个除数的平滑切换。由于分频器将除数更改同步至时钟周期结束，时钟发生器在更改除数时无需停止。同样，分频器将使能信号同步至时钟周期结束，避免时钟发生器使能或禁用时产生毛刺。始终开启的时钟发生器为永久激活状态，因此不设有使能控制。

若时钟发生器发生锁死且无法完成当前时钟周期，可通过 **KILL** 控制强制停止。此操作可能导致输出毛刺，从而破坏时钟驱动的逻辑。在使用 **KILL** 控制前，务必先重置目标逻辑。始终开启的时钟发生器为永久激活状态，因此不设有 **KILL** 控制。

#### ① 注意

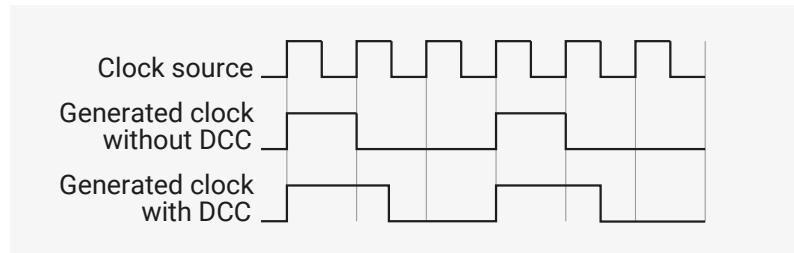

该时钟发生器设计已被广泛应用于多款芯片，且从未出现锁死现象。因 **KILL** 控制设计粗糙且不必要，不应将其作为使能控制的替代方案。

### 8.1.3.4. 占空比校正

分频器工作于输入时钟的上升沿，因此在除以奇数时无法产生均匀占空比的时钟信号。例如，除以3时，占空比为33.3%；除以5时，占空比为40%。

如果启用，占空比校正逻辑会将输出时钟的下降沿移至输入时钟的下降沿，并恢复50%的占空比。占空比校正可在时钟运行时启用或禁用。当进行偶数分频时，该功能不工作。

Figure 37. An example of `duty_cycle_correction`.

### 8.1.3.5. Clock Enables

Each clock goes to multiple destinations. With a few exceptions, each destination has two enables. Use the `WAKE_EN` registers to enable the clocks when the system is awake. Use the `SLEEP_EN` registers to enable the clocks when the system is in sleep mode. Enables help reduce power in the clock distribution networks for unused components. Any component that isn't clocked will retain its configuration so it can restart quickly.

**NOTE**

By default, the `WAKE_EN` and `SLEEP_EN` registers reset to `0x1`, which enables all clocks. Only use this feature for low-power designs.

#### 8.1.3.5.1. Clock enable exceptions

The following destinations don't have clock enables:

- The `clk_gpcclk0-clk_gpcclk03` generators.
- The processor cores, because they require a clock at all times to manage their own power-saving features.
- `clk_sys_busfabric` (in wake mode), because that would prevent the cores from accessing any chip registers, including those that control the clock enables.
- `clk_sys_clocks` (in wake mode), because that would prevent the cores from accessing the clocks control registers.

#### 8.1.3.5.2. System sleep mode

System sleep mode is entered automatically when both cores are in sleep and the DMA has no outstanding transactions. In system sleep mode, the clock enables described in the previous paragraphs are switched from the `WAKE_EN` registers to the `SLEEP_EN` registers. Sleep mode helps reduce power consumed in the clock distribution networks when the chip is inactive. If the user hasn't configured the `WAKE_EN` and `SLEEP_EN` registers, system sleep does nothing.

There is little value in using system sleep without taking other measures to reduce power before the cores are put to sleep. Things to consider include:

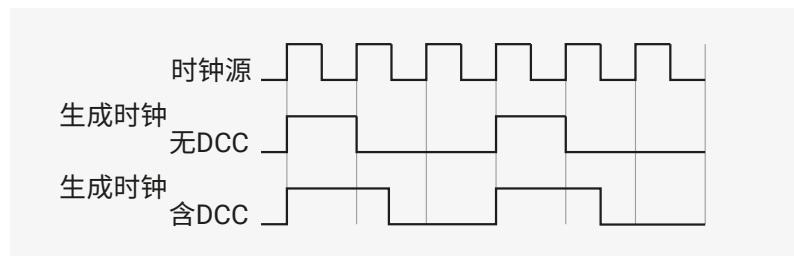

- Stop unused clock sources such as the PLLs and crystal oscillator.
- Reduce the frequencies of generated clocks by increasing the clock divisors.
- Stop external clocks.

For maximum power saving when the chip is inactive, the user should consider DORMANT (see [Section 6.5.3, "DORMANT state"](#)) mode in which clocks are sourced from the crystal oscillator and/or the ring oscillator and those clock sources are stopped.

For more information about sleep, see [Section 6.5.2, "SLEEP state"](#).

图37。占空比较正

示例

### 8.1.3.5. 时钟使能

每个时钟信号都分发至多个目的地。除少数例外，每个目的地设有两个使能信号。使用 `WAKE_EN` 寄存器在系统唤醒时启用时钟。使用 `SLEEP_EN` 寄存器在系统睡眠模式时启用时钟。使能信号有助于降低未使用组件时钟分配网络的功耗。任何未接收时钟的组件将保留其配置，以便快速重启。

#### ① 注意

默认情况下，`WAKE_EN` 和 `SLEEP_EN` 寄存器复位为 `0x1`，表示启用所有时钟。仅将此功能用于低功耗设计。

#### 8.1.3.5.1. 时钟使能例外

以下目标无时钟使能：

- 生成器 `clk_gpclk0-clk_gpclk03`。
- 处理器核心始终需要时钟以管理自身的节能功能。
- `clk_sys_busfabric`（唤醒模式下），因其阻止核心访问任何芯片寄存器，包括控制时钟使能的寄存器。
- `clk_sys_clocks`（唤醒模式下），因其阻止核心访问时钟控制寄存器。

#### 8.1.3.5.2. 系统睡眠模式

当两个核心均处于睡眠且DMA未完成事务时，系统自动进入系统睡眠模式。在系统睡眠模式下，上述时钟使能由 `WAKE_EN` 寄存器切换至 `SLEEP_EN` 寄存器。睡眠模式有助于降低芯片不活跃时时钟分配网络的功耗。如果用户未配置 `WAKE_EN` 和 `SLEEP_EN` 寄存器，系统睡眠将不会执行任何操作。

在将核心置于睡眠状态前未采取其他降低功耗措施时，单独使用系统睡眠的价值非常有限。需考虑的事项包括：

- 停止未使用的时钟源，如PLL和晶体振荡器。
- 通过增加时钟分频器来降低生成时钟的频率。
- 停止外部时钟。

为在芯片非活动时实现最大功耗节省，用户应考虑使用 DORMANT 模式（参见第 6.5.3 节，“DORMANT 状态”），该模式下时钟源由晶体振荡器和/或环形振荡器提供，且这些时钟源将被停止。

有关睡眠的更多信息，详见第 6.5.2 节，“SLEEP 状态”。

### 8.1.4. Frequency counter

The frequency counter measures the frequency of internal and external clocks by counting the clock edges seen over a test interval. The interval is defined by counting cycles of `clk_ref`, which must be driven either from XOSC or a stable external source of known frequency.

The user can pick between accuracy and test time using the `FC0_INTERVAL` register. Table 542, “Frequency Counter Test Interval vs Accuracy” shows this trade off:

Table 542. Frequency Counter Test Interval vs Accuracy

Interval Register	Test Interval	Accuracy
0	1µs	2048kHz
1	2µs	1024kHz
2	4µs	512kHz
3	8µs	256kHz
4	16µs	128kHz
5	32µs	64kHz
6	64µs	32kHz
7	125µs	16kHz
8	250µs	8kHz
9	500µs	4kHz
10	1ms	2kHz
11	2ms	1kHz
12	4ms	500Hz
13	8ms	250Hz
14	16ms	125Hz
15	32ms	62.5Hz

### 8.1.5. Resus

It is possible to write software that inadvertently stops `clk_sys`. This normally causes an unrecoverable lock-up of the cores and the on-chip debugger, leaving the user unable to trace the problem. To mitigate against unrecoverable core lock-up, an automatic **resuscitation circuit** is provided; this switches `clk_sys` to a known good clock source (`clk_ref`) if it detects no edges over a user-defined interval. `clk_ref` can be driven from the XOSC, ROSC or an external source. The interval is programmable via `CLK_SYS_RESUS_CTRL`.

#### WARNING

There is no way for resus to revive the chip if `clk_ref` is also stopped.

To enable the resus:

- Set the timeout interval.
- Set the `ENABLE` bit in `CLK_SYS_RESUS_CTRL`.

To detect a resus event:

- Enable the `CLK_SYS_RESUS` interrupt by setting the interrupt enable bit in `INTE`.

### 8.1.4. 频率计数器

频率计通过计数测试间隔内检测到的时钟边缘来测量内部及外部时钟频率。该间隔由计数 `clk_ref` 周期定义，且 `clk_ref` 必须由 XOSC 或已知频率的稳定外部信号源驱动。

用户可通过 FC0\_INTERVAL 寄存器在准确度与测试时间之间进行权衡选择。表 542，“频率计测试间隔与准确度”展示了此权衡关系：

表 542。频率计测试间隔与准确度

间隔寄存器	测试间隔	准确度
0	1μs	2048kHz
1	2μs	1024kHz
2	4μs	512kHz
3	8μs	256kHz
4	16μs	128kHz
5	32μs	64kHz
6	64μs	32kHz
7	125μs	16kHz
8	250μs	8kHz
9	500μs	4kHz
10	1ms	2kHz
11	2ms	1kHz
12	4ms	500Hz
13	8ms	250Hz
14	16ms	125Hz
15	32ms	62.5Hz

### 8.1.5. 复苏 (Resus)

可能会编写出无意中停止 `clk_sys` 的软件。这通常会导致核心及片上调试器不可恢复的锁死，用户无法追踪问题。为防止核心不可恢复锁死，提供了自动复苏电路；若在用户定义的时间间隔内检测不到信号边沿，该电路会将 `clk_sys` 切换至已知的良好时钟源 (`clk_ref`)。`clk_ref` 可由 XOSC、ROSC 或外部时钟源驱动。该时间间隔可通过 CLK\_SYS\_RESUS\_CTRL 进行编程。

#### ● 警告

若 `clk_ref` 停止，则复苏电路无法使芯片恢复正常。

启用复苏电路：

- 设置超时间隔。
- 在 CLK\_SYS\_RESUS\_CTRL 中设置 `ENABLE` 位。

检测 resus 事件的方法：

- 通过设置 INT\_E 中的中断使能位，启用 CLK\_SYS\_RESUS 中断。

- Enable the `CLOCKS_DEFAULT_IRQ` processor interrupt (see [Section 3.2, “Interrupts”](#)).

Resus is intended as a debugging aid, so the user can trace the software error that triggered the resus, then correct the error and reboot. It is possible to continue running after a resus event by reconfiguring `clk_sys`, then clearing the resus by writing the `CLEAR` bit in `CLK_SYS_RESUS_CTRL`.

### **⚠️ WARNING**

Only use resus for debugging. If `clk_sys` runs slower than expected, a resus could trigger. This could result in a `clk_sys` glitch, which could corrupt the chip.

## 8.1.6. Programmer’s model

### 8.1.6.1. Configuring a clock generator

The SDK defines an enum of clocks:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/clocks.h) Lines 30 - 42

```

30 typedef enum clock_num_rp2350 {
31 clk_gpout0 = 0, ///< Select CLK_GPOUT0 as clock source
32 clk_gpout1 = 1, ///< Select CLK_GPOUT1 as clock source
33 clk_gpout2 = 2, ///< Select CLK_GPOUT2 as clock source
34 clk_gpout3 = 3, ///< Select CLK_GPOUT3 as clock source
35 clk_ref = 4, ///< Select CLK_REF as clock source
36 clk_sys = 5, ///< Select CLK_SYS as clock source
37 clk_peri = 6, ///< Select CLK_PERI as clock source
38 clk_hstx = 7, ///< Select CLK_HSTX as clock source
39 clk_usb = 8, ///< Select CLK_USB as clock source
40 clk_adc = 9, ///< Select CLK_ADC as clock source
41 CLK_COUNT
42 } clock_num_t;

```

Additionally, the SDK defines a struct to describe the registers of a clock generator:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/clocks.h) Lines 116 - 137

```

116 typedef struct {
117 _REG_(CLOCKS_CLK_GPOUT0_CTRL_OFFSET) // CLOCKS_CLK_GPOUT0_CTRL
118 // Clock control, can be changed on-the-fly (except for auxsrc)
119 // 0x10000000 [28] ENABLED (0) clock generator is enabled
120 // 0x00100000 [20] NUDGE (0) An edge on this signal shifts the phase of the
121 // output by...
122 // 0x00030000 [17:16] PHASE (0x0) This delays the enable signal by up to 3 cycles
123 // of the...
124 // 0x00001000 [12] DC50 (0) Enables duty cycle correction for odd divisors, can
125 // be...
126 // 0x00000800 [11] ENABLE (0) Starts and stops the clock generator cleanly
127 // 0x00000400 [10] KILL (0) Asynchronously kills the clock generator, enable
128 // must be...
129 // 0x000001e0 [8:5] AUXSRC (0x0) Selects the auxiliary clock source, will glitch
130 // when switching
131 io_rw_32 ctrl;
132
133 _REG_(CLOCKS_CLK_GPOUT0_DIV_OFFSET) // CLOCKS_CLK_GPOUT0_DIV
134 // 0xfffff000 [31:16] INT (0x0001) Integer part of clock divisor, 0 -> max+1, can
135 // be...
136 // 0x0000ffff [15:0] FRAC (0x0000) Fractional component of the divisor, can be

```

- 启用 `CLOCKS_DEFAULT_IRQ` 处理器中断（参见第 3.2 节，“中断”）。

Resus 旨在作为调试辅助工具，帮助用户追踪触发 resus 的软件错误，随后修正错误并重启。可通过重新配置 `clk_sys`，随后在 `CLK_SYS_RESUS_CTRL` 中写入 `CLEAR` 位以清除 resus，从而在 resus 事件后继续运行。

### ● 警告

仅限于将 resus 用于调试。若 `clk_sys` 运行速率低于预期，可能会触发 resus。这可能导致 `clk_sys` 故障，进而损坏芯片。

## 8.1.6. 程序员模型

### 8.1.6.1. 配置时钟发生器

SDK 定义了时钟的枚举类型：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/clocks.h) 第 30 - 42 行

```

30 typedef enum clock_num_rp2350 {
31 clk_gpout0 = 0, //< 选择 CLK_GPOUT0 作为时钟源
32 clk_gpout1 = 1, //< 选择 CLK_GPOUT1 作为时钟源
33 clk_gpout2 = 2, //< 选择 CLK_GPOUT2 作为时钟源
34 clk_gpout3 = 3, //< 选择 CLK_GPOUT3 作为时钟源
35 clk_ref = 4, //< 选择 CLK_REF 作为时钟源
36 clk_sys = 5, //< 选择 CLK_SYS 作为时钟源
37 clk_peri = 6, //< 选择 CLK_PERI 作为时钟源
38 clk_hstx = 7, //< 选择 CLK_HSTX 作为时钟源
39 clk_usb = 8, //< 选择 CLK_USB 作为时钟源
40 clk_adc = 9, //< 选择 CLK_ADC 作为时钟源
41 CLK_COUNT
42 } clock_num_t;

```

此外，SDK 定义了一个结构体，用于描述时钟发生器的寄存器：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/clocks.h) 第 116 - 137 行

```

116 typedef struct {
117 _REG_(CLOCKS_CLK_GPOUT0_CTRL_OFFSET) // CLOCKS_CLK_GPOUT0_CTRL
118 // 时钟控制，除auxsrc外可动态调整
119 // 0x10000000 [28] ENABLED (0) 时钟发生器已启用
120 // 0x00100000 [20] NUDGE (0) 此信号的边沿会使输出相位发生偏移
 偏移幅度为...
121 // 0x00030000 [17:16] PHASE (0x0) 此项将使能信号延迟最多3个周期
 的...

137 } clock_hw_t;

```

Clock configuration requires the following pieces of information:

- The frequency of the clock source
- The mux / aux mux position of the clock source
- The desired output frequency

The SDK provides `clock_configure` to configure a clock:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/p2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/p2_common/hardware_clocks/clocks.c) Lines 40 - 133

```

40 static void clock_configure_internal(clock_handle_t clock, uint32_t src, uint32_t auxsrc,
41 uint32_t actual_freq, uint32_t div) {
42 clock_hw_t *clock_hw = &clocks_hw->clk[clock];
43
44 // If increasing divisor, set divisor before source. Otherwise set source
45 // before divisor. This avoids a momentary overspeed when e.g. switching
46 // to a faster source and increasing divisor to compensate.
47 if (div > clock_hw->div)
48 clock_hw->div = div;
49
50 // If switching a glitchless slice (ref or sys) to an aux source, switch
51 // away from aux *first* to avoid passing glitches when changing aux mux.
52 // Assume (!!!) glitchless source 0 is no faster than the aux source.
53 if (has_glitchless_mux(clock) && src ==
54 CLOCKS_CLK_SYS_CTRL_SRC_VALUE_CLKSRC_CLK_SYS_AUX) {
55 hw_clear_bits(&clock_hw->ctrl, CLOCKS_CLK_REF_CTRL_SRC_BITS);
56 while (!(clock_hw->selected & 1u))
57 tight_loop_contents();
58 }
59
60 // If no glitchless mux, cleanly stop the clock to avoid glitches
61 // propagating when changing aux mux. Note it would be a really bad idea
62 // to do this on one of the glitchless clocks (clk_sys, clk_ref).
63 else {
64 // Disable clock. On clk_ref and clk_sys this does nothing,
65 // all other clocks have the ENABLE bit in the same position.
66 hw_clear_bits(&clock_hw->ctrl, CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS);
67 if (configured_freq[clock] > 0) {
68 // Delay for 3 cycles of the target clock, for ENABLE propagation.
69 // Note XOSC_COUNT is not helpful here because XOSC is not
70 // necessarily running, nor is timer...
71 uint delay_cyc = configured_freq[clk_sys] / configured_freq[clock] + 1;
72 busy_wait_at_least_cycles(delay_cyc * 3);
73 }
74 }
75
76 // Set aux mux first, and then glitchless mux if this clock has one
77 hw_write_masked(&clock_hw->ctrl,
78 (auxsrc << CLOCKS_CLK_SYS_CTRL_AUXSRC_LSB),
79 CLOCKS_CLK_SYS_CTRL_AUXSRC_BITS
80);

```

```

 动态修改
131 io_rw_32 div;
132
133 _REG_(CLOCKS_CLK_GPOUT0_SELECTED_OFFSET) // CLOCKS_CLK_GPOUT0_SELECTED
134 // 指示当前选定的源 (单热编码)
135 // 0x00000001 [0] CLK_GPOUT0_SELECTED (1) 该切片无毛刺多路复用器
136 (仅限于...
137 io_ro_32 selected;
138 } clock_hw_t;

```

时钟配置需要以下信息：

- 时钟源的频率
- 时钟源的多路复用器/辅助多路复用器位置
- 目标输出频率

SDK 提供了 `clock_configure` 函数用于配置时钟：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) 第40至133行

```

40 static void clock_configure_internal(clock_handle_t clock, uint32_t src, uint32_t auxsrc,
41 uint32_t actual_freq, uint32_t div) {
42 clock_hw_t *clock_hw = &clocks_hw->clk[clock];
43
44 // 如果增加除数，应先设置除数，再设置时钟源。否则，先设置时钟源
45 // 再设置除数。这样可以避免例如在切换
46 // 至更快的时钟源并增加除数以进行补偿时发生瞬时过速。
47 if (div > clock_hw->div)
48 clock_hw->div = div;
49
50 // 若将无毛刺时钟切片 (ref或sys) 切换至辅助源，须先从辅助源切换
51 // 以避免切换辅助多路复用器时产生毛刺。
52 // 假定 (!!!) 无毛刺源θ的速度不超过辅助源。
53 if (has_glitchless_mux(clock) && src ==
54 CLOCKS_CLK_SYS_CTRL_SRC_VALUE_CLKSRC_CLK_SYS_AUX) {
55 hw_clear_bits(&clock_hw->ctrl, CLOCKS_CLK_REF_CTRL_SRC_BITS);
56 while (!(clock_hw->selected & 1u))
57 tight_loop_contents();
58 }
59 // 如无毛刺多路复用器，则需干净地停止时钟以避免毛刺
60 // 在更改辅助多路复用器时传播。请注意，在
61 // 无毛刺时钟 (clk_sys, clk_ref) 上执行此操作将带来严重后果。
62 else {
63 // 禁用时钟。在 clk_ref 和 clk_sys 上此操作无效，
64 // 其他所有时钟的 ENABLE 位均位于相同位置。
65 hw_clear_bits(&clock_hw->ctrl, CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS);
66 if (configured_freq[clock] > 0) {
67 // 延迟目标时钟 3 个周期，以确保 ENABLE 信号传播。
68 // 注意此处 XOSC_COUNT 无效，因为 XOSC 不一定
69 // 运行，定时器也不一定运行...
70 uint delay_cyc = configured_freq[clk_sys] / configured_freq[clock] + 1;
71 busy_wait_at_least_cycles(delay_cyc * 3);
72 }
73 }
74 // 先设置辅助多路复用器，若该时钟具备无毛刺多路复用器，则随后设置它
75 hw_write_masked(&clock_hw->ctrl,
76 (auxsrc << CLOCKS_CLK_SYS_CTRL_AUXSRC_LSB),
77 CLOCKS_CLK_SYS_CTRL_AUXSRC_BITS
78);

```

```

79 if (has_glitchless_mux(clock)) {
80 hw_write_masked(&clock_hw->ctrl,
81 src << CLOCKS_CLK_REF_CTRL_SRC_LSB,
82 CLOCKS_CLK_REF_CTRL_SRC_BITS
83);
84 while (!(clock_hw->selected & (1u << src)))
85 tight_loop_contents();
86 }
87
88 // Enable clock. On clk_ref and clk_sys this does nothing,
89 // all other clocks have the ENABLE bit in the same position.
90 hw_set_bits(&clock_hw->ctrl, CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS);
91
92 // Now that the source is configured, we can trust that the user-supplied
93 // divisor is a safe value.
94 clock_hw->div = div;
95 configured_freq[clock] = actual_freq;
96 }
97
98 bool clock_configure(clock_handle_t clock, uint32_t src, uint32_t auxsrc, uint32_t src_freq,
99 uint32_t freq) {
100 assert(src_freq >= freq);
101
102 if (freq > src_freq)
103 return false;
104
105 uint64_t div64 = (((uint64_t) src_freq) << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) / freq;
106 uint32_t div, actual_freq;
107 if (div64 >> 32) {
108 // set div to 0 for maximum clock divider
109 div = 0;
110 actual_freq = src_freq >> (32 - CLOCKS_CLK_GPOUT0_DIV_INT_LSB);
111 } else {
112 div = (uint32_t) div64;
113 actual_freq = (uint32_t) (((uint64_t) src_freq) << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) /
114 div;
115 }
116
117 clock_configure_internal(clock, src, auxsrc, actual_freq, div);
118 // Store the configured frequency
119 return true;
120}
121
122 void clock_configure_int_divider(clock_handle_t clock, uint32_t src, uint32_t auxsrc,
123 uint32_t src_freq, uint32_t int_divider) {
124 clock_configure_internal(clock, src, auxsrc, src_freq / int_divider, int_divider <<
125 CLOCKS_CLK_GPOUT0_DIV_INT_LSB);
126 }
127
128 void clock_configure_undivided(clock_handle_t clock, uint32_t src, uint32_t auxsrc, uint32_t
129 src_freq) {
130 clock_configure_internal(clock, src, auxsrc, src_freq, 1u <<
131 CLOCKS_CLK_GPOUT0_DIV_INT_LSB);
132 }
```

`clocks_init` calls `clock_configure` for each clock. The following example shows the `clk_sys` configuration:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/pico\\_runtime\\_init/runtime\\_init\\_clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/pico_runtime_init/runtime_init_clocks.c) Lines 100 - 104

```

100 // CLK SYS = PLL SYS (usually) 125MHz / 1 = 125MHz
101 clock_configure_undivided(clk_sys,
102 CLOCKS_CLK_SYS_CTRL_SRC_VALUE_CLKSRC_CLK_SYS_AUX,
```

```

79 if (has_glitchless_mux(clock)) {
80 hw_write_masked(&clock_hw->ctrl,
81 src << CLOCKS_CLK_REF_CTRL_SRC_LSB,
82 CLOCKS_CLK_REF_CTRL_SRC_BITS
83);
84 while (!(clock_hw->selected & (1u << src)))
85 tight_loop_contents();
86 }
87
88 // 启用时钟。在 clk_ref 和 clk_sys 上此操作无效，
89 // 所有其他时钟的 ENABLE 位均位于相同位置。
90 hw_set_bits(&clock_hw->ctrl, CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS);
91
92 // 源配置完成后，可确认用户提供的
93 // 分频值为安全值。
94 clock_hw->div = div;
95 configured_freq[clock] = actual_freq;
96 }
97
98 bool clock_configure(clock_handle_t clock, uint32_t src, uint32_t auxsrc, uint32_t src_freq,
99 uint32_t freq) {
100 assert(src_freq >= freq);
101
102 if (freq > src_freq)
103 return false;
104
105 uint64_t div64 = (((uint64_t) src_freq) << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) / freq;
106 uint32_t div, actual_freq;
107
108 if (div64 >> 32) {
109 // 设置分频器为最大值 0
110 div = 0;
111 actual_freq = src_freq >> (32 - CLOCKS_CLK_GPOUT0_DIV_INT_LSB);
112 } else {
113 div = (uint32_t) div64;
114 actual_freq = (uint32_t) (((uint64_t) src_freq) << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) /
115 div;
116 }
117
118 clock_configure_internal(clock, src, auxsrc, actual_freq, div);
119 // 存储已配置的频率
120 return true;
121
122 void clock_configure_int_divider(clock_handle_t clock, uint32_t src, uint32_t auxsrc,
123 uint32_t src_freq, uint32_t int_divider) {
124 clock_configure_internal(clock, src, auxsrc, src_freq / int_divider, int_divider <<
125 CLOCKS_CLK_GPOUT0_DIV_INT_LSB);
126 }
127
128 void clock_configure_undivided(clock_handle_t clock, uint32_t src, uint32_t auxsrc, uint32_t
129 src_freq) {
130 clock_configure_internal(clock, src, auxsrc, src_freq, 1u <<
131 CLOCKS_CLK_GPOUT0_DIV_INT_LSB);
132 }
```

`clocks_init` 调用`clock_configure`函数配置每个时钟。以下示例展示了`clk_sys`的配置：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/pico\\_runtime\\_init/runtime\\_init\\_clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/pico_runtime_init/runtime_init_clocks.c) 第100至104行

```

100 // CLK SYS = PLL SYS (通常) 125MHz / 1 = 125MHz
101 clock_configure_undivided(clk_sys,
102 CLOCKS_CLK_SYS_CTRL_SRC_VALUE_CLKSRC_CLK_SYS_AUX,
```

```
103 CLOCKS_CLK_SYS_CTRL_AUXSRC_VALUE_CLKSRC_PLL_SYS,
104 SYS_CLK_HZ);
```

Once a clock is configured, call `clock_get_hz` to get the output frequency in Hz.

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) Lines 137 - 139

```
137 uint32_t clock_get_hz(clock_handle_t clock) {
138 return configured_freq[clock];
139 }
```

### ⚠️ WARNING

The frequency returned by `clock_get_hz` will be inaccurate if the provided source frequency is incorrect.

#### 8.1.6.2. Using the frequency counter

To use the frequency counter, the programmer must:

1. Set the reference frequency: `clk_ref`.
2. Set the mux position of the source they want to measure. See `FC0_SRC`.
3. Wait for the `DONE` status bit in `FC0_STATUS` to be set.
4. Read the result.

The SDK defines a `frequency_count` function that takes the source as an argument and returns the frequency in kHz:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) Lines 147 - 174

```
147 uint32_t frequency_count_khz(uint src) {
148 fc_hw_t *fc = &clocks_hw->fc0;
149
150 // If frequency counter is running need to wait for it. It runs even if the source is NULL
151 while(fc->status & CLOCKS_FC0_STATUS_RUNNING_BITS) {
152 tight_loop_contents();
153 }
154
155 // Set reference freq
156 fc->ref_khz = clock_get_hz(clk_ref) / 1000;
157
158 // FIXME: Don't pick random interval. Use best interval
159 fc->interval = 10;
160
161 // No min or max
162 fc->min_khz = 0;
163 fc->max_khz = 0xffffffff;
164
165 // Set SRC which automatically starts the measurement
166 fc->src = src;
167
168 while(!(fc->status & CLOCKS_FC0_STATUS_DONE_BITS)) {
169 tight_loop_contents();
170 }
171
172 // Return the result
173 return fc->result >> CLOCKS_FC0_RESULT_KHZ_LSB;
174 }
```

```
103 CLOCKS_CLK_SYS_CTRL_AUXSRC_VALUE_CLKSRC_PLL_SYS,
104 SYS_CLK_HZ);
```

一旦时钟配置完成，请调用`clock_get_hz`以获取输出频率（单位：赫兹）。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) 第137至139行

```
137 uint32_t clock_get_hz(clock_handle_t clock) {
138 return configured_freq[clock];
139 }
```

### ● 警告

如果输入的源频率不正确，`clock_get_hz`返回的频率将不准确。

## 8.1.6.2 使用频率计数器

使用频率计数器时，程序员必须：

1. 设置参考频率：`clk_ref`。
2. 设置所测量信号的多路复用位置。参见 FC0\_SRC。
3. 等待 FC0\_STATUS 中的 `DONE` 状态位被置位。
4. 读取测量结果。

SDK 定义了`frequency_count`函数，该函数以源为参数，返回以 kHz 为单位的频率：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) 第147行至174行

```
147 uint32_t frequency_count_khz(uint src) {
148 fc_hw_t *fc = &clocks_hw->fc0;
149
150 // 若频率计数器正在运行，则需等待其完成。即使源为NULL，该计数器仍会运行
151 // while(fc->status & CLOCKS_FC0_STATUS_RUNNING_BITS) {
152 tight_loop_contents();
153 }
154
155 // 设置参考频率
156 fc->ref_khz = clock_get_hz(clk_ref) / 1000;
157
158 // FIXME: 避免随机选择间隔，应使用最佳间隔 159 fc->interval = 10;
159
160 // 无最小值或最大值限制
161 fc->min_khz = 0;
162 fc->max_khz = 0xffffffff;
163
164 // 设置SRC，自动启动测量
165 fc->src = src;
166
167
168 while(!(fc->status & CLOCKS_FC0_STATUS_DONE_BITS)) {
169 tight_loop_contents();
170 }
171
172 // 返回结果
173 return fc->result >> CLOCKS_FC0_RESULT_KHZ_LSB;
174 }
```

There is also a wrapper function to change the unit to MHz:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/include/hardware/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/include/hardware/clocks.h) Lines 377 - 379

```
377 static inline float frequency_count_mhz(uint src) {
378 return ((float) (frequency_count_khz(src))) / KHZ;
379 }
```

The frequency counter can also be used in a test mode. This allows the hardware to check if the frequency is between a minimum and a maximum frequency, set in `FC0_MIN_KHZ` and `FC0_MAX_KHZ`. This mode will set one of the following bits in `FC0_STATUS` when `DONE` is set:

- `SLOW`: if the frequency is below the specified range
- `PASS`: if the frequency is within the specified range
- `FAST`: if the frequency is above the specified range
- `DIED`: if the clock is stopped or stops running

Test mode will also set the `FAIL` bit if `DIED`, `FAST`, or `SLOW` are set.

### 8.1.6.3. Configuring a GPIO output clock

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) Lines 245 - 263

```
245 void clock_gpio_init_int_frac16(uint gpio, uint src, uint32_t div_int, uint16_t div_frac16)
{
 // note this includes an invalid_params_if before defaulting to clk_gpout0
 uint gpclk = gpio_to_gpout_clock_handle(gpio, clk_gpout0);
 248
 invalid_params_if(HARDWARE_CLOCKS, div_int >> REG_FIELD_WIDTH(
 CLOCKS_CLK_GPOUT0_DIV_INT));
 250 // Set up the gpclk generator
 251 clocks_hw->clk[gpclk].ctrl = (src << CLOCKS_CLK_GPOUT0_CTRL_AUXSRC_LSB) |
 CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS;
 253 #ifdef REG_FIELD_WIDTH(CLOCKS_CLK_GPOUT0_DIV_FRAC) == 16
 254 clocks_hw->clk[gpclk].div = (div_int << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) | (div_frac16 <<
 CLOCKS_CLK_GPOUT0_DIV_FRAC_LSB);
 255 #elif REG_FIELD_WIDTH(CLOCKS_CLK_GPOUT0_DIV_FRAC) == 8
 256 clocks_hw->clk[gpclk].div = (div_int << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) | ((div_frac16 <<
 8u) << CLOCKS_CLK_GPOUT0_DIV_FRAC_LSB);
 257 #else
 258 #error unsupported number of fractional bits
 259 #endif
 260
 // Set gpio pin to gpclock function
 262 gpio_set_function(gpio, GPIO_FUNC_GPCK);
 263 }
```

### 8.1.6.4. Configuring a GPIO input clock

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) Lines 300 - 330

```
300 bool clock_configure_gpin(clock_handle_t clock, uint gpio, uint32_t src_freq, uint32_t freq)
{
 // Configure a clock to run from a GPIO input
```

还提供了一个用于将单位转换为MHz的封装函数：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/include/hardware/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/include/hardware/clocks.h) 第377行至379行

```
377 static inline float frequency_count_mhz(uint src) {
378 return ((float)(frequency_count_khz(src))) / KHZ;
379 }
```

频率计数器亦可用于测试模式。该模式允许硬件检测频率是否处于FC0\_MIN\_KHZ与FC0\_MAX\_KHZ设定的最小值与最大值之间。当 DONE位被置位时，FC0\_STATUS中的以下位之一将被设置：

- **SLOW**: 如果频率低于指定范围
- **PASS**: 如果频率在指定范围内
- **FAST**: 如果频率高于指定范围
- **DIED**: 如果时钟停止或停止运行

测试模式同样会在设置了 **DIED**、**FAST** 或 **SLOW** 时置位 **FAIL** 位。

### 8.1.6.3. 配置GPIO输出时钟

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) 第245至263行

```
245 void clock_gpio_init_int_frac16(uint gpio, uint src, uint32_t div_int, uint16_t div_frac16)
{
246 // 注意，此处包含一个invalid_params_if，默认使用clk_gpout0
247 uint gpclk = gpio_to_gpout_clock_handle(gpio, clk_gpout0);
248
249 invalid_params_if(HARDWARE_CLOCKS, div_int >> REG_FIELD_WIDTH(
250 CLOCKS_CLK_GPOUT0_DIV_INT));
251 // 设置 gpclk 生成器
252 clocks_hw->clk[gpclk].ctrl = (src << CLOCKS_CLK_GPOUT0_CTRL_AUXSRC_LSB) |
253 CLOCKS_CLK_GPOUT0_CTRL_ENABLE_BITS;
254 #ifdef REG_FIELD_WIDTH(CLOCKS_CLK_GPOUT0_DIV_FRAC) == 16
255 clocks_hw->clk[gpclk].div = (div_int << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) | (div_frac16 <<
256 CLOCKS_CLK_GPOUT0_DIV_FRAC_LSB);
257 #elif REG_FIELD_WIDTH(CLOCKS_CLK_GPOUT0_DIV_FRAC) == 8
258 clocks_hw->clk[gpclk].div = (div_int << CLOCKS_CLK_GPOUT0_DIV_INT_LSB) | ((div_frac16

### 8.1.6.4. 配置GPIO输入时钟

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) 第300至330行

```
300 bool clock_configure_gpin(clock_handle_t clock, uint gpio, uint32_t src_freq, uint32_t freq)
{
301 // 配置时钟以从GPIO输入引脚驱动
```

```

302 uint gpin = 0;
303 if (gpio == 20) gpin = 0;
304 else if (gpio == 22) gpin = 1;
305 else if (gpio == 12) gpin = 0;
306 else if (gpio == 14) gpin = 1;
307 else {
308 invalid_params_if(HARDWARE_CLOCKS, true);
309 }
310
311 // Work out sources. GPIN is always an auxsrc
312 uint src = 0;
313
314 // GPIN1 == GPIN0 + 1
315 uint auxsrc = gpin0_src[clock] + gpin;
316
317 if (has_glitchless_mux(clock)) {
318 // AUX src is always 1
319 src = 1;
320 }
321
322 // Set the GPIO function
323 gpio_set_function(gpio, GPIO_FUNC_GPCK);
324
325 // Now we have the src, auxsrc, and configured the gpio input
326 // call clock_configure to run the clock from a gpio
327 return clock_configure(clock, src, auxsrc, src_freq, freq);
328 }
```

### 8.1.6.5. Enabling resus

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) Lines 221 - 243

```

221 void clocks_enable_resus(resus_callback_t resus_callback) {
222 // Restart clk_sys if it is stopped by forcing it
223 // to the default source of clk_ref. If clk_ref stops running this will
224 // not work.
225
226 // Store user's resus callback
227 _resus_callback = resus_callback;
228
229 irq_set_exclusive_handler(CLOCKS_IRQ, clocks_irq_handler);
230
231 // Enable the resus interrupt in clocks
232 clocks_hw->inte = CLOCKS_INTE_CLK_SYS_RESUS_BITS;
233
234 // Enable the clocks irq
235 irq_set_enabled(CLOCKS_IRQ, true);
236
237 // 2 * clk_ref freq / clk_sys_min_freq;
238 // assume clk_ref is 3MHz and we want clk_sys to be no lower than 1MHz
239 uint timeout = 2 * 3 * 1;
240
241 // Enable resus with the maximum timeout
242 clocks_hw->resus.ctrl = CLOCKS_CLK_SYS_RESUS_CTRL_ENABLE_BITS | timeout;
243 }
```

```

302 uint gpin = 0;
303 if (gpio == 20) gpin = 0;
304 else if (gpio == 22) gpin = 1;
305 else if (gpio == 12) gpin = 0;
306 else if (gpio == 14) gpin = 1;
307 else {
308 invalid_params_if(HARDWARE_CLOCKS, true);
309 }
310
311 // 计算信号源。GPIN 始终为 auxsrc 312 uint src = 0;

313
314 // GPIN1 == GPIN0 + 1
315 uint auxsrc = gpin0_src[clock] + gpin;
316
317 if (has_glitchless_mux(clock)) {
318 // AUX 源始终为 1
319 src = 1;
320 }
321
322 // 设置 GPIO 功能
323 gpio_set_function(gpio, GPIO_FUNC_GPCK);
324
325 // 现在已有 src、auxsrc，并已配置 gpio 输入
326 // 调用 clock_configure 以通过 gpio 运行时钟
327 return clock_configure(clock, src, auxsrc, src_freq, freq);
328 }

```

### 8.1.6.5. 启用复苏功能

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/clocks.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/clocks.c) 第 221 至 243 行

```

221 void clocks_enable_resus(resus_callback_t resus_callback) {
222 // 如果clk_sys停止，则强制其
223 // 重启到clk_ref的默认时钟源。如果clk_ref停止运行，这将224 // 无法生效。
224
225 // 保存用户的resus回调函数
226 _resus_callback = resus_callback;
227
228 irq_set_exclusive_handler(CLOCKS_IRQ, clocks_irq_handler);
229
230 // 在clocks模块中启用resus中断
231 clocks_hw->inte = CLOCKS_INTE_CLK_SYS_RESUS_BITS;
232
233 // 启用clocks中断
234 irq_set_enabled(CLOCKS_IRQ, true);
235
236 // 2 * clk_ref频率 / clk_sys_min_freq
237 // 假设clk_ref为3MHz，且期望clk_sys不低于1MHz
238 uint timeout = 2 * 3 * 1;
239
240 // 启用具有最大超时的复苏功能
241 clocks_hw->resus.ctrl = CLOCKS_CLK_SYS_RESUS_CTRL_ENABLE_BITS | timeout;
242
243 }

```

### 8.1.6.6. Configuring sleep mode

Sleep mode is active when neither processor core nor the DMA are requesting clocks. For example, sleep mode is active when the DMA is not active and both core 0 and core 1 are waiting for an interrupt.

The `SLEEP_EN` registers set what clocks run in sleep mode. The `hello_sleep` example ([hello\\_sleep\\_aon.c in the pico-playground GitHub repository](#)) illustrates how to put the chip to sleep until the AON Timer fires.

#### NOTE

`clk_sys` is always sent to `proc0` and `proc1` during sleep mode, as some logic must be clocked for the processor to wake up again.

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/pico\\_sleep/sleep.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/pico_sleep/sleep.c) Lines 159 - 183

```

159 void sleep_goto_sleep_until(struct timespec *ts, aon_timer_alarm_handler_t callback)
160 {
161
162 // We should have already called the sleep_run_from_dormant_source function
163 // This is only needed for dormancy although it saves power running from xosc while
164 // sleeping
165 //assert(dormant_source_valid(_dormant_source));
166
167 clocks_hw->sleep_en0 = CLOCKS_SLEEP_EN0_CLK_REF_POWMAN_BITS;
168 clocks_hw->sleep_en1 = 0x0;
169
170 aon_timer_enable_alarm(ts, callback, false);
171
172 stdio_flush();
173
174 // Enable deep sleep at the proc
175 processor_deep_sleep();
176
177 // Go to sleep
178 __wfi();
179 }
```

### 8.1.7. List of registers

The clocks registers start at a base address of `0x40010000` (defined as `CLOCKS_BASE` in SDK).

Table 543. List of `CLOCKS` registers

Offset	Name	Info
0x00	<code>CLK_GPOUT0_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x04	<code>CLK_GPOUT0_DIV</code>	
0x08	<code>CLK_GPOUT0_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x0c	<code>CLK_GPOUT1_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x10	<code>CLK_GPOUT1_DIV</code>	
0x14	<code>CLK_GPOUT1_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x18	<code>CLK_GPOUT2_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)
0x1c	<code>CLK_GPOUT2_DIV</code>	
0x20	<code>CLK_GPOUT2_SELECTED</code>	Indicates which src is currently selected (one-hot)
0x24	<code>CLK_GPOUT3_CTRL</code>	Clock control, can be changed on-the-fly (except for auxsrc)

### 8.1.6.6. 配置睡眠模式

当处理器核心和 DMA 均未请求时钟时，睡眠模式处于激活状态。例如，当 DMA 不活跃且核心0与核心1均在等待中断时，睡眠模式即处于激活状态。

`SLEEP_EN` 寄存器用于设置睡眠模式下运行的时钟。hello\_sleep 示例（hello\_sleep\_aon.c，位于 pico-playground GitHub 仓库）演示了如何使芯片进入睡眠，直到 AON 定时器触发。

#### 注意

`clk_sys` 在睡眠模式期间始终发送至 `proc0` 和 `proc1`，因为处理器必须为部分逻辑提供时钟，以便醒来。

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/pico\\_sleep/sleep.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/pico_sleep/sleep.c) 第159至183行

```

159 void sleep_goto_sleep_until(struct timespec *ts, aon_timer_alarm_handler_t callback)
160 {
161
162 // 我们应已调用 sleep_run_from_dormant_source 函数
163 // 该函数仅在休眠模式下需要，尽管它节省了休眠时使用 xosc 运行的功耗
164
165 //assert(dormant_source_valid(_dormant_source));
166
167 clocks_hw->sleep_en0 = CLOCKS_SLEEP_EN0_CLK_REF_POWMAN_BITS;
168 clocks_hw->sleep_en1 = 0x0;
169
170 aon_timer_enable_alarm(ts, callback, false);
171
172 stdio_flush();
173
174 // 启用处理器深度睡眠
175 processor_deep_sleep();
176
177 // 进入睡眠状态
178 __wfi();
179 }
```

### 8.1.7. 寄存器列表

时钟寄存器的起始地址为 `0x40010000`（在 SDK 中定义为 `CLOCKS_BASE`）。

表543. CLOCKS 寄存器列表

偏移量	名称	说明
0x00	<code>CLK_GPOUT0_CTRL</code>	时钟控制，可动态更改（auxsrc除外）
0x04	<code>CLK_GPOUT0_DIV</code>	
0x08	<code>CLK_GPOUT0_SELECTED</code>	指示当前选定的src（单热编码）
0x0c	<code>CLK_GPOUT1_CTRL</code>	时钟控制，可动态更改（auxsrc除外）
0x10	<code>CLK_GPOUT1_DIV</code>	
0x14	<code>CLK_GPOUT1_SELECTED</code>	指示当前选定的src（单热编码）
0x18	<code>CLK_GPOUT2_CTRL</code>	时钟控制，可动态更改（auxsrc除外）
0x1c	<code>CLK_GPOUT2_DIV</code>	
0x20	<code>CLK_GPOUT2_SELECTED</code>	指示当前选定的src（单热编码）
0x24	<code>CLK_GPOUT3_CTRL</code>	时钟控制，可动态更改（auxsrc除外）

Offset	Name	Info
0x28	CLK_GPOUT3_DIV	
0x2c	CLK_GPOUT3_SELECTED	Indicates which src is currently selected (one-hot)
0x30	CLK_REF_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x34	CLK_REF_DIV	
0x38	CLK_REF_SELECTED	Indicates which src is currently selected (one-hot)
0x3c	CLK_SYS_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x40	CLK_SYS_DIV	
0x44	CLK_SYS_SELECTED	Indicates which src is currently selected (one-hot)
0x48	CLK_PERI_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x4c	CLK_PERI_DIV	
0x50	CLK_PERI_SELECTED	Indicates which src is currently selected (one-hot)
0x54	CLK_HSTX_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x58	CLK_HSTX_DIV	
0x5c	CLK_HSTX_SELECTED	Indicates which src is currently selected (one-hot)
0x60	CLK_USB_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x64	CLK_USB_DIV	
0x68	CLK_USB_SELECTED	Indicates which src is currently selected (one-hot)
0x6c	CLK_ADC_CTRL	Clock control, can be changed on-the-fly (except for auxsrc)
0x70	CLK_ADC_DIV	
0x74	CLK_ADC_SELECTED	Indicates which src is currently selected (one-hot)
0x78	DFTCLK_XOSC_CTRL	
0x7c	DFTCLK_ROSC_CTRL	
0x80	DFTCLK_LPOSC_CTRL	
0x84	CLK_SYS_RESUS_CTRL	
0x88	CLK_SYS_RESUS_STATUS	
0x8c	FC0_REF_KHZ	Reference clock frequency in kHz
0x90	FC0_MIN_KHZ	Minimum pass frequency in kHz. This is optional. Set to 0 if you are not using the pass/fail flags
0x94	FC0_MAX_KHZ	Maximum pass frequency in kHz. This is optional. Set to 0xffffffff if you are not using the pass/fail flags
0x98	FC0_DELAY	Delays the start of frequency counting to allow the mux to settle Delay is measured in multiples of the reference clock period
0x9c	FC0_INTERVAL	The test interval is 0.98us * 2**interval, but let's call it 1us * 2**interval The default gives a test interval of 250us
0xa0	FC0_SRC	Clock sent to frequency counter, set to 0 when not required Writing to this register initiates the frequency count
0xa4	FC0_STATUS	Frequency counter status

偏移量	名称	说明
0x28	CLK_GPOUT3_DIV	
0x2c	CLK_GPOUT3_SELECTED	指示当前选定的src（单热编码）
0x30	CLK_REF_CTRL	时钟控制，可动态更改（auxsrc除外）
0x34	CLK_REF_DIV	
0x38	CLK_REF_SELECTED	指示当前选定的src（单热编码）
0x3c	CLK_SYS_CTRL	时钟控制，可动态更改（auxsrc除外）
0x40	CLK_SYS_DIV	
0x44	CLK_SYS_SELECTED	指示当前选定的src（单热编码）
0x48	CLK_PERI_CTRL	时钟控制，可动态更改（auxsrc除外）
0x4c	CLK_PERI_DIV	
0x50	CLK_PERI_SELECTED	指示当前选定的src（单热编码）
0x54	CLK_HSTX_CTRL	时钟控制，可动态更改（auxsrc除外）
0x58	CLK_HSTX_DIV	
0x5c	CLK_HSTX_SELECTED	指示当前选定的src（单热编码）
0x60	CLK_USB_CTRL	时钟控制，可动态更改（auxsrc除外）
0x64	CLK_USB_DIV	
0x68	CLK_USB_SELECTED	指示当前选定的src（单热编码）
0x6c	CLK_ADC_CTRL	时钟控制，可动态更改（auxsrc除外）
0x70	CLK_ADC_DIV	
0x74	CLK_ADC_SELECTED	指示当前选定的src（单热编码）
0x78	DFTCLK_XOSC_CTRL	
0x7c	DFTCLK_ROSC_CTRL	
0x80	DFTCLK_LPOS_C_CTRL	
0x84	CLK_SYS_RESUS_CTRL	
0x88	CLK_SYS_RESUS_STATUS	
0x8c	FC0_REF_KHZ	参考时钟频率，单位为kHz
0x90	FC0_MIN_KHZ	最小通过频率，单位为kHz。此项为可选项。如不使用通过/失败标志，设为0
0x94	FC0_MAX_KHZ	最大通过频率，单位为kHz。此项为可选项。如不使用通过/失败标志，设为0xffffffff
0x98	FC0_DELAY	延迟频率计数开始以允许多路复用器稳定 延迟以参考时钟周期倍数计量
0x9c	FC0_INTERVAL	测试间隔为0.98微秒 × 2**interval，但可视为1微秒 × 2**interval 默认测试间隔为250微秒
0xa0	FC0_SRC	发送至频率计数器的时钟，不需要时设为0 写入此寄存器以启动频率计数
0xa4	FC0_STATUS	频率计数器状态

Offset	Name	Info
0xa8	FC0_RESULT	Result of frequency measurement, only valid when status_done=1
0xac	WAKE_EN0	enable clock in wake mode
0xb0	WAKE_EN1	enable clock in wake mode
0xb4	SLEEP_EN0	enable clock in sleep mode
0xb8	SLEEP_EN1	enable clock in sleep mode
0xbc	ENABLED0	indicates the state of the clock enable
0xc0	ENABLED1	indicates the state of the clock enable
0xc4	INTR	Raw Interrupts
0xc8	INTE	Interrupt Enable
0xcc	INTF	Interrupt Force
0xd0	INTS	Interrupt status after masking & forcing

## CLOCKS: CLK\_GPOUT0\_CTRL Register

Offset: 0x00

### Description

Clock control, can be changed on-the-fly (except for auxsrc)

Table 544.  
CLK\_GPOUT0\_CTRL  
Register

Bits	Description	Type	Reset
31:29	Reserved.	-	-
28	<b>ENABLED:</b> clock generator is enabled	RO	0x0
27:21	Reserved.	-	-
20	<b>NUDGE:</b> An edge on this signal shifts the phase of the output by 1 cycle of the input clock This can be done at any time	RW	0x0
19:18	Reserved.	-	-
17:16	<b>PHASE:</b> This delays the enable signal by up to 3 cycles of the input clock This must be set before the clock is enabled to have any effect	RW	0x0
15:13	Reserved.	-	-
12	<b>DC50:</b> Enables duty cycle correction for odd divisors, can be changed on-the-fly	RW	0x0
11	<b>ENABLE:</b> Starts and stops the clock generator cleanly	RW	0x0
10	<b>KILL:</b> Asynchronously kills the clock generator, enable must be set low before deasserting kill	RW	0x0
9	Reserved.	-	-
8:5	<b>AUXSRC:</b> Selects the auxiliary clock source, will glitch when switching	RW	0x0
	Enumerated values:		
	0x0 → CLKSRC_PLL_SYS		
	0x1 → CLKSRC_GPIO		

偏移量	名称	说明
0xa8	FC0_RESULT	频率测量结果，仅在status_done=1时有效
0xac	WAKE_EN0	在唤醒模式下启用时钟
0xb0	WAKE_EN1	在唤醒模式下启用时钟
0xb4	SLEEP_EN0	在睡眠模式下启用时钟
0xb8	SLEEP_EN1	在睡眠模式下启用时钟
0xbc	启用0	指示时钟启用状态
0xc0	启用1	指示时钟启用状态
0xc4	中断	原始中断
0xc8	INTE	中断使能
0xcc	INTF	中断触发
0xd0	INTS	掩码与强制后的中断状态

4:0	保留。	-	-

## CLOCKS: CLK\_PERI\_DIV Register

**Offset:** 0x4c

Table 563.  
CLK\_PERI\_DIV  
Register

Bits	Description	Type	Reset
31:18	Reserved.	-	-
17:16	<b>INT:</b> Integer part of clock divisor, 0 → max+1, can be changed on-the-fly	RW	0x1
15:0	Reserved.	-	-

## CLOCKS: CLK\_PERI\_SELECTED Register

**Offset:** 0x50

### Description

Indicates which src is currently selected (one-hot)

Table 564.  
CLK\_PERI\_SELECTED  
Register

Bits	Description	Type	Reset
31:1	Reserved.	-	-
0	This slice does not have a glitchless mux (only the AUX_SRC field is present, not SRC) so this register is hardwired to 0x1.	RO	0x1

## CLOCKS: CLK\_HSTX\_CTRL Register

**Offset:** 0x54

### Description

Clock control, can be changed on-the-fly (except for auxsrc)

Table 565.  
CLK\_HSTX\_CTRL  
Register

Bits	Description	Type	Reset
31:29	Reserved.	-	-
28	<b>ENABLED:</b> clock generator is enabled	RO	0x0
27:21	Reserved.	-	-
20	<b>NUDGE:</b> An edge on this signal shifts the phase of the output by 1 cycle of the input clock This can be done at any time	RW	0x0
19:18	Reserved.	-	-
17:16	<b>PHASE:</b> This delays the enable signal by up to 3 cycles of the input clock This must be set before the clock is enabled to have any effect	RW	0x0
15:12	Reserved.	-	-
11	<b>ENABLE:</b> Starts and stops the clock generator cleanly	RW	0x0
10	<b>KILL:</b> Asynchronously kills the clock generator, enable must be set low before deasserting kill	RW	0x0
9:8	Reserved.	-	-
7:5	<b>AUXSRC:</b> Selects the auxiliary clock source, will glitch when switching	RW	0x0
	Enumerated values:		
	0x0 → CLK_SYS		
	0x1 → CLKSRC_PLL_SYS		

## 时钟 (CLOCKS) : CLK\_PERI\_DIV 寄存器

偏移量: 0x4c

表 563。  
CLK\_PERI\_DIV  
寄存器

位	描述	类型	复位
31:18	保留。	-	-
17:16	<b>INT:</b> 时钟除数的整数部分，范围 $0 \rightarrow \text{max}+1$ ，可动态调整	读写	0x1
15:0	保留。	-	-

## 时钟 (CLOCKS) : CLK\_PERI\_SELECTED 寄存器

偏移: 0x50

### 说明

指示当前选定的src (单热编码)

表 564。  
CLK\_PERI\_SELECTED  
寄存器

位	描述	类型	复位
31:1	保留。	-	-
0	该切片不具备无毛刺多路复用器（仅包含 AUX_SRC 字段，未包含 SRC 字段），因此该寄存器硬编码为 0x1。	只读	0x1

## 时钟 (CLOCKS) : CLK\_HSTX\_CTRL 寄存器

偏移: 0x54

### 说明

时钟控制，可动态更改 (auxsrc除外)

表 565。  
CLK\_HSTX\_CTRL  
寄存器

位	描述	类型	复位
31:29	保留。	-	-
28	启用：时钟发生器已启用	只读	0x0
27:21	保留。	-	-
20	<b>NUDGE:</b> 该信号的边沿将输出相位移动一个输入时钟周期  此操作可在任何时间执行	读写	0x0
19:18	保留。	-	-
17:16	相位：该字段可延迟使能信号，最长达输入时钟的3个周期 本字段必须在启用时钟前设置，方可生效	读写	0x0
15:12	保留。	-	-
11	启用：干净地启动或停止时钟发生器	读写	0x0
10	终止：异步终止时钟发生器，取消终止前必须先将启用信号置低	读写	0x0
9:8	保留。	-	-
7:5	辅助源：选择辅助时钟源，切换时将产生毛刺	读写	0x0

## CLOCKS: CLK\_SYS\_RESUS\_CTRL 寄存器

偏移: 0x84

Table 577.  
CLK\_SYS\_RESUS\_CTR  
L Register

Bits	Description	Type	Reset
31:17	Reserved.	-	-
16	<b>CLEAR:</b> For clearing the resus after the fault that triggered it has been corrected	RW	0x0
15:13	Reserved.	-	-
12	<b>FRCE:</b> Force a resus, for test purposes only	RW	0x0
11:9	Reserved.	-	-
8	<b>ENABLE:</b> Enable resus	RW	0x0
7:0	<b>TIMEOUT:</b> This is expressed as a number of clk_ref cycles and must be $\geq 2 \times \text{clk\_ref\_freq}/\text{min\_clk\_tst\_freq}$	RW	0xff

## CLOCKS: CLK\_SYS\_RESUS\_STATUS Register

Offset: 0x88

Table 578.  
CLK\_SYS\_RESUS\_STA  
TUS Register

Bits	Description	Type	Reset
31:1	Reserved.	-	-
0	<b>RESUSSED:</b> Clock has been resuscitated, correct the error then send ctrl_clear=1	RO	0x0

## CLOCKS: FC0\_REF\_KHZ Register

Offset: 0x8c

Table 579.  
FC0\_REF\_KHZ Register

Bits	Description	Type	Reset
31:20	Reserved.	-	-
19:0	Reference clock frequency in kHz	RW	0x000000

## CLOCKS: FC0\_MIN\_KHZ Register

Offset: 0x90

Table 580.  
FC0\_MIN\_KHZ  
Register

Bits	Description	Type	Reset
31:25	Reserved.	-	-
24:0	Minimum pass frequency in kHz. This is optional. Set to 0 if you are not using the pass/fail flags	RW	0x00000000

## CLOCKS: FC0\_MAX\_KHZ Register

Offset: 0x94

Table 581.  
FC0\_MAX\_KHZ  
Register

Bits	Description	Type	Reset
31:25	Reserved.	-	-
24:0	Maximum pass frequency in kHz. This is optional. Set to 0xffffffff if you are not using the pass/fail flags	RW	0x1fffffff

## CLOCKS: FC0\_DELAY Register

Offset: 0x98

表 577。  
CLK\_SYS\_RESUS\_CTR  
L 寄存器

位	描述	类型	复位
31:17	保留。	-	-
16	<b>CLEAR</b> : 用于故障修正后清除复位	读写	0x0
15:13	保留。	-	-
12	<b>FRCE</b> : 强制复位, 仅限测试用途	读写	0x0
11:9	保留。	-	-
8	<b>ENABLE</b> : 启用复位	读写	0x0
7:0	<b>TIMEOUT</b> : 以clk_ref周期计, 且须 $\geq 2 \times \text{clk\_ref\_freq}/\text{min\_clk\_tst\_freq}$	读写	0xff

## CLOCKS: CLK\_SYS\_RESUS\_STATUS 寄存器

偏移: 0x88

表 578。  
CLK\_SYS\_RESUS\_STA  
TUS 寄存器

位	描述	类型	复位
31:1	保留。	-	-
0	<b>RESUSSED</b> : 时钟已复位, 需纠正错误后发送 ctrl_clear=1	只读	0x0

## CLOCKS: FC0\_REF\_KHZ 寄存器

偏移量: 0x8c

表 579。  
FC0\_REF\_KHZ 寄存器

位	描述	类型	复位
31:20	保留。	-	-
19:0	参考时钟频率, 单位为kHz	读写	0x000000

## CLOCKS: FC0\_MIN\_KHZ 寄存器

偏移量: 0x90

表 580。  
FC0\_MIN\_KHZ  
寄存器

位	描述	类型	复位
31:25	保留。	-	-
24:0	最小通过频率, 单位为kHz。此项为可选项。如不使用通过/失败标志, 设为0	读写	0x00000000

## CLOCKS: FC0\_MAX\_KHZ 寄存器

偏移: 0x94

表 581。  
FC0\_MAX\_KHZ  
寄存器

位	描述	类型	复位
31:25	保留。	-	-
24:0	最大通过频率, 单位为kHz。此项为可选项。如不使用通过/失败标志, 设为0x1fffffff	读写	0x1fffffff

## CLOCKS: FC0\_DELAY 寄存器

偏移: 0x98

Table 582. FC0\_DELAY Register

Bits	Description	Type	Reset
31:3	Reserved.	-	-
2:0	Delays the start of frequency counting to allow the mux to settle Delay is measured in multiples of the reference clock period	RW	0x1

## CLOCKS: FC0\_INTERVAL Register

Offset: 0x9c

Table 583.  
FC0\_INTERVAL Register

Bits	Description	Type	Reset
31:4	Reserved.	-	-
3:0	The test interval is 0.98us * 2**interval, but let's call it 1us * 2**interval The default gives a test interval of 250us	RW	0x8

## CLOCKS: FC0\_SRC Register

Offset: 0xa0

Table 584. FC0\_SRC Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	Clock sent to frequency counter, set to 0 when not required Writing to this register initiates the frequency count	RW	0x00
	Enumerated values:		
0x00	→ NULL		
0x01	→ PLL_SYS_CLKSRC_PRIMARY		
0x02	→ PLL_USB_CLKSRC_PRIMARY		
0x03	→ ROSC_CLKSRC		
0x04	→ ROSC_CLKSRC_PH		
0x05	→ XOSC_CLKSRC		
0x06	→ CLKSRC_GPIN0		
0x07	→ CLKSRC_GPIN1		
0x08	→ CLK_REF		
0x09	→ CLK_SYS		
0x0a	→ CLK_PERI		
0x0b	→ CLK_USB		
0x0c	→ CLK_ADC		
0x0d	→ CLK_HSTX		
0x0e	→ LPOSOC_CLKSRC		
0x0f	→ OTP_CLK2FC		
0x10	→ PLL_USB_CLKSRC_PRIMARY_DFT		

## CLOCKS: FC0\_STATUS Register

Offset: 0xa4

表582。FC0\_DELAY 寄存器

位	描述	类型	复位
31:3	保留。	-	-
2:0	延迟频率计数开始以允许多路复用器稳定 延迟以参考时钟周期倍数计量	读写	0x1

## CLOCKS: FC0\_INTERVAL 寄存器

偏移: 0x9c

表583。  
FC0\_INTERVAL 寄存器

位	描述	类型	复位
31:4	保留。	-	-
3:0	测试间隔为 $0.98\text{微秒} \times 2^{\text{interval}}$ , 但可视为 $1\text{微秒} \times 2^{\text{interval}}$ 默认测试间隔为250微秒	读写	0x8

## CLOCKS: FC0\_SRC 寄存器

偏移: 0xa0

表584。FC0\_SRC 寄存器

**8.2. 晶体振荡器 (XOSC)****8.2.1. 概述**

Figure 38. The XOSC is an amplifier. When a piezoelectric crystal is connected across XIN and XOUT, the amplified feedback drives the crystal into mechanical resonance. This creates a precise reference for on-chip clock generation. External signals can also be driven directly into XIN.

The Crystal Oscillator (XOSC) uses an external crystal to produce an accurate reference clock. RP2350 supports 1 MHz to 50 MHz crystals and the RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#)) uses a 12 MHz crystal. The reference clock is distributed to the PLLs, which can be used to multiply the XOSC frequency to provide accurate high speed clocks. For example, they can generate a 48 MHz clock which meets the frequency accuracy requirement of the USB interface and a 150 MHz maximum speed system clock. The XOSC clock is also a clock source for the clock generators and can be used directly if required.

If the user already has an accurate clock source, it is possible to drive an external clock directly into XIN (aka XI), and disable the oscillator circuit. In this mode XIN can be driven at up to 50 MHz.

To use XOSC clock externally, output it to a GPIO pin using one of the `clk_gpclk0-clk_gpclk3` generators. You cannot take XOSC output directly from the XIN (XI) or XOUT (XO) pins.

#### NOTE

A minimum crystal frequency of 5 MHz is needed for the PLL. See [Section 8.6, "PLL"](#).

#### 8.2.1.1. Recommended crystals

For the best performance and stability across typical operating temperature ranges, it is recommended to use the Abracon ABM8-272-T3. You can source the [ABM8-272-T3](#) directly from Abracon or from an authorised reseller. The Abracon ABM8-272-T3 has the following specifications:

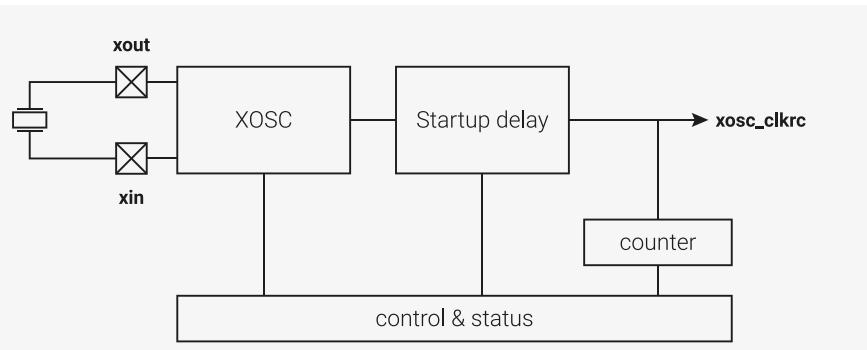

Table 597. Key Crystal Specifications.

Parameters	Minimum	Typical	Maximum	Units	Notes
Center Frequency	12.000	12.000	12.000	MHz	
Operation Mode	Fundamental-AT	Fundamental-AT	Fundamental-AT		
Operating Temperature	-40		+85	°C	
Storage Temperature	-55		+125	°C	
Frequency Tolerance (25 °C)	-30		+30	ppm	
Frequency Stability (25 °C)	-30		+30	ppm	
Equivalent Series Resistance (R1)			50	Ω	
Shunt Capacitance (C0)			3.0	pF	
Load Capacitance (CL)	10	10	10	pF	
Drive Level		10	200	μW	
Aging	-5		+5	ppm	@25±3 °C, 1st year
Insulation Resistance	500			MΩ	@100 Vdc±15 V

Even if you use a crystal with similar specifications, you will need to test the circuit over a range of temperatures to

图 38. XOSC 是一款放大器。当压电晶体连接于 XIN 与 XOUT 之间时，放大反馈驱动晶体进入机械谐振状态。由此为片上时钟生成提供了精确的参考。

外部信号亦可直接驱动至 XIN。

晶体振荡器（XOSC）采用外部晶体产生精确参考时钟。RP2350 支持 1 MHz 至 50 MHz 的晶体，RP2350 参考设计（见《RP2350 硬件设计，最小设计示例》）采用 12 MHz 晶体。参考时钟分配至 PLL，PLL 可对 XOSC 频率进行倍频，进而提供精确的高速时钟。例如，它们可以产生一个48 MHz的时钟，满足USB接口对频率精度的要求，同时产生一个最高150 MHz的系统时钟。XOSC时钟亦为时钟发生器的时钟源，如有需要可直接使用。

若用户已有精确时钟源，可直接将外部时钟送入 XIN（又称 XI），并禁用振荡器电路。在此模式下，XIN 输入时钟频率最高可达 50 MHz。

如需外部使用 XOSC 时钟，可通过 `clk_gpclk0` 至 `clk_gpclk3` 发生器，将其输出至 GPIO 引脚。不可直接从 XIN (XI) 或 XOUT (XO) 引脚获取 XOSC 输出。

#### 注意

PLL 最低晶体振荡频率为 5 MHz。详见第 8.6 节，“PLL”。

#### 8.2.1.1 推荐晶体振荡器

为确保最佳性能及典型工作温度范围内的稳定性，建议选用 Abracon ABM8-272-T3 晶体振荡器。您可直接向 Abracon 或其授权经销商采购该型号。Abracon ABM8-272-T3 的规格如下：

表 597 主晶体规格

参数	最小值	典型值	最大值	单位	备注
中心频率	12.000	12.000	12.000	MHz	
工作模式	基频-AT	基频-AT	基频-AT		
工作温度	-40		+85	°C	
存储温度	-55		+125	°C	
频率公差 (25 °C)	-30		+30	ppm	
频率稳定性 (25 °C)	-30		+30	ppm	
等效串联电阻 (R1)			50	Ω	
并联电容 (C0)			3.0	pF	
负载电容 (CL)	10	10	10	pF	
驱动等级		10	200	μW	
老化	-5		+5	ppm	@25±3 °C, 第一年
绝缘电阻	500			MΩ	@100 Vdc±15 V

即使使用规格相近的晶体，仍需对电路在不同温度范围内进行测试，

ensure stability.

The crystal oscillator is powered from the VDDIO voltage. As a result, the Abracon crystal and that particular damping resistor are tuned for 3.3V operation. If you use a different IO voltage, you will need to re-tune.

Any changes to crystal parameters risk instability across any components connected to the crystal circuit.

If you can't source the recommended crystal directly from Abracon or a reseller, contact [applications@raspberrypi.com](mailto:applications@raspberrypi.com).

Raspberry Pi Pico 2 has been specifically tuned for the specifications of the Abracon ABM8-272-T3 crystal. For an example of how to use a crystal with RP2350, see the Raspberry Pi Pico 2 board schematic in Appendix B of [Raspberry Pi Pico 2 Datasheet](#) and the [Raspberry Pi Pico 2 design files](#).

### 8.2.2. Changes from RP2040

- Maximum crystal frequency increased from 15 MHz to 50 MHz, when appropriate range is selected in `CTRL.FREQ_RANGE`

**i NOTE**

The above change applies when using the XOSC as a crystal oscillator, with a crystal connected between the `XIN` and `XOUT` pins. When using the XOSC `XIN` pin as a CMOS clock input from an external oscillator, the maximum is always 50 MHz. You do not have to configure `CTRL.FREQ_RANGE` for the CMOS input case. The CMOS input behaviour is the same as RP2040.

**i NOTE**

The maximum `clk_ref` frequency is 25 MHz. If you use a >25 MHz crystal as the source of `clk_ref`, you must divide the XOSC output using the `clk_ref` divider.

### 8.2.3. Usage

The XOSC is disabled on chip startup and RP2350 boots using the Ring Oscillator (ROSC). To start the XOSC, the programmer must set the `CTRL_ENABLE` register. The XOSC is not immediately usable because it takes time for the oscillations to build to sufficient amplitude. This time will be dependent on the chosen crystal but will be of the order of a few milliseconds. The XOSC incorporates a timer controlled by the `STARTUP_DELAY` register to automatically manage this, which sets a flag (`STATUS_STABLE`) when the XOSC clock is usable.

### 8.2.4. Startup delay

The `STARTUP_DELAY` register specifies how many clock cycles must be seen from the crystal before it can be used. This is specified in multiples of 256. The SDK `xosc_init` function sets this value. The 1 ms default is sufficient for the RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#)) which runs the XOSC at 12 MHz. When the timer expires, the `STATUS_STABLE` flag will be set to indicate the XOSC output can be used.

Before starting the XOSC the programmer must ensure the `STARTUP_DELAY` register is correctly configured. The required value can be calculated by:

$$(f_{Crystal} \times t_{Stable}) \div 256$$

So with a 12 MHz crystal and a 1 ms wait time, the calculation is:

$$(12 \times 10^6 \cdot 1 \times 10^{-3}) \div 256 \approx 47$$

以确保稳定性。

晶体振荡器由VDDIO电压供电。因此，Abracon 晶体及其特定的阻尼电阻均已针对3.3V操作进行调校。若使用不同的 IO 电压，则需重新调校。

任何对晶体参数的更改均可能导致连接晶体电路的组件发生不稳定。

若无法直接从 Abracon 或其经销商处获取推荐晶体，请联系 [applications@raspberrypi.com](mailto:applications@raspberrypi.com)。

Raspberry Pi Pico 2 已专门针对 Abracon ABM8-272-T3 晶体规格调校。有关在 RP2350 上使用晶体的示例，请参阅 Raspberry Pi Pico 2 数据手册附录 B 中的电路原理图及 Raspberry Pi Pico 2 设计文件。

### 8.2.2. 相较于 RP2040 的变更

- 当在CTRL.FREQ\_RANGE中选择适当范围时，最大晶体振荡频率由15 MHz提升至50 MHz。  
[CTRL.FREQ\\_RANGE](#)

#### **i 注意**

上述更改适用于将XOSC作为晶体振荡器时，晶体连接于 **XIN** 和 **XOUT** 引脚之间。当使用XOSC的XIN引脚作为外部振荡器的CMOS时钟输入时，最大频率始终为50 MHz。对于CMOS输入情况，无需配置CTRL.FREQ\_RANGE。CMOS输入行为与RP2040一致。

#### **i 注意**

最大 **clk\_ref** 频率为25 MHz。如果使用频率高于25 MHz的晶体作为 **clk\_ref** 的源，必须通过 **clk\_ref** 分频器分频XOSC输出。

### 8.2.3. 使用方法

XOSC在芯片启动时被禁用，RP2350引导时使用环形振荡器（ROSC）。要启动XOSC，程序员必须设置[CTRL\\_ENABLE](#)寄存器。XOSC不可立即使用，因为振荡需一定时间才能达到足够幅度。该时间依所选晶体而定，通常为数毫秒量级。XOSC 包含由[STARTUP\\_DELAY](#)寄存器控制的定时器以自动管理该过程，当XOSC时钟可用时，定时器将设置一个标志（[STATUS\\_STABLE](#)）。

### 8.2.4. 启动延迟

STARTUP\_DELAY寄存器规定必须从晶体观察多少个时钟周期后方可使用。该值以256的倍数表示。SDK中的xosc\_init函数设置该值。对于以12 MHz运行XOSC的RP2350参考设计（参见RP2350硬件设计，最小设计示例），默认的1毫秒延时足够。当定时器到期时，STATUS\_STABLE标志将被设置，表明XOSC输出可用。

启动XOSC之前，程序员必须确保[STARTUP\\_DELAY](#)寄存器已正确配置。所需值可通过以下公式计算：

$$(f_{Crystal} \times t_{Stable}) \div 256$$

因此，对于12 MHz晶体和1毫秒等待时间，计算如下：

$$(12 \times 10^6 \cdot 1 \times 10^{-3}) \div 256 \approx 47$$

**NOTE**

The value is rounded up to the nearest integer, so the wait time will be just over 1 ms.

### 8.2.5. XOSC counter

The **COUNT** register provides a method of managing short software delays. To use this method:

1. Write a value to the **COUNT** register. The register automatically begins to count down to zero at the XOSC frequency.
2. Poll the register until it reaches zero.

This is preferable to using NOPs in software loops because it is independent of the core clock frequency, the compiler, and the execution time of the compiled code.

### 8.2.6. DORMANT mode

In DORMANT mode (see [Section 6.5.3, “DORMANT state”](#)), all of the on-chip clocks can be paused to save power. This is particularly useful in battery-powered applications. RP2350 wakes from DORMANT mode by interrupt: either from an external event, such as an edge on a GPIO pin, or from the AON Timer. This must be configured before entering DORMANT mode. To use the AON Timer to trigger a wake from DORMANT mode, it must be clocked from the LPOS or from an external source.

To enter DORMANT mode:

1. Switch all internal clocks to be driven from XOSC or ROSC and stop the PLLs.
2. Choose an oscillator (XOSC or ROSC). Write a specific 32-bit value to the **DORMANT** register of the chosen oscillator to stop it.

When exiting DORMANT mode, the chosen oscillator will restart. If you chose XOSC, the frequency will be more precise, but the restart will take more time due to startup delay (>1 ms on the RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#))). If you chose ROSC, the frequency will be less precise, but the start-up time is very short (approximately 1µs). See [Section 6.5.3.1, “Waking from the DORMANT state”](#) for the events which cause the system to exit DORMANT mode.

**NOTE**

You must stop the PLLs before entering DORMANT mode.

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_xosc/xosc.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_xosc/xosc.c) Lines 56 - 63

```

56 void xosc_dormant(void) {
57 // WARNING: This stops the xosc until woken up by an irq
58 xosc_hw->dormant = XOSC_DORMANT_VALUE_DORMANT;
59 // Wait for it to become stable once woken up
60 while(!(xosc_hw->status & XOSC_STATUS_STABLE_BITS)) {
61 tight_loop_contents();
62 }
63 }
```

**i 注意**

该值向上取整至最接近的整数，因此等待时间将略超过1毫秒。

### 8.2.5. XOSC 计数器

COUNT寄存器提供了一种管理短时软件延迟的方法。使用该方法步骤如下：

1. 向COUNT寄存器写入一个值。寄存器自动以XOSC频率开始倒计数至零。
2. 轮询该寄存器，直至其值为零。

这比在软件循环中使用NOP指令更为优选，因为它不依赖核心时钟频率、编译器以及已编译代码的执行时间。

### 8.2.6. DORMANT 模式

在休眠模式（参见第6.5.3节，“休眠状态”）中，所有片上时钟均可暂停以节省功耗。这对于电池供电的应用尤为有用。RP2350通过中断从休眠模式唤醒：中断源可以是外部事件，如GPIO引脚的边沿触发，或AON定时器触发。此项必须在进入休眠模式前进行配置。要使用AON定时器触发从休眠模式的唤醒，时钟必须来自LPOSC或外部时钟源。

进入休眠（DORMANT）模式：

1. 将所有内部时钟切换为由XOSC或ROSC驱动，并停止锁相环（PLLs）。
2. 选择一个振荡器（XOSC或ROSC），向所选振荡器的 DORMANT 寄存器写入特定32位数值以停止其运行。

退出休眠模式时，所选振荡器将重新启动。若选择XOSC，频率更为精确，但由于启动延迟（RP2350参考设计中>1毫秒，详见《RP2350硬件设计，最简设计示例》），重启时间较长。若选择ROSC，频率精度较低，但启动时间极短（约1μs）。有关导致系统退出休眠模式的事件，请参见章节6.5.3.1“从休眠（DORMANT）状态唤醒”。

**i 注意**

进入休眠模式前，必须停止锁相环（PLLs）。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_xosc/xosc.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_xosc/xosc.c) 第56至63行

```

56 void xosc_dormant(void) {
57 // 警告：此操作将停止xosc，直到由中断唤醒
58 xosc_hw->dormant = XOSC_DORMANT_VALUE_DORMANT;
59 // 唤醒后，等待其稳定
60 while(!(xosc_hw->status & XOSC_STATUS_STABLE_BITS)) {
61 tight_loop_contents();
62 }
63 }
```

**⚠️ WARNING**

If you do not configure IRQ before entering DORMANT mode, neither oscillator will restart.

See [Section 6.5.6.2, "DORMANT"](#) for a complete example of DORMANT mode using the XOSC.

### 8.2.7. Programmer's model

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/xosc.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/xosc.h) Lines 27 - 57

```

19:14	Reserved.	-	-
13:0	<b>DELAY</b> : in multiples of 256*xtal_period. The reset value of 0xc4 corresponds to approx 50 000 cycles.	RW	0x00c4

## XOSC: COUNT Register

Offset: 0x10

Table 603. COUNT Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	A down counter running at the xosc frequency which counts to zero and stops. Can be used for short software pauses when setting up time sensitive hardware. To start the counter, write a non-zero value. Reads will return 1 while the count is running and 0 when it has finished. Minimum count value is 4. Count values <4 will be treated as count value =4. Note that synchronisation to the register clock domain costs 2 register clock cycles and the counter cannot compensate for that.	RW	0x0000

## 8.3. Ring oscillator (ROSC)

### 8.3.1. Overview

The Ring Oscillator (ROSC) is an on-chip oscillator built from a ring of inverters. It requires no external components and is started automatically during RP2350 power up. It provides the clock to the cores during boot. The frequency of the ROSC is programmable and it can directly provide a high speed clock to the cores, but the frequency varies with Process, Voltage, and Temperature (PVT) so it cannot provide clocks for components that require an accurate frequency such as the AON Timer, USB, and ADC. The frequency can be randomised to provide some protection against attempts to recover the system clock from power traces. Methods for mitigating unwanted frequency variation are discussed in [Section 8.1, “Overview”](#), but these are only relevant to very low power designs. For most applications requiring accurate clock frequencies, switch to the XOSC and PLLs. During boot, the ROSC runs at a nominal 11MHz and is guaranteed to be in the range 4.6MHz to 19.6MHz without randomisation and 4.6MHz to 24.0MHz with randomisation.

#### NOTE

RP2350 A3 and later enable randomisation by default, and the bootrom quadruples the ROSC base frequency by reducing `DIV` to 2. As a result, `clk_sys` is guaranteed to range between 18.4 MHz and 96.0 MHz. `clk_ref` is maintained at a nominal 11 MHz by increasing its divisor. This change increases the sensitivity of the glitch detectors, which have an inverse relationship with clock period, consequently better protecting the ROM’s early boot paths.

After the chip has booted, the programmer can choose to continue running from the ROSC and increase its frequency or start the Crystal Oscillator (XOSC) and PLLs. You can disable the ROSC when you’ve switched the system clocks to the XOSC. Each oscillator has advantages; switch between them to achieve the best solution for your application.

位	描述	类型	复位
20	<b>X4</b> : 将 startup_delay 乘以 4, 以防万一。复位值由可掩码编程的锁存单元控制, 备用于从 XOSC 启动且默认启动延迟不足的情况。	读写	0x0
19:14	保留。	-	-
13:0	<b>DELAY</b> : 以 $256 \times \text{xtal\_period}$ 的倍数计。复位值 0xc4 约等于 50,000 个时钟周期。	读写	0x00c4

## XOSC: COUNT 寄存器

偏移: 0x10

表603. COUNT 寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	<p>一个以 xosc 频率运行的递减计数器, 计数到零后停止。 可用于设置时间敏感硬件时实现短暂的软件延迟。</p> <p>要启动计数器, 请写入非零值。计数器运行时读取返回 1, 计数结束后返回 0。 最小计数值为4。计数值小于4的, 将视为计数值等于4。 请注意, 同步至寄存器时钟域需耗费2个寄存器时钟周期, 计数器无法对此进行补偿。</p>	读写	0x0000

## 8.3. 环形振荡器 (ROSC)

### 8.3.1. 概述

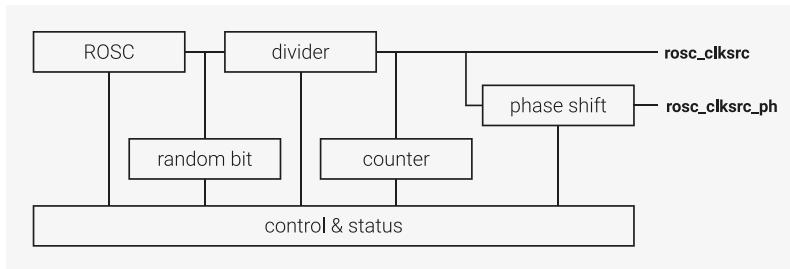

环形振荡器 (ROSC) 是一种由反相器环构成的片上振荡器。该振荡器无需外部组件, 在RP2350上电时自动启动。启动过程中为处理器内核提供时钟。ROSC的频率可编程, 能够直接为内核提供高速时钟, 但其频率随工艺(Process)、电压(Voltage)及温度(Temperature) (PVT) 变化, 因而无法为需高频率精度的组件如AON定时器、USB及ADC提供时钟。频率可随机化, 以防止通过电源轨迹恢复系统时钟的尝试。第8.1节“概述”中讨论了缓解频率变化的方法, 但这些方法仅适用于极低功耗设计。对于大多数需要精确时钟频率的应用, 请切换至XOSC和PLL。启动过程中, ROSC以名义11MHz运行, 并保证在无随机化时频率范围为4.6MHz至19.6MHz, 随机化时范围为4.6MHz至24.0MHz。

#### ① 注意

RP2350 A3及后续版本默认启用随机化, 启动只读存储器 (bootrom) 通过将 DIV降低至2, 使ROSC基频提升四倍。因此, `clk_sys`保证在18.4 MHz至96.0 MHz范围内, `clk_ref`则通过增加除数保持在名义11 MHz。该调整提升了毛刺检测器的灵敏度, 灵敏度与时钟周期成反比, 进而更有效地保护只读存储器的早期启动路径。

芯片启动后, 程序员可选择继续使用ROSC并提升其频率, 或启动晶体振荡器 (XOSC) 和PLL。系统时钟切换至XOSC后, 可禁用ROSC。每种振荡器均具优势; 在它们之间切换, 以实现您的应用的最佳解决方案。

Figure 39. ROSC overview.

### 8.3.2. Changes from RP2040

Frequency randomisation feature added.

### 8.3.3. Changes between RP2350 revisions

RP2350 A3 changes the reset values of `FREQA.DS0_RANDOM` and `FREQA.DS1_RANDOM` from `0` to `1`. See [Hardware changes](#) for information about related changes made to the clock configuration at reset. See [Bootrom changes](#) for related changes made in the A3 boot ROM.

### 8.3.4. ROSC/XOSC trade-offs

The ROSC has several advantages:

- Flexibility due to programmable frequency
- Low power requirements
- No need for internal or external components
- Optional frequency randomisation improves security

Because the ROSC has programmable frequency, it can provide a fast core clock without starting the PLLs and can generate slower peripheral clocks by dividing by clock generators ([Section 8.1, “Overview”](#)). The ROSC starts immediately and responds immediately to frequency controls. It retains the frequency setting when entering and exiting the DORMANT state (see [Section 6.5.3, “DORMANT state”](#)). However, the user must be aware that the frequency may have drifted when exiting the DORMANT state due to changes in the supply voltage and the chip temperature.

The disadvantage of the ROSC is its frequency variation with PVT (Process, Voltage, and Temperature), which makes it unsuitable for generating precise clocks or for applications where software execution timing is important. However, the PVT frequency variation can be exploited to provide automatic frequency scaling to maximise performance. This is discussed in [Section 8.1, “Overview”](#).

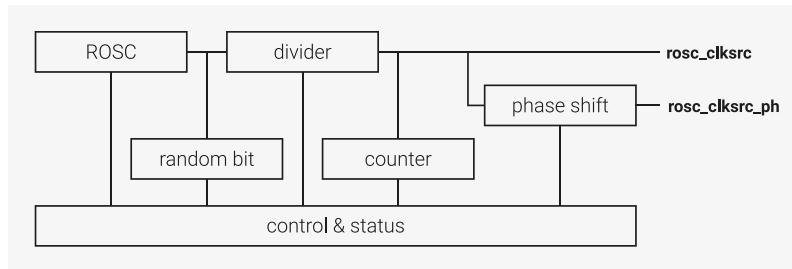

The only advantage of the XOSC is its accurate frequency, but this is an overriding requirement in many applications.

The XOSC has the following disadvantages:

- the requirement for external components (a crystal, etc.)
- higher power consumption
- slow startup time (>1ms)
- fixed, low frequency

PLLs are required to produce higher-frequency clocks. They consume more power and take significant time to start up or change frequency. Exiting DORMANT mode is much slower than for ROSC because the XOSC must restart and the PLLs must be reconfigured.

图39. ROSC  
概述。

### 8.3.2. 相较于 RP2040 的变更

新增频率随机化功能。

### 8.3.3. RP2350 修订版本之间的变更

RP2350 A3将FREQA.DS0\_RANDOM和FREQA.DS1\_RANDOM的复位值由 0 改为 1。有关复位时钟配置相关更改的信息，请参见硬件更改。有关A3版Boot ROM中相关更改的信息，请参见Bootrom更改一节。

### 8.3.4. ROSC 与 XOSC 的权衡

ROSC具有以下几个优势：

- 频率可编程，灵活性强
- 低功耗需求
- 无需内部或外部组件
- 可选的频率随机化功能提升安全性

由于ROSC具备可编程频率，能够在不启用PLL的情况下提供快速的核心时钟，并通过时钟发生器分频（第 8.1节，“概述”）产生较慢的外设时钟。ROSC能够立即启动并即时响应频率控制。在进入及退出DORMANT状态时，保持频率设置（参见第6.5.3节，“DORMANT状态”）。但用户必须注意，因电源电压和芯片温度变化，退出DORMANT状态时频率可能发生漂移。

ROSC 的缺点在于其频率随 PVT（工艺、电压和温度）变化，因而不适用于生成精确时钟或软件执行时序关键的应用。然而，PVT 频率变化可被利用，实现自动频率调节以最大化性能。相关内容详见第8.1节，“概述”。

XOSC 唯一的优点是频率精确，但在许多应用中这是不可替代的核心需求。

XOSC 存在以下缺点：

- 需要外部元件（如晶体等）
- 功耗较高
- 启动时间较长 (>1毫秒)
- 频率固定且较低

必须通过 PLL 产生更高频率时钟。PLL 消耗更多功率且启动或频率切换所需时间较长。退出休眠（DORMANT）模式远慢于ROSC，因需重新启动 XOSC 并重新配置 PLL。

### 8.3.5. Modifying the frequency

The ROSC is arranged as 8 stages, each with programmable drive. The ROSC provides two methods of controlling the frequency. The frequency range controls the number of stages in the ROSC loop and the [FREQA](#) & [FREQB](#) registers control the drive strength of the stages.

To change the frequency range, write to the [FREQ\\_RANGE](#) register, which controls the number of stages in the ROSC loop. The [FREQ\\_RANGE](#) register supports the following configurations:

Table 604. ROSC stage ranges

Name	Number of stages	Range (stages)
LOW	8	0-7
MEDIUM	6	2-7
HIGH	4	4-7
TOOHIGH	2	6-7

Change [FREQ\\_RANGE](#) one step at a time until you reach the desired range. When increasing the frequency range, ROSC output will not glitch, so the output clock can continue to be used. When decreasing the frequency range, ROSC output *will* glitch, so you must select an alternate clock source for the modules clocked by ROSC or hold them in reset during the transition.

The behaviour has not been fully characterised, but the MEDIUM range will be approximately 1.33 times the LOW range, the HIGH range will be 2 times the LOW range and the TOOHIGH range will be 4 times the LOW range. The TOOHIGH range is aptly named. It should not be used because the internal logic of the ROSC will not run at that frequency.

The [FREQA](#) and [FREQB](#) registers control the drive strength of the stages in the ROSC loop. As the drive strength increases, the delay through the stage decreases and the oscillation frequency increases. Each stage has 3 drive strength control bits. Each bit turns on an additional drive, therefore each stage has 4 drive strength settings equal to the number of bits set, with 0 being the default, 1 being double drive, 2 being triple drive and 3 being quadruple drive. Extra drives do not have a linear effect on frequency: the second has less impact than the first, the third has less impact than the second, and so on. To ensure smooth transitions, change one drive strength bit at a time. When [FREQ\\_RANGE](#) shortens the ROSC loop, the bypassed stages still propagate the signal and therefore their drive strengths must be set to at least the same level as the lowest drive strength in the stages that are in the loop. This will not affect the oscillation frequency.

### 8.3.6. Randomising the frequency

Randomisation is enabled by setting the drive strength controls for the first two stages of the ROSC loop to [DS0\\_RANDOM](#) and [DS1\\_RANDOM](#). An LFSR then provides the drive strength controls for those two stages which are always included in the loop regardless of the [FREQ\\_RANGE](#) setting. It is recommended to randomise both stages. When the low [FREQ\\_RANGE](#) is selected the randomiser will increase the frequency by up to 22% of the default. The increase will be approximately half of that if only one stage is randomised. The LFSR can be seeded by writing to the [RANDOM](#) register. This can be done at any time but will restart the randomiser.

### 8.3.7. ROSC divider

The ROSC frequency is too fast to be used directly, so it is divided in an integer divider controlled by the [DIV](#) register. You can change [DIV](#) while the ROSC is running, and the output clock will change frequency without glitching. The default divisor is 8, which ensures the output clock is in the specified range on chip startup.

The divider has two outputs, [rosclksrc](#) and [rosclksrc\\_ph](#). [rosclksrc\\_ph](#) is a phase shifted version of [rosclksrc](#). This is primarily intended for use during product development; the outputs are identical if the [PHASE](#) register is left in its default state.

### 8.3.5. 频率调整

ROSC 设计为8级，每级均具可编程驱动能力。ROSC 提供两种控制频率的方法。频率范围控制 ROSC 环路中的级数，**FREQ\_A**和**FREQ\_B**寄存器控制各级的驱动强度。

要更改频率范围，请写入 **FREQ\_RANGE**寄存器，该寄存器控制 ROSC 环路中的级数。

**FREQ\_RANGE**寄存器支持以下配置：

表 604. ROSC  
级数范围

名称	级数数量	范围（级数）
低	8	0-7
中	6	2-7
高	4	4-7
超高	2	6-7

逐步更改 **FREQ\_RANGE**寄存器，直至达到所需范围。增加频率范围时，ROSC 输出不会产生抖动，输出时钟可继续使用。降低频率范围时，ROSC 输出会产生抖动，必须为由 ROSC 作为时钟源的模块选择备用时钟源，或在转换期间将其复位。

该行为尚未完全表征，但中范围约为低范围的 1.33 倍，高范围为低范围的 2 倍，超高范围为低范围的 4 倍。**TOOHIGH** 范围名称准确。不应使用该频率，因为 ROSC 的内部逻辑无法在该频率下运行。

**FREQ\_A** 和 **FREQ\_B** 寄存器控制 ROSC 环路中各级的驱动强度。随着驱动强度增加，级内延迟减小，振荡频率提高。每一级设有 3 个驱动强度控制位。每个位开启一个额外驱动，因此每一级具有 4 种驱动强度设置，等同于已设置位数，0 为默认，1 为双驱动，2 为三驱动，3 为四驱动。额外驱动对频率影响呈非线性：第二个驱动效果低于第一个，第三个驱动效果低于第二个，依此类推。为确保切换平滑，每次请仅调整一个驱动强度位。当 **FREQ\_RANGE** 缩短 ROSC 环路时，被绕过的级仍然传递信号，因此其驱动强度必须至少保持不低于环路内最低驱动强度。此操作不会影响振荡频率。

### 8.3.6. 频率随机化

通过将ROSC环路前两个阶段的驱动强度控制设置为 **DS0\_RANDOM**和 **DS1\_RANDOM**，即可启用随机化。LFSR随后为这两个阶段提供驱动强度控制，无论**FREQ\_RANGE**如何设置，这两个阶段始终包含在环路中。建议对两个阶段均启用随机化。当选择低**FREQ\_RANGE**时，随机化器将使频率增加高达默认值的22%。如果仅随机化其中一个阶段，频率提升约为该值的一半。LFSR可通过写入**RANDOM**寄存器进行种子初始化。此操作可随时执行，但会重启随机化器。

### 8.3.7. ROSC 分频器

ROSC频率过快，无法直接使用，因此通过由 **DIV**寄存器控制的整数分频器进行分频。您可在ROSC运行时更改 **DIV**，输出时钟频率将无毛刺地变化。默认除数为8，以确保芯片启动时输出时钟处于指定范围内。

分频器具有两个输出，分别为**rosc\_clksrc**和**rosc\_clksrc\_ph**。**rosc\_clksrc\_ph**是**rosc\_clksrc**的相位偏移版本。此功能主要用于产品开发阶段；若 **PHASE**寄存器保持默认状态，两个输出将完全相同。

### 8.3.8. Random number generator

When the system clocks are running from the XOSC, you can use the ROSC to generate random numbers. Enable the ROSC and read the `RANDOMBIT` register to get a 1-bit random number; to get an `n`-bit value, read it `n` times. This does not meet the requirements of randomness for security systems because it can be compromised, but it may be useful in less critical applications. If the cores are running from the ROSC, the value will not be random because the timing of the register read will be correlated to the phase of the ROSC.

### 8.3.9. ROSC counter

The `COUNT` register provides a method of managing short software delays. To use this method:

1. Write a value to the `COUNT` register. The register automatically begins to count down to zero at the ROSC frequency.
2. Poll the register until it reaches zero.

This is preferable to using NOPs in software loops because it is independent of the core clock frequency, the compiler, and the execution time of the compiled code.

### 8.3.10. DORMANT mode

In DORMANT mode (see [Section 6.5.3, “DORMANT state”](#)), all of the on-chip clocks can be paused to save power. This is particularly useful in battery-powered applications. RP2350 wakes from DORMANT mode by interrupt: either from an external event, such as an edge on a GPIO pin, or from the AON Timer. This must be configured before entering DORMANT mode. To use the AON Timer to trigger a wake from DORMANT mode, it must be clocked from the LPOSC or from an external source.

To enter DORMANT mode:

1. Switch all internal clocks to be driven from XOSC or ROSC and stop the PLLs.
2. Choose an oscillator (XOSC or ROSC). Write a specific 32-bit value to the `DORMANT` register of the chosen oscillator to stop it.

When exiting DORMANT mode, the chosen oscillator will restart. If you chose XOSC, the frequency will be more precise, but the restart will take more time due to startup delay (>1ms on the RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#))). If you chose ROSC, the frequency will be less precise, but the start-up time is very short (approximately 1μs). See [Section 6.5.3.1, “Waking from the DORMANT state”](#) for the events which cause the system to exit DORMANT mode.

#### NOTE

You must stop the PLLs before entering DORMANT mode.

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/hardware\\_rosc/rosc.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/hardware_rosc/rosc.c) Lines 56 - 61

```

56 void rosc_set_dormant(void) {
57 // WARNING: This stops the rosc until woken up by an irq
58 rosc_write(&rosc_hw->dormant, ROSC_DORMANT_VALUE_DORMANT);
59 // Wait for it to become stable once woken up
60 while(!(rosc_hw->status & ROSC_STATUS_STABLE_BITS));
61 }
```

### 8.3.8. 随机数发生器

当系统时钟由XOSC驱动时，可使用ROSC生成随机数。启用ROSC并读取 **RANDOMBIT** 寄存器以获取单比特随机数；若需获取 **n** 比特随机值，则需读取该寄存器 **n** 次。此方法不满足安全系统对随机性的要求，因其易受攻击，但在较低风险应用中仍可能适用。若核心由ROSC驱动，则读取值不具随机性，因为寄存器读取时间与ROSC相位相关。

### 8.3.9. ROSC 计数器

**COUNT** 寄存器提供了一种管理短时软件延迟的方法。使用该方法步骤如下：

1. 向 **COUNT** 寄存器写入一个值。该寄存器自动开始以ROSC频率倒计时至零。
2. 轮询该寄存器，直至其值为零。

这比在软件循环中使用NOP指令更为优选，因为它不依赖核心时钟频率、编译器以及已编译代码的执行时间。

### 8.3.10. DORMANT 模式

在休眠模式（参见第6.5.3节，“休眠状态”）中，所有片上时钟均可暂停以节省功耗。这对于电池供电的应用尤为有用。RP2350通过中断从休眠模式唤醒：中断源可以是外部事件，如GPIO引脚的边沿触发，或AON定时器触发。此项必须在进入休眠模式前进行配置。要使用AON定时器触发从休眠模式的唤醒，时钟必须来自LPOSC或外部时钟源。

进入休眠（DORMANT）模式：

1. 将所有内部时钟切换为由XOSC或ROSC驱动，并停止锁相环（PLLs）。
2. 选择一个振荡器（XOSC或ROSC），向所选振荡器的 **DORMANT** 寄存器写入特定32位数值以停止其运行。

退出休眠模式时，所选振荡器将重新启动。如果选择XOSC，频率将更为精确，但因启动延迟，重启时间较长（RP2350参考设计中启动延迟超过1毫秒，详见RP2350硬件设计——最小设计示例）。如果选择ROSC，频率较不精确，但启动时间极短（约1微秒）。有关导致系统退出休眠模式的事件，请参见章节6.5.3.1“从休眠（DORMANT）状态唤醒”。

#### 注意

进入休眠模式前，必须停止锁相环（PLLs）。

Pico Extras: [https://github.com/raspberrypi/pico-extras/blob/master/src/rp2\\_common/hardware\\_rosc/rosc.c](https://github.com/raspberrypi/pico-extras/blob/master/src/rp2_common/hardware_rosc/rosc.c) 第56至61行

```

56 void rosc_set_dormant(void) {
57 // 警告：此操作将停止rosc，直至通过irq唤醒
58 rosc_write(&rosc_hw->dormant, ROSC_DORMANT_VALUE_DORMANT);
59 // 唤醒后等待osc稳定
60 while(!(rosc_hw->status & ROSC_STATUS_STABLE_BITS));
61 }
```

**⚠️ WARNING**

If you do not configure IRQ before entering DORMANT mode, neither oscillator will restart.

See [Section 6.5.6.2, "DORMANT"](#) for some examples of dormant mode.

### 8.3.11. List of registers

The ROSC registers start at a base address of `0x400e8000` (defined as `ROSC_BASE` in SDK).

Table 605. List of ROSC registers

Offset	Name	Info
0x00	<a href="#">CTRL</a>	Ring Oscillator control
0x04	<a href="#">FREQA</a>	Ring Oscillator frequency control A
0x08	<a href="#">FREQB</a>	Ring Oscillator frequency control B
0x0c	<a href="#">RANDOM</a>	Loads a value to the LFSR randomiser
0x10	<a href="#">DORMANT</a>	Ring Oscillator pause control
0x14	<a href="#">DIV</a>	Controls the output divider
0x18	<a href="#">PHASE</a>	Controls the phase shifted output
0x1c	<a href="#">STATUS</a>	Ring Oscillator Status
0x20	<a href="#">RANDOMBIT</a>	Returns a 1 bit random value
0x24	<a href="#">COUNT</a>	A down counter running at the ROSC frequency which counts to zero and stops.

### ROSC: CTRL Register

**Offset:** 0x00

#### Description

Ring Oscillator control

Table 606. CTRL Register

Bits	Description	Type	Reset
31:24	Reserved.	-	-
23:12	<b>ENABLE:</b> On power-up this field is initialised to ENABLE The system clock must be switched to another source before setting this field to DISABLE otherwise the chip will lock up The 12-bit code is intended to give some protection against accidental writes. An invalid setting will enable the oscillator.	RW	-
	Enumerated values:		
	0xd1e → DISABLE		
	0xfb → ENABLE		

**● 警告**

如果未在进入DORMANT模式前配置IRQ，则振荡器不会重新启动。

请参见第6.5.6.2节，“DORMANT”，其中包含休眠模式的一些示例。

### 8.3.11. 寄存器列表

ROSC寄存器的基地址为 `0x400e8000`（在SDK中定义为ROSC\_BASE）。

表605.

	0xfa7 → HIGH		
	0xfa6 → TOOHIGH		

## ROSC: FREQA Register

Offset: 0x04

### Description

The FREQA & FREQB registers control the frequency by controlling the drive strength of each stage  
The drive strength has 4 levels determined by the number of bits set  
Increasing the number of bits set increases the drive strength and increases the oscillation frequency  
0 bits set is the default drive strength  
1 bit set doubles the drive strength  
2 bits set triples drive strength  
3 bits set quadruples drive strength  
For frequency randomisation set both DS0\_RANDOM=1 & DS1\_RANDOM=1

Table 607. FREQA Register

Bits	Description	Type	Reset

	0xfa7 → 高		
	0xfa6 → 过高		

## ROSC: FREQA 寄存器

偏移: 0x04

### 描述

FREQA 和 FREQB 寄存器通过控制各阶段的驱动强度来调节频率。驱动强度分为四档，由设置的位数决定。增加设置的位数将提高驱动强度及振荡频率。

- 0 位设置为默认驱动强度
- 1 位设置时驱动强度翻倍
- 2 位设置时驱动强度增至三倍
- 3 位设置时驱动强度增至四倍

频率随机化时，请同时设置 DS0\_RANDOM=1 和 DS1\_RANDOM=1

表 607. FREQA 寄存器

Offset: 0x24

Table 615. COUNT Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	A down counter running at the ROSC frequency which counts to zero and stops. To start the counter write a non-zero value. Can be used for short software pauses when setting up time sensitive hardware.	RW	0x0000

## 8.4. Low Power oscillator (LPOSC)

The Low Power Oscillator (LPOSC) provides a clock signal to the always-on logic when the main crystal oscillator is powered down in a low power ([P1.x](#)) state. It operates at a nominal 32.768kHz and is an RC oscillator, requiring no external components. The oscillator's output clock is used to sequence initial chip start up and transition to and from low-power states. It can also be used by the AON Timer, see [Section 12.10, “Always-on timer”](#).

The oscillator starts up as soon as the core power supply is available and power-on reset has been released. If brownout detection is enabled, the oscillator will be disabled when a core supply brownout is detected, but will restart as soon as the core supply has recovered and brownout reset has been released. The oscillator's frequency takes around 1ms to stabilise, and the chip will be held in reset during this period.

### 8.4.1. Frequency accuracy and calibration

The low power oscillator has an initial frequency accuracy of  $\pm 20\%$ . However, it can be trimmed to  $\pm 1.5\%$  using the [TRIM](#) field in the [LPOSC](#) register. 63 trim steps are available, each between 1% and 3% of the oscillator's initial frequency. The frequency can be trimmed down by 32 steps or up by 31 steps. See [Table 616, “low power oscillator output frequency and trimming”](#) and [Section 8.4.3, “List of registers”](#) for details.

Table 616. Low power oscillator output frequency and trimming

Parameter	Description	Min	Typ	Max	Units
$F_{0,\text{initial}}$	initial output frequency	26.2144	32.768	39.3216	kHz
$\text{trim}_{\text{STEP}}$	frequency trim step	-	1	3	% of initial output frequency
$F_{0,\text{trimmed}}$	trimmed output frequency	32.27648	32.768	33.25952	kHz

Frequency drift with temperature:  $\pm 14\%$ .

## 8.4. 低功耗振荡器 (LPOSC)

低功耗振荡器 (LPOSC) 在主晶体振荡器关闭以进入低功耗 (P1.x) 状态时，为始终打开的逻辑电路提供时钟信号。它以标称32.768kHz频率运行，是一种RC振荡器，无需外部元件。振荡器的输出时钟用于控制芯片初始启动的时序，以及低功耗状态之间的转换。该振荡器亦可供始终开启定时器(AON Timer)使用，详见第12.10节“始终开启定时器”。

振荡器在核心电源供应可用且上电复位解除后即开始启动。若启用欠压检测，检测到核心电源欠压时振荡器将被禁用；但核心电源恢复且欠压复位解除后，振荡器将重新启动。振荡器频率约需1毫秒稳定，在此期间芯片将保持复位状态。

### 8.4.1. 频率精度与校准

低功耗振荡器初始频率精度为±20%。然而，可通过LPOSC寄存器中的TRIM字段将其调节至±1.5%。提供63个调节档位，每档调节范围为振荡器初始频率的1%至3%。频率可降低32步或提高31步。详见表616，“低功耗振荡器输出频率及校准”，以及第8.4.3节“寄存器列表”。

表616。低功耗  
振荡器输出  
频率及  
校准

参数	描述	最小值	典型值	最大值	单位
$F_{0,\text{initial}}$	初始输出频率	26.2144	32.768	39.3216	kHz
校准步进	频率校准步进	-	1	3	占初始输出频率的百分比
$F_{0,\text{trimmed}}$	校准后输出频率	32.27648	32.768	33.25952	kHz

频率随温度漂移：±14%。

Frequency drift with power supply voltage:  $\pm 20\%$ .

### 8.4.2. Using an external low-power clock

Instead of using the low-power RC oscillator, an external 32.768 kHz low power clock signal can be provided on one of GPIO 12, 14, 20, or 22. Alternatively, those GPIOs can be used to provide a 1 kHz or 1 Hz tick. See [Section 12.10.5.2, "Using an external clock in place of LPOSC"](#) and [Section 12.10.7, "Using an external clock or tick from GPIO"](#) for more details.

### 8.4.3. List of registers

The low power oscillator shares register address space with other power management subsystems in the always-on domain. The address space is referred to as POWMAN elsewhere in this document. A complete list of POWMAN registers is provided in [Section 6.4, "Power management \(POWMAN\) registers"](#), but information on registers associated with the low power oscillator is repeated here.

The POWMAN registers start at a base address of `0x40100000` (defined as `POWMAN_BASE` in SDK).

- [LPOSC](#)
- [EXT\\_TIME\\_REF](#)
- [LPOSC\\_FREQ\\_KHZ\\_INT](#)
- [LPOSC\\_FREQ\\_KHZ\\_FRAC](#)

## 8.5. Tick generators

### 8.5.1. Overview

The tick generators provide time references for several blocks:

- System timers: TIMER0 and TIMER1 ([Section 12.8, "System timers"](#))
- RISC-V platform timer ([Section 3.1.8, "RISC-V platform timer"](#))
- Arm Cortex-M33 SysTick timers for core 0 and core 1
- The watchdog timer ([Section 12.9, "Watchdog"](#))

A **tick** is a periodic signal which provides a timebase for a timer or counter. These signals are similar to clocks, although they do not drive the clock inputs of any registers on the chip. The use of ticks as opposed to clocks makes it simpler to distribute timebase information that is independent of any subsystem clocks. For example, the system timers (TIMER0 and TIMER1) should continue to count once per microsecond even as the system clock varies according to processor demand.

The tick generators use `clk_ref` as their reference clock (see [Section 8.1, "Overview"](#) for an overview of system-level clocks including `clk_ref`). Ideally, `clk_ref` will be configured to use the crystal oscillator ([Section 8.2, "Crystal oscillator \(XOSC\)"](#)) to provide an accurate reference. The generators divide `clk_ref` internally to generate a tick signal for each destination.

The SDK expects a nominal 1  $\mu$ s timebase for the system timers and the RISC-V platform timer. Similarly the Cortex-M33 SysTick timers require a 1  $\mu$ s timebase to match the hardwired value of 100,000 in the `SYST_CALIB` register, which standard Arm software uses to scale SysTick delays. However, you may need to scale these timebases differently if your software has specific requirements such as a longer maximum delay on the 24-bit SysTick peripherals. The tick generator can scale each destination's tick timebase independently of the others.

For a 12 MHz reference clock, set the cycle count to 12 to generate a 1  $\mu$ s tick. A 1 MHz clock has a period of 1  $\mu$ s, so

频率随电源电压漂移： $\pm 20\%$ 。

### 8.4.2. 使用外部低功率时钟

可不使用低功耗RC振荡器，而改由GPIO 12、14、20或22之一提供外部32.768 kHz低功耗时钟信号。或者，这些GPIO可用于提供1 kHz或1 Hz时钟脉冲。详见第12.10.5.2节“使用外部时钟替代低功耗振荡器”及第12.10.7节“利用GPIO输入外部时钟或时钟脉冲”。

### 8.4.3. 寄存器列表

低功耗振荡器与始终通电域中的其他电源管理子系统共享寄存器地址空间。本文档其他部分将该地址空间称为POWMAN。第6.4节“电源管理（POWMAN）寄存器”中提供了POWMAN寄存器的完整列表，但与低功耗振荡器相关的寄存器信息在此处重复说明。

POWMAN寄存器的基址起始于 `0x40100000`（在SDK中定义为POWMAN\_BASE）。

- [LPOSC\\_FREQ\\_KHZ\\_FRAC](#)

## 8.5. 计时发生器

### 8.5.1. 概述

时钟发生器为多个模块提供时间参考：

- 系统定时器：TIMER0和TIMER1（第12.8节，“系统定时器”）
- RISC-V平台定时器（第3.1.8节，“RISC-V平台定时器”）
- Arm Cortex-M33核心0和核心1的SysTick定时器
- 看门狗定时器（第12.9节，“看门狗”）

时钟脉冲（**tick**）是一种周期性信号，为定时器或计数器提供时间基准。这些信号类似于时钟，但并不驱动芯片上任何寄存器的时钟输入。使用时钟滴答（**ticks**）而非时钟信号，使得分发独立于任何子系统时钟的时间基准信息更加简便。例如，系统定时器（TIMER0 和 TIMER1）应当即使系统时钟根据处理器需求变化，仍每微秒持续计数一次。

时钟滴答发生器以 `clk_ref` 作为参考时钟（详见第8.1节“概述”，该节包括 `clk_ref` 在内的系统级时钟概述）。理想情况下，应将 `clk_ref` 配置为使用晶体振荡器（第8.2节“晶体振荡器（XOSC）”）以提供精准参考。发生器内部对 `clk_ref` 进行分频，以生成各目标的时钟滴答信号。

SDK期望系统定时器和RISC-V平台定时器具备名义上的1  $\mu$ s时间基准。同样，Cortex-M33 SysTick定时器要求1  $\mu$ s时间基准，以匹配SYST\_CALIB寄存器中硬连线的100,000值，此为标准Arm软件用于校准SysTick延迟的参数。然而，如果您的软件具有特定要求，例如对24位SysTick外设设置更长的最大延迟，则可能需要对这些时间基准进行不同的缩放。计时器生成器可以独立缩放每个目标的计时基准，互不影响。

对于12 MHz参考时钟，将周期计数设置为12以生成1  $\mu$ s的时钟周期。1 MHz时钟的周期为1  $\mu$ s，因此，

the hardware needs to count for 12 times as many clock cycles to get a 1 µs tick from a reference running at 12 × 1 MHz.

Before changing the cycle count, always stop the tick generator with the [TIMER0\\_CTRL.ENABLE](#) bit. You can re-enable once the tick generator is configured.

### 8.5.2. List of registers

The tick generator registers start at a base address of [0x40108000](#) (defined as [TICKS\\_BASE](#) in SDK).

## 8.6. PLL

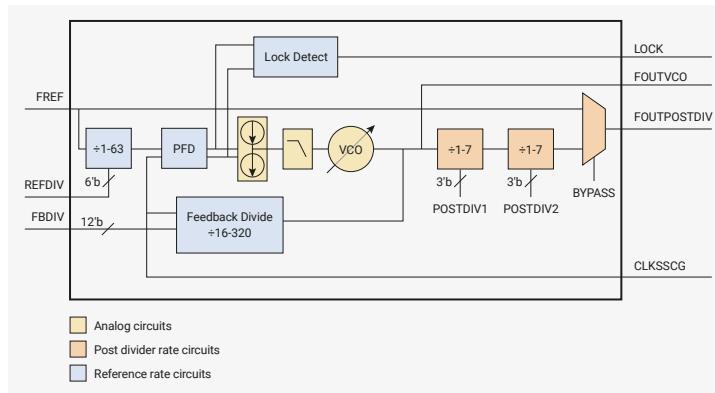

### 8.6.1. Overview

The PLL takes a reference clock and multiplies it using a Voltage Controlled Oscillator (VCO) with a feedback loop. The VCO runs at high frequencies: between 750 MHz and 1600 MHz. As a result, there are two **post dividers** that can divide the VCO frequency before it is distributed to the clock generators on the chip.

There are two PLLs in RP2350. They are:

- **pll\_sys** - used to generate up to a 150 MHz system clock
- **pll\_usb** - used to generate a 48 MHz USB reference clock

Figure 40. On both PLLs, the FREF (reference) input is connected to the crystal oscillator's XIN (X1) input. The PLL contains a VCO, which is locked to a constant ratio of the reference clock via the feedback loop (phase-frequency detector and loop filter). This can synthesise very high frequencies, which may be divided down by the post-dividers.

The routing between PLLs and system-level clocks is flexible. For example, you could run USB off a division of the system PLL (e.g. 144 MHz / 3 = 48 MHz), leaving the USB PLL free for other uses such as the HSTX peripheral or a general-purpose clock output on a GPIO.

### 8.6.2. Changes from RP2040

- RP2350 added an interrupt that fires if the PLL loses lock. See CS.LOCK\_N.

## 8.6. PLL

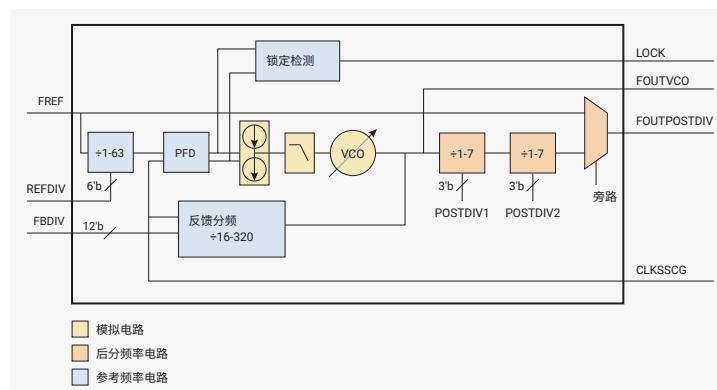

### 8.6.1. 概述

PLL采用参考时钟，并通过带反馈回路的电压控制振荡器（VCO）进行倍频。VCO工作于高频率：750 MHz至1600 MHz之间。因此，有两个后分频器，可在将VCO频率分配至芯片上的时钟发生器之前进行分频。

RP2350中设有两个PLL，它们分别是：

- `pll_sys` - 用于生成最高150 MHz的系统时钟
- `pll_usb` - 用于生成48 MHz的USB参考时钟

图40。两个PLL中，REF（参考）输入连接至晶体振荡器的XIN（XI）输入端。PLL包含一个VCO，通过反馈环路（相位-频率检测器和环路滤波器）锁定参考时钟的固定比率。该结构可合成极高频率，随后可由后置分频器进行分频。

PLL与系统级时钟之间的路由具有灵活性。例如，可通过系统PLL的分频信号驱动USB（例如 $144 \text{ MHz} / 3 = 48 \text{ MHz}$ ），同时释放USB PLL供HSTX外围设备或GPIO上的通用时钟输出等其他用途。

### 8.6.2. 相较于 RP2040 的变化

- RP2350新增当PLL失锁时触发的中断，详见CS.LOCK\_N。

### 8.6.3. Calculating PLL parameters

To configure the PLL, you must know the frequency of the reference clock, which is routed directly from the crystal oscillator. This will often be a 12 MHz crystal, for compatibility with RP2350's USB bootrom. The PLL's final output frequency  $F_{OUTPOSTDIV}$  can then be calculated as  $(F_{REF} / REFDIV) \times FBDIV / (POSTDIV1 \times POSTDIV2)$ . With a desired output frequency in mind, you must select PLL parameters according to the following constraints of the PLL design:

- minimum reference frequency ( $F_{REF} / REFDIV$ ) is 5 MHz
- oscillator frequency ( $F_{OUTVCO}$ ) must be in the range 750 MHz-1600 MHz
- feedback divider ( $FBDIV$ ) must be in the range 16-320
- the post dividers  $POSTDIV1$  and  $POSTDIV2$  must be in the range 1-7
- maximum input frequency ( $F_{REF} / REFDIV$ ) is VCO frequency divided by 16, due to minimum feedback divisor

You must also respect the maximum frequencies of the chip's clock generators (attached to  $F_{OUTPOSTDIV}$ ). For the system PLL this is 150 MHz, and for the USB PLL, 48 MHz. If using a crystal oscillator with a frequency of less than 75 MHz,  $REFDIV$  should be 1 assuming a VCO of 1200 MHz-1600 MHz. If using a fast crystal with a low VCO frequency, the reference divisor may need to be increased to keep the PLL input within a suitable range.

 **TIP**

When two different values are required for  $POSTDIV1$  and  $POSTDIV2$ , assign the higher value to  $POSTDIV1$  for lower power consumption.

In the RP2350 reference design (see [Hardware design with RP2350, Minimal Design Example](#)), which attaches a 12 MHz crystal to the crystal oscillator, the minimum VCO frequency is  $12\text{ MHz} \times 63 = 756\text{ MHz}$ , and the maximum VCO frequency is  $12\text{ MHz} \times 133 = 1596\text{ MHz}$ . As a result,  $FBDIV$  must remain in the range 63 to 133 to avoid leaving the supported range of VCO frequencies. Setting  $FBDIV$  to 100 would synthesise a 1200 MHz VCO frequency. A  $POSTDIV1$  value of 6 and a  $POSTDIV2$  value of 2 would divide this by 12 in total, producing a clean 100 MHz at the PLL's final output.

#### 8.6.3.1. Jitter versus power consumption

Often, several sets of PLL configuration parameters achieve the desired output frequency (or a close approximation). You decide whether to prioritise lower power consumption or lower **jitter**: cycle-to-cycle variation in the PLL's output clock period. Jitter decreases as VCO frequency increases, because you can use higher post-divide values. Consider the following scenarios:

- 1500 MHz VCO / 6 / 2 = 125 MHz
- 750 MHz VCO / 6 / 1 = 125 MHz

The 1500 MHz configuration uses the most power, but produces the least jitter. The 750 MHz configuration uses the least power, but produces the most jitter.

You can slightly adjust the desired output frequency to allow for a much lower VCO frequency by bringing the output to a closer rational multiple of the input. Some frequencies are not be achievable at all with a possible VCO frequency and combination of divisors.

Because RP2350's digital logic compensates for the worst possible jitter on the system clock, this doesn't affect system stability. However, applications often require a highly accurate clock for data transfers that follow the USB specification, which defines a maximum amount of allowable jitter.

#### 8.6.3.2. Calculating parameters with vcocalc.py

SDK provides a Python script that searches for the best VCO and post divider options for a desired output frequency:

### 8.6.3. PLL 参数计算

要配置PLL，必须确认参考时钟频率，该时钟直接由晶体振荡器引出。这通常是12 MHz的晶体，以确保与RP2350的USB只读存储器（bootrom）兼容。PLL的最终输出频率 $F_{OUTPOSTDIV}$ 可按公式  $(F_{REF} / REFDIV) \times FBDIV / (POSTDIV1 \times POSTDIV2)$  计算。在确定目标输出频率的前提下，须依据PLL设计的以下约束条件选择PLL参数：

- 最小参考频率 ( $F_{REF} / REFDIV$ ) 不得低于5 MHz
- 振荡器频率 ( $F_{OUTVCO}$ ) 应保持在750 MHz至1600 MHz之间
- 反馈分频器 ( $FBDIV$ ) 须介于16至320之间
- 后置分频器  $POSTDIV1$  和  $POSTDIV2$  的取值范围为1至7
- 最大输入频率 ( $F_{REF} / REFDIV$ ) 等于VCO频率除以16，此限制源于反馈分频器的最小值要求

您亦须遵守芯片时钟发生器的最大频率限制（连接至 $F_{OUTPOSTDIV}$ ）。系统PLL的最大频率为150 MHz，USB PLL为48 MHz。若使用频率低于75 MHz的晶体振荡器，且假设VCO频率在1200 MHz至1600 MHz之间，则 $REFDIV$ 应设为1。若使用高速晶体且VCO频率偏低，可能需要增加参考分频器以确保PLL输入频率处于合适范围内。

#### 提示

当  $POSTDIV1$  与  $POSTDIV2$  需赋予不同数值时，应将较大数值指定给  $POSTDIV1$  以降低功耗。

在RP2350参考设计中（见RP2350硬件设计，最简设计示例），将12 MHz晶体连接至晶体振荡器，最小VCO频率为 $12 \text{ MHz} \times 63 = 756 \text{ MHz}$ ，最大VCO频率为 $12 \text{ MHz} \times 133 = 1596 \text{ MHz}$ 。因此， $FBDIV$ 须保持在63到133之间，以免超出VCO频率支持范围。将 $FBDIV$ 设置为100将合成1200 MHz的VCO频率。 $POSTDIV1$ 值为6且 $POSTDIV2$ 值为2将总共除以12，产生PLL最终输出的纯净100 MHz信号。

#### 8.6.3.1. 抖动与功耗

通常，有多组PLL配置参数可实现所需的输出频率（或近似值）。

您需决定是优先降低功耗，还是优先降低抖动——PLL输出时钟周期的逐周期变化。由于可使用更高的后除数值，抖动随VCO频率的升高而减小。请参考以下示例：

- 1500 MHz VCO / 6 / 2 = 125 MHz
- 750 MHz VCO / 6 / 1 = 125 MHz

1500 MHz配置功耗最高，但抖动最小。750 MHz配置功耗最低，但抖动最大。

您可以略微调整所需的输出频率，通过将输出频率调整为输入频率的更接近的有理倍数，从而允许使用更低的VCO频率。某些频率在可能的VCO频率和分频器组合下根本无法实现。

由于RP2350的数字逻辑能够补偿系统时钟上的最严重抖动，因此这不会影响系统稳定性。然而，应用通常需要高精度时钟以满足USB规范中定义的最大允许抖动要求，从而确保数据传输的准确性。

#### 8.6.3.2 使用vcocalc.py计算参数

SDK提供了一个Python脚本，用于搜索所需输出频率的最佳VCO和后级分频选项：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/scripts/vcocalc.py](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/scripts/vcocalc.py)

```

```

Given an input and output frequency, this script finds the best possible set of PLL parameters. When the script finds multiple equally good combinations, it returns the parameters which yield the highest VCO frequency, for the best output stability. Pass the `-l` or `--low-vco` flag to prefer lower frequencies, which reduce power consumption. Pass the `--vco-max` flag to limit the maximum VCO frequency. If the script cannot find an exact match given the provided constraints, it outputs the closest reasonable match instead.

The following example uses the script to request a 48 MHz output with the best output stability:

```

$./vcocalc.py 48
Requested: 48.0 MHz
Achieved: 48.0 MHz
REFDIV: 1
FBDIV: 120 (VCO = 1440.0 MHz)
PD1: 6
PD2: 5

```

This can also be output as CMake for configuring an SDK application:

```

51 continue
52 if margin < best_margin or (abs(margin - best_margin) < 1e-9 and
53 vco_is_better):
54 best = (out, fbdv, pd1, pd2, refdiv, vco)
55 best_margin = margin
56
57 best_out, best_fbdv, best_pd1, best_pd2, best_refdiv, best_vco = best
58
59 if best[0] > 0:
60 cmake_output = \
61 f"""target_compile_definitions({args.cmake_executable_name} PRIVATE
62 PLL_SYS_REFDIV={best_refdiv}
63 PLL_SYS_VCO_FREQ_HZ={int((args.input * 1_000_000) / best_refdiv * best_fbdv)}
64 PLL_SYS_POSTDIV1={best_pd1}
65 PLL_SYS_POSTDIV2={best_pd2}
66 SYS_CLK_HZ={int((args.input * 1_000_000) / (best_refdiv * best_pd1 * best_pd2) *
67 best_fbdv)}"""
67 """
68 if not args.cmake_only:
69 print("请求频率: {} MHz".format(args.output))
70 print("实际频率: {} MHz".format(best_out))
71 print("REFDIV: {}".format(best_refdiv))
72 print("FBDIV: {} (VCO = {} MHz)".format(best_fbdv, args.input / best_refdiv *
73 best_fbdv))
74 print("PD1: {}".format(best_pd1))
75 print("PD2: {}".format(best_pd2))
76 if best_refdiv != 1:
77 print(
78 "\n这需要一个非默认的REFDIV值。\\n"
79 "请在您的CMakeLists.txt中添加以下内容以应用REFDIV:\\n"
80)
81 elif args.cmake or args.cmake_only:
82 print("")
83 print(cmake_output)
84 else:
85 sys.exit("未找到解决方案")

```

给定输入和输出频率，脚本将寻找最佳的PLL参数组合。当脚本找到多个同等优良的组合时，将返回产生最高VCO频率的参数，以确保最佳输出稳定性。传递 `-l` 或 `--low-vco` 标志以优先选择较低频率，从而降低功耗。传递 `--vco-max` 标志以限制最大VCO频率。若脚本无法依据提供的约束找到精确匹配，则输出最接近的合理匹配。

以下示例演示如何使用脚本请求48 MHz输出以实现最佳输出稳定性：

```

$./vcocalc.py 48
请求频率: 48.0 MHz
实现频率: 48.0 MHz
REFDIV: 1
FBDIV: 120 (VCO = 1440.0 MHz)
PD1: 6
PD2: 5

```

这也可作为配置 SDK 应用程序的 CMake 输出：

```
$./vcocalc.py 48 --cmake
Requested: 48.0 MHz
Achieved: 48.0 MHz
REFDIV: 1
FBDIV: 120 (VCO = 1440.0 MHz)
PD1: 6
PD2: 5

target_compile_definitions(<program> PRIVATE
 PLL_SYS_REFDIV=1
 PLL_SYS_VCO_FREQ_HZ=1440000000
 PLL_SYS_POSTDIV1=6
 PLL_SYS_POSTDIV2=5
)
```

You can also pass `--cmake-only` to get just the CMake output, and `--cmake-executable-name` to replace the `<program>` with the name of the target program you are configuring.

The following example uses the script to request a 48 MHz output with the lowest power consumption:

```
$./vcocalc.py -l 48
Requested: 48.0 MHz
Achieved: 48.0 MHz
REFDIV: 1
FBDIV: 64 (VCO = 768.0 MHz)
PD1: 4
PD2: 4
```

The following example uses the script to request a 125 MHz output with the lowest power consumption, with the reference divisor `REFDIV` fixed at a value of 1. Even though we stated a preference for slower VCO frequencies, the resulting frequency remains quite high:

```
$./vcocalc.py -l 125 --lock-refdiv=1
Requested: 125.0 MHz
Achieved: 125.0 MHz
REFDIV: 1
FBDIV: 125 (VCO = 1500.0 MHz)
PD1: 6
PD2: 2
```

This happens when the best match for your requested output *requires* a high VCO frequency. The script always returns the best match, preferring lower VCO frequencies only when there are multiple, equally good matches.

You can work around this by restricting the upper VCO frequency. The following example uses the script to request a 125 MHz system clock, restricting the search to VCO frequencies below 800 MHz. There is no exact match, so the script considers near (but not exact) frequency matches. Relaxing the search to allow nearby non-exact matches significantly reduces the minimum VCO frequency compared to the previous example:

```
$./vcocalc.py -l 125 --lock-refdiv=1 --vco-max=800
Locking REFDIV to 1
Requested: 125.0 MHz
Achieved: 126.0 MHz
REFDIV: 1
FBDIV: 63 (VCO = 756.0 MHz)
PD1: 6
```

```
$./vcocalc.py 48 --cmake
请求频率: 48.0 MHz
实现频率: 48.0 MHz
REFDIV: 1
FBDIV: 120 (VCO = 1440.0 MHz)
PD1: 6
PD2: 5

target_compile_definitions(<program> PRIVATE
 PLL_SYS_REFDIV=1
 PLL_SYS_VCO_FREQ_HZ=1440000000
 PLL_SYS_POSTDIV1=6
 PLL_SYS_POSTDIV2=5
)
```

您还可以传递`--cmake-only`参数仅获取 CMake 输出，使用`--cmake-executable-name`参数将 `<program>` 替换为您正在配置的目标程序名称。

以下示例使用该脚本请求一个功耗最低的 48 MHz 输出：

```
$./vcocalc.py -l 48
请求频率: 48.0 MHz
实现频率: 48.0 MHz
REFDIV: 1
FBDIV: 64 (VCO = 768.0 MHz)
PD1: 4
PD2: 4
```

以下示例使用脚本请求 125 MHz 输出，以实现最低功耗，参考除数 `REFDIV` 固定为 1。尽管我们表示偏好较低的 VCO 频率，但最终频率仍然相当高：

```
$./vcocalc.py -l 125 --lock-refdiv=1
请求频率: 125.0 MHz
实际频率: 125.0 MHz
REFDIV: 1
FBDIV: 125 (VCO = 1500.0 MHz)
PD1: 6
PD2: 2
```

当您的请求输出所需的最佳匹配产生高 VCO 频率时，会出现这种情况。脚本始终返回最佳匹配，仅当存在多个同等优良的匹配时，才偏好较低的 VCO 频率。

您可以通过限制 VCO 频率的上限来规避此问题。以下示例使用脚本请求 125 MHz 系统时钟，限制搜索 VCO 频率低于 800 MHz。由于无精确匹配，脚本会考虑接近（但非精确）的频率匹配。放宽搜索条件以允许附近的非精确匹配，与前例相比，显著降低了最低 VCO 频率：

```
$./vcocalc.py -l 125 --lock-refdiv=1 --vco-max=800
将REFDIV锁定为1
请求频率: 125.0 MHz
达到频率: 126.0 MHz
REFDIV: 1
FBDIV: 63 (VCO = 756.0 MHz)
PD1: 6
```

PD2 : 1

A 126 MHz system clock may be a tolerable deviation from the desired 125 MHz, and generating this clock consumes less power at the PLL.

By default the script also searches reference divisors, which may give a closer match to your requested output, or enable higher or lower VCO frequencies (depending on preference). The following example allows the script to search **FBDIV** values:

```
$./vcocalc.py -l 125
Requested: 125.0 MHz
Achieved: 125.0 MHz
REFDIV: 2
FBDIV: 125 (VCO = 750.0 MHz)
PD1: 6
PD2: 1

This requires a non-default REFDIV value.
Add the following to your CMakeLists.txt to apply the REFDIV:
```

```
target_compile_definitions(<program> PRIVATE
 PLL_SYS_REFDIV=2
 PLL_SYS_VCO_FREQ_HZ=750000000
 PLL_SYS_POSTDIV1=6
 PLL_SYS_POSTDIV2=1
)
```

This finds a solution with exactly the requested output, at exactly the minimum VCO frequency of 750 MHz.

All of the above assume a 12 MHz crystal. RP2350 supports a range of XOSC frequencies documented in [Section 8.2, "Crystal oscillator \(XOSC\)"](#). Suppose we had a 32 MHz crystal, and required a 150 MHz system clock, the maximum supported on RP2350. You can specify the input frequency with the **--input** or **-i** flag, as shown in the following example:

```
$./vcocalc.py 150 -i 32
Requested: 150.0 MHz
Achieved: 150.0 MHz
REFDIV: 2
FBDIV: 75 (VCO = 1200.0 MHz)
PD1: 4
PD2: 2

This requires a non-default REFDIV value.
Add the following to your CMakeLists.txt to apply the REFDIV:
```

```
target_compile_definitions(<program> PRIVATE
 PLL_SYS_REFDIV=2
 PLL_SYS_VCO_FREQ_HZ=1200000000
 PLL_SYS_POSTDIV1=4
 PLL_SYS_POSTDIV2=2
)
```

## 8.6.4. Configuration

The SDK uses the following PLL settings:

PD2 : 1

126 MHz的系统时钟相较于目标125 MHz可能为可容忍的偏差，且PLL在生成此时钟时功耗更低。

默认情况下，脚本也会搜索参考分频器，这可能使输出更接近期望值，或允许更高或更低的VCO频率（视偏好而定）。下例允许脚本搜索**FBDIV**值：

```
$./vcocalc.py -l 125
请求频率: 125.0 MHz
实际频率: 125.0 MHz
REFDIV: 2
FBDIV: 125 (VCO = 750.0 MHz)
PD1: 6
PD2: 1
```

这需要非默认的REFDIV值。

请将以下内容添加到您的 CMakeLists.txt 文件中以应用 REFDIV：

```
target_compile_definitions(<program> PRIVATE
 PLL_SYS_REFDIV=2
 PLL_SYS_VCO_FREQ_HZ=750000000
 PLL_SYS_POSTDIV1=6
 PLL_SYS_POSTDIV2=1
)
```

此方法将找到一个解决方案，输出精确符合请求值，且VCO频率恰为最低750 MHz。

[上述内容均假设12 MHz晶体振荡器。RP2350支持的XOSC频率范围详见第8.2节“晶体振荡器（XOSC）”。](#)假设我们使用32 MHz晶体，并需150 MHz系统时钟频率，这是RP2350支持的最大值。您可通过 `--input` 或 `-i` 参数指定输入频率，示例如下：

```
$./vcocalc.py 150 -i 32
请求频率: 150.0 MHz
实际频率: 150.0 MHz
REFDIV: 2
FBDIV: 75 (VCO = 1200.0 MHz)
PD1: 4
PD2: 2
```

这需要非默认的REFDIV值。

请将以下内容添加到您的 CMakeLists.txt 文件中以应用 REFDIV：

```
target_compile_definitions(<program> PRIVATE
 PLL_SYS_REFDIV=2
 PLL_SYS_VCO_FREQ_HZ=1200000000
 PLL_SYS_POSTDIV1=4
 PLL_SYS_POSTDIV2=2
)
```

## 8.6.4. 配置

该 SDK 使用以下 PLL 设置：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/include/hardware/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/include/hardware/clocks.h) Lines 143 - 164

```

143 // There are two PLLs in RP-series microcontrollers:
144 // 1. The 'SYS PLL' generates the system clock, the frequency is defined by 'SYS_CLK_KHZ'.
145 // 2. The 'USB PLL' generates the USB clock, the frequency is defined by 'USB_CLK_KHZ'.
146 //
147 // The two PLLs use the crystal oscillator output directly as their reference frequency input;
148 // the PLLs reference
149 // frequency cannot be reduced by the dividers present in the clocks block. The crystal
150 // frequency is defined by 'XOSC_HZ' (or
151 // 'XOSC_KHZ' or 'XOSC_MHZ').
152 //
153 // The system's default definitions are correct for the above frequencies with a 12MHz
154 // crystal frequency. If different frequencies are required, these must be defined in
155 // the board configuration file together with the revised PLL settings
156 // Use 'vcocalc.py' to check and calculate new PLL settings if you change any of these
157 // frequencies.
158 //
159 // Default PLL configuration RP2040:
160 // REF FBDIV VCO POSTDIV
161 // PLL SYS: 12 / 1 = 12MHz * 125 = 1500MHz / 6 / 2 = 125MHz
162 // PLL USB: 12 / 1 = 12MHz * 100 = 1200MHz / 5 / 5 = 48MHz
163 //
164 // Default PLL configuration RP2350:
165 // REF FBDIV VCO POSTDIV
166 // PLL SYS: 12 / 1 = 12MHz * 125 = 1500MHz / 5 / 2 = 150MHz
167 // PLL USB: 12 / 1 = 12MHz * 100 = 1200MHz / 5 / 5 = 48MHz

```

The `pll_init` function in the SDK (examined below) asserts that all of these conditions are true before attempting to configure the PLL.

The SDK defines the PLL control registers as a struct. It then maps them into memory for each instance of the PLL.

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/pll.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/pll.h) Lines 27 - 74

```

27 typedef struct {
28 _REG_(PLL_CS_OFFSET) // PLL_CS
29 // Control and Status
30 // 0x80000000 [31] LOCK (0) PLL is locked
31 // 0x40000000 [30] LOCK_N (0) PLL is not locked +
32 // 0x00000100 [8] BYPASS (0) Passes the reference clock to the output instead of
33 // the...
34 // 0x0000003f [5:0] REFDIV (0x01) Divides the PLL input reference clock
35 io_rw_32 cs;
36

```

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_clocks/include/hardware/clocks.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_clocks/include/hardware/clocks.h) 第143至164行

```

143 // RP 系列微控制器中包含两个 PLL：
144 // 1. 'SYS PLL' 生成系统时钟，其频率由 `SYS_CLK_KHZ` 定义。
145 // 2. 'USB PLL' 生成 USB 时钟，其频率由 `USB_CLK_KHZ` 定义。
146 //
147 // 两个 PLL 直接使用晶振输出作为参考频率输入；
// PLL 的参考
148 // 频率无法被时钟模块中的分频器降低。晶振频率由 `XOSC_HZ`（或 149 // `XOSC_KHZ` 或 `XOSC_MHZ`）定义
//
150 //
151 // 对于上述频率，系统的默认定义在12MHz 晶体频率下是准确的
152 // 晶体频率。如需其他频率，必须在
153 // 板级配置文件中定义相应频率及修改后的PLL 设置
154 // 更改任一频率后，请使用 `vcocalc.py` 校验及计算新的PLL设置。

155 //
156 // RP2040 默认PLL 配置：
157 // REF FBDIV VCO POSTDIV
158 // PLL SYS: 12 / 1 = 12MHz * 125 = 1500MHz / 6 / 2 = 125MHz
159 // PLL USB: 12 / 1 = 12MHz * 100 = 1200MHz / 5 / 5 = 48MHz
160 //
161 // RP2350 默认PLL 配置：
162 // REF FBDIV VCO POSTDIV
163 // PLL SYS: 12 / 1 = 12MHz * 125 = 1500MHz / 5 / 2 = 150MHz
164 // PLL USB: 12 / 1 = 12MHz * 100 = 1200MHz / 5 / 5 = 48MHz

```

SDK 中的 `pll_init` 函数（如下所示）会在尝试配置 PLL 之前断言所有条件均为真。

SDK 将 PLL 控制寄存器定义为结构体。随后，它将该结构映射到每个 PLL 实例的内存中。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/pll.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/pll.h) 第 27 至 74 行

```

27 typedef struct {
28 _REG_(PLL_CS_OFFSET) // PLL_CS
29 // 控制与状态
30 // 0x80000000 [31] LOCK (0) PLL 已锁定
31 // 0x40000000 [30] LOCK_N (0) PLL 未锁定 +
32 // 0x00000100 [8] BYPASS (0) 使用参考时钟直接传递到输出

73 io_ro_32 ints;
74 } pll_hw_t;

```

The SDK defines `pll_init`, which is used to configure or reconfigure a PLL. It starts by clearing any previous power state in the PLL, then calculates the appropriate feedback divider value. There are assertions to check that these values satisfy the constraints above.

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_pll/pll.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_pll/pll.c) Lines 13 - 21

```

13 void pll_init(PLL pll, uint refdiv, uint vco_freq, uint post_div1, uint post_div2) {
14 uint32_t ref_freq = XOSC_HZ / refdiv;
15
16 // Check vco freq is in an acceptable range
17 assert(vco_freq >= PICO_PLL_VCO_MIN_FREQ_HZ && vco_freq <= PICO_PLL_VCO_MAX_FREQ_HZ);
18
19 // What are we multiplying the reference clock by to get the vco freq
20 // (The regs are called div, because you divide the vco output and compare it to the
21 // refclk)
21 uint32_t fbdv = vco_freq / ref_freq;

```

The programming sequence for the PLL is as follows:

1. Program the reference clock divider (is a divide by 1 in the RP2350 case).
2. Program the feedback divider.
3. Turn on the main power and VCO.
4. Wait for the VCO to achieve a stable frequency, as indicated by the `LOCK` status flag.
5. Set up post dividers and turn them on.

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_pll/pll.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_pll/pll.c) Lines 42 - 69

```

42 if ((pll->cs & PLL_CS_LOCK_BITS) &&
43 (refdiv == (pll->cs & PLL_CS_REFDIV_BITS)) &&
44 (fbdv == (pll->fbdv_int & PLL_FBDIV_INT_BITS)) &&
45 (pdiv == (pll->prim & (PLL_PRIM_POSTDIV1_BITS | PLL_PRIM_POSTDIV2_BITS)))) {
46 // do not disrupt PLL that is already correctly configured and operating
47 return;
48 }
49

```

```

53 io_rw_32 prim;
54
55 _REG_(PLL_INTR_OFFSET) // PLL_INTR
56 // 原始中断
57 // 0x00000001 [0] LOCK_N_STICKY (0)
58 io_rw_32 intr;
59
60 _REG_(PLL_INTE_OFFSET) // PLL_INTE
61 // 中断使能
62 // 0x00000001 [0] LOCK_N_STICKY (0)
63 io_rw_32 inte;
64
65 _REG_(PLL_INTF_OFFSET) // PLL_INTF
66 // 中断强制
67 // 0x00000001 [0] LOCK_N_STICKY (0)
68 io_rw_32 intf;
69
70 _REG_(PLL_INTS_OFFSET) // PLL_INTS
71 // 掩码与强制后的中断状态
72 // 0x00000001 [0] LOCK_N_STICKY (0)
73 io_ro_32 ints;
74 } pll_hw_t;

```

SDK 定义了 `pll_init`，用于配置或重新配置 PLL。该函数首先清除 PLL 之前的电源状态，然后计算适当的反馈分频值。有断言用于验证这些值是否满足上述约束条件。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_pll/pll.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_pll/pll.c), 第13至21行

```

13 void pll_init(PLL pll, uint refdiv, uint vco_freq, uint post_div1, uint post_div2) {
14 uint32_t ref_freq = XOSC_HZ / refdiv;
15
16 // 检查 VCO 频率是否处于允许范围内
17 assert(vco_freq >= PICO_PLL_VCO_MIN_FREQ_HZ && vco_freq <= PICO_PLL_VCO_MAX_FREQ_HZ);
18
19 // 计算将参考时钟乘以多少倍得到 VCO 频率
20 // (寄存器命名为 div，是因为通过分频 VCO 输出后与参考时钟比较)
21
22 uint32_t fbdv = vco_freq / ref_freq;

```

PLL 的编程顺序如下：

1. 编程参考时钟分频器（RP2350 情况下为除以 1）。
2. 编程反馈分频器。
3. 开启主电源和压控振荡器（VCO）。
4. 等待 VCO 达到稳定频率，由 `LOCK` 状态标志指示。
5. 设置后置分频器并启动。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_pll/pll.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_pll/pll.c) 第 42 至 69 行

```

42 if ((pll->cs & PLL_CS_LOCK_BITS) &&
43 (refdiv == (pll->cs & PLL_CS_REFDIV_BITS)) &&
44 (fbdv == (pll->fbdv_int & PLL_FBDIV_INT_BITS)) &&
45 (pdiv == (pll->prim & (PLL_PRIM_POSTDIV1_BITS | PLL_PRIM_POSTDIV2_BITS)))) {
46 // 不要干扰已正确配置并运行中的 PLL
47 return;
48 }
49

```

```

50 reset_unreset_block_num_wait_blocking(PLL_RESET_NUM(pll));
51
52 // Load VCO-related dividers before starting VCO
53 pll->cs = refdiv;
54 pll->fbdiv_int = fbddiv;
55
56 // Turn on PLL
57 uint32_t power = PLL_PWR_PD_BITS | // Main power
58 PLL_PWR_VCOPD_BITS; // VCO Power
59
60 hw_clear_bits(&pll->pwr, power);
61
62 // Wait for PLL to lock
63 while (!(pll->cs & PLL_CS_LOCK_BITS)) tight_loop_contents();
64
65 // Set up post dividers
66 pll->prim = pdiv;
67
68 // Turn on post divider
69 hw_clear_bits(&pll->pwr, PLL_PWR_POSTDIVPD_BITS);

```

The VCO turns on first, followed by the post dividers, so the PLL does not output a dirty clock while waiting for the VCO to lock.

### 8.6.5. List of Registers

The PLL\_SYS and PLL\_USB registers start at base addresses of `0x40050000` and `0x40058000` respectively (defined as `PLL_SYS_BASE` and `PLL_USB_BASE` in SDK).

Table 636. List of PLL registers

Offset	Name	Info
0x00	CS	Control and Status
0x04	PWR	Controls the PLL power modes.
0x08	FBDIV_INT	Feedback divisor
0x0c	PRIM	Controls the PLL post dividers for the primary output
0x10	INTR	Raw Interrupts
0x14	INTE	Interrupt Enable
0x18	INTF	Interrupt Force
0x1c	INTS	Interrupt status after masking & forcing

### PLL: CS Register

Offset: 0x00

#### Description

Control and Status

GENERAL CONSTRAINTS:

Reference clock frequency min=5MHz, max=800MHz

Feedback divider min=16, max=320

VCO frequency min=400MHz, max=1600MHz

Table 637. CS Register

Bits	Description	Type	Reset
31	<b>LOCK</b> : PLL is locked	RO	0x0

```

50 reset_unreset_block_num_wait_blocking(PLL_RESET_NUM(pll));
51
52 // 在启动 VCO 之前加载与 VCO 相关的分频器
53 pll->cs = refdiv;
54 pll->fbdiv_int = fbdiv;
55
56 // 启动 PLL
57 uint32_t power = PLL_PWR_PD_BITS | // 主电源
58 PLL_PWR_VCOPD_BITS; // VCO 电源
59
60 hw_clear_bits(&pll->pwr, power);
61
62 // 等待 PLL 锁定
63 while (!(pll->cs & PLL_CS_LOCK_BITS)) tight_loop_contents();
64
65 // 设置后置分频器
66 pll->prim = pddiv;
67
68 // 启用后置分频器
69 hw_clear_bits(&pll->pwr, PLL_PWR_POSTDIVPD_BITS);

```

VCO 先启动，随后开启后置分频器，因此在等待 VCO 锁定期间，PLL 不会输出杂讯时钟。

### 8.6.5. 寄存器列表

PLL\_SYS 和 PLL\_USB 寄存器的基址分别为 `0x40050000` 和 `0x40058000`（在 SDK 中定义为 `PLL_SYS_BASE` 和 `PLL_USB_BASE`）。

表 636. PLL 寄存器列表

偏移量	名称	说明
0x00	CS	控制与状态
0x04	PWR	控制 PLL 电源模式。
0x08	FBDIV_INT	反馈除数
0x0c	PRIM	控制主输出的 PLL 后置分频器
0x10	中断	原始中断
0x14	INTE	中断使能
0x18	INTF	中断触发
0x1c	INTS	掩码与强制后的中断状态

#### PLL：CS 寄存器

偏移: 0x00

##### 描述

控制与状态

通用约束条件：

参考时钟频率 最小值=5MHz, 最大值=800MHz

反馈除数 最小值=16, 最大值=320

VCO 频率 最小值=400MHz, 最大值=1600MHz

表 637. CS 寄存器

位	描述	类型	复位
31	LOCK: PLL 已锁定	只读	0x0

Bits	Description	Type	Reset
30	<b>LOCK_N</b> : PLL is not locked Ideally this is cleared when PLL lock is seen and this should never normally be set	WC	0x0
29:9	Reserved.	-	-
8	<b>BYPASS</b> : Passes the reference clock to the output instead of the divided VCO. The VCO continues to run so the user can switch between the reference clock and the divided VCO but the output will glitch when doing so.	RW	0x0
7:6	Reserved.	-	-
5:0	<b>REFDIV</b> : Divides the PLL input reference clock. Behaviour is undefined for div=0. PLL output will be unpredictable during refdiv changes, wait for lock=1 before using it.	RW	0x01

## PLL: PWR Register

Offset: 0x04

### Description

Controls the PLL power modes.

Table 638. PWR Register

Bits	Description	Type	Reset
31:6	Reserved.	-	-
5	<b>VCOPD</b> : PLL VCO powerdown To save power set high when PLL output not required or bypass=1.	RW	0x1
4	Reserved.	-	-

# Chapter 9. GPIO

## ⚠ CAUTION

Under certain conditions, pull-down does not function as expected. For more information, see [RP2350-E9](#).

## 9.1. Overview

RP2350 has up to 54 multi-functional General Purpose Input / Output (GPIO) pins, divided into two banks:

### Bank 0

30 user GPIOs in the QFN-60 package (RP2350A), or 48 user GPIOs in the QFN-80 package

### Bank 1

six QSPI IOs, and the USB DP/DM pins

You can control each GPIO from software running on the processors, or by a number of other functional blocks. To meet USB rise and fall specifications, the analogue characteristics of the USB pins differ from the GPIO pads. As a result, we do not include them in the 54 GPIO total. However, you can still use them for UART, I<sup>2</sup>C, or processor-controlled GPIO through the single-cycle IO subsystem (SIO).

In a typical use case, the QSPI IOs are used to execute code from an external flash device, leaving 30 or 48 Bank 0 GPIOs for the programmer to use. The QSPI pins might become available for general purpose use when booting the chip from internal OTP, or controlling the chip externally through SWD in an IO expander application.

All GPIOs support digital input and output. Several Bank 0 GPIOs can also be used as inputs to the chip's Analogue to Digital Converter (ADC):

- GPIOs 26 through 29 inclusive (four total) in the QFN-60 package
- GPIOs 40 through 47 (eight total) in the QFN-80 package

Bank 0 supports the following functions:

- Software control via SIO – [Section 3.1.3, “GPIO control”](#)
- Programmable IO (PIO) – [Chapter 11, \*PIO\*](#)
- 2 × SPI – [Section 12.3, “SPI”](#)
- 2 × UART – [Section 12.1, “UART”](#)
- 2 × I<sup>2</sup>C (two-wire serial interface) – [Section 12.2, “I<sup>2</sup>C”](#)
- 8 × two-channel PWM in the QFN-60 package, or 12 × in QFN-80 – [Section 12.5, “PWM”](#)
- 2 × external clock inputs – [Section 8.1.2.4, “External clocks”](#)
- 4 × general purpose clock output – [Section 8.1, “Overview”](#)
- 4 × input to ADC in the QFN-60 package, or 8 × in QFN-80 – [Section 12.4, “ADC and Temperature Sensor”](#)
- 1 × HSTX high-speed interface – [Section 12.11, “HSTX”](#)
- 1 × auxiliary QSPI chip select, for a second XIP device – [Section 12.14, “QSPI memory interface \(QMI\)”](#)
- CoreSight execution trace output – [Section 3.5.7, “Trace”](#)
- USB VBUS management – [Section 12.7.3.10, “VBUS control”](#)
- External interrupt requests, level or edge-sensitive – [Section 9.5, “Interrupts”](#)

Bank 1 contains the QSPI and USB DP/DM pins and supports the following functions:

# 第9章. GPIO

## ⚠ 警告

在某些情况下，下拉功能无法达到预期效果。更多信息，请参见RP2350-E9。

## 9.1. 概述

RP2350配备最多54个多功能通用输入/输出（GPIO）引脚，分为两个组别：

### 存储区0

QFN-60封装（RP2350A）中有30个用户GPIO，或QFN-80封装中有48个用户GPIO

### 存储区1

六个QSPI IO引脚及USB DP/DM引脚

您可以通过处理器上运行的软件，或其他多个功能模块对每个GPIO进行控制。为满足USB信号上升和下降时间的规格要求，USB引脚的模拟特性与GPIO焊盘不同。因此，我们未将其计入54个GPIO的总数。然而，您仍可通过单周期IO子系统（SIO）将其用作UART、I2C或处理器控制的GPIO。

在典型应用场景中，QSPI IO用于从外部闪存执行代码，剩余30个或48个Bank 0 GPIO可供开发者使用。当芯片通过内部OTP引导，或在IO扩展应用中通过SWD进行外部控制时，QSPI引脚可能可用作通用引脚。

所有GPIO均支持数字输入和输出。部分Bank 0 GPIO亦可用作芯片模拟-数字转换器（ADC）的输入：

- QFN-60封装中GPIO 26至29（共计四个）
- QFN-80封装中GPIO 40至47（共计八个）

Bank 0支持以下功能：

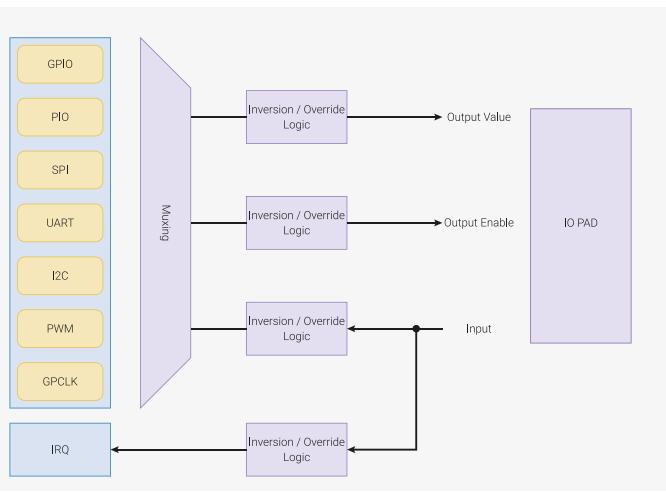

- [通过SIO的软件控制](#) —— 第3.1.3节，“GPIO控制”
- 可编程输入输出（PIO）—— 第11章， [PIO](#)
- 2 × SPI—— 第12.3节，“SPI”
- 2 × UART—— 第12.1节，“UART”
- 2 × I2C（双线串行接口）—— 第12.2节，“I2C”
- 8 × QFN-60封装中为双通道PWM，QFN-80封装中为12通道—— 第12.5节，“PWM”
- 2 × [外部时钟输入](#) —— 第8.1.2.4节，“外部时钟”
- 4 × [通用时钟输出](#) —— 第8.1节，“概述”
- 4 × [QFN-60封装中的ADC输入](#)，或[QFN-80封装中的8×输入](#) —— 第12.4节，“ADC和温度传感器”
- 1 × HSTX高速接口 —— 第12.11节，“HSTX”
- 1 × [辅助QSPI芯片选择](#)，用于第二个XIP设备 —— 第12.14节，“QSPI存储接口（QMI）”
- CoreSight执行跟踪输出 —— 第3.5.7节，“跟踪”
- USB VBUS管理 —— 第12.7.3.10节，“VBUS控制”
- 外部中断请求，电平触发或边沿触发 —— 第9.5节，“中断”

Bank 1包含QSPI和USB DP/DM引脚，支持以下功能：

- Software control via SIO – [Section 3.1.3, “GPIO control”](#)
- Flash execute in place ([Section 4.4, “External flash and PSRAM \(XIP\)”](#)) via QSPI Memory Interface (QMI) – [Section 12.14, “QSPI memory interface \(QMI\)”](#)
- UART – [Section 12.1, “UART”](#)
- I2C (two-wire serial interface) – [Section 12.2, “I2C”](#)

The logical structure of an example IO is shown in [Figure 41](#).

*Figure 41. Logical structure of a GPIO. Each GPIO can be controlled by one of a number of peripherals, or by software control registers in the SIO. The function select (FSEL) selects which peripheral output is in control of the GPIO’s direction and output level, and which peripheral input can see this GPIO’s input level. These three signals (output level, output enable, input level) can also be inverted or forced high or low, using the GPIO control registers.*

## 9.2. Changes from RP2040

RP2350 GPIO differs from RP2040 in the following ways:

- 18 more GPIOs in the QFN-80 package
- Addition of a third PIO to GPIO functions
- USB DP/DM pins can be used as GPIO
- Addition of isolation register to pad registers (preserves pad state while in a low power state, cleared by software on power up)
- Changed default reset state of pad controls
- Both Secure and Non-secure access to GPIOs (see [Section 10.6](#))
- Double the number of GPIO interrupts to differentiate between Secure and Non-secure
- Interrupt summary registers added so you can quickly see which GPIOs have pending interrupts

## 9.3. Reset state

At first power up, Bank 0 IOs (GPIOs 0 through 29 in the QFN-60 package, and GPIOs 0 through 47 in the QFN-80 package) assume the following state:

- Output buffer is high-impedance
- Input buffer is disabled
- Pulled low
- Isolation latches are set to latched ([Section 9.7](#))

The pad output disable bit (`GPIO0.OD`) for each pad is clear at reset, but the IO muxing is reset to the null function,

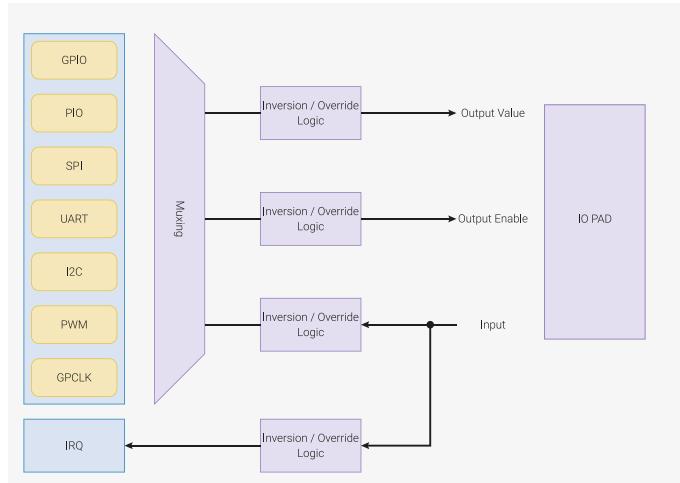

- 通过SIO的软件控制 —— 第3.1.3节，“GPIO控制”
- 通过QSPI存储接口（QMI）实现闪存原地执行（第4.4节，“外部闪存和PSRAM（XIP）”） — 第12.14节，“QSPI存储接口（QMI）”
- UART — 第12.1节，“UART”
- I2C（双线串行接口） — 第12.2节，“I2C”

示例IO的逻辑结构如图41所示。

图41。GPIO的逻辑结构。

每个GPIO可由多个外设之一控制，或由SIO中的软件控制寄存器控制。

功能选择（FSEL）决定哪个外设的输出控制GPIO的方向和输出电平，以及哪个外设输入能读取该GPIO的输入电平。这三种信号（输出电平、输出使能、输入电平）也可通过GPIO控制寄存器进行反向或强制高低电平处理。

## 9.2. 相较于 RP2040 的变化

RP2350 GPIO与RP2040的主要差异如下：

- QFN-80封装中增加18个GPIO
- GPIO功能中增加第三个PIO
- USB DP/DM引脚可用作GPIO
- 在引脚寄存器中增加隔离寄存器（低功耗状态下保持引脚状态，上电后由软件清除）
- 更改了引脚控制的默认复位状态
- GPIO 支持安全访问和非安全访问（详见第10.6节）
- GPIO 中断数量加倍，以区分安全和非安全访问
- 新增中断汇总寄存器，便于快速检查哪些 GPIO 存在待处理中断

## 9.3. 复位状态

首次上电时，Bank 0 IO（QFN-60 封装中 GPIO 0 至 29，QFN-80 封装中 GPIO 0 至 47）处于以下状态：

- 输出缓冲器呈高阻抗状态
- 输入缓冲器被禁用
- 下拉状态
- 隔离锁存器设置为锁存状态（详见第9.7节）

每个引脚的输出禁用位（GPIO0.OD）在复位时为清零，但 IO 复用重置为无功能状态，

which ensures that the output buffer is high-impedance.

### **! IMPORTANT**

The pad reset state is different from RP2040, which only disables digital inputs on GPIOs 26 through 29 (as of version B2) and does not have isolation latches. Applications must enable the pad input (`GPIO0.IE = 1`) and disable pad isolation latches (`GPIO0.ISO = 0`) before using the pads for digital I/O. The `gpio_set_function()` SDK function performs these tasks automatically.

Bank 1 IOs have the same reset state as Bank 0 GPIOs, except for the input enable (IE) resetting to 1, and different pull-up/pull-down states: SCK, SD0 and SD1 are pull-down, but SD2, SD3 and CSn are pull-up.

### **i NOTE**

To use a Bank 0 GPIO as a second chip select, you need an external pull-up to ensure the second QSPI device does not power up with its chip select asserted.

The pads return to the reset state on any of the following:

- A brownout reset
- Asserting the RUN pin low
- Setting SW-DP CDBGRSTREQ via SWD
- Setting RP-AP rescue reset via SWD

If a pad's isolation latches are in the latched state (Section 9.7) then resetting the PADS and IO registers does not physically return the pad to its reset state. The isolation latches prevent upstream signals from propagating to the pad. Clear the ISO bit to allow signals to propagate.

## 9.4. Function select

To allocate a function to a GPIO, write to the `FUNCSEL` field in the `CTRL` register corresponding to the pin. For a list of GPIOs and corresponding registers, see Table 645. For an example, see `GPIO0_CTRL`. The descriptions for the functions listed in this table can be found in Table 646.

Each GPIO can only select one function at a time. Each peripheral input (e.g. UART0 RX) should only be selected by one GPIO at a time. If you connect the same peripheral input to multiple GPIOs, the peripheral sees the logical OR of these GPIO inputs.

以确保输出缓冲器处于高阻抗状态。

### ！重要

引脚复位状态与 RP2040 不同，后者仅在 GPIO 26 至 29（自 B2 版本起）禁用数字输入，且无隔离锁存器。应用程序必须启用 pad 输入（GPIO0.IE = 1）并禁用 pad 隔离锁存器（GPIO0.ISO = 0），方可将 pads 用于数字 I/O。SDK 函数 `gpio_set_function()` 会自动完成此类操作。

Bank 1 的 IO 复位状态与 Bank 0 的 GPIO 相同，唯输入使能（IE）复位为 1，且上下拉状态存在差异：SCK、SD0 和 SD1 为下拉，SD2、SD3 与 CSn 为上拉。

### ！注意

若要将 Bank 0 GPIO 用作第二个片选，需外接上拉电阻，以确保第二个 QSPI 设备在片选未被激活时不会上电。

pads 在任一以下情况下将恢复至复位状态：

- 欠压（褐化）复位
- 将 RUN 引脚拉低
- 通过 SWD 设置 SW-DP 的 CDBG\_RSTREQ
- 通过 SWD 设置 RP-AP 救援复位

如果引脚的隔离锁存器处于锁存状态（第9.7节），那么重置PADS和IO寄存器不会将该引脚物理恢复到复位状态。隔离锁存器防止上游信号传播至引脚。

清除ISO位以允许信号传播。

## 9.4. 功能选择

要为GPIO分配功能，请写入相应引脚的 `CTRL` 寄存器中的`FUNCSEL`字段。有关GPIO及对应寄存器的列表，请参见表645。示例请参见`GPIO0_CTRL`。表中列出功能的说明详见表646。

每个GPIO一次只能选择一项功能。每个外设输入（如UART0 RX）应一次仅被一个GPIO选择。若将相同外设输入连接至多个GPIO，外设将接收到这些GPIO输入的逻辑或。

Table 645. General Purpose Input/Output (GPIO) Bank 0 Functions

*Table 646. GPIO User Bank function descriptions*

Function Name	Description
SPIx	Connect one of the internal PL022 SPI peripherals to GPIO.
UARTx	Connect one of the internal PL011 UART peripherals to GPIO.
I2Cx	Connect one of the internal DW I2C peripherals to GPIO.
PWMx A/B	Connect a PWM slice to GPIO. There are twelve PWM slices, each with two output channels (A/B). The B pin can also be used as an input, for frequency and duty cycle measurement.
SIO	Software control of GPIO from the Single-cycle IO (SIO) block. The SIO function ( <a href="#">F5</a> ) must be selected for the processors to drive a GPIO, but the input is always connected, so software can check the state of GPIOs at any time.
PIOx	Connect one of the programmable IO blocks (PIO) to GPIO. PIO can implement a wide variety of interfaces, and has its own internal pin mapping hardware, allowing flexible placement of digital interfaces on Bank 0 GPIOs. The PIO function ( <a href="#">F6</a> , <a href="#">F7</a> , <a href="#">F8</a> ) must be selected for PIO to drive a GPIO, but the input is always connected, so the PIOs can always see the state of all pins.
HSTX	Connect the high-speed transmit peripheral (HSTX) to GPIO.
CLOCK GPINx	General purpose clock inputs. Can be routed to a number of internal clock domains on RP2350, e.g. to provide a 1Hz clock for the AON Timer, or can be connected to an internal frequency counter.
CLOCK GPOUTx	General purpose clock outputs. Can drive a number of internal clocks (including PLL outputs) onto GPIOs, with optional integer divide.
TRACECLK, TRACEDATAx	CoreSight execution trace output from Cortex-M33 processors (Arm-only).
USB OVCUR DET/VBUS DET/VBUS EN	USB power control signals to/from the internal USB controller.
QMI CS1n	Auxiliary chip select for QSPI bus, to allow execute-in-place from an additional flash or PSRAM device.

Bank 1 function select operates identically to Bank 0, but its registers are in a different register block, starting with [USBPHY\\_DP\\_CTRL](#).

*Table 647. GPIO Bank 1 Functions*

Pin	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11
USB DP			UART1 TX	I2C0 SDA		SIO						
USB DM			UART1 RX	I2C0 SCL		SIO						
QSPI SCK	QMI SCK		UART1 CTS	I2C1 SDA		SIO						UART1 TX
QSPI CSn	QMI CS0n		UART1 RTS	I2C1 SCL		SIO						UART1 RX
QSPI SD0	QMI SD0		UART0 TX	I2C0 SDA		SIO						
QSPI SD1	QMI SD1		UART0 RX	I2C0 SCL		SIO						
QSPI SD2	QMI SD2		UART0 CTS	I2C1 SDA		SIO						UART0 TX
QSPI SD3	QMI SD3		UART0 RTS	I2C1 SCL		SIO						UART0 RX

*Table 648. GPIO bank 1 function descriptions*

Function Name	Description
UARTx	Connect one of the internal PL011 UART peripherals to GPIO.
I2Cx	Connect one of the internal DW I2C peripherals to GPIO.

表646。GPIO 用户  
Bank 功能  
说明

功能名称	描述
SPIx	将内部 PL022 SPI 外设之一连接至 GPIO。
UARTx	将内部 PL011 UART 外设之一连接至 GPIO。
I2Cx	将内部 DW I2C 外设之一连接至 GPIO。
PWMx A/B	将 PWM 片段连接至 GPIO。共有十二个 PWM 片段，每个包含两个输出通道（A/B）。B 引脚亦可用作输入，用于频率及占空比测量。
SIO	通过单周期输入输出单元（SIO）对 GPIO 进行软件控制。处理器驱动 GPIO 时必须选择 SIO 功能（ <a href="#">F5</a> ），但输入端始终连接，因而软件可随时检测 GPIO 状态。
PIOx	将可编程输入输出模块（PIO）之一连接至 GPIO。PIO 能实现多种接口，且配备内部管脚映射硬件，允许数字接口灵活分布于 Bank 0 GPIO 上。必须选择 PIO 功能（ <a href="#">F6</a> 、 <a href="#">F7</a> 、 <a href="#">F8</a> ）以使 PIO 驱动 GPIO，但输入始终连接，因此 PIO 始终可检测所有管脚状态。
HSTX	将高速传输外设（HSTX）连接至 GPIO。
时钟 GPINx	通用时钟输入。可路由至 RP2350 的多个内部时钟域，例如为 AON 定时器提供 1Hz 时钟，或连接至内部频率计数器。
时钟 GPOUTx	通用时钟输出。可将多个内部时钟（包括 PLL 输出）驱动至 GPIO，支持可选的整数分频。
TRACECLK, TRACEDATAx	来自 Cortex-M33 处理器（仅限 Arm 架构）的 CoreSight 执行跟踪输出。
USB 过流检测 / VBUS 电源线 检测 / VBUS 电源线使能	USB 电源控制信号与内部 USB 控制器间的连接。
QMI CS1n	QSPI 总线辅助芯片选择，用以支持从附加闪存或 PSRAM 设备即取即执行。

Bank 1 功能选择的操作与 Bank 0 完全相同，但其寄存器位于不同的寄存器块，起始地址为 [USBPHY\\_DP\\_CTRL](#)。

表647。GPIO Bank  
1功能

引脚	F0	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11

USB DM			UART1 RX	I2C0 时钟线 (SCL)		SIO						
QSPI SCK	QMI SCK		UART1 CTS	I2C1 数据线 (SDA)		SIO						UART1 TX
QSPI CSn	QMI CS0n		UART1 RTS	I2C1 时钟线 (SCL)		SIO						UART1 RX
QSPI SD0	QMI SD0		UART0 TX	I2C0 SDA		SIO						
QSPI SD1	QMI SD1		UART0 接收 (RX)	I2C0 时钟线 (SCL)		SIO						
QSPI SD2	QMI SD2		UART0 清除发送 (CTS)	I2C1 数据线 (SDA)		SIO						UART0 TX
QSPI SD3	QMI SD3		UART0 请求发送 (RTS)	I2C1 时钟线 (SCL)		SIO						UART0 接收 (RX)

表648。GPIO Bank  
1功能  
描述

功能名称	描述
UARTx	将内部 PL011 UART 外设之一连接至 GPIO。
I2Cx	将内部 DW I2C 外设之一连接至 GPIO。

Function Name	Description
SIO	Software control of GPIO, from the single-cycle IO (SIO) block. The SIO function ( <a href="#">F5</a> ) must be selected for the processors to drive a GPIO, but the input is always connected, so software can check the state of GPIOs at any time.
QMI	QSPI memory interface peripheral, used for execute-in-place from external QSPI flash or PSRAM memory devices.

The six QSPI Bank GPIO pins are typically used by the XIP peripheral to communicate with an external flash device. However, there are two scenarios where the pins can be used as software-controlled GPIOs:

- If a SPI or Dual-SPI flash device is used for execute-in-place, then the SD2 and SD3 pins are not used for flash access, and can be used for other GPIO functions on the circuit board.
- If RP2350 is used in a flashless configuration (USB and OTP boot only), then all six pins can be used for software-controlled GPIO functions.

## 9.5. Interrupts

An interrupt can be generated for every GPIO pin in four scenarios:

- Level High: the GPIO pin is a logical 1
- Level Low: the GPIO pin is a logical 0
- Edge High: the GPIO has transitioned from a logical 0 to a logical 1
- Edge Low: the GPIO has transitioned from a logical 1 to a logical 0

The level interrupts are not latched. This means that if the pin is a logical 1 and the level high interrupt is active, it will become inactive as soon as the pin changes to a logical 0. The edge interrupts are stored in the [INTR](#) register and can be cleared by writing to the [INTR](#) register.

There are enable, status, and force registers for three interrupt destinations: proc 0, proc 1, and dormant\_wake. For proc 0 the registers are enable ([PROC0\\_INTE0](#)), status ([PROC0\\_INTS0](#)), and force ([PROC0\\_INTF0](#)). Dormant wake is used to wake the ROSC or XOSC up from dormant mode. See [Section 6.5.6.2](#) for more information on dormant mode.

There is an interrupt output for each combination of IO bank, IRQ destination, and security domain. In total there are twelve such outputs:

- IO Bank 0 to dormant wake (Secure and Non-secure)
- IO Bank 0 to proc 0 (Secure and Non-secure)
- IO Bank 0 to proc 1 (Secure and Non-secure)
- IO QSPI to dormant wake (Secure and Non-secure)
- IO QSPI to proc 0 (Secure and Non-secure)
- IO QSPI to proc 1 (Secure and Non-secure)

Each interrupt output has its own array of enable registers (INTE) that configures which GPIO events cause the interrupt to assert. The interrupt asserts when at least one enabled event occurs, and de-asserts when all enabled events have been acknowledged via the relevant INTR register.

This means the user can watch for several GPIO events at once.

Summary registers can be used to quickly check for pending GPIO interrupts. See [IRQSUMMARY\\_PROC0\\_NONSECURE0](#) for an example.

功能名称	描述
SIO	通过单周期 IO (SIO) 模块进行 GPIO 的软件控制。处理器驱动 GPIO 时必须选择 SIO 功能 ( <a href="#">F5</a> )，但输入端始终连接，因而软件可随时检测 GPIO 状态。
QMI	QSPI 存储器接口外设，用于从外部 QSPI 闪存或 PSRAM 存储器设备执行就地操作。

这六个QSPI Bank GPIO引脚通常由XIP外设用以与外部闪存设备通信。

然而，存在两种情形允许将这些引脚用作软件控制的GPIO：

- 若SPI或Dual-SPI闪存设备用于执行就地操作，则SD2和SD3引脚不用于闪存访问，可用于电路板上的其他GPIO功能。
- 若RP2350采用无闪存配置（仅支持USB及OTP启动），则所有六个引脚均可用作软件控制的GPIO。

## 9.5. 中断

每个GPIO引脚在以下四种情形下均可生成中断：

- 高电平：GPIO引脚逻辑值为1
- 低电平：GPIO引脚逻辑值为0
- 上升沿：GPIO已从逻辑0变为逻辑1
- 下降沿：GPIO已从逻辑1变为逻辑0

电平中断未被锁存。这意味着，如果引脚处于逻辑1且电平中断处于激活状态，一旦引脚变为逻辑0，该中断将立即失效。边沿中断存储于 [INTR](#) 寄存器中，可通过写入 [INTR](#) 寄存器进行清除。

针对三个中断目标：proc 0、proc 1及dormant\_wake，设有使能、状态及强制寄存器。proc 0的寄存器为使能 (PROC0\_INTE0)、状态 (PROC0\_INTS0) 和强制 (PROC0\_INTF0)。Dormant wake用于将ROSC或XOSC从休眠模式唤醒。有关休眠模式的详细信息，请参见第6.5.6.2节。

每个 IO 银行、中断请求目标和安全域的组合均对应一个中断输出。此类输出总计十二个：

- IO 银行 0 到休眠唤醒（安全域和非安全域）
- IO 银行 0 到处理器 0（安全域和非安全域）
- IO 银行 0 到处理器 1（安全域和非安全域）
- IO QSPI 到休眠唤醒（安全域和非安全域）
- IO QSPI 到处理器 0（安全域和非安全域）
- IO QSPI 到处理器 1（安全域和非安全域）

每个中断输出均拥有独立的使能寄存器数组 (INTE)，用于配置何种 GPIO 事件会触发中断。当至少发生一个已使能事件时，中断即被触发；当所有已使能事件均通过相应 INTR 寄存器确认后，中断将被撤销。

这意味着用户能够同时监控多个 GPIO 事件。

汇总寄存器可用于快速检查待处理的 GPIO 中断。示例请参见 IRQSUMMARY\_PROC0\_NONSECURE0。

## 9.6. Pads

### **⚠ CAUTION**

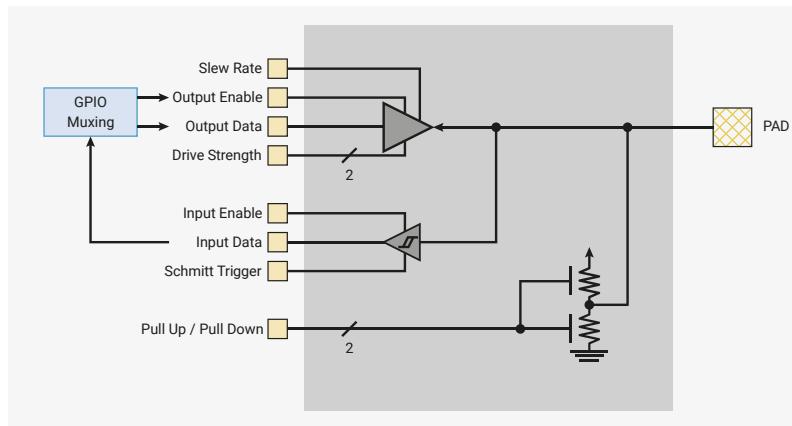

Under certain conditions, pull-down does not function as expected. For more information, see [RP2350-E9](#).

Each GPIO is connected off-chip via a **pad**. Pads are the electrical interface between the chip's internal logic and external circuitry. They translate signal voltage levels, support higher currents and offer some protection against electrostatic discharge (ESD) events. You can adjust pad electrical behaviour to meet the requirements of external circuitry in the following ways:

- Output drive strength can be set to 2mA, 4mA, 8mA or 12mA.
- Output slew rate can be set to slow or fast.
- Input hysteresis (Schmitt trigger mode) can be enabled.
- A pull-up or pull-down can be enabled, to set the output signal level when the output driver is disabled.
- The input buffer can be disabled, to reduce current consumption when the pad is unused, unconnected or connected to an analogue signal.

An example pad is shown in [Figure 42](#).

Figure 42. Diagram of a single IO pad.

The pad's Output Enable, Output Data and Input Data ports connect, via the IO mux, to the function controlling the pad. All other ports are controlled from the pad control register. You can use this register to disable the pad's output driver by overriding the Output Enable signal from the function controlling the pad. See [GPIO0](#) for an example of a pad control register.

Both the output signal level and acceptable input signal level at the pad are determined by the digital IO supply (IOVDD). IOVDD can be any nominal voltage between 1.8V and 3.3V, but to meet specification when powered at 1.8V, the pad input thresholds must be adjusted by writing a 1 to the pad **VOLTAGE\_SELECT** registers. By default, the pad input thresholds are valid for an IOVDD voltage between 2.5V and 3.3V. Using a voltage of 1.8V with the default input thresholds is a safe operating mode, but it will result in input thresholds that don't meet specification.

### **▬ WARNING**

Using IOVDD voltages greater than 1.8V, with the input thresholds set for 1.8V may result in damage to the chip.

Pad input threshold are adjusted on a per bank basis, with separate **VOLTAGE\_SELECT** registers for the pads associated with the User IO bank (IO Bank 0) and the QSPI IO bank. However, both banks share the same digital IO supply (IOVDD), so both register should always be set to the same value.

Pad register details are available in [Section 9.11.3, "Pad Control - User Bank"](#) and [Section 9.11.4, "Pad Control - QSPI Bank"](#).

## 9.6. 引脚

### ⚠ 警告

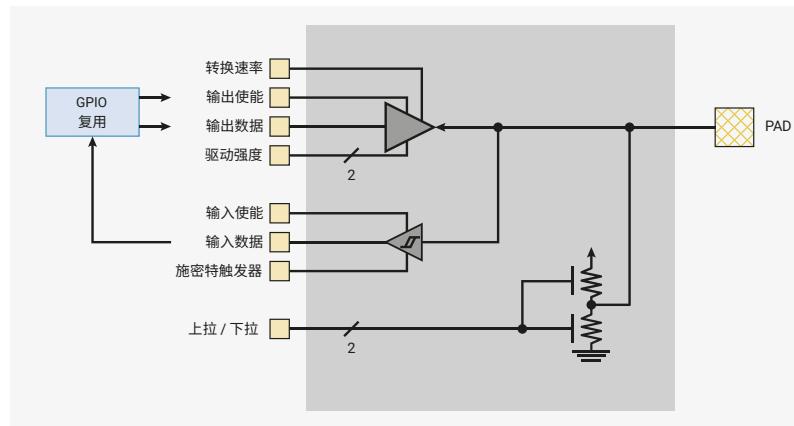

在某些情况下，下拉功能无法达到预期效果。更多信息，请参见RP2350-E9。

每个GPIO均通过一个 **pad**与芯片外部连接。Pad是芯片内部逻辑与外部电路之间的电气接口。它们转换信号电压等级，支持更高电流，并提供对静电放电（ESD）事件的部分保护。您可以通过以下方式调整pad的电气性能，以满足外部电路的要求：

- 输出驱动强度可设置为2mA、4mA、8mA或12mA。
- 输出转换速率可设置为慢速或快速。
- 可启用输入迟滞（施密特触发模式）。
- 可启用上拉或下拉电阻，以在输出驱动器禁用时设置输出信号电平。
- 可禁用输入缓冲区，以在pad未使用、未连接或连接至模拟信号时降低电流消耗。

图42展示了pad的一个示例。

图42。单个IO引脚示意图

该引脚的输出使能、输出数据和输入数据端口通过IO复用器连接至控制该引脚的功能模块。

其他所有端口均由引脚控制寄存器控制。可通过该寄存器覆盖控制引脚功能的输出使能信号，从而禁用引脚的输出驱动器。有关引脚控制寄存器的示例，请参见GPIO0。

引脚的输出信号电平与输入信号的可接受电平均由数字IO电源（IOVDD）决定。

IOVDD可为1.8V至3.3V之间任一标称电压，但为满足1.8V供电条件下的规格，须通过向该引脚的VOLTAGE\_SELECT寄存器写入1来调整输入阈值。默认情况下，引脚输入阈值适用于IOVDD电压范围为2.5V至3.3V。使用1.8V电压配合默认输入阈值可确保安全运行，但输入阈值将不符合规格要求。

### ⚠ 警告

使用高于1.8V的IOVDD电压，而输入阈值设置为1.8V，可能会导致芯片损坏。

垫输入阈值按银行单独调整，分别对应用户IO银行（IO银行0）和QSPI IO银行的VOLTAGE\_SELECT寄存器。但两个银行共用相同的数字IO电源（IOVDD），因此两个寄存器应始终设置为相同的值。

垫寄存器详情见第9.11.3节“垫控制—用户银行”及第9.11.4节“垫控制—QSPI银行”。

### 9.6.1. Bus keeper mode

For each pad, only the pull-up or the pull-down resistor can be enabled at any given time. It is impossible to enable both simultaneously. Instead, if you set both the `GPIO0.PDE` and `GPIO0.PUE` bits simultaneously then you enable **bus keeper** mode, where the pad is:

- Pulled up when its input is high.
- Pulled down when its input is low.

When the output buffer is disabled, and the pad is not driven by any external source, this mode weakly retains the pad's current logical state. The pad does not float to mid-rail.

Bus keeper mode relies on control logic in the switched core domain, so does not function when the core is powered down. Rather, powering down the core when bus keeper mode is enabled latches the current output controls (pull-up or pull-down) in the pad isolation latches, as described in [Section 9.7](#).

## 9.7. Pad isolation latches

RP2350 features extended low-power states that allow all internal logic, with the exception of POWMAN and some CoreSight debug logic, to fully power down under software control. This includes powering down all peripherals, the IO muxing, and the pad control registers, which brings with it the risk that pad signals may experience unwanted transitions when entering and exiting low-power states.

To ensure that pad states are well-defined at all times, all signals passing from the switched core power domain to the pads pass through **isolation latches**. In normal operation, the latches are transparent, so the pads are controlled fully by logic inside the switched core power domain, such as UARTs or the processors. However, when the ISO bit for each pad is set (e.g. `GPIO0.ISO`) or the switched core domain is powered down, the control signals currently presented to that pad are **latched** until the isolation is disabled. This includes the output enable state, output high/low level, and pull-up/pull-down resistor enable. The input signal from the pad back into the switched core domain is not isolated.

Consequently, when switched core logic is powered down, all Bank 0 and Bank 1 pads maintain the output state they held immediately before the power down, unless overridden by always-on logic in POWMAN. When the switched core power domain powers back up, all the GPIO ISO bits reset to 1, so the pre-power down state continues to be maintained until user software starts up and clears the ISO bit to indicate it is ready to use the pad again. Pads whose IO muxing has not yet been set up can be left isolated indefinitely, and will maintain their pre-power down state.

when software has finished setting up the IO muxing for a given pad, and the peripheral that is to be muxed in, the ISO bit should be cleared. At this point the isolation latches will become transparent again: output signals passing through the IO muxing block are now reflected in the pad output state, so peripherals can communicate with the outside world. This process allows the switched core domain to be power cycled without causing any transitions on the pad outputs that may interfere with the operation of external hardware connected to the pads.

#### NOTE

Non-SDK applications ported from RP2040 must clear the ISO bit before using a GPIO, as this feature was not present on RP2040. The SDK automatically clears the ISO bit when `gpio_set_function()` is called.

The isolation latches themselves are reset by the always-on power domain reset, namely any one of:

- Power-on reset
- Brownout reset
- RUN pin being asserted low
- SW-DP CDBGRSTREQ
- RP-AP rescue reset

The latches reset to the reset value of the signal being isolated. For example, on Bank 0 GPIOs, the input enable control

### 9.6.1. 总线保持器模式

每个垫在任何时刻仅能启用上拉电阻或下拉电阻之一。不可能同时启用二者。相反，如果同时设置GPIO0.PDE和GPIO0.PUE位，将启用总线保持器模式，此时垫状态为：

- 当其输入为高电平时，输出被拉高。
- 当其输入为低电平时，输出被拉低。

当输出缓冲器被禁用且引脚未被任何外部源驱动时，此模式会弱保持引脚当前的逻辑状态。该引脚不会漂移至中间电平。

总线保持器模式依赖切换核心域中的控制逻辑，因此在核心断电时无法工作。相反，当总线保持器模式启用且核心断电时，会如第9.7节所述，将当前输出控制（上拉或下拉）锁存于引脚隔离锁存器中。

## 9.7. 引脚隔离锁存器

RP2350具备扩展低功耗状态，允许除POWMAN及部分CoreSight调试逻辑外，所有内部逻辑在软件控制下完全断电。这包括关闭所有外设、IO复用及引脚控制寄存器，但同时也存在引脚信号在进入和退出低功耗状态时发生非预期切换的风险。

为确保引脚状态始终定义明确，所有从切换核心电源域传递至引脚的信号均经过隔离锁存器。在正常操作情况下，锁存器处于透明状态，因此引脚完全由切换核心电源域内的逻辑控制，如UART或处理器。然而，当每个引脚的ISO位被设置（例如GPIO0.ISO）或切换核心电源域断电时，当前传递到该引脚的控制信号将被锁存，直到隔离被禁用。这包括输出使能状态、输出高/低电平以及上拉/下拉电阻使能状态。来自引脚返回至切换核心电源域的输入信号不受隔离。

因此，当切换核心逻辑断电时，所有Bank 0和Bank 1引脚保持断电前的输出状态，除非被POWMAN中的常电逻辑覆盖。切换核心电源域重新上电后，所有GPIO ISO位复位为1，因此断电前的状态将持续保持，直到用户软件启动并清除ISO位，表明已准备重新使用该引脚。未设置IO复用的引脚可保持隔离状态，且可无限期维持断电前的状态。

当软件完成对指定引脚及其所复用的IO复用设置后，应当清除ISO位。此时，隔离锁存器将重新变为透明状态：通过IO复用模块传递的输出信号现已反映于引脚输出状态，外设可由此实现与外界的通信。

此过程允许对切换的核心域进行电源循环，而不会在引脚输出端产生任何可能干扰外部连接硬件正常运行的信号切换。

#### 注意

从RP2040移植的非SDK应用在使用GPIO之前必须清除ISO位，因RP2040不具备该功能。SDK在调用`gpio_set_function()`时会自动清除ISO位。

隔离锁存器由始终通电的电源域复位，具体复位条件包括以下任一项：

- 上电复位
- 欠压复位
- RUN 引脚被拉低
- SW-DP CDBGRSTREQ
- RP-AP 救援复位

锁存器复位为被隔离信号的复位值。例如，在 Bank 0 的 GPIO 上，输入使能控制

(`GPIO0.IE`) resets to 0 (input-disabled), so the isolation latches for these signals also take a reset value of 0. Resetting the isolation latch forces the pad to assume its reset state even *if it is currently isolated*.

The ISO control bits (e.g. `GPIO0.ISO`) are reset by the top-level switched core domain isolation signal, which is asserted by POWMAN before powering down the switched core domain and de-asserted after it is powered up. This means that entering and exiting a sleep state where the switched core domain is unpowered leaves all GPIOs isolated after power up; you can then re-engage them individually. The ISO control bits are not reset by the PADS register block reset driven by the RESETS control registers: resetting the PADS register block returns non-isolated pads to their reset state, but has no effect on isolated pads.

## 9.8. Processor GPIO controls (SIO)

The single-cycle IO subsystem ([Section 3.1](#)) contains memory-mapped GPIO registers. The processors can use these to perform input/output operations on GPIOs:

- The `GPIO_OUT` and `GPIO_HI_OUT` registers set the output level: 1 = high, 0 = low
- The `GPIO_OE` and `GPIO_HI_OE` registers set the output enable: 1 = output, 0 = input
- The `GPIO_IN` and `GPIO_HI_IN` registers read the GPIO inputs

These registers are all 32 bits in size. The low registers (e.g. `GPIO_OUT`) connect to GPIOs 0 through 31, and the high registers (e.g. `GPIO_HI_OUT`) connect to GPIOs 32 through 47, the QSPI pads, and the USB DM/DP pads.

For the output and output enable registers to take effect, the SIO function must be selected on each GPIO (function 5). However, the GPIO input registers read back the GPIO input values even when the SIO function is not selected, so the processor can always check the input state of any pin.

The SIO GPIO registers are shared between the two processors and between the Secure and Non-secure security domains. This avoids programming errors introduced by selecting multiple GPIO functions for access from different contexts.

Non-secure code's view of the SIO registers is restricted by the Non-secure GPIO mask defined in `GPIO_NSmask0` and `GPIO_NSmask1`. Non-secure writes to Secure GPIOs are ignored. Non-secure reads of Secure GPIOs return 0.

These registers are documented in more detail in the SIO GPIO register section ([Section 3.1.3](#)).

The DMA cannot access registers in the SIO subsystem. The recommended method to DMA to GPIOs is a PIO program that continuously transfers TX FIFO data to the GPIO outputs, which provides more consistent timing than DMA directly into GPIO registers.

## 9.9. GPIO coprocessor port

Coprocessor port 0 on each Cortex-M33 processor connects to a GPIO coprocessor interface. These coprocessor instructions provide fast access to the SIO GPIO registers from Arm software:

- The equivalent of any SIO GPIO register access is a single instruction, without having to materialise a 32-bit register address beforehand
- An indexed write operation on any single GPIO is a single instruction
- 64 bits can be read/written in a single instruction

This reduces the timing impact of GPIO accesses on surrounding software, for example when GPIO tracing has been added to interrupt handlers diagnose complex timing issues.

Both Secure and Non-secure code may access the coprocessor. Non-secure code sees a restricted view of the GPIO registers, defined by ACCESSCTRL `GPIO_NSmask0/1`.

The GPIO coprocessor instruction set is documented in [Section 3.6.1](#).

(GPIO0.IE) 复位为 0 (输入禁用)，因此这些信号的隔离锁存器也被复位为 0。复位隔离锁存器会强制端口即使当前处于隔离状态，仍恢复到其复位状态。

ISO 控制位（例如 GPIO0.ISO）由顶层切换核心域隔离信号复位，该信号由 POWMAN 在切换核心域断电前断言，通电后取消断言。这意味着进入和退出切换核心域断电的睡眠状态后，所有 GPIO 都维持隔离状态；随后您可以逐个重新启用它们。ISO 控制位不会被由 RESETS 控制寄存器驱动的 PADS 寄存器块复位影响：复位 PADS 寄存器块会将非隔离端口恢复到复位状态，但对隔离端口无效。

## 9.8. 处理器 GPIO 控制 (SIO)

单周期IO子系统（第3.1节）包含内存映射的GPIO寄存器。处理器可利用这些寄存器对GPIO执行输入/输出操作：

- GPIO\_OUT 和 GPIO\_HI\_OUT 寄存器用于设置输出电平：1 表示高电平，0 表示低电平。
- GPIO\_OE 和 GPIO\_HI\_OE 寄存器用于设置输出使能：1 表示输出，0 表示输入。
- GPIO\_IN 和 GPIO\_HI\_IN 寄存器用于读取GPIO的输入信号。

所有这些寄存器均为32位。低位寄存器（如 GPIO\_OUT）连接GPIO 0至31，高位寄存器（如 GPIO\_HI\_OUT）连接GPIO 32至47，以及QSPI焊盘和USB DM/DP焊盘。

要使输出及输出使能寄存器生效，必须为每个GPIO选择SIO功能（function 5）。

但即使未选择SIO功能，GPIO输入寄存器仍会返回GPIO的输入值，因此处理器始终能够检测任意引脚的输入状态。

SIO GPIO寄存器在两个处理器之间以及安全和非安全安全域之间共享。此举避免了因从不同上下文选择多个GPIO功能进行访问而引起的编程错误。

非安全代码对SIO寄存器的访问受限于GPIO\_NSmask0和GPIO\_NSmask1中定义的非安全GPIO掩码。对安全GPIO的非安全写入将被忽略。非安全读取安全GPIO将返回0。

这些寄存器在SIO GPIO寄存器部分（第3.1.3节）中有更为详细的文档说明。

DMA无法访问SIO子系统中的寄存器。推荐使用的DMA传输至GPIO的方法是通过PIO程序持续将TX FIFO数据传输至GPIO输出，这相比直接DMA写入GPIO寄存器能提供更为一致的时序。

## 9.9. GPIO 协处理器端口

每个Cortex-M33处理器的协处理器端口 0连接至GPIO协处理器接口。这些协处理器指令为Arm软件提供了快速访问SIO GPIO寄存器的能力：

- 任何SIO GPIO寄存器访问的等效操作均为单条指令，无需预先计算32位寄存器地址
- 对任意单个GPIO的索引写操作即为单条指令
- 单条指令即可读写64位数据

这降低了GPIO访问对周边软件时序的影响，例如在中断处理程序中添加GPIO跟踪以诊断复杂时序问题时。

安全代码与非安全代码均可访问协处理器。非安全代码仅能查看由ACCESSCTRL GPIO\_NSmask0/1定义的GPIO寄存器受限视图。

GPIO协处理器指令详见第3.6.1节。

## 9.10. Software examples

### 9.10.1. Select an IO function

An IO pin can perform many different functions and must be configured before use. For example, you may want it to be a `UART_TX` pin, or a `PWM` output. The SDK provides `gpio_set_function` for this purpose. Many SDK examples call `gpio_set_function` early on to enable printing to a UART.

The SDK starts by defining a structure to represent the registers of IO Bank 0, the User IO bank. Each IO has a status register, followed by a control register. For `N` IOs, the SDK instantiates the structure containing a status and control register as `io[N]` to repeat it `N` times.

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/p2350/hardware\\_structs/include/hardware/structs/io\\_bank0.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/p2350/hardware_structs/include/hardware/structs/io_bank0.h) Lines 179 - 445

```

179 typedef struct {
180 io_bank0_status_ctrl_hw_t io[48];
181
182 uint32_t _pad0[32];
183
184 // (Description copied from array index 0 register IO_BANK0_IRQSUMMARY_PROC0_SECURE0
185 applies similarly to other array indexes)
186 _REG_(IO_BANK0_IRQSUMMARY_PROC0_SECURE0_OFFSET) // IO_BANK0_IRQSUMMARY_PROC0_SECURE0
187 // 0x80000000 [31] GPIO31 (0)

```

## 9.10. 软件示例

### 9.10.1. 选择 IO 功能

IO引脚可执行多种功能，使用前必须配置。例如，您可能希望其作为 `UART_TX`引脚，或作为 `PWM`输出。SDK提供了`gpio_set_function`以实现该配置。许多SDK示例通常在早期调用`gpio_set_function`，以启用UART打印。

该SDK首先定义了一个结构体，用以表示IO Bank 0，即用户IO Bank的寄存器。每个IO均包含一个状态寄存器，随后是一个控制寄存器。对于 `N`个IO，SDK实例化包含状态与控制寄存器的结构体，作为 `io[N]`重复 `N`次。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware\\_structs/include/hardware/structs/io\\_bank0.h](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2350/hardware_structs/include/hardware/structs/io_bank0.h) 第179行至445行

```

179 typedef struct {
180 io_bank0_status_ctrl_hw_t io[48];
181
182 uint32_t _pad0[32];
183
184 // (描述摘自数组索引0寄存器IO_BANK0_IRQSUMMARY_PROC0_SECURE0, 其他数组索引亦适用)
185
186 _REG_(IO_BANK0_IRQSUMMARY_PROC0_SECURE0_OFFSET) // IO_BANK0_IRQSUMMARY_PROC0_SECURE0

444 };
445 } io_bank0_hw_t;

```

A similar structure is defined for the pad control registers for IO bank 1. By default, all pads come out of reset ready to use, with input enabled and output disable set to 0. Regardless, `gpio_set_function` in the SDK sets the input enable and clears the output disable to engage the pad's IO buffers and connect internal signals to the outside world. Finally, the desired function select is written to the IO control register (see [GPIO0\\_CTRL](#) for an example of an IO control register).

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_gpio/gpio.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/gpio.c) Lines 36 - 53

```

36 // Select function for this GPIO, and ensure input/output are enabled at the pad.
37 // This also clears the input/output/irq override bits.
38 void gpio_set_function(uint gpio, gpio_function_t fn) {
39 check_gpio_param(gpio);
40 invalid_params_if(HARDWARE_GPIO, ((uint32_t)fn << IO_BANK0_GPIO0_CTRL_FUNCSEL_LSB) &
41 ~IO_BANK0_GPIO0_CTRL_FUNCSEL_BITS);
42 // Set input enable on, output disable off
43 hw_write_masked(&pads_bank0_hw->io[gpio],
44 PADS_BANK0_GPIO0_IE_BITS,
45 PADS_BANK0_GPIO0_IE_BITS | PADS_BANK0_GPIO0_OD_BITS
46);
47 // Zero all fields apart from fsel; we want this IO to do what the peripheral tells it.
48 // This doesn't affect e.g. pullup/pulldown, as these are in pad controls.
49 io_bank0_hw->io[gpio].ctrl = fn << IO_BANK0_GPIO0_CTRL_FUNCSEL_LSB;
50 // Remove pad isolation now that the correct peripheral is in control of the pad

```

```

433 // 0x00000002 [1] GPIO00_LEVEL_HIGH (0)
434 // 0x00000001 [0] GPIO00_LEVEL_LOW (0)
435 io_rw_32_intr[6];
436
437 union {
438 struct {
439 io_bank0_irq_ctrl_hw_t proc0_irq_ctrl;
440 io_bank0_irq_ctrl_hw_t proc1_irq_ctrl;
441 io_bank0_irq_ctrl_hw_t dormant_wake_irq_ctrl;
442 };
443 io_bank0_irq_ctrl_hw_t irq_ctrl[3];
444 };
445 } io_bank0_hw_t;

```

为 IO bank 1 的引脚控制寄存器定义了相似的结构体。默认情况下，所有引脚复位后均可直接使用，输入使能且输出禁用设置为0。无论如何，SDK中的`gpio_set_function`函数会设置输入使能，并清除输出禁止，从而激活引脚的IO缓冲区并将内部信号连接到外部。最后，将所需的功能选择写入IO控制寄存器（参见GPIO0\_CTRL以获取IO控制寄存器的示例）。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_gpio/gpio.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/gpio.c) 第36至53行

```

36 // 选择此GPIO的功能，并确保引脚的输入和输出处于使能状态。
37 // 此外，还会清除输入、输出及中断覆盖位。
38 void gpio_set_function(uint gpio, gpio_function_t fn) {
39 check_gpio_param(gpio);
40 invalid_params_if(HARDWARE_GPIO, ((uint32_t)fn << IO_BANK0_GPIO00_CTRL_FUNCSEL_LSB) &
41 ~IO_BANK0_GPIO00_CTRL_FUNCSEL_BITS);
42 // 设置输入使能为开启，输出禁用为关闭
43 hw_write_masked(&pads_bank0_hw->io[gpio],
44 PADS_BANK0_GPIO00_IE_BITS,
45 PADS_BANK0_GPIO00_IE_BITS | PADS_BANK0_GPIO00_OD_BITS
46);
47 // 除 fsel 外，将所有字段清零；我们期望该 IO 按照外设的指示执行。
48 // 这不会影响诸如上拉/下拉，因为这些控制位于引脚控制寄存器中。
49 io_bank0_hw->io[gpio].ctrl = fn << IO_BANK0_GPIO00_CTRL_FUNCSEL_LSB;
50 // 当正确的外设接管引脚控制时，取消引脚隔离

```

```

50 hw_clear_bits(&pads_bank0_hw->io[gpio], PADS_BANK0_GPIO0_ISO_BITS);
51 }
```

### 9.10.2. Enable a GPIO interrupt

The SDK provides a method of being interrupted when a GPIO pin changes state:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_gpio/gpio.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/gpio.c) Lines 186 - 196

```

186 void gpio_set_irq_enabled(uint gpio, uint32_t events, bool enabled) {
187 // either this call disables the interrupt or callback should already be set.
188 // this protects against enabling the interrupt without callback set
189 assert(!enabled || irq_has_handler(IO_IRQ_BANK0));
190
191 // Separate mask/force/status per-core, so check which core called, and
192 // set the relevant IRQ controls.
193 io_bank0_irq_ctrl_hw_t *irq_ctrl_base = get_core_num() ?
194 &io_bank0_hw->proc1_irq_ctrl : &io_bank0_hw-
195 >proc0_irq_ctrl;
196 _gpio_set_irq_enabled(gpio, events, enabled, irq_ctrl_base);
196 }
```

`gpio_set_irq_enabled` uses a lower level function `_gpio_set_irq_enabled`:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_gpio/gpio.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/gpio.c) Lines 173 - 184

```

173 static void _gpio_set_irq_enabled(uint gpio, uint32_t events, bool enabled,
174 io_bank0_irq_ctrl_hw_t *irq_ctrl_base) {
175 // Clear stale events which might cause immediate spurious handler entry
176 gpio_acknowledge_irq(gpio, events);
177
178 io_rw_32 *en_reg = &irq_ctrl_base->inte[gpio / 8];
179 events <= 4 * (gpio % 8);
180
181 if (enabled)
182 hw_set_bits(en_reg, events);
183 else
184 hw_clear_bits(en_reg, events);
184 }
```

The user provides a pointer to a callback function that is called when the GPIO event happens. An example application that uses this system is `hello_gpio_irq`:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/gpio/hello\\_gpio\\_irq/hello\\_gpio\\_irq.c](https://github.com/raspberrypi/pico-examples/blob/master/gpio/hello_gpio_irq/hello_gpio_irq.c)

```

1 /**
2 * Copyright (c) 2020 Raspberry Pi (Trading) Ltd.
3 *
4 * SPDX-License-Identifier: BSD-3-Clause
5 */
6
7 #include <stdio.h>
8 #include "pico/stlib.h"
9 #include "hardware/gpio.h"
10
11 #define GPIO_WATCH_PIN 2
12
```

```

50 hw_clear_bits(&pads_bank0_hw->io[gpio], PADS_BANK0_GPIO0_ISO_BITS);
51 }

```

## 9.10.2. 启用 GPIO 中断

SDK 提供了在 GPIO 引脚状态变化时触发中断的方法：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_gpio/gpio.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/gpio.c) 第186至196行

```

186 void gpio_set_irq_enabled(uint gpio, uint32_t events, bool enabled) {
187 // 此调用要么禁用中断，要么回调函数应已设置。
188 // 防止在未设置回调函数时启用中断。
189 assert(!enabled || irq_has_handler(IO_IRQ_BANK0));
190
191 // 每核心分离的掩码 / 强制 / 状态，故检查调用的核心，
192 // 并设置相应的 IRQ 控制。
193 io_bank0_irq_ctrl_hw_t *irq_ctrl_base = get_core_num() ?
194 &io_bank0_hw->proc1_irq_ctrl : &io_bank0_hw-
195 >proc0_irq_ctrl;
196 _gpio_set_irq_enabled(gpio, events, enabled, irq_ctrl_base);
197 }

```

`gpio_set_irq_enabled` 调用了更底层函数 `_gpio_set_irq_enabled`：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_gpio/gpio.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_gpio/gpio.c) Lines 173 - 184

```

173 static void _gpio_set_irq_enabled(uint gpio, uint32_t events, bool enabled,
174 io_bank0_irq_ctrl_hw_t *irq_ctrl_base) {
175 // 清除可能导致立即出现虚假中断处理的陈旧事件
176 gpio_acknowledge_irq(gpio, events);
177
178 io_rw_32 *en_reg = &irq_ctrl_base->inte[gpio / 8];
179 events <= 4 * (gpio % 8);
180
181 if (enabled)
182 hw_set_bits(en_reg, events);
183 else
184 hw_clear_bits(en_reg, events);
185 }

```

用户需提供一个回调函数指针，以在GPIO事件发生时被调用。使用该系统的示例应用程序为 `hello_gpio_irq`：

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/gpio/hello\\_gpio\\_irq/hello\\_gpio\\_irq.c](https://github.com/raspberrypi/pico-examples/blob/master/gpio/hello_gpio_irq/hello_gpio_irq.c)

```

1 /**

3 *
4 * SPDX许可证标识符: BSD-3-Clause
5 */
6
7 #include <stdio.h>
8 #include "pico/stl.h"
9 #include "hardware/gpio.h"
10
11 #define GPIO_WATCH_PIN 2
12

```

```

13 static char event_str[128];
14
15 void gpio_event_string(char *buf, uint32_t events);
16
17 void gpio_callback(uint gpio, uint32_t events) {
18 // Put the GPIO event(s) that just happened into event_str
19 // so we can print it
20 gpio_event_string(event_str, events);
21 printf("GPIO %d %s\n", gpio, event_str);
22 }
23
24 int main() {
25 stdio_init_all();
26
27 printf("Hello GPIO IRQ\n");
28 gpio_init(GPIO_WATCH_PIN);
29 gpio_set_irq_enabled_with_callback(GPIO_WATCH_PIN, GPIO_IRQ_EDGE_RISE |
30 GPIO_IRQ_EDGE_FALL, true, &gpio_callback);
31
32 // Wait forever
33 while (1);
34 }
35
36 static const char *gpio_irq_str[] = {
37 "LEVEL_LOW", // 0x1
38 "LEVEL_HIGH", // 0x2
39 "EDGE_FALL", // 0x4
40 "EDGE_RISE" // 0x8
41 };
42
43 void gpio_event_string(char *buf, uint32_t events) {
44 for (uint i = 0; i < 4; i++) {
45 uint mask = (1 << i);
46 if (events & mask) {
47 // Copy this event string into the user string
48 const char *event_str = gpio_irq_str[i];
49 while (*event_str != '\0') {
50 *buf++ = *event_str++;
51 }
52 events &= ~mask;
53
54 // If more events add ", "
55 if (events) {
56 *buf++ = ',';
57 *buf++ = ' ';
58 }
59 }
60 }
61 *buf++ = '\0';
62 }

```

## 9.11. List of registers

### 9.11.1. IO - User Bank

The User Bank IO registers start at a base address of `0x40028000` (defined as `IO_BANK0_BASE` in SDK).

```

13 static char event_str[128];
14
15 void gpio_event_string(char *buf, uint32_t events);
16
17 void gpio_callback(uint gpio, uint32_t events) {
18 // 将刚刚发生的 GPIO 事件写入 event_str
19 // 以便打印输出
20 gpio_event_string(event_str, events);
21 printf("GPIO %d %s\n", gpio, event_str);
22 }
23
24 int main() {
25 stdio_init_all();
26
27 printf("Hello GPIO IRQ\n");
28 gpio_init(GPIO_WATCH_PIN);
29 gpio_set_irq_enabled_with_callback(GPIO_WATCH_PIN, GPIO_IRQ_EDGE_RISE |
30 GPIO_IRQ_EDGE_FALL, true, &gpio_callback);
31
32 // 永久等待
33 while (1);
34 }
35
36 static const char *gpio_irq_str[] = {
37 "LEVEL_LOW", // 0x1
38 "LEVEL_HIGH", // 0x2
39 "EDGE_FALL", // 0x4
40 "EDGE_RISE" // 0x8
41 };
42
43 void gpio_event_string(char *buf, uint32_t events) {
44 for (uint i = 0; i < 4; i++) {
45 uint mask = (1 << i);
46 if (events & mask) {
47 // 将该事件字符串复制至用户缓冲区
48 const char *event_str = gpio_irq_str[i];
49 while (*event_str != '\0') {
50 *buf++ = *event_str++;
51 }
52 events &= ~mask;
53
54 // 如事件仍存在，追加 ", "
55 if (events) {
56 *buf++ = ',';
57 *buf++ = ' ';
58 }
59 }
60 }
61 *buf++ = '\0';
62 }

```

## 9.11. 寄存器列表

### 9.11.1. IO - 用户银行

用户银行 IO 寄存器起始于基地址 `0x40028000` (在 SDK 中定义为 `IO_BANK0_BASE`)。

31:27	保留。	-	-
26	<b>IRQTOPROC</b> : 覆盖后传递给处理器的中断	只读	0x0
25:18	保留。	-	-
17	<b>INFROMPAD</b> : 滤波与覆盖前的引脚输入信号	只读	0x0
16:14	保留。	-	-
13	<b>OETOPAD</b> : 寄存器覆盖后传递给引脚的输出使能	只读	0x0
12:10	保留。	-	-
9	<b>OUTTOPAD</b> : 寄存器覆盖后传递给引脚的输出信号	只读	0x0
8:0	保留。	-	-

## IO\_QSPI: GPIO\_QSPI\_SD2\_CTRL 寄存器

偏移: 0x034

表 832。  
GPIO\_QSPI\_SD2\_CTR  
L 寄存器

位	描述	类型	复位
31:30	保留。	-	-
29:28	<b>IRQOVER</b>	读写	0x0
	枚举值:		
	0x0 → NORMAL: 不反转中断		
	0x1 → INVERT: 反转中断		
	0x2 → LOW: 使中断保持低电平		
	0x3 → HIGH: 使中断保持高电平		
27:18	保留。	-	-
17:16	<b>INOVER</b>	读写	0x0
	枚举值:		
	0x0 → NORMAL: 不反转外围输入		
	0x1 → INVERT: 反转外围输入		
	0x2 → LOW: 使外围输入保持低电平		
	0x3 → HIGH: 使外围输入保持高电平		
15:14	<b>OEOVER</b>	读写	0x0
	枚举值:		
	0x0 → NORMAL: 由 funcsel 选择的外设信号驱动输出使能		
	0x1 → INVERT: 由 funcsel 选择的外设信号的反相信号驱动输出使能		
	0x2 → DISABLE: 禁用输出		
	0x3 → ENABLE: 启用输出		
13:12	<b>OUTOVER</b>	读写	0x0

Bits	Description	Type	Reset
	Enumerated values:		
	0x0 → NORMAL: drive output from peripheral signal selected by funcsel		
	0x1 → INVERT: drive output from inverse of peripheral signal selected by funcsel		
	0x2 → LOW: drive output low		
	0x3 → HIGH: drive output high		
11:5	Reserved.	-	-
4:0	<b>FUNCSEL</b> : 0-31 → selects pin function according to the gpio table 31 == NULL	RW	0x1f
	Enumerated values:		
	0x00 → XIP_SD2		
	0x02 → UART0_CTS		
	0x03 → I2C1_SDA		
	0x05 → SIO_62		
	0x0b → UART0_TX		
	0x1f → NULL		

## IO\_QSPI: GPIO\_QSPI\_SD3\_STATUS Register

Offset: 0x038

Table 833.  
GPIO\_QSPI\_SD3\_STAT  
US Register

Bits	Description	Type	Reset
31:27	Reserved.	-	-
26	<b>IRQTOPROC</b> : interrupt to processors, after override is applied	RO	0x0
25:18	Reserved.	-	-
17	<b>INFROMPAD</b> : input signal from pad, before filtering and override are applied	RO	0x0
16:14	Reserved.	-	-
13	<b>OETOPAD</b> : output enable to pad after register override is applied	RO	0x0
12:10	Reserved.	-	-
9	<b>OUTTOPAD</b> : output signal to pad after register override is applied	RO	0x0
8:0	Reserved.	-	-

## IO\_QSPI: GPIO\_QSPI\_SD3\_CTRL Register

Offset: 0x03c

Table 834.  
GPIO\_QSPI\_SD3\_CTRL  
Register

Bits	Description	Type	Reset
31:30	Reserved.	-	-
29:28	<b>IRQOVER</b>	RW	0x0
	Enumerated values:		

位	描述	类型	复位
	枚举值：		
	0x0 → NORMAL：驱动输出由funcsel选择的外设信号		
	0x1 → INVERT：驱动输出由funcsel选择的外设信号的反相信号		
	0x2 → LOW：驱动输出低电平		
	0x3 → HIGH：驱动输出高电平		
11:5	保留。	-	-
4:0	<b>FUNCSEL</b> : 0-31 → 根据gpio表选择引脚功能 31 == NULL	读写	0x1f
	枚举值：		
	0x00 → XIP_SD2		
	0x02 → UART0_CTS		
	0x03 → I2C1_SDA		
	0x05 → SIO_62		
	0x0b → UART0_TX		
	0x1f → NULL

## PADS\_BANK0: VOLTAGE\_SELECT Register

Offset: 0x00

Table 852.  
VOLTAGE\_SELECT  
Register

Bits	Description	Type	Reset
31:1	Reserved.	-	-
0	Voltage select. Per bank control	RW	0x0
	Enumerated values:		
	0x0 → 3V3: Set voltage to 3.3V (DVDD >= 2V5)		
	0x1 → 1V8: Set voltage to 1.8V (DVDD ≤ 1V8)		

## PADS\_BANK0: GPIO0 Register

Offset: 0x04

Table 853. GPIO0  
Register

Bits	Description	Type	Reset
31:9	Reserved.	-	-
8	<b>ISO</b> : Pad isolation control. Remove this once the pad is configured by software.	RW	0x1
7	<b>OD</b> : Output disable. Has priority over output enable from peripherals	RW	0x0
6	<b>IE</b> : Input enable	RW	0x0
5:4	<b>DRIVE</b> : Drive strength.	RW	0x1
	Enumerated values:		
	0x0 → 2MA		
	0x1 → 4MA		
	0x2 → 8MA		
	0x3 → 12MA		
3	<b>PUE</b> : Pull up enable	RW	0x0
2	<b>PDE</b> : Pull down enable	RW	0x1
1	<b>SCHMITT</b> : Enable schmitt trigger	RW	0x1
0	<b>SLEWFAST</b> : Slew rate control. 1 = Fast, 0 = Slow	RW	0x0

# Chapter 10. Security

This chapter describes the RP2350 security model and the hardware that implements it. This chapter contains two separate overviews: one for Arm, and one for RISC-V. The architectures have distinct security features and levels of bootrom support.

## 10.1. Overview (Arm)

RP2350 provides hardware and bootrom security features for three purposes:

1. Prevent unauthorised code from running on the device
2. Prevent unauthorised reading of user code and data
3. Isolate trusted and untrusted software, running concurrently on the device, from one another

Point 1 is referred to in this datasheet as **secure boot**. Secure boot is a prerequisite to points two and three because running unauthorised code on the device allows that code to access device internals. The bootrom secure boot implementation and related hardware security features implement the root of trust for secure RP2350 applications; bootrom contents are fixed at design time and immutable.

Point 2 is referred to in this datasheet as **encrypted boot**. Encrypted boot is an additional layer of protection which makes it more difficult to clone devices, or dump and reverse-engineer device firmware. Encrypted boot is implemented using a signed decryption stage prepended to a binary as a post-build step. Encrypted boot stores decryption keys in on-device OTP memory, which can be locked down after use.

Point 3 allows applications to enforce internal security boundaries such that one part of an application being compromised does not allow access to critical hardware, such as the voltage regulator or protected OTP storage used for cryptographic keys.

Hardware features such as the glitch detector and redundancy coprocessor mitigate common classes of fault injection attacks and help maintain boot integrity, even when an attacker has physical access.

### 10.1.1. Secure boot

You can permanently alter blank RP2350 devices to restrict code execution to only your own code. With further alteration, you can revoke the ability to run older software versions.

The RP2350 bootrom uses a cryptographic **signature** to distinguish authentic from inauthentic binaries. A signature is a hash of the binary signed with the user's private key. You can include signatures in binary images compiled for RP2350 devices. Signatures use the SHA-256 hash algorithm and secp256k1 ECDSA elliptic curve cipher to authenticate binaries. The bootrom authenticates binaries using the following steps:

1. Calculate a SHA-256 hash using image code and data when loading the binary.
2. Verify the image's signature using the user's public key, which is also stored in the image.
3. Check the included, verified signature (from step 2) against the calculated SHA-256 hash value for the binary (from step 1).
4. Check the image's public key against a SHA-256 key fingerprint stored in OTP.

If both checks succeed, the bootrom assumes someone in possession of the private key registered by an OTP public key fingerprint calculated the same SHA-256 hash. Based on the properties of hash functions, the bootrom assumes that the binary contents have not been altered since the signature was generated. This proves that this is an authentic binary signed by the owner of the private key, so the bootrom will entertain the idea of running the binary.

The image may also have an anti-rollback version number (`rollback.major.minor`) that the bootrom checks against a

# 第10章 安全性

本章介绍RP2350安全模型及其实现该模型的硬件。本章包含两个独立概述：一个针对Arm架构，另一个针对RISC-V架构。各架构具有不同的安全特性及bootrom支持级别。

## 10.1. 概述 (Arm)

RP2350为以下三项目的提供硬件及bootrom安全特性：

1. 防止未经授权的代码在设备上运行
2. 防止未经授权读取用户代码和数据
3. 隔离设备上同时运行的可信软件与不可信软件

本数据手册中提及的点 1称为**安全启动**。安全启动是第2点和第3点的先决条件，因为在设备上运行未经授权的代码将允许该代码访问设备内部结构。bootrom 的安全启动实现及相关硬件安全特性构成了安全RP2350应用的信任根。

bootrom 内容在设计阶段固化且不可更改。

本数据表中将第 2点称为加密启动。加密启动作为额外的保护层，使设备克隆、固件转储及逆向工程变得更加困难。加密启动通过在构建后阶段向二进制文件前附加签名的解密过程来实现。加密启动将解密密钥存储于设备上的一次性可编程 (OTP) 存储器中，且可在使用后被锁定。

第 3点允许应用程序实施内部安全边界，确保应用程序某部分遭到破坏时，不得访问诸如电压调节器或用于加密密钥的受保护OTP存储等关键硬件。

毛刺检测器和冗余协处理器等硬件特性可有效缓解常见类别的故障注入攻击，即使攻击者具备物理访问权限，也有助于维护启动完整性。

### 10.1.1. 安全启动

您可以永久更改空白的 RP2350 设备，以限制只执行您自己的代码。通过进一步修改，您可以撤销运行旧版本软件的权限。

RP2350 启动只读存储器使用加密签名来区分真伪二进制文件。签名是对二进制文件哈希后，使用用户私钥进行签名的结果。您可以将签名包含在为 RP2350 设备编译的二进制映像中。签名采用 SHA-256 哈希算法及 secp256k1 ECDSA 椭圆曲线密码算法对二进制文件进行身份验证。启动只读存储器通过以下步骤对二进制文件进行认证：

1. 加载二进制文件时，对映像代码和数据计算 SHA-256 哈希值。
2. 使用存储在映像中的用户公钥验证映像签名。
3. 将已包含且通过验证的签名（第 2 步）与第 1 步计算的二进制文件 SHA-256 哈希值进行比对。
4. 将映像的公钥与存储于 OTP 中的 SHA-256 密钥指纹进行核对。

如果两项检查均通过，bootrom 则假设持有由 OTP 公钥指纹注册的私钥者计算出了相同的 SHA-256 哈希值。基于哈希函数的性质，bootrom 假定该二进制内容自签名生成以来未被篡改。这证明该二进制文件为私钥所有者签署的真实文件，因此 bootrom 会考虑执行该二进制。

映像还可能包含防回滚版本号 (`rollback.major.minor`)，bootrom 会将其与

counter stored in OTP. The bootrom refuses to boot images with *rollback* versions lower than the OTP counter number, and automatically increments the OTP counter upon booting a higher version. This is useful if older binaries have known vulnerabilities, as installing a newer version automatically revokes the ability to downgrade to older versions. Incrementing the *major* and *minor* versions allows you to express a preference for newer, higher binary versions without blocking execution of older, lower-versioned binaries. For more discussion of bootrom anti-rollback support, see [Section 5.1.11](#).

RP2350 can boot from any of the following sources:

- Directly on external flash via execute-in-place (XIP)
- Loading into SRAM from external flash
- Loading into SRAM from user-specified OTP contents
- Loading into SRAM via USB or other serial bootloader
- Loading into SRAM via debugger

RP2350 enforces signatures on all of these boot media, with the exception of the debugger, when an external host has control of RP2350's processors and can completely skip execution of the bootrom. Disabling debug is part of the secure boot enable procedure outlined in [Section 10.5](#).

Although signatures *can* be enforced on a flash execute-in-place binary, we do not recommend it. With this boot media, flash contents can change between checks and execution. For example, an attacker could emulate a QSPI device using an FPGA or another microcontroller. Instead, load your complete application into SRAM and verify it in-place before execution. RP2350 has sufficient SRAM capacity to do this with most applications.

Pure-software secure boot implementations are susceptible to fault injection attacks when an attacker has physical access to the device, as is often the case for embedded hardware. Our very own Pico is a popular tool for voltage fault injection. Instead of potentially booting an unauthorised binary, the RP2350 glitch detectors ([Section 10.9](#)) and redundancy coprocessor ([Section 3.6.3](#)) mitigate fault injection attacks by detecting out-of-envelope operation and bringing the system to a safe halt. To enable the glitch detectors, set the `CRIT1.GLITCH_DETECTOR_ENABLE` OTP flag. The redundancy coprocessor is always used by the bootrom.

To learn more about how to enable secure boot on a blank RP2350 device, see [Section 10.5](#).

### 10.1.2. Encrypted boot

RP2350 contains 8 kB of OTP, which can be protected at 128-byte page granularity. This protection comes in the following forms:

- **hard locks**, which permanently revoke read or write access by Secure or Non-secure code
- **soft locks**, which revoke permissions only until the next reset of the OTP block.

Encrypted boot stores decryption keys in OTP, and protects the keys from later boot stages using soft locks.

RP2350 supports loading encrypted binaries from external flash into SRAM, which can then decrypt their own contents in-place. Many implementations are possible, but as a concrete example, this section describes the flash-resident binary encryption support provided by the SDK and `picotool`.

1. First, the developer should process a plain SRAM binary into an encrypted binary. To encrypt your binary, the SDK completes the following steps after a build:
  - a. Sign the payload binary using the **boot private key**, if you didn't already do this during the build.
  - b. Encrypt the payload binary using the **encryption key** (*not* the private key).
  - c. Append a small **decryption stage** to the binary that contains a modified copy of the payload's `IMAGE_DEF` (the original is unreadable, as it is encrypted).
  - d. Sign the decryption stage together with the encrypted contents, using the boot private key.

Encrypted binaries boot as packaged RAM binaries ([Section 5.1.10](#)), decrypting themselves in-place. To boot an

存储于 OTP 中的计数器进行比对。bootrom 拒绝启动回滚版本低于 OTP 计数器的映像，并在启动更高版本时自动递增 OTP 计数器。该机制在旧版本二进制存在已知漏洞时尤为重要，因为安装新版本会自动撤销回滚至旧版本的权限。

递增 `major` 及 `minor` 版本号能体现对较新、更高版本二进制的偏好，且不会阻止执行较旧、版本较低的二进制。有关只读存储器防回滚支持的更多讨论，请参见第 5.1.11 节。

RP2350 可以从以下任一源启动：

- 通过原地执行（XIP）直接从外部闪存启动
- 从外部闪存加载至 SRAM
- 从用户指定的一次性可编程（OTP）内容加载至 SRAM
- 通过 USB 或其他串行引导加载程序加载至 SRAM
- 通过调试器加载至 SRAM

当外部主机控制 RP2350 的处理器且可完全跳过只读存储器执行时，RP2350 对所有这些启动介质强制执行签名验证，但调试器除外。禁用调试是第 10.5 节所述安全启动启用程序的一部分。

虽然可以对闪存原地执行的二进制文件强制执行签名，但我们并不推荐这样做。因为使用该启动介质时，闪存内容可能在校验和执行间发生变化。例如，攻击者可能使用 FPGA 或其他微控制器模拟 QSPI 设备。建议将完整应用程序加载至 SRAM，并在执行前进行原地验证。RP2350 具备充足的 SRAM 容量，可满足大多数应用的需求。

纯软件的安全启动实现易受到故障注入攻击，尤其是在攻击者具备对设备的物理访问权限时，这种情况在嵌入式硬件中尤为常见。我们自主研发的 Pico 是一种广受欢迎的电压故障注入工具。RP2350 的故障检测器（第 10.9 节）与冗余协处理器（第 3.6.3 节）通过检测超出正常范围的操作并将系统安全地停止，减轻故障注入攻击，从而避免潜在的未经授权二进制程序启动。要启用故障检测器，请设置 CRIT1.GLITCH\_DETECTOR\_ENABLE 一次性可编程（OTP）标志位。

启动只读存储器（BootROM）始终使用冗余协处理器。

欲了解如何在空白 RP2350 设备上启用安全启动，请参阅第 10.5 节。

### 10.1.2. 加密启动

RP2350 含有 8 kB 的一次性可编程存储器（OTP），支持以 128 字节页面为粒度进行保护。该保护措施包括以下几种形式：

- 硬锁，永久撤销安全或非安全代码的读写权限。
- 软锁，仅在 OTP 块下一次复位之前撤销权限。

加密启动将解密密钥存储于 OTP，并通过软锁保护该密钥免受后续启动阶段的访问。

RP2350 支持将加密二进制文件从外部闪存加载至 SRAM，然后可在原位解密其内容。实现方式多样，但作为具体示例，本节介绍 SDK 与 `picotool` 提供的闪存驻留二进制加密支持。

1. 首先，开发者应将明文 SRAM 二进制文件转换为加密二进制文件。为加密您的二进制文件，SDK 在构建后执行以下步骤：

- a. 若未在构建过程中完成，请使用 **boot 私钥** 对有效载荷二进制文件进行签名。
- b. 使用 **加密密钥**（非私钥）对有效载荷二进制文件进行加密。
- c. 向二进制文件追加一个小型解密阶段，其中包含有效载荷的 `IMAGE_DEF` 的修改副本（原始版本因加密而不可读取）。
- d. 使用启动私钥对解密阶段及加密内容共同进行签名。

加密二进制文件作为打包的 RAM 二进制文件启动（见第 5.1.10 节），并在原位自行解密。启动

encrypted binary, the bootrom completes the following steps:

1. Loads the entire encrypted binary into SRAM.
2. Verifies the signature of the decryption stage, then jumps into the **decryption stage**, comprised of the following steps:
  - a. Reads the decryption key stored in OTP (this stage may soft-lock that OTP page until next boot).
  - b. Decrypts the encrypted binary payload using the decryption key.
  - c. Calls the `chain_image()` bootrom API ([Section 5.4.8.2](#)) on the decrypted region of SRAM.
3. Verifies the decrypted binary payload in the same manner as it verified the decryption stage, then jumps into the binary.

The decryption stage is not itself encrypted, but it is signed. Storing the decryption stage in the clear does not present additional risk because the source code for the decryption stage is open source and highly scrutinised. Without the decryption key, the encrypted payload cannot be read. Because the key only exists on-device, static analysis of the encrypted binary cannot recover it.

Resetting the OTP to reopen soft locks also resets the processors. Upon reset, the processors re-run the decryption stage and re-lock the page with the decryption key. The `BOOTDIS` register allows the bootrom to detect OTP resets and disable the watchdog and POWMAN boot vectors. This ensures that the decryption stage is not skipped and the key remains protected.

#### NOTE

The decryption stage is deliberately not included in the bootrom, so that it can be updated. The bootrom handles only public key cryptography, so there is no concern of power analysis attacks, but this reasoning does not apply to the decryption stage. Power analysis mitigations require iteration as techniques improve.

This scheme supports designs where the decryption key is accessible only to the decryption stage. When the decryption key is also required at runtime to read additional encrypted flash contents on-demand, processor security features and OTP page locks can restrict key access to a small subset of trusted code, such as a TF-M Secure Storage service.

In addition to software mitigations provided by the decryption stage, RP2350 supports randomising the frequency controls of its internal ring oscillator ([Section 8.3](#)) to make it more difficult to recover the system clock from power traces.

Encrypted execute-in-place is not supported in hardware, but the spare 32 MB cached XIP window ([Section 4.4.1](#)) can provide software-defined execute-in-place by trapping cache misses and pinning at the miss address. This may be used to transparently decrypt data on-demand from external flash.

### 10.1.3. Isolating trusted and untrusted software

In security- or safety-critical applications, access must be limited to those who need it. For example, a JPEG decode library should not be able to access the core voltage regulator and increase DVDD to 3.3 V (unless you are decompressing a very large JPEG). The Cortex-M33 processors contain hardware that separates two execution contexts, known as Secure and Non-secure, and enforces a number of invariants between them, such as:

- Non-secure code cannot access Secure memory
- The Secure context cannot execute Non-secure memory
- Non-secure code cannot directly access peripherals managed by Secure code
- Non-secure code cannot prevent Secure interrupts from being serviced

By making less of your code able to access your most critical hardware and data, you reduce the chance of accidentally exposing this critical hardware and data to the outside world. For a high-level explanation of how the Cortex-M33 implements this, see [Section 10.2](#). For full details, see [Armv8-M Architecture Reference Manual](#).

加密二进制文件时，启动只读存储器（bootrom）完成以下步骤：

1. 将整个加密二进制文件加载至SRAM。
2. 验证解密阶段的签名后，跳转至**解密阶段**，包含以下步骤：
  - a. 读取存储于OTP中的解密密钥（此阶段可能会软锁定该OTP页，直至下一次启动）。
  - b. 使用解密密钥对加密的二进制负载进行解密。
  - c. 在SRAM中解密的区域调用[chain\\_image\(\)](#)启动只读存储器API（见第5.4.8.2节）。
3. 以与验证解密阶段相同方式验证解密后的二进制负载，随后跳转执行该二进制文件。

解密阶段本身未加密，但已签名。以明文存储解密阶段不会带来额外风险，因其源代码为开源且经过严格审查。没有解密密钥，无法读取加密载荷。由于密钥仅存在于设备内部，静态分析加密二进制文件无法恢复该密钥。

重置OTP以重新开启软锁也将重置处理器。复位后，处理器会重新执行解密阶段，使用解密密钥重新锁定页面。BOOTDIS寄存器允许bootrom检测OTP复位并禁用看门狗及POWMAN启动向量。此举确保解密阶段不会被跳过，密钥始终受到保护。

### 注意

解密阶段故意未包含在bootrom中，以便能够进行更新。bootrom仅处理公钥密码学，因此无需担心功率分析攻击，但该考虑不适用于解密阶段。针对功率分析的缓解措施需随着技术进步不断更新迭代。

该方案支持设计中，解密密钥仅对解密阶段可见。当解密密钥在运行时也需按需读取额外加密闪存内容时，处理器安全特性及OTP页面锁定可将密钥访问限制在极少数受信任代码内，如TF-M安全存储服务。

除了解密阶段提供的软件缓解措施外，RP2350 支持对其内部环形振荡器的频率控制进行随机化（第8.3节），以增加从电源踪迹恢复系统时钟的难度。

硬件不支持加密执行就地，但备用的32 MB 缓存XIP窗口（第4.4.1节）可以通过捕获缓存未命中并固定未命中地址，提供软件定义的执行就地功能。该功能可用于按需透明地解密外部闪存中的数据。

### 10.1.3. 隔离可信与不可信软件

在安全或安全关键应用中，必须将访问权限限制于必要的人员。例如，JPEG解码库不应能够访问核心电压调节器并将DV DD提升至3.3 V（除非您正在解压缩一个非常大的JPEG文件）。Cortex-M33处理器包含用于分隔两个执行上下文的硬件机制，分别称为安全和非安全，并在它们之间强制执行多项不变性，例如：

- 非安全代码无法访问安全内存
- 安全上下文无法执行非安全内存
- 非安全代码无法直接访问由安全代码管理的外设
- 非安全代码无法阻止安全中断被处理

通过减少可访问最关键硬件与数据的代码数量，可以降低意外将这些关键硬件与数据暴露给外部的风险。有关 Cortex-M3 3 实现此功能的高级说明，请参见第10.2节。详细信息请参考 Armv8-M 架构参考手册。

To make the programming model of Secure and Non-secure software consistent, and to avoid overhead in Non-secure code, RP2350 extends Secure/Non-secure separation throughout the system. For example, DMA channels can be assigned for Secure or Non-secure use. Using this extended separation, Non-secure code can use DMA transfers to accelerate peripheral accesses without endangering security model invariants (such as Non-secure code using the DMA to read Secure memory).

The key hardware features that enable Secure/Non-secure separation throughout the system are:

- The Cortex-M33's implementation of the Secure and Non-secure states ([Section 10.2](#))
- The DMA's implementation of matching per-channel security states ([Section 10.7](#))
- The system-level bus access filtering implemented by ACCESSCTRL ([Section 10.6](#))
- Peripheral-level filtering, such as the per-GPIO access filtering of the SIO GPIO registers ([Section 3.1.1](#))

## 10.2. Processor security features (Arm)

The Cortex-M33 processors on RP2350 are configured with the following standard Arm security features:

- Support for the Armv8-M Security extension
- 8× security attribution unit (SAU) regions
- 8× Secure and 8× Non-secure memory protection unit (MPU) regions

These features are covered exhaustively in the [Armv8-M Architecture Reference Manual](#), the Cortex-M33 Technical Reference Manual, and the Cortex-M33 section of this datasheet ([Section 3.7](#)). This section gives a high-level overview of these features, as well as a description of the implementation-defined attribution unit included in RP2350.

### 10.2.1. Background

The Cortex-M33 processors on RP2350 support the Armv8-M Security Extension. Hardware in the processor maintains two separate execution contexts, called the Secure and Non-secure domains. Access to important data, such as cryptographic keys, or hardware, such as the system voltage regulator, can be limited to the Secure domain. Separating execution into these domains prevents Non-secure execution from interfering with Secure execution. When this datasheet uses the (capitalised) terms **Secure** and **Non-secure**, we refer to these two Arm security domains and the associated bus attributes.

Code running in the Non-secure domain is not necessarily malicious. Consider complex protocols and stacks like USB, whose implementation is expected to be easily-exploited and prone to fatal crashes. Restricting such software to the Non-secure domain helps isolate critical software from the consequences of those design decisions. The RP2350 bootrom, for example, runs all of its USB code in the Non-secure domain so the USB code does not have to be considered in the design of critical parts of the bootrom, such as boot signature enforcement.

At any given moment, an Armv8-M processor implementing the Security Extension is in either the Secure execution state or the Non-secure execution state. Based on the current state, the processor limits the executable memory regions and the memory regions accessible via load/store instructions. All of the processor's AHB accesses are tagged according to the state that originated them, so that peripherals and the system bus fabric itself can filter transfers based on security domain, for example, using the access control lists described in [Section 10.6](#).

An internal processor peripheral called the Security Attribution Unit (SAU) defines, from the processor's point of view, which address ranges are accessible to the Secure and Non-secure domains. The number of distinct address ranges which can be decoded by the SAU is limited, which is why system-level bus filters are provided for assigning peripherals to security domains.

The processor changes security state synchronously using special function calls between states. When an interrupt routed to the Secure domain occurs, the processor can also change security state asynchronously if in the Non-secure state, or vice versa (if enabled).

Both Cortex-M33 processors on RP2350 implement the security extension, so each processor maintains its own Secure

为了使安全软件与非安全软件的编程模型保持一致，并避免非安全代码的额外开销，RP2350 在整个系统中扩展了安全/非安全隔离。例如，DMA 通道可分配用于安全或非安全使用。借助此扩展隔离，非安全代码可通过 DMA 传输加速外设访问，同时不危及安全模型的约束（如非安全代码通过 DMA 读取安全内存）。

实现系统内安全与非安全分离的关键硬件特性包括：

- Cortex-M33对安全态与非安全态的实现（第10.2节）
- DMA对每通道安全状态匹配的实现（第10.7节）
- ACCESSCTRL实现的系统级总线访问过滤（第10.6节）
- 外围设备级过滤，例如SIO GPIO寄存器的每GPIO访问过滤（第3.1.1节）

## 10.2. 处理器安全特性（Arm）

RP2350上的Cortex-M33处理器配置了以下标准Arm安全特性：

- 支持Armv8-M安全扩展
- 8个安全归属单元（SAU）区域
- 8个安全和8个非安全内存保护单元（MPU）区域

这些特性在Armv8-M架构参考手册、Cortex-M33技术参考手册及本数据手册Cortex-M33章节（第3.7节）中均有详尽介绍。本节提供这些特性的高级概述，并描述RP2350中包含的实现定义归属单元。

### 10.2.1. 背景

RP2350上的Cortex-M33处理器支持Armv8-M安全扩展。处理器硬件维护两个独立的执行上下文，称为安全域和非安全域。对重要数据，如加密密钥，或硬件，如系统电压调节器的访问，可以限制在安全域内。将执行分离到这些域中，防止非安全执行干扰安全执行。当本数据手册使用大写术语 **Secure** 和 **Non-secure** 时，我们指代这两个Arm安全域及其相关的总线属性。

运行在非安全域中的代码不一定是恶意的。考虑到像USB这样复杂的协议和协议栈，其实现预期容易被利用且易发生致命崩溃。将此类软件限制在非安全域，有助于将关键软件与这些设计决策的后果隔离开来。例如，RP2350的bootrom在非安全域中运行所有USB代码，因此USB代码无需纳入bootrom关键部分的设计，如启动签名强制。

在任一时刻，实施安全扩展的 Armv8-M 处理器处于安全执行状态或非安全执行状态。根据当前状态，处理器限制可执行的内存区域及通过加载/存储指令可访问的内存区域。处理器所有的 AHB 访问均根据其来源状态进行标记，以便外设和系统总线结构本身可基于安全域过滤传输，例如，使用第10.6节所述的访问控制列表。

内部处理器外设——安全属性单元（SAU）从处理器视角定义哪些地址范围对安全域和非安全域可访问。SAU 可解码的不同地址范围数量有限，因此系统级总线过滤器用于将外设分配给安全域。

处理器通过状态间的特殊函数调用同步切换安全状态。当路由至安全域的中断发生时，若当前处于非安全状态，处理器也可异步切换安全状态，反之亦然（若已启用）。

RP2350上的两个Cortex-M33处理器均实现了安全扩展，因此每个处理器均保持其独立的安全

and Non-secure context. The Secure and Non-secure contexts on each core can communicate, for example using shared memory or the Secure/Non-secure SIO mailbox FIFOs. If the cores are used symmetrically (i.e. a shared dual-core Secure context, and a shared dual-core Non-secure context), software must synchronise the processor SAUs so that memory writable from a Non-secure context on one core is not executable in a Secure context on the other core. The DMA MPU, which supports the same region shape and count as the SAU, must also be kept synchronised with the processor SAUs.

It may be simpler to use the cores asymmetrically, implementing all Secure services on one core only. The `FORCE_CORE_NS` register can make all core 1 accesses appear Non-secure on the system bus, for the purpose of security filtering implemented in the fabric and peripherals, as well as for SIO registers banked over Secure/Non-secure. However, this does not affect PPB accesses. This does not affect core 1 internally, so it can still maintain its own Secure/Non-secure context. However, system hardware will consider all core 1 accesses Non-secure.

### 10.2.2. IDAU address map

The Cortex-M33 provides an implementation-defined attribution unit (IDAU) interface, which allows system implementers such as Raspberry Pi Ltd to augment the security attribution map defined by the SAU. The RP2350 IDAU is a hardwired address decode network, with no user configuration. Its address map is as follows:

Start (hex)	End (hex)	Contents	IDAU Attribute
00000000	000042ff	Arm boot	Exempt
00004300	00007dff	USB/RISC-V boot	Non-secure (instruction fetch), Exempt (load/store)
00007e00	00007ffff	Bootrom SGs	Secure and Non-secure-Callable
10000000	1fffffff	XIP	Non-secure
20000000	20081ffff	SRAM	Non-secure
40000000	4fffffff	APB	Exempt
50000000	5fffffff	AHB	Exempt
d0000000	dfffffff	SIO	Exempt

**Exempt** regions are not checked by the processor against its current security state. Effectively, the processor considers these regions Secure when the processor is in the Secure state, and Non-secure when the processor is in the Non-secure state.

Peripherals are marked Exempt because you're expected to assign them to security domains using the controls in ACCESSCTRL ([Section 10.6](#)). This approach avoids relying on SAU regions, which are too limited for meaningful peripheral assignment, and eliminates the need for separate Secure and Non-secure peripheral mirrors, which can cause programming errors.

The SIO is marked Exempt because it is internally banked over Secure and Non-secure based on the bus access's security attribute, which generally matches the processor's current security state.

As peripherals are Exempt, RP2350 forbids processor instruction fetch from peripherals, by physically disconnecting the bus. Processors fail to fetch instructions from peripherals even if the default MPU permissions are overridden to allow execute permission. Exempt regions permit both Secure and Non-secure access, and TrustZone-M forbids the combination of Non-secure-writable and Secure-executable, so this is a necessary restriction. The same consideration does not apply to the bootrom as the ROM is physically immutable.

The first part of the bootrom is Exempt, because it contains routines expected to be called by both Secure and Non-secure software in cases where it may not be desirable for Non-secure code to elevate through a Secure Gateway. An example of this is the bootrom `memcpy()` implementation. Code in the Exempt ROM region is hardened against return-oriented programming (ROP) attacks using the redundancy coprocessor's stack canary instructions.

After a certain watermark, which may vary depending on ROM revision, the ROM becomes IDAU-Non-secure for the purpose of instruction fetch. If a Non-secure SAU region is placed over the bootrom (which is expected to be the case

与非安全上下文。每个核心上的安全与非安全上下文可以相互通信，例如使用共享内存或安全/非安全SIO邮箱FIFO。如果核心对称使用（即共享的双核安全上下文和共享的双核非安全上下文），软件必须同步处理器SAU，以确保从一个核心非安全上下文可写的内存在另一个核心的安全上下文中不可执行。

支持与SAU相同区域形状和数量的DMA MPU，也必须与处理器SAU保持同步。

采用非对称的核心使用方式可能更为简便，将所有安全服务仅实现于一个核心。[FORCE\\_CORE\\_NS](#)寄存器可使所有核心1对系统总线的访问在安全结构和外设实施的安全筛选中，以及对于以安全/非安全方式划分的SIO寄存器组，均被视为非安全访问。

然而，这不影响PPB访问。这不影响核心1的内部状态，因此它仍可维持其自身的安全/非安全上下文。然而，系统硬件将所有核心1的访问视为非安全访问。

## 10.2.2. IDAU地址映射

Cortex-M33提供了一个实现定义的特征归属单元（IDAU）接口，允许系统实现者如Raspberry Pi Ltd扩展SAU所定义的安全归属映射。RP2350的IDAU为硬连线地址解码网络，不支持用户配置。其地址映射如下：

起始地址（十六进制）	结束地址（十六进制）	内容	IDAU属性
00000000	000042ff	Arm启动	豁免
00004300	00007dff	USB/RISC-V启动	非安全（指令抓取），豁免（加载/存储）
00007e00	00007ffff	Bootrom安全组	安全及非安全可调用
10000000	1fffffff	XIP	非安全
20000000	20081fff	SRAM	非安全
40000000	4fffffff	APB	豁免
50000000	5fffffff	AHB	豁免
d0000000	dfffffff	SIO	豁免

免检区域不会被处理器依据其当前安全状态进行检查。实际上，当处理器处于安全状态时，处理器将这些区域视为安全；而当处于非安全状态时，则视为非安全。

外设被标记为免检，因为您需要使用ACCESSCTRL（第10.6节）中的控制项将其分配到安全域。此方法避免依赖安全属性单元（SAU）区域，其范围过于有限，无法对外设进行有效分配，同时也消除了对独立的安全与非安全外设镜像的需求，防止了编程错误的发生。

SIO被标记为免检，因为其内部根据总线访问的安全属性在安全与非安全之间进行银行切换，该属性通常与处理器当前的安全状态对应。

鉴于外设为免检，RP2350通过物理断开总线，禁止处理器从外设处取指。即便覆盖默认MPU权限以允许执行，处理器仍无法从外设取指。免除区域允许安全和非安全访问，且TrustZone-M禁止非安全可写与安全可执行的组合，因此此限制为必要。对于bootrom，不适用相同考虑，因为只读存储器在物理上不可变更。

bootrom的第一部分为免除区域，因其包含预期由安全与非安全软件调用的例程，在某些情况下，非安全代码通过安全网关提升权限并不理想。例如bootrom `memcpy()`的实现。免除只读存储器区域内代码通过冗余协处理器的栈哨兵指令强化了对返回导向编程（ROP）攻击的防护能力。

在某一水位线之后，该水位线因只读存储器版本不同可能有所差异，仅用于指令取指目的，该只读存储器区域变为IDAU非安全区域。若非安全SAU区域覆盖bootrom（通常为在安全网关区域获得正确NSC属性），

in general, to get the correct NSC attribute on the Secure Gateway region), this part of the ROM becomes non-executable to Secure code. Consequently, this part of the bootrom is not ROP-hardened. This part of the ROM contains the NSBOOT (including USB boot) implementation, as well as a RISC-V Armv6-M emulator that can be used to emulate most of the bootrom on RISC-V processors. This region is only implemented on the instruction-side IDAU query: this is an implementation detail that improves timing on the load/store IDAU query, and does not have security implications (given the mask ROM is inherently unwritable) other than that the `tt` instruction will not be aware of this region.

The final 512 bytes of the bootrom has the **Secure, Non-secure-Callable** (NSC) attribute. This means it contains entry points for Non-secure calls into Secure code. Note that for this IDAU-defined attribute to take effect, the SAU-defined attribute for this range must also be NSC or lower. The recommended configuration is a single Non-secure SAU region covering the entirety of the bootrom. The bootrom exits into user code with the SAU enabled, and SAU region 7 active and covering the entirety of the bootrom.

XIP and SRAM are Non-secure in the IDAU, as they are expected to be divided using the SAU. When the SAU and IDAU differ, if the IDAU attribute is not Exempt, the processor takes whichever is greater out of the SAU and IDAU attribute, in the order Secure > Non-secure-Callable > Non-secure.

Addresses not listed in this table are not decoded by the system AHB crossbar, and will return bus faults if accessed. In these ranges, the ROM's IDAU map is mirrored every 32 kB up to `0x0fffffff`. The remaining addresses in the IDAU are Non-secure.

## 10.3. Overview (RISC-V)

The RP2350 bootrom does not implement secure boot for RISC-V processors. Secure flash boot can still be implemented on RISC-V by storing secure boot code in OTP and disabling other boot media via the `BOOT_FLAGS0` row in OTP. However, this is not supported natively by the RP2350 bootrom.

The RISC-V processors on RP2350 implement Machine and User execution modes, and the standard Physical Memory Protection unit (PMP), which can be used to enforce internal security or safety boundaries. See [Section 10.4](#).

Non-processor-specific hardware security features, such as debug disable OTP flags and the glitch detectors, are functionally identically between Arm and RISC-V. However, the redundancy coprocessor (RCP) is not accessible from the RISC-V processors, as it uses a Cortex-M33-specific coprocessor interface.

## 10.4. Processor security features (RISC-V)

The Hazard3 processors on RP2350 implement the following standard RISC-V security features:

- Machine and User execution modes (M-mode and U-mode)
- The Physical Memory Protection unit (PMP)

M-mode has full access to the processor's internal status registers, but U-mode does not. The processor's bus accesses are tagged with its current execution mode and filtered by ACCESSCTRL bus filters, as described in [Section 10.6.2](#).

The processor starts in M-mode, and enters M-mode upon taking any trap (exception or interrupt). It enters U-mode only by executing a return-from-M-mode instruction, `mret`, with previous privilege set to U-mode. This means all interrupts initially target M-mode, but can be de-privileged to U-mode via software routing. Because stacks are software-managed on RISC-V, software cooperation is required to fully separate the two execution contexts, though there are enough hardware hooks to make this possible. For more details about interrupts and exceptions on RISC-V, and how they relate to the core's privilege levels, see [Section 3.8.4](#).

The PMP is a memory protection unit built into each RISC-V processor that filters every instruction execution address and every load/store address against a list of permission regions. The Hazard3 instances on RP2350 are configured with 8 PMP regions each, with a 32-byte granule and naturally-aligned power-of-2 region support only.

Additionally, there are 3 PMP-hardwired regions, which set a default User-mode RW permission on peripherals and a

该只读存储器部分对安全代码变为不可执行。因此，该bootrom部分未进行ROP强化。该ROM部分包括NSBOOT（含USB启动）实现及可用于在RISC-V处理器上模拟绝大多数bootrom功能的RISC-V Armv6-M仿真器。该区域仅通过指令侧IDAU查询实现：此为一项实现细节，旨在提升加载/存储IDAU查询的时序性能，无安全影响（鉴于掩码只读存储器本质不可写）——且 `tt` 指令对该区域不予识别。

引导只读存储器的最后512字节具有**安全、非安全可调用(NSC)**属性。这意味着该区域包含从非安全态调用安全态代码的入口点。请注意，若要使该IDAU定义的属性生效，相应范围内的SAU定义属性亦必须为NSC或更低级别。推荐配置为使用单个非安全SAU区域覆盖整个引导只读存储器。引导只读存储器在启用SAU的情况下退出至用户代码，SAU区域 7已激活并覆盖整个引导只读存储器。

XIP与SRAM在IDAU中被定义为非安全区，因其预期使用SAU划分。当SAU与IDAU属性不一致时，如果IDAU属性非免除，则处理器将按照“安全 > 非安全可调用 > 非安全”的顺序选取两者中级别更高者。

本表未列地址不会被系统AHB交叉总线解码，访问时将触发总线故障。在这些范围内，只读存储器的IDAU映射每32 kB镜像一次，直到 `0x0地址fffffff`。IDAU中剩余的地址均为非安全地址。

### 10.3. 概述 (RISC-V)

RP2350的bootrom未针对RISC-V处理器实现安全启动。尽管可以通过将安全启动代码存储在OTP中，并通过OTP中的BO OT\_FLAGS0行禁用其他启动介质来实现基于RISC-V的安全闪存启动，但RP2350的bootrom本身并不支持此功能。

RP2350上的RISC-V处理器实现了机器模式和用户模式执行，以及标准的物理内存保护单元（PMP），可用于强制执行内部安全或安全边界。详见第10.4节。

非处理器特定的硬件安全功能，如调试禁用OTP标志和故障检测器，在Arm和RISC-V之间功能一致。然而，冗余协处理器（RCP）因使用基于Cortex-M33的协处理器接口，RISC-V处理器无法访问。

### 10.4. 处理器安全特性 (RISC-V)

RP2350上的Hazard3处理器实现了以下标准RISC-V安全特性：

- 机器执行模式和用户执行模式（M模式和U模式）
- 物理内存保护单元（PMP）

M模式拥有对处理器内部状态寄存器的完全访问权限，而U模式则没有。处理器的总线访问会根据当前执行模式进行标记，并通过ACCESSCTRL总线过滤器进行过滤，如第10.6.2节所述。

处理器以M模式启动，并在发生任何陷阱（异常或中断）时进入M模式。仅当执行返回M模式指令 `mret` 且先前权限级为U模式时，处理器才切换至U模式。这意味着所有中断最初均定位于M模式，但可通过软件路由降级至U模式。鉴于RISC-V中栈由软件管理，完全分离这两种执行上下文需要软件配合，尽管存在足够的硬件钩子以实现此目的。有关RISC-V中断和异常的详细信息及其与核心权限级别的关系，请参阅第3.8.4节。

PMP是内置于每个RISC-V处理器中的内存保护单元，用于对每条指令执行地址及每个加载/存储地址进行权限区域列表的过滤。RP2350上的Hazard3实例各配置有8个PMP区域，支持32字节粒度以及自然对齐的2的幂次方区域。

此外，还存在3个PMP硬连线区域，为外设设置默认的用户模式读写权限，

User-mode RWX permission on the ROM. These are assigned region numbers 8 through 10. Because lower-numbered regions always take precedence, any dynamically-configured region can override these hardwired regions.

There are many more peripherals than PMP regions. In typical use-cases, the programmer assigns these peripherals blanket U-mode RW permissions. Because hardwired regions are much cheaper than dynamically-configured regions, it was more efficient to use hardwired regions. These regions are included because the peripherals are expected to be assigned using ACCESSCTRL, rather than PMP. The hardwired regions play a similar role to the Exempt regions in the RP2350 Cortex-M IDAU.

Together with the ACCESSCTRL filters, these PMP regions are an effective mechanism for partitioning between addresses accessible from U-mode and addresses not accessible from U-mode. Hazard3 includes one custom PMP feature, the [PMPCFGM0](#) register, which allows the PMP to set **M-mode** permissions as well as U-mode without locking. This is useful for preventing accidental (but not deliberate) access to a memory region.

## 10.5. Secure boot enable procedure

To enable secure boot:

1. Program at least one public key fingerprint into OTP, starting at [BOOTKEY0\\_0](#).
2. Mark programmed keys as valid by programming [BOOT\\_FLAGS1.KEY\\_VALID](#).
3. Optionally, mark unused keys as invalid by programming [BOOT\\_FLAGS1.KEY\\_INVALID](#) – this is recommended to prevent a malicious actor installing their own boot keys at a later date.
  - o [KEY\\_INVALID](#) takes precedence over [KEY\\_VALID](#), which prevents more keys from being added later.
  - o Program [KEY\\_INVALID](#) with additional bits to revoke keys at a later time.
4. Disable debugging by programming [CRIT1.DEBUG\\_DISABLE](#), [CRIT1.SECURE\\_DEBUG\\_DISABLE](#), or installing a debug key ([Section 3.5.9.2](#)).
5. Optionally, enable the glitch detector ([Section 10.9](#)) by programming [CRIT1.GLITCH\\_DETECTOR\\_ENABLE](#) and setting the desired sensitivity in [CRIT1.GLITCH\\_DETECTOR\\_SENS](#).
6. Disable unused boot options such as USB and UART boot in [BOOT\\_FLAGS0](#).
7. Enable secure boot, by programming [CRIT1.SECURE\\_BOOT\\_ENABLE](#).

### WARNING

*This procedure is irreversible.* Before programming, ensure that you are using the correct public key, correctly hashed. [picotool](#) supports programming keys into OTP from standard PEM files, performing the fingerprint hashing automatically. Programming the wrong key will make it impossible to run code on your device.

## 10.6. Access control

The access control registers (ACCESSCTRL) define permissions required to access GPIOs and bus endpoints such as peripherals and memory devices.

For each bus endpoint (for example, [PIO0](#)), a bus access control register such as [PIO0](#) controls which AHB5 managers can access it, and at which bus security levels. This register has further implications, such as access to the [RESETS](#) controls for that block. For a full explanation of the bus access control registers, see [Section 10.6.2](#).

For each GPIO, including the QSPI and USB DP/DM pins, a bit in the [GPIO\\_NSmask0](#) and [GPIO\\_NSmask1](#) register can be set to make that GPIO accessible to both the Secure and Non-secure domains, or clear to make it Secure-only. This has system-wide implications, controlling:

- GPIO visibility to the Non-secure SIO

并为只读存储器设置用户模式可读写执行（RWX）权限。这些区域编号为 8 至 10。由于编号较低的区域始终优先，任何动态配置的区域均可覆盖这些硬连线区域。

外设数量远远多于 PMP 区域数量。在典型使用场景中，程序员通常赋予这些外设统一的用户模式读写权限。由于硬连线区域成本远低于动态配置区域，使用硬连线区域更为高效。包含这些区域的原因是外设预期通过 ACCESSCTRL 进行权限分配，而非通过 PMP。硬连线区域的作用类似于 RP2350 Cortex-M IDAU 中的豁免区域。

结合ACCESSCTRL过滤器，这些PMP区域是区分U模式可访问地址与U模式不可访问地址的有效机制。Hazard3包含一项定制PMP功能，即PMPCFGM0寄存器，允许PMP设置 M模式权限及U模式权限，且无需锁定。

此功能对于防止对内存区域的意外（而非故意）访问十分有效。

## 10.5. 安全启动启用流程

启用安全启动：

1. 至少将一个公钥指纹写入OTP，起始地址为BOOTKEY0\_0。
2. 通过写入BOOT\_FLAGS1.KEY\_VALID将已写入的密钥标记为有效。
3. 可选地，建议通过写入BOOT\_FLAGS1.KEY\_INVALID将未使用的密钥标记为无效，以防止恶意行为者日后安装自有启动密钥。
  - KEY\_INVALID 优先于 KEY\_VALID，防止后续添加更多密钥。
  - 通过写入带有额外位的KEY\_INVALID，以便未来撤销密钥。
4. 通过写入CRIT1.DEBUG\_DISABLE、CRIT1.SECURE\_DEBUG\_DISABLE或安装调试密钥（参见第3.5.9.2节）来禁用调试功能。
5. 可选地，通过编程CRIT1.GLITCH\_DETECTOR\_ENABLE并在CRIT1.GLITCH\_DETECTOR\_SENS中设置所需灵敏度，以启用故障检测器（第10.9节）。
6. 在BOOT\_FLAGS0中禁用未使用的启动选项，如USB启动和UART启动。
7. 通过编程CRIT1.SECURE\_BOOT\_ENABLE启用安全启动功能。

### ● 警告

该操作不可逆。编程前，请确保使用正确且已正确哈希的公钥。[picotool](#)支持从标准PEM文件将密钥编程至OTP，并自动执行指纹哈希处理。编程错误的密钥将导致设备无法运行代码。

## 10.6. 访问控制

访问控制寄存器（ACCESSCTRL）定义访问GPIO及总线端点（如外设和存储设备）所需的权限。

对于每个总线端点（例如 [PIO0](#)），总线访问控制寄存器（如PIO0）控制哪些AHB5管理器可访问该端点及其访问的总线安全级别。该寄存器还涉及对该模块 [RESETS](#) 控制的访问权限。有关总线访问控制寄存器的完整说明，请参见第10.6.2节。

对于每个GPIO，包括QSPI和USB DP/DM引脚，GPIO\_NSmask0和GPIO\_NSmask1寄存器中的位可被设置，使该GPIO对安全域和非安全域均可访问，或清零使其仅对安全域可访问。这具有系统范围的影响，控制：

- 非安全SIO对GPIO的可见性

- Non-secure code access to that GPIO's IO muxing and pad control registers
- GPIO selection access to peripherals accessible only via Secure bus access

ACCESSCTRL registers are always fully readable by the processors in any security or privilege state, so that Non-secure software can enumerate the hardware it is allowed to access. However, writes to ACCESSCTRL are strictly controlled. Unprivileged writes, and writes from the DMA, return a bus fault. Writes from a Non-secure, Privileged ([NSP](#)) context are generally ignored, with the sole exception of the Non-secure, Unprivileged ([NSU](#)) bits in bus access control registers. The [NSU](#) bits are Non-secure-writable if and only if the [NSP](#) bit is set.

Writes can be further locked down using the [LOCK](#) register. This causes writes from specific managers to be ignored.

For a full list of effects, see [Section 10.6.1](#).

To reduce the risk of accidental writes, all ACCESSCTRL registers, except [GPIO\\_NSMASK0](#) and [GPIO\\_NSMASK1](#), require the 16-bit value [0xacce](#) to be present in the most-significant 16 bits of the write data. To achieve this, OR the value [0xacce0000](#) with your write data. Atomic SET/CLR/XOR alias writes must also include this value. DMA writes are also forbidden, to avoid accidentally wiping permissions with a misconfigured DMA channel.

### **! IMPORTANT**

Writes with the upper 16 bits not equal to [0xacce](#) both fail and *return a bus fault* (instead of silently leaving the permissions unchanged).

Finally, the [FORCE\\_CORE\\_NS](#) register makes core 1's bus accesses appear to be Non-secure at system level. This supports schemes where all Secure services run on core 0, and therefore core 1 should not be able to access Secure hardware.

## 10.6.1. GPIO access control

The GPIO Non-secure access mask registers, [GPIO\\_NSMASK0](#) and [GPIO\\_NSMASK1](#), contain one bit per GPIO. The layout of these two registers matches the layout of the SIO GPIO registers ([Section 3.1.3](#)), including the positions of the QSPI and USB DM/DP bits. Each GPIO is accessible to Non-secure software if and only if the relevant [GPIO\\_NSMASK](#) bit is set. This prevents Non-secure software from interfering with or observing GPIOs used by Secure software.

All system-level GPIO controls, such as the IO and pad control registers, are shared by Secure and Non-secure code. However, access to these registers is filtered on a GPIO-by-GPIO basis according to the [GPIO\\_NSMASK](#) registers. This means that the same code can run unmodified in either a Secure or Non-secure context, and Secure software does not have to implement any interfaces for Non-secure GPIO access, provided that the appropriate GPIO security mask has been configured.

Setting a [GPIO\\_NSMASK](#) bit has the following effects on the corresponding GPIO:

- The relevant SIO GPIO register bit ([Section 3.1.3](#)) becomes accessible through bus access to the Non-secure SIO.
  - Otherwise the bit is read-only zero.
- The relevant SIO GPIO register bit becomes accessible to Non-secure code using GPIO coprocessor instructions ([Section 3.6.1](#)).
  - Otherwise the bit is read-only zero.
  - Non-secure code may execute GPIO coprocessor instructions if and only if coprocessor [0](#) is granted to Non-secure in [NSACR](#), and enabled in the Non-secure PPB instance of the [CPACR](#) register.
- The relevant IO control register ([Section 9.11.1](#) or [Section 9.11.2](#)) becomes accessible to Non-secure code.
  - Otherwise it is read-only zero.
- GPIO functions for Secure-only peripherals can not be selected on this GPIO
  - Attempting to select such a peripheral will select the null function ([0x1f](#)) instead

- 非安全代码对该GPIO的IO复用和引脚控制寄存器的访问
- 通过仅限安全总线访问的外设对GPIO的选择性访问权限

ACCESSCTRL寄存器始终可由任何安全或特权状态下的处理器完全读取，以便非安全软件能够枚举其被授权访问的硬件。然而，对ACCESSCTRL的写入受到严格限制。

非特权写入及来自DMA的写入将导致总线错误。来自非安全、特权（NSP）上下文的写入通常被忽略，唯一例外是总线访问控制寄存器中非安全、非特权（NSU）位的写入。仅当NSP位被设置时，NSU位才为非安全可写。

写操作可通过LOCK寄存器进一步锁定。此操作会导致特定管理器的写入被忽略。

详见第10.6.1节中的完整影响列表。

为降低意外写入风险，除GPIO\_NSMASK0和GPIO\_NSMASK1外，所有ACCESSCTRL寄存器的写入数据最高16位必须包含16位值0xacce。为此，应将值0xacce0000与写入数据执行按位或（OR）操作。原子SET/CLR/XOR别名写入同样必须携带该值。DMA写入被禁止，以避免配置错误的DMA通道意外清除权限。

### ！重要

当写入数据最高16位不等于0xacce时，写入操作将失败且返回总线错误（而非静默保持权限不变）。

最后，FORCE\_CORE\_NS寄存器使核心1的总线访问在系统级别表现为非安全访问。此方案支持所有安全服务运行于核心0，因此核心1不应能够访问安全硬件。

## 10.6.1. GPIO访问控制

GPIO非安全访问掩码寄存器GPIO\_NSmask0和GPIO\_NSmask1包含每个GPIO对应的一位。这两个寄存器的布局与SIO GPIO寄存器（第3.1.3节）布局一致，包括QSPI及USB DM/DP位的位置。当且仅当相关的GPIO\_NSmask位被设置时，非安全软件才能访问对应的GPIO。此举防止非安全软件干扰或监视安全软件使用的GPIO。

所有系统级GPIO控制寄存器，如IO和垫控制寄存器，均为安全及非安全代码共享。

但对这些寄存器的访问根据GPIO\_NSmask寄存器逐GPIO进行过滤。这意味着相同代码可在安全或非安全上下文中无需修改地运行，且只要已配置相应的GPIO安全掩码，安全软件无需为非安全GPIO访问实现任何接口。

设置GPIO\_NSmask位会对对应的GPIO产生以下影响：

- 相关SIO GPIO寄存器位（第3.1.3节）可通过对非安全SIO的总线访问进行访问。
  - 否则该位为只读零。
- 相关SIO GPIO寄存器位通过GPIO协处理器指令（第3.6.1节）对非安全代码开放访问权限。（第3.6.1节）。
  - 否则该位为只读零。
  - 非安全代码仅在NSACR中授予非安全权限访问协处理器0且在CPACR寄存器的非安全PPB实例中启用时，才能执行GPIO协处理器指令。
- 相关IO控制寄存器（第9.11.1节或第9.11.2节）对非安全代码开放访问权限。
  - 否则其为只读零。
- 该GPIO无法选择仅限安全外设的GPIO功能。
  - 试图选择此类外设时，将选择空功能（0x1f）替代。

- If a Secure-only peripheral is selected at the time that this GPIO is made Non-secure-accessible, then the selection will be changed to the null function.
- The relevant pad control register ([Section 9.11.3](#) or [Section 9.11.4](#)) becomes accessible to Non-secure code.
  - Otherwise it is read-only zero.
- Interrupts for this GPIO are routed to the Non-secure GPIO interrupts, `IO_IRQ_BANK0_NS` and `IO_IRQ_QSPI_NS`, rather than the default Secure interrupts, `IO_IRQ_BANK0` and `IO_IRQ_QSPI`. (See [Section 3.2](#) for the system IRQ listing.)
- The relevant GPIO interrupt control and status bits, e.g. `PROCO_INTS0`, become accessible to Non-secure code.
  - Otherwise they are read-only zero.
- The GPIO can be read by PIO instances which are Non-secure-accessible.
  - Otherwise it reads as zero.
  - Like the SIO, PIO can observe GPIOs even when not function-selected, so additional logic masks Secure-only GPIOs from Non-secure-accessible PIO instances

**i NOTE**

Due to [RP2350-E3](#), on RP2350A (QFN-60), access to the `PADS_BANK0` registers is controlled by the wrong bits of `GPIO_NSMASK`. On QFN-60 you must disable Non-secure access to the pads registers, and implement a software interface for Non-secure code to manipulate its assigned PADS registers.

### 10.6.2. Bus access control

The bus access control registers define which combinations of Secure/Non-secure and Privileged/Unprivileged are permitted to access each downstream bus port. This mechanism also assigns peripherals to security domains. Additionally, the bus access control registers define which upstream sources (processor 0/1, DMA or debugger) are permitted.

Hardware filters on the system bus ([Section 2.1](#)) check each access against the permission list for its destination. The filter shoots down accesses which do not meet the criteria specified in ACCESSCTRL register for that destination; the access does not reach its destination, and instead a bus error is returned directly from the bus fabric. There is no effect on the destination register, and no data is returned. Bus errors result in an exception on the offending processor, or an error flag raised on the offending DMA channel.

There are 8 bits in each register (for example the `ADC` register). The `SP`, `SU`, `NSP` and `NSU` bits correspond to the processor security state from which a bus transfer originated, or the security level of the originating DMA channel:

- The `SP` bit allows access from:
  - Privileged software running in the Secure domain on an Arm processor
  - Machine-mode software on a RISC-V processor
  - A DMA channel with a security level of `SP` (3)
- The `SU` bit must be set, in addition to the `SP` bit, to allow access from:
  - User (unprivileged) software running in the Secure domain on an Arm processor
  - A DMA channel with a security level of `SU` (2)
- The `NSP` bit allow access from:
  - Privileged software running in the Non-secure domain on an Arm processor
  - Privileged Arm software running in the Secure domain on core 1, when `FORCE_CORE_NS.CORE1` is set
  - Machine-mode RISC-V software running on core 1, when `FORCE_CORE_NS.CORE1` is set
  - A DMA channel with a security level of `NSP` (1)

- 如果在将该GPIO设置为非安全访问时选择了仅安全外设，则该选择将被更改为空功能。
- 相关引脚控制寄存器（第9.11.3节或第9.11.4节）变为非安全代码可访问。
  - 否则其为只读零。
- 该GPIO的中断将路由至非安全GPIO中断IO\_IRQ\_BANK0\_NS和IO\_IRQ\_QSPI\_NS，而非默认的安全中断IO\_IRQ\_BANK0和IO\_IRQ\_QSPI。（系统IRQ列表详见第3.2节。）
- 相关GPIO中断控制和状态位，例如PROC0\_INTS0，变为非安全代码可访问。
  - 否则，其值为只读零。
- 该GPIO可被非安全访问的PIO实例读取。
  - 否则，读取值为零。
  - 类似于SIO，PIO即使未选择功能，仍可监视GPIO，因此附加逻辑会将仅安全GPIO掩码至非安全访问的PIO实例。

**i 注意**

由于RP2350-E3，在RP2350A（QFN-60）上，访问 PADS\_BANK0 寄存器由GPIO\_NSMASK 中的错误位控制。在QFN-60封装上，必须禁用对PADS寄存器的非安全访问，并为非安全代码实现一个软件接口，以操作其分配的PADS寄存器。

### 10.6.2. 总线访问控制

总线访问控制寄存器定义了允许何种安全/非安全与特权/非特权组合访问每个下游总线端口。该机制还将外设分配到安全域。

此外，总线访问控制寄存器定义了允许哪些上游来源（处理器0/1、DMA或调试器）访问。

系统总线上的硬件过滤器（第2.1节）会针对每次访问检查其目标对应的权限列表。过滤器会阻止不符合该目标ACCESSC\_TRL寄存器中规定条件的访问；访问无法达到其目标，总线结构将直接返回总线错误。对目标寄存器无影响，且不返回任何数据。总线错误会导致违规处理器产生异常，或在违规的DMA通道上置位错误标志。

每个寄存器包含8位（例如ADC寄存器）。SP、SU、NSP和NSU位对应于发起总线传输的处理器安全状态或发起DMA通道的安全级别：

- SP位允许以下对象访问：
  - 运行于Arm处理器安全域内的特权软件
  - 运行于RISC-V处理器上的机器模式软件
  - 安全级别为 SP (3) 的DMA通道
- 必须设置 SU位且 SP位已设置，方可允许以下对象访问：
  - 运行于Arm处理器安全域内的用户（非特权）软件
  - 安全级别为 SU (2) 的DMA通道
- NSP位允许以下对象访问：
  - 运行于Arm处理器非安全域内的特权软件
  - 当设置FORCE\_CORE\_NS.CORE1时，运行于核心1安全域内的特权Arm软件
  - 当设置FORCE\_CORE\_NS.CORE1时，运行于核心1的机器模式RISC-V软件
  - 安全级别为 NSP (1) 的DMA通道

- The **NSU** bit must be set, in addition to the **NSP** bit, to allow access from:
  - User (unprivileged) software running in the Non-secure domain on an Arm processor
  - User (unprivileged) Arm software running on core 1 when **FORCE\_CORE\_NS.CORE1** is set
  - User-mode software on a RISC-V processor
  - A DMA channel with a security level of **NSU** (0)

**NOTE**

The security/privilege of AHB Mem-AP accesses are configurable, and have the same bus security/privilege level as load/stores from the corresponding security/privilege context on that processor. There is one AHB Mem-AP for each Arm processor.

**NOTE**

RISC-V Debug-mode memory accesses have the same bus security/privilege level as Machine-mode software running on that processor, and RISC-V System Bus Access through the Debug Module has the same bus security/privilege level as Machine-mode software running on core 1.

The **DBG**, **DMA**, **CORE1** and **CORE0** bits must be set in addition to the relevant security/privilege bits, in order to allow access from a particular bus manager. The **DBG** bit corresponds to any of:

- Accesses from either Arm processor's AHB Mem-AP
- Accesses from either RISC-V core in Debug mode
- Accesses from RISC-V System Bus Access

Separating debug access controls from software-driven processor access means that, even with software locked out of a register block, the developer may still be able to access that block from the debugger.

Most bus access permission bits are Secure, Privileged-writable only. The sole exception is the **NSU** bit, which is also writable from a Non-secure, Privileged context if and only if the **NSP** bit in the same register is set. The intention is that once the Secure domain has granted Non-secure access, it is then up to Non-secure software to decide whether to grant Unprivileged access within the Non-secure domain.

### 10.6.2.1. Default permissions

Most bus endpoints default to Secure access only, from any master, but there are exceptions. The following default to fully open access (any combination of security/privilege) from any master (for example, because they are expected to be divided up by the processors' internal memory protection hardware):

- Boot ROM ([Section 4.1](#))
- XIP ([Section 4.4](#))
- SRAM ([Section 4.2](#))
- SYSINFO ([Section 12.15.1](#))

The following default to Secure, Privileged access (**SP**) only, from any manager:

- XIP\_AUX (DMA FIFOs) ([Section 4.4.3](#))
- SHA-256 ([Section 12.13](#))

The following default to Secure, Privileged access (**SP**) only, with DMA access forbidden by default:

- POWMAN ([Chapter 6](#)), which includes power management and voltage regulator control registers
- True random number generator ([Section 12.12](#))

- 必须设置 **NSP**位和 **NSU**位，方可允许以下访问：
  - 运行于Arm处理器非安全域的用户（非特权）软件
  - 当设置**FORCE\_CORE\_NS.CORE1**时，运行于核心1的用户（非特权）Arm软件
  - 运行于RISC-V处理器上的用户模式软件
  - 安全级别为 **NSU** (0) 的DMA通道

**注意**

AHB Mem-AP访问的安全性及特权级别可配置，其总线安全性及特权级别与对应处理器中相应安全/特权上下文的加载/存储操作相同。每个Arm处理器配置有一个AHB Mem-AP。

**注意**

RISC-V调试模式的内存访问，其总线安全性及特权级别与运行于该处理器的机器模式软件相同；通过调试模块进行的RISC-V系统总线访问，其总线安全性及特权级别与运行于核心1的机器模式软件相同。

必须在相关安全/特权位之外，额外设置**DBG**、**DMA**、**CORE1**和**CORE0**位，方可允许特定总线管理器的访问。**DBG**位对应以下任一情况：

- 来自任一Arm处理器的AHB Mem-AP的访问
- 处于调试模式的任一RISC-V核心的访问
- 来自RISC-V系统总线的访问

将调试访问控制与软件驱动的处理器访问分离意味着，即使软件被锁定无法访问寄存器块，开发者仍可通过调试器访问该寄存器块。

大多数总线访问权限位均为安全、仅特权可写。唯一例外为**NSU**位，仅当同一寄存器中的**NSP**位被设置时，非安全特权上下文亦可写入该位。其目的在于，一旦安全域授予非安全访问权后，由非安全软件决定是否在非安全域内授予非特权访问。

### 10.6.2.1. 默认权限

大多数总线端点默认只允许来自任何主控设备的安全访问，但存在例外。以下端点默认对任何主控设备完全开放访问（任意安全级别与权限组合）（例如，因为它们预期由处理器的内部存储保护硬件进行划分）：

- 启动只读存储器（第4.1节）
- XIP（第4.4节）
- SRAM（第4.2节）
- 系统信息（SYSINFO，第12.15.1节）

以下端点默认只允许来自任何管理者的安全且特权访问（**SP**）：

- XIP\_AUX（DMA FIFO）（第4.4.3节）
- SHA-256（第12.13节）

以下端点默认只允许安全且特权访问（**SP**），且默认禁止DMA访问：

- 电源管理器（POWMAN，第6章），包括电源管理及电压调节器控制寄存器
- 真正随机数生成器（第12.12节）

- Clock control registers ([Section 8.1](#))
- XOSC ([Section 8.2](#))
- ROSC ([Section 8.3](#))
- SYSCFG ([Section 12.15.2](#))
- PLLs ([Section 8.6](#))
- Tick generators ([Section 8.5](#))
- Watchdog ([Section 12.9](#))
- PSM ([Section 7.4](#))
- XIP control registers ([Section 4.4.5](#))
- QMI ([Section 12.14](#))
- CoreSight trace DMA FIFO
- CoreSight self-hosted debug window

Any bus endpoint not in any of the above lists defaults to Secure access only, from any manager,

#### 10.6.2.2. Other effects of bus permissions

To avoid contradictory configurations such as a Secure-only peripheral being selected on a Non-secure-accessible GPIO, and to improve portability between Secure and Non-secure software, the bus access permission lists propagate to certain other system-level hardware:

- The reset controls for a given peripheral in the RESETS block ([Section 7.5](#)) are Non-secure-accessible if and only if the peripheral itself is Non-secure-accessible.
  - Non-secure access to the RESETS block itself must also be granted via the **RESETS** bus access register.
- Non-secure-inaccessible peripherals cannot be function-selected on Non-secure-accessible GPIOs. Attempting to do so selects the null GPIO function (`0x1f`).
- PIO blocks which are accessible to Non-secure, and those which are not, can not perform cross-PIO operations such as observing each other's interrupt flags.
- PIO blocks which are accessible to Non-secure can not read Secure-only GPIOs.
- DMA channels below the least-set effective permission bit (ignoring **SU** when **SP** is clear, and ignoring **NSU** when **NSP** is clear) are disconnected from that peripheral's DREQ signals.

#### 10.6.2.3. Blocks without bus access control

There are four memory-mapped blocks which do not have bus access control registers in ACCESSCTRL:

- The Cortex-M PPB is internal to the processors, and is banked internally over Secure/Non-secure.
- The SIO is also banked internally over Secure/Non-secure access.
- ACCESSCTRL itself is always world-readable and has its own internal filtering for writes.
- Boot RAM is hardwired for Secure access only.

### 10.6.3. List of registers

The ACCESSCTRL registers start at a base address of `0x40060000` (defined as **ACCESSCTRL\_BASE** in the SDK).

- 时钟控制寄存器（第8.1节）
- XOSC（第8.2节）
- ROSC（第8.3节）
- SYSCFG（第12.15.2节）
- 锁相环（第8.6节）
- 时钟发生器（第8.5节）
- 看门狗（第12.9节）
- PSM（第7.4节）
- XIP控制寄存器（第4.4.5节）
- QMI（第12.14节）
- CoreSight 追踪 DMA FIFO
- CoreSight自托管调试窗口

任何未包含于上述列表的总线端点，默认仅允许安全访问，且可被任何管理器访问。

### 10.6.2.2 总线权限的其他影响

为避免诸如在非安全可访问GPIO上选择安全专用外设等矛盾配置，并提升安全与非安全软件间的可移植性，总线访问权限列表会传播至某些其他系统级硬件：

- RESETS模块（第7.5节）中某外设的复位控制仅当该外设自身为非安全可访问时，才为非安全可访问。
  - 非安全访问RESETS块本身也必须通过RESETS总线访问寄存器进行授权。
- 非安全不可访问的外设不能在非安全可访问的GPIO上选择功能。尝试这样操作将选择无效GPIO功能（`0x1f`）。
- 对非安全可访问和非安全不可访问的PIO块，均无法执行跨PIO操作，例如监测彼此的中断标志。
- 非安全可访问的PIO块无法读取仅限安全的GPIO。
- DMA通道低于最小已设有效权限位（`SP`置0时忽略 `SU`，`NSP`置0时忽略 `NSU`）将与该外设的DREQ信号断开。

### 10.6.2.3. 无总线访问控制的模块

ACCESSCTRL中有四个内存映射模块没有总线访问控制寄存器：

- Cortex-M的PPB为处理器内部组件，在安全/非安全域间内部切换共享。
- SIO内部通过安全/非安全访问方式实现银行切换。
- ACCESSCTRL始终为全局可读，并具备自身的内部写入过滤机制。
- 启动只读存储器仅支持安全访问且为硬连线连接。

### 10.6.3. 寄存器列表

ACCESSCTRL寄存器起始于基地址 `0x40060000`（SDK中定义为ACCESSCTRL\_BASE）。

Table 911. List of  
ACCESSCTRL  
registers

Offset	Name	Info
0x00	LOCK	<p>Once a LOCK bit is written to 1, ACCESSCTRL silently ignores writes from that master. LOCK is writable only by a Secure, Privileged processor or debugger.</p> <p>LOCK bits are only writable when their value is zero. Once set, they can never be cleared, except by a full reset of ACCESSCTRL.</p> <p>Setting the LOCK bit does not affect whether an access raises a bus error. Unprivileged writes, or writes from the DMA, will continue to raise bus errors. All other accesses will continue not to.</p>
0x04	FORCE_CORE_NS	<p>Force core 1's bus accesses to always be Non-secure, no matter the core's internal state.</p> <p>Useful for schemes where one core is designated as the Non-secure core, since some peripherals may filter individual registers internally based on security state but not on master ID.</p>
0x08	CFGRESET	<p>Write 1 to reset all ACCESSCTRL configuration, except for the LOCK and FORCE_CORE_NS registers.</p> <p>This bit is used in the RP2350 bootrom to quickly restore ACCESSCTRL to a known state during the boot path.</p> <p>Note that, like all registers in ACCESSCTRL, this register is not writable when the writer's corresponding LOCK bit is set, therefore a master which has been locked out of ACCESSCTRL can not use the CFGRESET register to disturb its contents.</p>
0x0c	GPIO_NSMASK0	<p>Control whether GPIO0...31 are accessible to Non-secure code. Writable only by a Secure, Privileged processor or debugger.</p> <p>0 → Secure access only</p> <p>1 → Secure + Non-secure access</p>
0x10	GPIO_NSMASK1	Control whether GPIO32..47 are accessible to Non-secure code, and whether QSPI and USB bitbang are accessible through the Non-secure SIO. Writable only by a Secure, Privileged processor or debugger.
0x14	ROM	Control access to ROM. Defaults to fully open access.
0x18	XIP_MAIN	Control access to XIP_MAIN. Defaults to fully open access.
0x1c	SRAM0	Control access to SRAM0. Defaults to fully open access.
0x20	SRAM1	Control access to SRAM1. Defaults to fully open access.
0x24	SRAM2	Control access to SRAM2. Defaults to fully open access.
0x28	SRAM3	Control access to SRAM3. Defaults to fully open access.
0x2c	SRAM4	Control access to SRAM4. Defaults to fully open access.
0x30	SRAM5	Control access to SRAM5. Defaults to fully open access.
0x34	SRAM6	Control access to SRAM6. Defaults to fully open access.
0x38	SRAM7	Control access to SRAM7. Defaults to fully open access.

表911。ACCES SCTRL 寄存器列表

偏移量	名称	说明
0x00	LOCK	<p>一旦LOCK位被写入1，ACCESSCTRL将静默忽略该主控的写入操作。LOCK仅可由安全的特权处理器或调试器写入。</p> <p>LOCK位仅当其值为零时方可写入。一旦设置，除非对ACCES SCTRL进行完全复位，否则LOCK位不可清除。</p> <p>设置LOCK位不会影响访问是否引发总线错误。非特权写入或DMA写入仍将引发总线错误。所有其他访问则继续不引发总线错误。</p>
0x04	FORCE_CORE_NS	<p>无论核心内部状态如何，强制核心1的总线访问始终为非安全访问。</p> <p>适用于将一核心指定为非安全核心的方案，因某些外围设备可能基于安全状态而非主控ID内部筛选单个寄存器。</p>
0x08	CFGRESET	<p>写入1以重置所有ACCESSCTRL配置，但不包括LOCK和FORC E_CORE_NS寄存器。</p> <p>该位用于RP2350只读存储器启动程序中，在启动过程中快速将ACCESSCTRL恢复至已知状态。</p> <p>请注意，与ACCESSCTRL中所有寄存器一样，当写入者对应的LOCK位被设置时，本寄存器不可写，因此，已被LOCK位锁定、无法访问ACCESSCTRL的主控不能使用CFGRESET寄存器更改内容。</p>
0x0c	GPIO_NSMASK0	<p>控制GPIO0...31是否允许非安全代码访问。</p> <p>仅允许安全、特权处理器或调试器写入。</p> <p>0 → 仅限安全访问</p> <p>1 → 安全与非安全访问</p>
0x10	GPIO_NSMASK1	控制GPIO32..47是否允许非安全代码访问，以及是否允许通过非安全SIO访问QSPI和USB位操作。仅允许安全、特权处理器或调试器写入。
0x14	只读存储器	控制只读存储器的访问权限。默认设置为完全开放访问。
0x18	XIP_MAIN	控制XIP_MAIN的访问权限。默认设置为完全开放访问。
0x1c	SRAM0	控制SRAM0的访问权限。默认设置为完全开放访问。
0x20	SRAM1	控制SRAM1的访问权限。默认设置为完全开放访问。
0x24	SRAM2	控制SRAM2的访问权限。默认设置为完全开放访问。
0x28	SRAM3	控制SRAM3的访问权限。默认设置为完全开放访问。
0x2c	SRAM4	控制SRAM4的访问权限。默认设置为完全开放访问。
0x30	SRAM5	控制SRAM5的访问权限。默认设置为完全开放访问。
0x34	SRAM6	控制SRAM6的访问权限。默认设置为完全开放访问。
0x38	SRAM7	控制SRAM7的访问权限。默认设置为完全开放访问。

Offset	Name	Info
0x3c	SRAM8	Control access to SRAM8. Defaults to fully open access.
0x40	SRAM9	Control access to SRAM9. Defaults to fully open access.
0x44	DMA	Control access to DMA. Defaults to Secure access from any master.
0x48	USBCTRL	Control access to USBCTRL. Defaults to Secure access from any master.
0x4c	PIO0	Control access to PIO0. Defaults to Secure access from any master.
0x50	PIO1	Control access to PIO1. Defaults to Secure access from any master.
0x54	PIO2	Control access to PIO2. Defaults to Secure access from any master.
0x58	CORESIGHT_TRACE	Control access to CORESIGHT_TRACE. Defaults to Secure, Privileged processor or debug access only.
0x5c	CORESIGHT_PERIPH	Control access to CORESIGHT_PERIPH. Defaults to Secure, Privileged processor or debug access only.
0x60	SYSINFO	Control access to SYSINFO. Defaults to fully open access.
0x64	RESETS	Control access to RESETS. Defaults to Secure access from any master.
0x68	IO_BANK0	Control access to IO_BANK0. Defaults to Secure access from any master.
0x6c	IO_BANK1	Control access to IO_BANK1. Defaults to Secure access from any master.
0x70	PADS_BANK0	Control access to PADS_BANK0. Defaults to Secure access from any master.
0x74	PADS_QSPI	Control access to PADS_QSPI. Defaults to Secure access from any master.
0x78	BUSCTRL	Control access to BUSCTRL. Defaults to Secure access from any master.
0x7c	ADC	Control access to ADC. Defaults to Secure access from any master.
0x80	HSTX	Control access to HSTX. Defaults to Secure access from any master.
0x84	I2C0	Control access to I2C0. Defaults to Secure access from any master.
0x88	I2C1	Control access to I2C1. Defaults to Secure access from any master.
0x8c	PWM	Control access to PWM. Defaults to Secure access from any master.
0x90	SPI0	Control access to SPI0. Defaults to Secure access from any master.
0x94	SPI1	Control access to SPI1. Defaults to Secure access from any master.

偏移量	名称	说明
0x3c	SRAM8	控制SRAM8的访问权限。默认设置为完全开放访问。
0x40	SRAM9	控制SRAM9的访问权限。默认设置为完全开放访问。
0x44	DMA	控制DMA的访问权限。默认允许任何主设备进行安全访问。
0x48	USBCTRL	控制USBCTRL的访问权限。默认允许任何主设备进行安全访问。
0x4c	PIO0	控制PIO0的访问权限。默认允许任何主设备进行安全访问。
0x50	PIO1	控制PIO1的访问权限。默认允许任何主设备进行安全访问。
0x54	PIO2	控制对PIO2的访问。默认为任何主设备的安全访问。
0x58	CORESIGHT_TRACE	控制对CORESIGHT_TRACE的访问。默认为仅限安全特权处理器或调试访问。
0x5c	CORESIGHT_PERIPH	控制对CORESIGHT_PERIPH的访问。默认为仅限安全特权处理器或调试访问。
0x60	SYSINFO	控制对SYSINFO的访问。默认完全开放访问。
0x64	复位	控制对RESETS的访问。默认为任何主设备的安全访问。
0x68	IO_BANK0	控制对IO_BANK0的访问。默认为任何主设备的安全访问。
0x6c	IO_BANK1	控制对IO_BANK1的访问。默认为任何主设备的安全访问。
0x70	PADS_BANK0	控制对PADS_BANK0的访问。默认为任何主设备的安全访问。
0x74	PADS_QSPI	控制对PADS_QSPI的访问。默认为任何主设备的安全访问。
0x78	BUSCTRL	控制对BUSCTRL的访问。默认为任何主设备的安全访问。
0x7c	ADC	控制对ADC的访问。默认为任何主设备的安全访问。
0x80	HSTX	控制对HSTX的访问。默认为任何主设备的安全访问。
0x84	I2C0	控制对I2C0的访问。默认为任何主设备的安全访问。
0x88	I2C1	控制对I2C1的访问， 默认为任何主控的安全访问。
0x8c	PWM	控制对PWM的访问， 默认为任何主控的安全访问。
0x90	SPI0	控制对SPI0的访问， 默认为任何主控的安全访问。
0x94	SPI1	控制对SPI1的访问， 默认为任何主控的安全访问。

Offset	Name	Info
0x98	TIMER0	Control access to TIMER0. Defaults to Secure access from any master.
0x9c	TIMER1	Control access to TIMER1. Defaults to Secure access from any master.
0xa0	UART0	Control access to UART0. Defaults to Secure access from any master.
0xa4	UART1	Control access to UART1. Defaults to Secure access from any master.
0xa8	OTP	Control access to OTP. Defaults to Secure access from any master.
0xac	TBMAN	Control access to TBMAN. Defaults to Secure access from any master.
0xb0	POWMAN	Control access to POWMAN. Defaults to Secure, Privileged processor or debug access only.
0xb4	TRNG	Control access to TRNG. Defaults to Secure, Privileged processor or debug access only.
0xb8	SHA256	Control access to SHA256. Defaults to Secure, Privileged access only.
0xbc	SYSCFG	Control access to SYSCFG. Defaults to Secure, Privileged processor or debug access only.
0xc0	CLOCKS	Control access to CLOCKS. Defaults to Secure, Privileged processor or debug access only.
0xc4	XOSC	Control access to XOSC. Defaults to Secure, Privileged processor or debug access only.
0xc8	ROSC	Control access to ROSC. Defaults to Secure, Privileged processor or debug access only.
0xcc	PLL_SYS	Control access to PLL_SYS. Defaults to Secure, Privileged processor or debug access only.
0xd0	PLL_USB	Control access to PLL_USB. Defaults to Secure, Privileged processor or debug access only.
0xd4	TICKS	Control access to TICKS. Defaults to Secure, Privileged processor or debug access only.
0xd8	WATCHDOG	Control access to WATCHDOG. Defaults to Secure, Privileged processor or debug access only.
0xdc	PSM	Control access to PSM. Defaults to Secure, Privileged processor or debug access only.
0xe0	XIP_CTRL	Control access to XIP_CTRL. Defaults to Secure, Privileged processor or debug access only.
0xe4	XIP_QMI	Control access to XIP_QMI. Defaults to Secure, Privileged processor or debug access only.
0xe8	XIP_AUX	Control access to XIP_AUX. Defaults to Secure, Privileged access only.

偏移量	名称	说明
0x98	TIMER0	控制对TIMER0的访问， 默认为任何主控的安全访问。
0x9c	TIMER1	控制对TIMER1的访问， 默认为任何主控的安全访问。

0xdc	PSM	控制对 PSM 的访问。默认仅限安全态、 特权处理器或调试访问。
0xe0	XIP_CTRL	控制对 XIP_CTRL 的访问。默认仅限安全态、 特权处理器或调试访问。
0xe4	XIP_QMI	控制对 XIP_QMI 的访问。默认仅限安全态、 特权处理器或调试访问。
0xe8	XIP_AUX	控制对 XIP_AUX 的访问。默认仅限安全且特权访问。

## ACCESSCTRL: LOCK Register

**Offset:** 0x00

### Description

Once a LOCK bit is written to 1, ACCESSCTRL silently ignores writes from that master. LOCK is writable only by a Secure, Privileged processor or debugger.

LOCK bits are only writable when their value is zero. Once set, they can never be cleared, except by a full reset of ACCESSCTRL.

Setting the LOCK bit does not affect whether an access raises a bus error. Unprivileged writes, or writes from the DMA, will continue to raise bus errors. All other accesses will continue not to.

Table 912. LOCK Register

Bits	Description	Type	Reset
31:4	Reserved.	-	-
3	<b>DEBUG</b>	RW	0x0
2	<b>DMA</b>	RO	0x1
1	<b>CORE1</b>	RW	0x0
0	<b>CORE0</b>	RW	0x0

## ACCESSCTRL: FORCE\_CORE\_NS Register

**Offset:** 0x04

### Description

Force core 1's bus accesses to always be Non-secure, no matter the core's internal state.

Useful for schemes where one core is designated as the Non-secure core, since some peripherals may filter individual registers internally based on security state but not on master ID.

Table 913.  
FORCE\_CORE\_NS Register

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>CORE1</b>	RW	0x0
0	Reserved.	-	-

## ACCESSCTRL: CFGRESET Register

**Offset:** 0x08

## ACCESSCTRL：LOCK 寄存器

偏移: 0x00

### 说明

一旦LOCK位被写入1，ACCESSCTRL将静默忽略该主控的写入操作。LOCK仅可由安全的特权处理器或调试器写入。

LOCK位仅当其值为零时方可写入。一旦设置，除非对ACCESSCTRL进行完全复位，否则LOCK位不可清除。

设置LOCK位不会影响访问是否引发总线错误。非特权写入或DMA写入仍将引发总线错误。所有其他访问则继续不引发总线错误。

1	<b>CORE1</b>	读写	0x0
0	<b>CORE0</b>	读写	0x0

## ACCESSCTRL：FORCE\_CORE\_NS 寄存器

偏移: 0x04

### 描述

无论核心内部状态如何，强制核心1的总线访问始终为非安全访问。

适用于将某一核心指定为非安全核心的方案，因为部分外设可能基于安全状态内部筛选单个寄存器，但不基于主控 ID。

## ACCESSCTRL: SRAM3 Register

**Offset:** 0x28

### Description

Control whether debugger, DMA, core 0 and core 1 can access SRAM3, and at what security/privilege levels they can do so.

Defaults to fully open access.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 922. SRAM3 Register

## ACCESSCTRL: SRAM4 Register

**Offset:** 0x2c

### Description

Control whether debugger, DMA, core 0 and core 1 can access SRAM4, and at what security/privilege levels they can do so.

Defaults to fully open access.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU</b> : 当值为1且NSP同时设置时, SRAM2可从非安全的非特权上下文访问。 仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x1

## ACCESSCTRL: SRAM3寄存器

偏移: 0x28

### 说明

控制调试器、DMA、核心0与核心1是否可访问SRAM3, 以及它们的安全与特权级别。

默认情况下, 访问权限完全开放。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

## ACCESSCTRL: DMA Register

**Offset:** 0x44

### Description

Control whether debugger, DMA, core 0 and core 1 can access DMA, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU:</b> 若为1, 且NSP亦被设置, 则SRAM8可从非安全非特权上下文访问。  仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x1

## ACCESSCTRL：SRAM9寄存器

偏移量: 0x40

### 描述

控制调试器、DMA、核心0和核心1是否可以访问SRAM9, 以及它们可在本寄存器中SP/NSP/SU/NSU所允许的安全/权限级别进行访问。

默认情况下, 访问权限完全开放。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

1	<b>NSP:</b> If 1, DMA can be accessed from a Non-secure, Privileged context.	RW	0x0
0	<b>NSU:</b> If 1, and NSP is also set, DMA can be accessed from a Non-secure, Unprivileged context.  This bit is writable from a Non-secure, Privileged context, if and only if the NSP bit is set.	RW	0x0

## ACCESSCTRL: USBCTRL Register

Offset: 0x48

### Description

Control whether debugger, DMA, core 0 and core 1 can access USBCTRL, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 930. USBCTRL Register

Bits	Description	Type	Reset

## ACCESSCTRL: PIO1 Register

**Offset:** 0x50

### Description

Control whether debugger, DMA, core 0 and core 1 can access PIO1, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU</b> : 若为1, 且 NSP 也被设置, 则可从非安全的非特权上下文访问 USBCTR L。  仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: PIO0 寄存器

偏移: 0x4c

### 说明

控制调试器、DMA、核心0和核心1是否能访问 PIO0, 以及其可访问的安全性与权限级别。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

0	<b>NSU:</b> If 1, and NSP is also set, RESETS can be accessed from a Non-secure, Unprivileged context.  This bit is writable from a Non-secure, Privileged context, if and only if the NSP bit is set.	RW	0x0

## ACCESSCTRL: IO\_BANK0 Register

Offset: 0x68

### Description

Control whether debugger, DMA, core 0 and core 1 can access IO\_BANK0, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
1	<b>NSP</b> : 若为1, SYSINFO 可从非安全特权上下文访问。	读写	0x1
0	<b>NSU</b> : 若为1, 且NSP同时被设置, SYSINFO可从非安全非特权上下文访问。  仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x1

## ACCESSCTRL: RESETS 寄存器

偏移量: 0x64

### 说明

控制调试器、DMA、核心0及核心1是否可以访问RESETS, 以及其访问所允许的安全／特权级别。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

表 937. RESETS 寄存器

位	描述	类型	复位
31:8	保留。	-	-
7	<b>DBG</b> : 若为1, 调试器可在本寄存器中SP/NSP/SU/NSU所允许的安全／特权级别下访问RESETS。	读写	0x1

5	<b>CORE1</b> : 如果设置为1, 则在本寄存器所允许的SP/NSP/SU/NSU安全/特权级别范围内, 核1可以访问RESETS。	读写	0x1
4	<b>CORE0</b> : 如果设置为1, 则在本寄存器所允许的SP/NSP/SU/NSU安全/特权级别范围内, 核0可以访问RESETS。	读写	0x1
3	<b>SP</b> : 如果设置为1, 则可以从安全特权上下文访问RESETS。	读写	0x1
2	<b>SU</b> : 如果设置为1, 且SP同时被设置, 则可以从安全非特权上下文访问RESETS。	读写	0x1
1	<b>NSP</b> : 如果设置为1, 则可以从非安全特权上下文访问RESETS。	读写	0x0
0	<b>NSU</b> : 如果设置为1, 且NSP同时被设置, 则可以从非安全非特权上下文访问RESETS。  仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: IO\_BANK0 寄存器

偏移: 0x68

### 描述

控制调试器、DMA、核0和核1是否可以访问 IO\_BANK0 以及其访问所处的安全/权限级别。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

## ACCESSCTRL: IO\_BANK1 Register

Offset: 0x6c

### Description

Control whether debugger, DMA, core 0 and core 1 can access IO\_BANK1, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 939. IO\_BANK1 Register

## ACCESSCTRL: PADS\_QSPI Register

**Offset:** 0x74

### Description

Control whether debugger, DMA, core 0 and core 1 can access PADS\_QSPI, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU:</b> 若为1且NSP同时被设置, IO_BANK1可从非安全非特权上下文访问。  仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: PADS\_BANK0寄存器

偏移: 0x70

### 描述

控制调试器、DMA、核心0与核心1是否可以访问PADS\_BANK0, 以及它们可在本寄存器中由SP/NSP/SU/NSU定义的何种安全/特权级别下访问。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

## ACCESSCTRL: HSTX Register

**Offset:** 0x80

### Description

Control whether debugger, DMA, core 0 and core 1 can access HSTX, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU</b> : 若为1, 且NSP亦已设置, BUSCTRL可从非安全无特权上下文进行访问。 仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: ADC寄存器

偏移: 0x7c

### 说明

控制调试器、DMA、核心0及核心1是否能够访问ADC，以及其对应的安全/特权访问级别。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入，惟当NSP位被设置时，NSU位可由非安全、特权环境写入。

## ACCESSCTRL: I2C0寄存器

偏移: 0x84

### 描述

控制调试器、DMA、核心0和核心1是否可访问I2C0, 以及它们可在何种安全/权限级别下访问。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

表945. I2C0  
寄存器

## ACCESSCTRL: I2C1 Register

**Offset:** 0x88

### Description

Control whether debugger, DMA, core 0 and core 1 can access I2C1, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 946. I2C1 Register

Bits	Description	Type	Reset

## ACCESSCTRL: PWM Register

**Offset:** 0x8c

### Description

Control whether debugger, DMA, core 0 and core 1 can access PWM, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU</b> : 若为1, 且NSP也被设置, 则I2C0可从非安全非特权环境访问。  仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: I2C1寄存器

偏移量: 0x88

### 描述

控制调试器、DMA、核心0和核心1对I2C1的访问权限及其安全/特权等级。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

0	<b>NSU:</b> If 1, and NSP is also set, UART1 can be accessed from a Non-secure, Unprivileged context.  This bit is writable from a Non-secure, Privileged context, if and only if the NSP bit is set.	RW	0x0

## ACCESSCTRL: OTP Register

Offset: 0xa8

### Description

Control whether debugger, DMA, core 0 and core 1 can access OTP, and at what security/privilege levels they can do so.

Defaults to Secure access from any master.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 954. OTP Register

## ACCESSCTRL: POWMAN Register

**Offset:** 0xb0

### Description

Control whether debugger, DMA, core 0 and core 1 can access POWMAN, and at what security/privilege levels they can do so.

Defaults to Secure, Privileged processor or debug access only.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU:</b> 若值为1且NSP同时设置，则OTP可从非安全非特权上下文访问。  仅当NSP位被设置时，此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL：TBMAN寄存器

偏移: 0xac

### 描述

控制调试器、DMA、核心0和核心1是否能够访问TBMAN，以及它们可以在何种安全/特权级别下进行访问。

默认允许任何主设备进行安全访问。

本寄存器仅能由安全、特权处理器或调试器写入，惟当NSP位被设置时，NSU位可由非安全、特权环境写入。

## ACCESSCTRL: XOSC Register

**Offset:** 0xc4

### Description

Control whether debugger, DMA, core 0 and core 1 can access XOSC, and at what security/privilege levels they can do so.

Defaults to Secure, Privileged processor or debug access only.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 961. XOSC Register

Bits	Description	Type	Reset

## ACCESSCTRL: ROSC Register

**Offset:** 0xc8

### Description

Control whether debugger, DMA, core 0 and core 1 can access ROSC, and at what security/privilege levels they can do so.

Defaults to Secure, Privileged processor or debug access only.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU:</b> 如果为1, 且NSP也被设置, 则可从非安全非特权上下文访问CLOCKS。 仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: XOSC 寄存器

偏移: 0xc4

### 说明

控制调试器、DMA、核心0和核心1是否可以访问XOSC, 以及它们可在何种安全性/权限级别下访问。

默认仅允许安全特权处理器或调试访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

## ACCESSCTRL: TICKS Register

**Offset:** 0xd4

### Description

Control whether debugger, DMA, core 0 and core 1 can access TICKS, and at what security/privilege levels they can do so.

Defaults to Secure, Privileged processor or debug access only.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

位	描述	类型	复位
0	<b>NSU</b> : 如果为1, 且NSP也被设置, PLL_SYS可从非安全、非特权上下文访问。 仅当NSP位被设置时, 此位才可由非安全、特权环境写入。	读写	0x0

## ACCESSCTRL: PLL\_USB寄存器

偏移量: 0xd0

### 说明

控制调试器、DMA、核0及核1对PLL\_USB的访问权限及其安全/特权级别。

默认仅允许安全特权处理器或调试访问。

本寄存器仅能由安全、特权处理器或调试器写入, 惟当NSP位被设置时, NSU位可由非安全、特权环境写入。

## ACCESSCTRL: XIP\_QMI Register

Offset: 0xe4

### Description

Control whether debugger, DMA, core 0 and core 1 can access XIP\_QMI, and at what security/privilege levels they can do so.

Defaults to Secure, Privileged processor or debug access only.

This register is writable only from a Secure, Privileged processor or debugger, with the exception of the NSU bit, which becomes Non-secure-Privileged-writable when the NSP bit is set.

Table 969. XIP\_QMI Register

## 10.7. DMA

The RP2350 system DMA is a peripheral which performs arbitrary reads and writes on memory. This means that, as with a processor, care is necessary to maintain isolation between memory or peripherals owned by different security domains. Any given processor context must not access memory or peripherals belonging to a more secure context. The DMA helps maintain this invariant by ensuring software can not use the DMA to access a more secure context on its behalf, including such cases as a processor programming the DMA to program the DMA.

RP2350 extends the processor security/privilege states to individual DMA channels, and the DMA filters its own memory accesses with a built-in memory protection unit (MPU) similarly capable to the Armv8-M SAU or the RISC-V PMP. When correctly configured, this allows multiple security domains to transparently and safely share DMA

位	描述	类型	复位

0	<b>NSU:</b> 如果为1，且NSP同时设置，XIP_AUX可从非安全非特权上下文访问。 仅当NSP位被设置时，此位才可由非安全、特权环境写入。	读写	0x0

## 10.7. DMA

RP2350系统DMA是一种外围设备，能够对内存执行任意读写操作。这意味着，类似于处理器，必须谨慎维护不同安全域拥有的内存或外围设备之间的隔离。任何处理器上下文均不得访问属于更高级安全上下文的内存或外围设备。DMA通过确保软件不能利用DMA访问更高级安全上下文（包括处理器通过编程DMA来配置DMA的情况）来维护该不变性。

RP2350 将处理器的安全/特权状态扩展至各个 DMA 通道，且 DMA 通过内置的内存保护单元（MPU）过滤其自身的内存访问，该 MPU 具备类似 Armv8-M SAU 或 RISC-V PMP 的功能。正确配置后，允许多个安全域透明且安全地共享 DMA

resources. It is also possible to assign the entire DMA block wholesale to a single security domain using the ACCESSCTRL registers ([Section 10.6](#)) if this fine-grained configuration is not desired.

This section gives an overview of the DMA's security features. The specific hardware details are documented in [Section 12.6.6](#).

### 10.7.1. Channel security attributes

Each channel is assigned a security level using the per-channel registers starting at [SECCFG\\_CH0](#). This defines:

- The minimum privilege required to configure and control the channel, or observe its status
- The bus privilege at which the channel performs its memory accesses

For the sake of comparing security levels, the DMA assigns the following total order to AHB5 security/privilege attributes: Secure + Privileged > Secure + Unprivileged > Non-secure + Privileged > Non-secure + Unprivileged.

A channel's security level can be changed freely up until any of the channel's control registers is written. After this point, its security level is locked, and cannot be changed until the DMA block resets. At reset, all channels become Secure + Privileged (security level = 3, the maximum).

The effects of the channel [SECCFG](#) registers are listed exhaustively in the relevant DMA documentation, [Section 12.6.6.1](#).

### 10.7.2. Memory protection unit

The RP2350 DMA features a memory protection unit that you can configure to set the security/privilege level required to access up to eight different address ranges, plus a default level for addresses not matched by any of those eight ranges. The addresses of all DMA reads and writes are checked against the MPU address map. If the originating channel's security level is lower than that defined in the address map, the access is filtered. A filtered access has no effect on the downstream bus, and returns a bus error to the offending channel.

The DMA memory protection unit is configured by DMA control registers starting from [MPU\\_CTRL](#). See [Section 12.6.6.3](#) for more details.

### 10.7.3. DREQ attributes

Channels are not permitted to interface with the DREQs of peripherals above their security level, as determined by the peripheral access controls in ACCESSCTRL. This is done to avoid any information being inferred from the timing of secure peripheral transfers, and because the clear handshake on the RP2040 DREQ can be used maliciously to cause a Secure DMA channel to overflow its destination FIFO and corrupt/lose data (for details about the DREQ handshake, see [Section 12.6.4.2](#)).

The DREQ security levels are driven by the ACCESSCTRL block access registers. ACCESSCTRL takes the index of the least-significant set bit in the 4-bit permission mask, having first ANDed the [SP](#) into [SU](#), and [NSP](#) into [SU](#). This creates a 2-bit integer which is compared with the DMA channel's security level to determine whether it can interface with this DREQ.

### 10.7.4. IRQ attributes

Each of the four shared DMA interrupt lines (IRQs) has a configurable security level. The IRQ's security level is compared with channel security levels, and with the bus privilege of accesses to the DMA's interrupt control registers, to determine:

- Whether a bus access is permitted to read/write the [INTE/INTF/INTS](#) registers for this IRQ
- Whether a given channel will be visible in this IRQ's [INTS](#) register (and therefore whether that channel will cause

资源。若不需此细粒度配置，也可通过 ACCESSCTRL 寄存器（第10.6节）将整个 DMA 模块整体分配给单一安全域。

本节概述了 DMA 的安全特性。具体硬件细节见第[12.6.6](#)节。

### 10.7.1. 通道安全属性

每个通道通过从 SECCFG\_CH0 开始的每通道寄存器分配安全级别。此级别定义：

- 配置和控制通道或监视其状态所需的最低特权级别
- 通道进行内存访问时使用的总线特权级别

为比较安全级别，DMA 对 AHB5 安全/特权属性建立以下全序关系：Secure + Privileged > Secure + Unprivileged > Non-secure + Privileged > Non-secure + Unprivileged。

在任一信道的控制寄存器被写入之前，信道的安全级别可自由更改。此后，其安全级别将被锁定，直至DMA块复位，才可更改。复位时，所有信道的安全级别均设为安全且特权（安全级别 = 3，最大值）。

信道 [SECCFG](#)寄存器的作用详尽列于相关DMA文档第12.6.6.1节。

### 10.7.2. 内存保护单元

RP2350 DMA配备内存保护单元，可配置访问最多八个不同地址范围所需的安全/特权级别，另设默认级别覆盖未匹配任何八个范围的地址。所有DMA读写操作的地址均会与MPU地址映射进行核对。若起始信道的安全级别低于映射中规定的级别，则该访问将被过滤。被过滤的访问不会影响下游总线，并将向违规信道返回总线错误。

DMA内存保护单元由从MPU\_CTRL开始的DMA控制寄存器进行配置。详情请参见第12.6.6.3节。

### 10.7.3. DREQ属性

通道不允许与其安全级别以上的外设的DREQ接口，该安全级别由ACCESSCTRL中的外设访问控制确定。此举旨在避免通过安全外设传输的时序推断任何信息，且由于RP2040 DREQ的清除握手信号可能被恶意利用，导致安全DMA通道使目标FIFO溢出并损坏或丢失数据（有关DREQ握手的详细信息，见第[12.6.4.2](#)节）。

DREQ的安全级别由ACCESSCTRL模块的访问寄存器驱动。ACCESSCTRL首先将 [SP](#)与 [SU](#)逻辑与，再将 [NSP](#)与 [SU](#)逻辑与，随后取4位权限掩码中最低有效位置位的索引。该过程生成一个2位整数，此整数将与DMA通道的安全级别进行比较，以决定其是否可与该DREQ接口。

### 10.7.4. IRQ属性

四条共享DMA中断线（IRQ）中的每一条均具有可配置的安全级别。IRQ的安全级别将与通道的安全级别以及访问DMA中断控制寄存器的总线权限进行比较，以确定：

- 是否允许总线访问读写该IRQ对应的 [INTE](#)/[INTF](#)/[INTS](#)寄存器
- 某特定通道是否将在该IRQ的 [INTS](#)寄存器中可见（进而决定该通道是否会触发

assertion of this IRQ)

- Whether a given channel can have its interrupt pending flag set/cleared via this IRQ's INTF/INTS registers

For a bus access to view/configure an IRQ, it must have a security level greater than or equal to the IRQ's security level. For an IRQ to observe a channel's interrupt pending flag, the IRQ must have a security level greater than or equal to the channel's security level. Consequently, for a bus to observe a channel's interrupt status, the bus access security level must be greater than or equal to the channel's security level.

For an IRQ to observe a channel's interrupt pending flag, it must have a security level greater than or equal to the channel's security level.

There is only one INTR register. Which channels' interrupts can be observed and cleared through INTR is determined by comparing channel security levels to the security level of the INTR bus access.

## 10.8. OTP

RP2350 contains 8 kB of OTP storage, organised as  $4096 \times 24$ -bit rows with hardware ECC protection. This is the only mutable, on-die, non-volatile storage. Boot signing keys and decryption keys are stored in OTP, and as such it is a vital part of the security architecture. This section gives a brief summary of OTP hardware protection features; [Chapter 13](#) documents the hardware in full.

The RP2350 OTP subsystem adds a hardware layer on top of the OTP storage array, to protect sensitive contents:

- OTP is protected at a 128-byte page granularity (see [Section 13.5](#))
  - Each page can be fully accessible, read-only, or fully inaccessible
  - Locks are defined separately for Secure, Non-secure and bootloader access
  - Programming OTP lock locations starting at `PAGE0_LOCK0` applies locks permanently
  - Writing to registers starting at `SW_LOCK0` advances locks to a less-permissive state until the next OTP reset
- OTP control registers used to access the SBPI interface are hardwired for Secure access only
  - The SBPI interface is used to program the OTP and configure power supply and analogue hardware
- The guarded read aliases provide higher assurance against deliberate OTP power supply manipulation during reads ([Section 13.1.1](#))
- Hardware reads the OTP array at startup for security hardware configuration ([Section 13.3.4](#))
  - The critical flags ([Section 13.4](#)) enable secure boot, enable the glitch detectors, and disable debug
  - The OTP hardware access keys ([Section 13.5.2](#)) provide further protection for OTP pages
  - The debug keys ([Section 3.5.9.2](#)) are an additional mechanism to conditionally lock down debug access

OTP also contains configuration for the RP2350 bootrom, particularly its secure boot implementation. [Section 13.10](#) lists all predefined OTP data locations. Boot configuration is stored in page 1, starting from `BOOT_FLAGS0`.

The bootrom can load and run code stored in OTP; see the bootrom documentation in [Section 5.10.7](#), and the OTP data listings starting from `OTPBOOT_SRC`. When secure boot is enabled, code loaded from OTP is subject to all of the usual requirements for image signing and versioning, so this code can form part of your secure boot chain. The `chain_image()` ROM API allows your OTP-resident bootloader to call back into the ROM to verify the next boot stage that it has loaded.

## 10.9. Glitch detector

The glitch detector detects loss of setup and hold margin in the system clock domain, which may be caused by deliberate external manipulation of the system clock or core supply voltage. When it detects loss, the glitch detector triggers a system reset rather than allowing software to continue to execute in a possibly undefined state. It responds

该IRQ的断言)

- 某特定通道是否可以通过该IRQ的INTF/INTS寄存器设置或清除其中断挂起标志

总线访问若欲查看或配置某IRQ，其安全级别必须大于或等于该IRQ的安全级别。

IRQ欲观察通道的中断挂起标志，该IRQ的安全级别必须大于或等于该通道的安全级别。因此，若总线欲观察某通道的中断状态，则总线访问的安全级别必须大于或等于该通道的安全级别。

为了使IRQ能够监控通道的中断挂起标志，其安全级别必须大于或等于该通道的安全级别。

仅有一个INTR寄存器。能通过INTR监控和清除的通道中断，是通过比较通道安全级别与INTR总线访问的安全级别决定的。

## 10.8. OTP

RP2350包含8 kB的OTP存储，组织为 $4096 \times 24$ 位行，并配备硬件ECC保护。这是唯一可变的片上非易失性存储。启动签名密钥和解密密钥存储于OTP中，因此其为安全架构的关键组成部分。本节简要概述了OTP硬件保护功能；第13章详细记录了该硬件。

RP2350 OTP子系统在OTP存储阵列之上增加硬件层，以保护敏感内容：

- OTP以128字节页为粒度进行保护（详见第13.5节）。
  - 每个页面可设为完全可访问、只读或完全不可访问
  - 锁定分别针对安全、非安全及引导加载程序访问单独定义
  - 从 PAGE0\_LOCK0 开始编程 OTP 锁定位将永久生效
  - 从 SW\_LOCK0 开始写入寄存器可将锁定状态提升至更严格的限制，直至下一次 OTP 重置
- 用于访问 SBPI 接口的 OTP 控制寄存器仅硬连线为安全访问模式
  - SBPI 接口用于编程 OTP 并配置电源及模拟硬件
- 保护读取别名在读取过程中提供更高保障，防止对 OTP 电源的故意操控（第 13.1.1 节）
- 硬件在启动时读取 OTP 数组以进行安全硬件配置（第 13.3.4 节）
  - 关键标志（第 13.4 节）启用安全启动、激活故障注入检测器并禁用调试功能
  - OTP 硬件访问密钥（第 13.5.2 节）为 OTP 页面提供额外保护
  - 调试密钥（第 3.5.9.2 节）为有条件限制调试访问的附加机制OTP 中还包含了 RP2350 只读存储器的配置

，特别是其安全启动实现。第13.10节列出了所有预定义的OTP数据位置。启动配置存储于第1页，起始于BOOT\_FLAGS0。启动只读存储器可加载并执行存储于OTP中的代码；详见第5.10.7节的启动只读存储器文档以及从OTPBO

OT\_SRC开始的OTP数据列表。启用安全启动时，从OTP加载的代码须满足所有常规的镜像签名与版本管理要求，因此该代码可作为安全启动链的一部分。chain\_image()只读存储器API允许位于OTP中的引导加载程序回调只读存储器，以验证其所加载的下一个启动阶段。

## 10.9. 故障检测器

毛刺检测器检测系统时钟域中建立时间和保持时间裕度的丢失，该情况可能由对系统时钟或核心电源电压的有意外部干扰引起。检测到丢失时，毛刺检测器将触发系统复位，而非允许软件在可能未定义的状态下继续运行。其响应

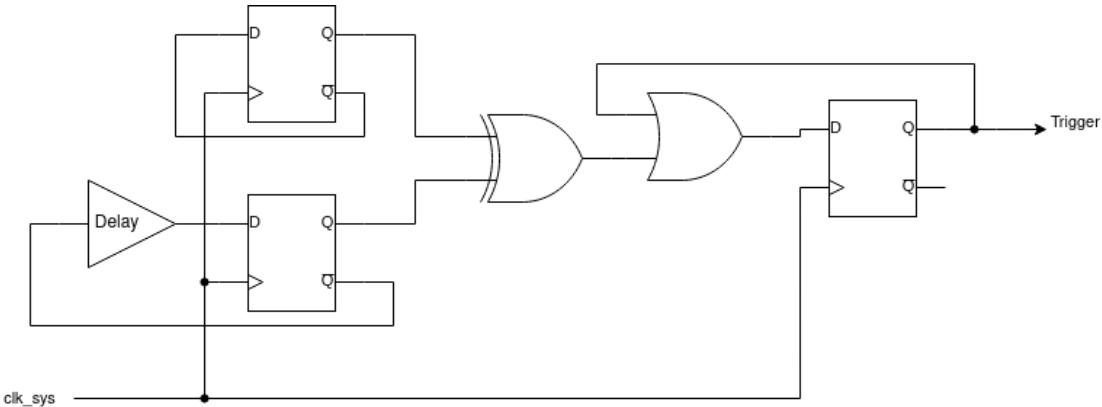

within one system clock cycle, unlike the brownout detector, which has much more limited analog bandwidth.

The glitch detector is disabled by default, and can be armed by setting the `GLITCH_DETECTOR_ENABLE` flag in OTP. For debugging purposes, you can also enable the glitch detector via the `ARM` register. This is not recommended in security-sensitive applications, as the system is vulnerable until the point that software can enable the detectors.

### 10.9.1. Theory of operation

The glitch detector is comprised of four identical detector circuits, based on a pair of D flip-flops. These detector circuits are each placed in different, physically distant locations within the core voltage domain.

*Figure 43. Glitch detector trigger circuit. Two flops each toggle on every system clock cycle. One has a programmable delay line in its feedback path, the other does not. Loss of setup or hold margin causes one of the flops to fail to toggle, so the flops values differ, setting the trigger output.*

The detector triggers when the two D-flops take on different values, which is impossible under normal circumstances. The delay line is programmable from 75% to 120% of the minimum system clock period in increments of 15%. Higher delays make the circuit more sensitive to loss of setup margin. To configure initial sensitivity, use the `GLITCH_DETECTOR_SENS` OTP flags. You can fine-tune sensitivity for each detector using the `SENSITIVITY` register.

Because the circuit is constructed from digital standard cells, it closely tracks the changes in propagation delay to nearby cells caused by voltage and temperature fluctuations. Therefore the delay line's propagation delay is specified as a fraction of the maximum system clock data path delay, rather than a fixed time in nanoseconds.

### 10.9.2. Trigger response

When any of the detectors fires, the corresponding bit in the `TRIG_STATUS` is set. If the glitch detector block is armed, this detector event also resets almost all logic in the switched core domain. The glitch detector is armed if:

- The `DISARM` register is not set to the disarming bit pattern, and at least one of the following is true:
  - The `GLITCH_DETECTOR_EN` OTP flag was programmed some time before the most recent reset of the OTP block
  - The `ARM` register is set to an arming bit pattern

This holds the majority of the switched core domain in reset for approximately 120 microseconds before releasing the reset. Specifically, this resets the PSM (Section 7.3), which resets all PSM-controlled resets starting with the processor cold reset domain, in addition to all blocks reset by the `RESETS` block, which is itself reset by the PSM. The detector circuits are also reset, as is the system watchdog including the watchdog scratch registers.

After a glitch detector-initiated reset, the `CHIP_RESET.HAD_GLITCH_DETECT` flag is set so that software can diagnose that the last reset was caused by a glitch detector trigger. Check the `TRIG_STATUS` register to see which detector fired. This can be useful for tuning the thresholds of individual detectors.

The only way to clear the detector circuits is to reset them, either via a full switched core domain reset (such as the `RUN` pin, the SW-DP reset request, a PoR/BoR reset, or a reset of the switched core domain configured by POWMAN controls), or by arming the glitch detector block so that the detectors reset along with the PSM.

Recovering from the glitch detector firing requires the low-power oscillator to be running (Section 8.4). Allowing the

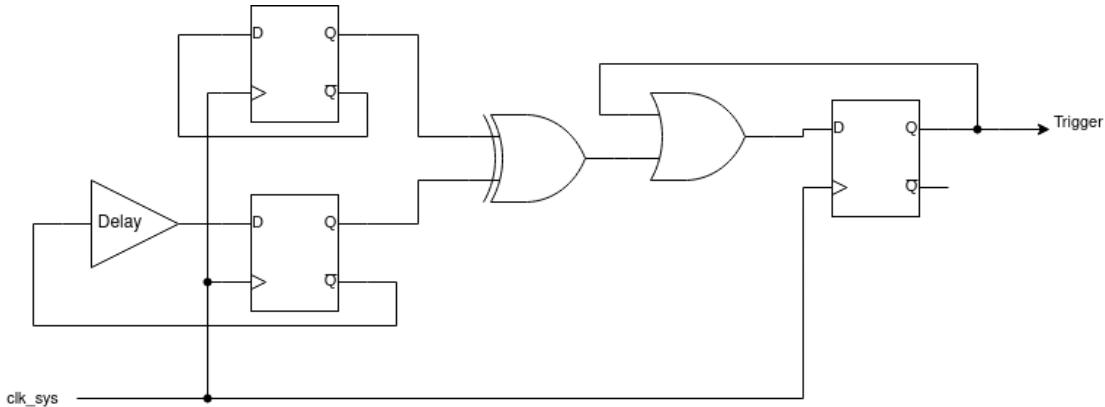

时间在一个系统时钟周期内，区别于欠压检测器，其模拟带宽显著受限。

缺陷检测器默认处于禁用状态，用户可通过在OTP中设置`GLITCH_DETECTOR_ENABLE`标志来激活。出于调试目的，也可通过ARM寄存器启用缺陷检测器。此操作不适用于安全敏感的应用场景，因为系统在软件启用检测器之前存在安全漏洞。

### 10.9.1. 工作原理

缺陷检测器由四个相同的检测电路组成，每个电路基于一对D触发器。这些检测电路分别部署于核心电压域内不同且物理上相距较远的位置。

图43。缺陷检测器触发电路。两组触发器在每个系统时钟周期均切换状态。其中一组在反馈路径中集成了可编程延迟线，而另一组则没有。若设置或保持时间裕度丢失，导致其中一个触发器未能完成切换，两组触发器的输出值将不一致，从而设置触发

检测器在两组D触发器输出值不一致时触发，该情况在正常运行时不应发生。

延迟线的可编程范围为最小系统时钟周期的75%至120%，以15%的增量进行调整。较高的延迟会使电路对设定裕度的损失更为敏感。要配置初始灵敏度，请使用`GLITCH_DETECTOR_SENS` OTP 标志位。您可以通过`SENSITIVITY` 寄存器对每个检测器的灵敏度进行微调。

由于该电路由数字标准单元构成，其传播延迟会紧密追踪电压和温度波动对邻近单元传播延迟所带来的影响。因此，延迟线的传播延迟被指定为最大系统时钟数据路径延迟的一个分数，而非固定纳秒时间。

### 10.9.2. 触发响应

当任一检测器触发时，对应的`TRIG_STATUS` 位将被置位。如果毛刺检测器模块已启动，此检测事件还将复位切换核心域中几乎所有逻辑单元。毛刺检测器启动的条件为：

- DISARM 寄存器未设置为解除启动的位模式，且满足以下至少一项条件：
  - `GLITCH_DETECTOR_ENOTP` 标志在 OTP 模块最近复位前已被编程。
  - ARM 寄存器被设置为启动位模式

这会将大部分切换核心域保持在复位状态约 120 微秒，然后释放复位。具体来说，这会复位 PSM（第 7.3 节），该模块复位所有由 PSM 控制的复位，从处理器冷复位域开始，此外复位所有由 RESETS 模块复位的模块，该模块本身由 PSM 复位。检测器电路以及系统看门狗，包括看门狗擦写寄存器，亦会被复位。

在由毛刺检测器触发的复位后，`CHIP_RESET.HAD_GLITCH_DETECT` 标志会被设置，以便软件能够诊断上次复位是由毛刺检测器触发引起的。检查`TRIG_STATUS` 寄存器，以确定是哪个检测器触发了复位。这对于调整各个检测器的阈值非常有用。

清除检测器电路的唯一方法是复位它们，可通过完全切换核心域复位（例如`RUN` 引脚、SW-DP 复位请求、PoR/BoR 复位，或由`POWMAN` 控制配置的切换核心域复位），或通过启动毛刺检测器模块，使检测器与 PSM 一同复位。

从故障检测器触发中恢复需要低功率振荡器处于运行状态（第8.4节）。允许

glitch detectors to fire when the LPOSC is disabled results in the chip holding itself in reset indefinitely until an external reset such as the [RUN](#) pin resets the detectors.

### 10.9.3. List of registers

The glitch detector control registers start at an address of [0x40158000](#).

*Table 971. List of GLITCH\_DETECTOR registers*

Offset	Name	Info
0x00	<a href="#">ARM</a>	<p>Forcibly arm the glitch detectors, if they are not already armed by OTP. When armed, any individual detector trigger will cause a restart of the switched core power domain's power-on reset state machine.</p> <p>Glitch detector triggers are recorded accumulatively in TRIG_STATUS. If the system is reset by a glitch detector trigger, this is recorded in POWMAN_CHIP_RESET.</p> <p>This register is Secure read/write only.</p>
0x04	<a href="#">DISARM</a>	
0x08	<a href="#">SENSITIVITY</a>	<p>Adjust the sensitivity of glitch detectors to values other than their OTP-provided defaults.</p> <p>This register is Secure read/write only.</p>
0x0c	<a href="#">LOCK</a>	
0x10	<a href="#">TRIG_STATUS</a>	<p>Set when a detector output triggers. Write-1-clear.</p> <p>(May immediately return high if the detector remains in a failed state. Detectors can only be cleared by a full reset of the switched core power domain.)</p> <p>This register is Secure read/write only.</p>
0x14	<a href="#">TRIG_FORCE</a>	<p>Simulate the firing of one or more detectors. Writing ones to this register will set the matching bits in STATUS_TRIG.</p> <p>If the glitch detectors are currently armed, writing ones will also immediately reset the switched core power domain, and set the reset reason latches in POWMAN_CHIP_RESET to indicate a glitch detector resets.</p> <p>This register is Secure read/write only.</p>

#### GLITCH\_DETECTOR: ARM Register

**Offset:** 0x00

*Table 972. ARM Register*

Bits	Description	Type	Reset
31:16	Reserved.	-	-

当低功率振荡器被禁用时，故障检测器触发会导致芯片持续保持复位状态，直到如 RUN引脚等外部复位信号重置检测器。

### 10.9.3. 寄存器列表

故障检测器控制寄存器的起始地址为 **0x40158000**。

表971。GLITCH\_DETECTOR 寄存器列表

偏移量	名称	说明
0x00	ARM	<p>如果故障检测器尚未被OTP授权，则强制启用故障检测器。启用后，任何单个检测器触发都会导致切换核心电源域的上电复位状态机重新启动。</p> <p>故障检测器触发的事件会累计记录在TRIG_STATUS中。如系统因故障检测器触发而复位，该情况会记录在POWMAN_CHIP_RESET中。</p> <p>该寄存器仅允许安全读写操作。</p>
0x04	解除启用	
0x08	灵敏度	<p>将故障检测器的灵敏度调整为OTP提供默认值以外的其他数值。</p> <p>该寄存器仅允许安全读写操作。</p>
0x0c	LOCK	
0x10	TRIG_STATUS	<p>当检测器输出触发时设置。写入1以清除。</p> <p>(若检测器持续处于失效状态，可能会立即返回高电平。检测器仅能通过完全重置切换的核心电源域予以清除。)</p> <p>该寄存器仅允许安全读写操作。</p>
0x14	TRIG_FORCE	<p>模拟一个或多个检测器的触发。写入1至此寄存器将设置STATUS_TRIG中的相应位。</p> <p>若故障检测器当前处于激活状态，写入1将立即重置切换的核心电源域，并在POWMAN_CHIP_RESET中设置复位原因锁存器，以指示故障检测器复位。</p> <p>该寄存器仅允许安全读写操作。</p>

#### GLITCH\_DETECTOR：ARM寄存器

偏移: 0x00

表972. ARM 寄存器

位	描述	类型	复位
31:16	保留。	-	-

Bits	Description	Type	Reset
15:0	Forcibly arm the glitch detectors, if they are not already armed by OTP. When armed, any individual detector trigger will cause a restart of the switched core power domain's power-on reset state machine.  Glitch detector triggers are recorded accumulatively in TRIG_STATUS. If the system is reset by a glitch detector trigger, this is recorded in POWMAN_CHIP_RESET.  This register is Secure read/write only.	RW	0x5bad
	Enumerated values:		
	0x5bad → NO: Do not force the glitch detectors to be armed		
	0x0000 → YES: Force the glitch detectors to be armed. (Any value other than ARM_NO counts as YES)		

## GLITCH\_DETECTOR: DISARM Register

Offset: 0x04

Table 973. DISARM Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	Forcibly disarm the glitch detectors, if they are armed by OTP. Ignored if ARM is YES.  This register is Secure read/write only.	RW	0x0000
	Enumerated values:		
	0x0000 → NO: Do not disarm the glitch detectors. (Any value other than DISARM_YES counts as NO)		
	0xdcaf → YES: Disarm the glitch detectors		

## GLITCH\_DETECTOR: SENSITIVITY Register

Offset: 0x08

### Description

Adjust the sensitivity of glitch detectors to values other than their OTP-provided defaults.

This register is Secure read/write only.

Table 974. SENSITIVITY Register

Bits	Description	Type	Reset
31:24	<b>DEFAULT</b>	RW	0x00
	Enumerated values:		
	0x00 → YES: Use the default sensitivity configured in OTP for all detectors. (Any value other than DEFAULT_NO counts as YES)		
	0xde → NO: Do not use the default sensitivity configured in OTP. Instead use the value from this register.		
23:16	Reserved.	-	-
15:14	<b>DET3_INV</b> : Must be the inverse of DET3, else the default value is used.	RW	0x0
13:12	<b>DET2_INV</b> : Must be the inverse of DET2, else the default value is used.	RW	0x0

位	描述	类型	复位

## 10.10. Factory test JTAG

RP2350 contains JTAG hardware that is used to test devices after manufacturing. It is not a public interface, but its capabilities are documented here for user risk assessment.

Much like the user-facing SWD debug, the JTAG interface is disabled at power-on, and enabled only once the OTP power-on state machine has completed. If the [CRIT1.SECURE\\_BOOT\\_ENABLE](#), [CRIT1.SECURE\\_DEBUG\\_DISABLE](#) or [CRIT1.DEBUG\\_DISABLE](#) flag is set, then the JTAG interface remains held in reset indefinitely, so it cannot be communicated with and cannot control internal hardware. The only way to re-enable the JTAG interface after setting one of these critical flags is to set the RMA OTP flag ([Section 10.11](#)), which also permanently disables read and write access to user OTP pages. The RMA flag itself is write-protected using the page 63 protection flags, so you can prevent untrusted software from programming the RMA flag.

To take the JTAG interface out of reset, write to bit 0 of the RP-AP control register, accessed via SWD. To connect the JTAG interface to GPIOs ([TCK](#), [TMS](#), [TDI](#), [TDO](#) on GPIO0 → 3), set bit 1 of the RP-AP control register. The RP-AP is always accessible, even when external debug is disabled, because it is also used to enter the debug keys ([Section 3.5.9.2](#)). However, attempts to remove the JTAG reset are ignored when any of the aforementioned critical OTP flags are set.

The JTAG interface provides:

- Standard test capabilities such as IDCODE and EXTEST (boundary scan); these are not guaranteed to be IEEE-compliant, as this is an internal factory test interface, not a user-facing debug port
- Full AHB bus access, with Secure and Privileged attributes and an HMASTER of 3 (debugger)
- Asynchronous access to a small subset of register controls, generally limited to clocks, oscillators and reset controls

The JTAG interface's AHB bus access is muxed in place of the DMA read port, when the JTAG interface is enabled.

Any and all details of the factory test JTAG interface, with the exception of which OTP flags disable and re-enable it, are subject to change with revisions of the RP2350 silicon.

## 10.11. Decommissioning

Devices returned to Raspberry Pi Ltd for fault analysis must be **decommissioned** before return, to restore factory test functionality. A device is decommissioned by programming the OTP [PAGE63\\_LOCK0.RMA](#) flag to 1. Return may be requested by Raspberry Pi Ltd when diagnosing systematic issues across a population of devices.

Setting the RMA flag has two effects:

- The factory test JTAG interface is re-enabled, irrespective of the values of any [CRIT1](#) flags.
- Pages 3 through 61 become permanently inaccessible: this is all pages that do not have predefined contents listed in [Section 13.10](#).

表97。

## 10.10. 工厂测试 JTAG

RP2350包含用于制造后设备测试的JTAG硬件。该接口非公开，但其功能已在此处记录，供用户进行风险评估。

与面向用户的 SWD 调试类似，JTAG 接口在上电时默认禁用，只有在 OTP 上电状态机完成后才被启用。若设置了 CRIT1\_SECURE\_BOOT\_ENABLE、CRIT1\_SECURE\_DEBUG\_DISABLE 或 CRIT1.DEBUG\_DISABLE 标志，JTAG 接口将被无限期保持复位状态，无法通信，也无法控制内部硬件。在设置上述任一关键标志后，唯一重新启用 JTAG 接口的方法是设置 RMA OTP 标志（详见第 10.11 节），但该操作同时永久禁止对用户 OTP 页的读写访问。RMA 标志本身通过第 63 页保护标志进行写保护，可防止不受信任的软件编程该标志。

要将 JTAG 接口从复位状态解除，可通过 SWD 访问并写入 RP-AP 控制寄存器的第 0 位。若要将 JTAG 接口连接至 GPIO (TCK、TMS、TDI、TDO 映射至 GPIO0 → 3)，请设置 RP-AP 控制寄存器的第 1 位。RP-AP 始终可访问，即使外部调试被禁用，因为它也用于输入调试密钥（见3.5.9.2节）。

然而，当任何上述关键 OTP 标志被设置时，尝试移除 JTAG 复位的操作将被忽略。

JTAG 接口提供：

- 标准测试功能，如 IDCODE 和 EXTEST（边界扫描）；这些功能不保证符合 IEEE 标准，因为这是内部工厂测试接口，而非面向用户的调试端口。
- 完整的 AHB 总线访问，具备安全和特权属性，HMASTER 为 3（调试器）。
- 对部分寄存器控制的异步访问，通常限于时钟、振荡器和复位控制。

当 JTAG 接口启用时，其 AHB 总线访问将复用 DMA 读端口。

工厂测试 JTAG 接口的所有细节，除禁用及重新启用该接口的 OTP 标志外，均可随 RP2350 硅片版本的修订而变更。

## 10.11. 退役

返还至 Raspberry Pi Ltd 进行故障分析的设备，必须在返还前完成退役操作，以恢复工厂测试功能。设备退役通过将 OTP PAGE63\_LOCK0.RMA 标志设置为 1 实现。当对大量设备进行系统性问题诊断时，Raspberry Pi Ltd 可能会要求返还设备。

设置 RMA 标志具有以下两项效果：

- 工厂测试的 JTAG 接口将被重新启用，无视任何 CRIT1 标志的状态。
- 第 3 至 61 页将永久无法访问：这些页为未在第 13.10 节中列出预定义内容的全部页。

The effect on OTP contents is as though all had been promoted to the inaccessible lock level:

- write attempts will fail
- read attempts will return all-ones, when read via an unguarded read alias, or bus faults, when read via a guarded read alias

The logic that disables OTP access and the logic that re-enables the test interface are driven from the same signal internally, so this bit does not provide external access to user OTP contents, provided no sensitive material is stored in pages 0, 1, 2, 62 or 63. Setting the RMA flag is irreversible, and may render the device permanently unusable, if it is configured to boot from OTP contents stored in pages 3 through 61.

After setting the RMA flag, test the OTP access (e.g. via the SWD interface) and verify for yourself that any sensitive data stored in OTP has been made inaccessible.

The page 63 lock word has no other function besides RMA because pages 62/63 contain the lock words themselves, each of which is protected by its own permissions. This means the RMA flag can be write-protected by setting either a hard or soft lock on page 63.

对 OTP 内容的影响相当于所有内容均提升至不可访问的锁定等级：

- 写入操作将失败；
- 读取操作通过非保护读取别名时返回全 1，通过保护读取别名时产生总线错误。

禁用 OTP 访问的逻辑与重新启用测试接口的逻辑由同一内部信号控制，只要页面 0、1、2、62 或 63 中不存在敏感材料，该位不会为用户 OTP 内容提供外部访问权限。设置 RMA 标志为不可逆操作；如果设备配置为从第 3 至第 61 页存储的 OTP 内容启动，可能导致设备永久无法使用。

设置 RMA 标志后，请测试 OTP 访问（例如通过 SWD 接口），并自行确认存储在 OTP 中的任何敏感数据已被阻止访问。

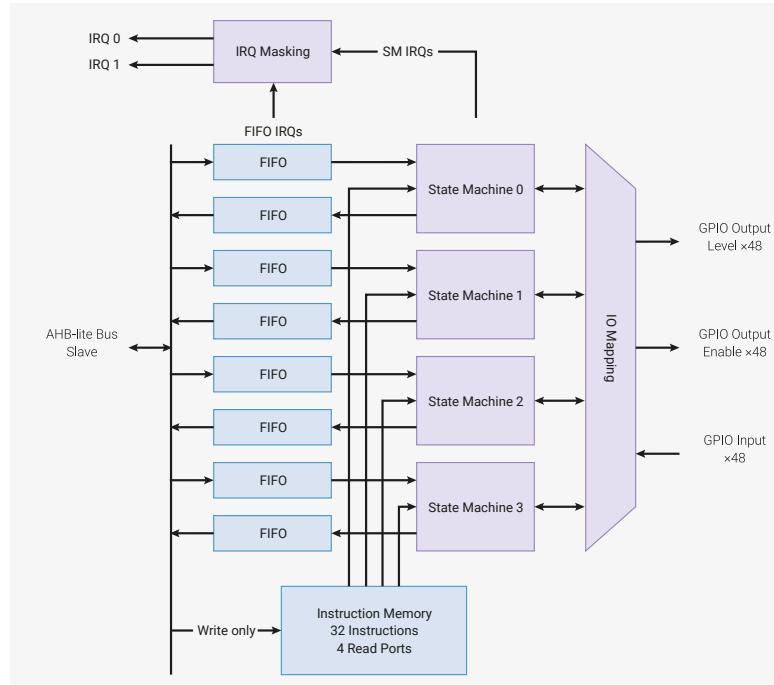

第 63 页的锁定字仅具备 RMA 功能，因为第 62 和 63 页包含锁定字本身，且每个锁定字均受其自身权限保护。这意味着通过对第 63 页设置硬锁或软锁，可以对 RMA 标志实施写保护。

# Chapter 11. PIO

## 11.1. Overview

RP2350 contains 3 identical PIO blocks. Each PIO block has dedicated connections to the bus fabric, GPIO and interrupt controller. The diagram for a single PIO block is shown below in [Figure 44](#).

**Figure 44.** PIO block-level diagram. There are three PIO blocks, each containing four state machines. The four state machines simultaneously execute programs from shared instruction memory. FIFO data queues buffer data transferred between PIO and the system. GPIO mapping logic allows each state machine to observe and manipulate up to 32 GPIOs.

The **programmable input/output block (PIO)** is a versatile hardware interface. It can support a variety of IO standards, including:

- 8080 and 6800 parallel bus
- I<sup>2</sup>C
- 3-pin I<sup>2</sup>S
- SDIO
- SPI, DSPI, QSPI
- UART
- DPI or VGA (via resistor DAC)

PIO is programmable in the same sense as a processor. There are three PIO blocks with four state machines. Each can independently execute sequential programs to manipulate GPIOs and transfer data. Unlike a general purpose processor, PIO state machines are specialised for IO, with a focus on determinism, precise timing, and close integration with fixed-function hardware. Each state machine is equipped with:

- Two 32-bit shift registers (either direction, any shift count)
- Two 32-bit scratch registers
- 4 × 32-bit bus FIFO in each direction (TX/RX), reconfigurable as 8 × 32 in a single direction
- Fractional clock divider (16 integer, 8 fractional bits)

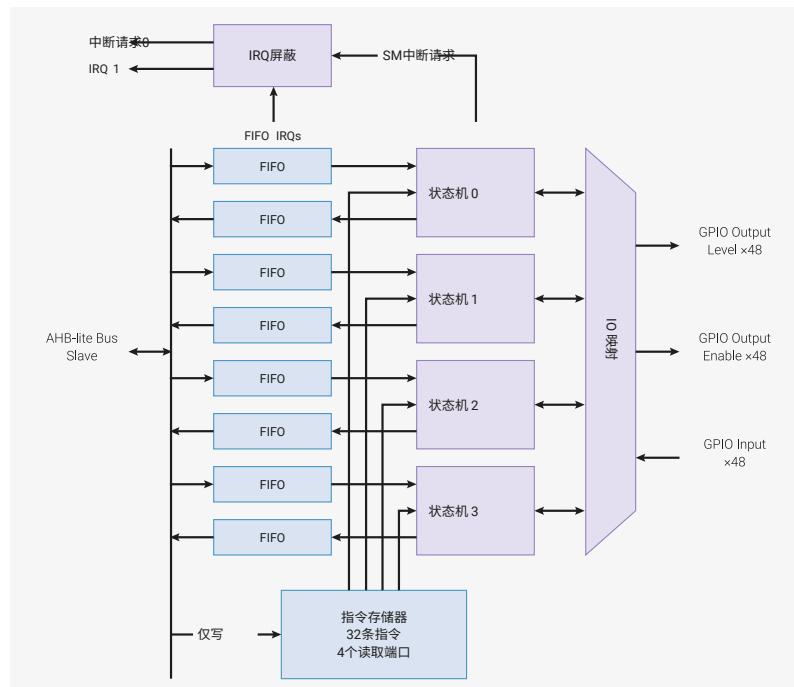

# 第11章 PIO

## 11.1. 概述

RP2350包含3个相同的PIO模块。每个PIO模块均设有专用连接，分别通向总线架构、GPIO及中断控制器。单个PIO模块的示意图如图44所示。

图 44. PIO 模块级示意图。共有三个 PIO 模块，每个模块包含四个状态机。这四个状态机同时从共享指令存储器执行程序。

FIFO 数据队列缓冲 PIO 与系统之间传输的数据。G PIO 映射逻辑允许每个状态机观察并操作最多 32 个 GPIO。

可编程输入/输出模块（PIO）是一种多功能硬件接口。它支持多种 IO 标准，包括：

- 8080 和 6800 并行总线
- I<sub>2</sub>C
- 3 针 I<sub>2</sub>S
- SDIO
- SPI、DSPI、QSPI
- UART
- DPI 或 VGA（通过电阻式 DAC）

PIO 的可编程性与处理器相同。共有三个 PIO 模块，每个含四个状态机。每个状态机均可独立执行顺序程序，以操作 GPIO 并传输数据。与通用处理器不同，PIO 状态机专门用于 IO，强调确定性、精确时序及与固定功能硬件的紧密集成。每个状态机配备：

- 两个 32 位移位寄存器（支持任意方向及任意移位数）
- 两个 32 位暂存寄存器
- 双向各 4×32 位总线 FIFO，可重新配置为单向 8×32 位
- 分数时钟分频器（16 位整数、8 位小数）

- Flexible GPIO mapping
- DMA interface (sustained throughput up to 1 word per clock from system DMA)
- IRQ flag set/clear/status

Each state machine, along with its supporting hardware, occupies approximately the same silicon area as a standard serial interface block, such as an SPI or I2C controller. However, PIO state machines can be configured and reconfigured dynamically to implement numerous different interfaces.

Making state machines programmable in a software-like manner, rather than a fully configurable logic fabric like a complex programmable logic device (CPLD), allows more hardware interfaces to be offered in the same cost and power envelope. This also presents a more familiar programming model, and simpler tool flow, to those who wish to exploit PIO's full flexibility by programming it directly, rather than using a pre-made interface from the PIO library.

PIO is performant as well as flexible, thanks to a carefully selected set of fixed-function hardware inside each state machine. When outputting DPI, PIO can sustain 360 Mb/s during the active scanline period when running from a 48 MHz system clock. In this example, one state machine handles frame/scanline timing and generates the pixel clock. Another handles the pixel data and unpacks run-length-encoded scanlines.

State machines' inputs and outputs are mapped to up to 32 GPIOs (limited to 30 GPIOs for RP2350). All state machines have independent, simultaneous access to any GPIO. For example, the standard UART code allows TX, RX, CTS and RTS to be any four arbitrary GPIOs, and I2C permits the same for SDA and SCL. The amount of freedom available depends on how exactly a given PIO program chooses to use PIO's pin mapping resources, but at the minimum, an interface can be freely shifted up or down by some number of GPIOs.

### 11.1.1. Changes from RP2040

RP2350 adds the following new registers and controls:

- **DBG\_CFGINFO.VERSION** indicates the PIO version, to allow PIO feature detection at runtime.
  - This 4-bit field was reserved-0 on RP2040 (indicating version 0), and reads as 1 on RP2350.
- **GPIOBASE** adds support for more than 32 GPIOs per PIO block.
  - Each PIO block is still limited to 32 GPIOs at a time, but **GPIOBASE** selects which 32.
- **CTRL.NEXT\_PIO\_MASK** and **CTRL.PREV\_PIO\_MASK** apply some **CTRL** register operations to state machines in neighbouring PIO blocks simultaneously.
  - **CTRL.NEXTPREV\_SM\_DISABLE** stops PIO state machines in multiple PIO blocks simultaneously.
  - **CTRL.NEXTPREV\_SM\_ENABLE** starts PIO state machines in multiple PIO blocks simultaneously.
  - **CTRL.NEXTPREV\_CLKDIV\_RESTART** synchronises the clock dividers of PIO state machines in multiple PIO blocks
- **SM0\_SHIFTCTRL.IN\_COUNT** masks unneeded IN-mapped pins to zero.
  - This is useful for **MOV x, PINS** instructions, which previously always returned a full rotated 32-bit value.
- **IRQ0\_INTE** and **IRQ1\_INTE** now expose all eight SM IRQ flags to system-level interrupts (not just the lower four).
- Registers starting from **RXF0\_PUTGET0** expose each RX FIFO's internal storage registers for random read or write access from the system,
  - The new **FJOIN\_RX\_PUT** FIFO join mode enables random writes from the state machine, and random reads from the system (for implementing status registers).
  - The new **FJOIN\_RX\_GET** FIFO join mode enables random reads from the state machine, and random writes from the system (for implementing control registers).
  - Setting both **FJOIN\_RX\_PUT** and **FJOIN\_RX\_GET** enables random read and write access from the state machine, but disables system access.

- 灵活的 GPIO 映射
- DMA 接口（系统 DMA 可持续吞吐量高达每个时钟周期 1 字）
- IRQ 标志设置／清除／状态

每个状态机及其辅助硬件所占用的硅面积大致相当于一个标准的串行接口模块，例如SPI或I2C控制器。然而，PIO状态机可以动态配置和重新配置，以实现多种不同的接口。

使状态机以类似软件编程的方式进行编程，而非像复杂可编程逻辑器件（CPLD）那样完全可配置的逻辑结构，能够在相同的成本和功耗范围内提供更多的硬件接口。这也为希望直接编程利用PIO全部灵活性的用户提供了更为熟悉的编程模型和更简便的工具流程，而无需依赖PIO库中的预制接口。

PIO不仅灵活，而且性能卓越，这得益于每个状态机内部精心挑选的一组固定功能硬件。当系统时钟为48 MHz时，PIO在输出DPI的活动扫描线期间能够维持360 Mb/s的数据传输速率。在本例中，一个状态机负责帧和扫描线的时序控制，并生成像素时钟。

另一个模块处理像素数据并解码行程长度压缩的扫描线。

状态机的输入与输出最多可映射至32个GPIO（RP2350限制为30个GPIO）。所有状态机均可独立且同时访问任意GPIO。例如，标准UART代码允许 TX、RX、CTS 和 RTS 任意指定为四个GPIO，I2C 对 SDA 和 SCL 亦同。可用自由度取决于特定PIO程序如何使用PIO的引脚映射资源，但至少接口可以在一定GPIO范围内自由上下移动。

### 11.1.1. 与 RP2040 的变化

RP2350新增以下寄存器与控制：

- **DBG\_CFGINFO.VERSION** 表明 PIO 版本，用以运行时检测 PIO 功能。
  - 此 4 位字段在 RP2040 上保留为 0（表示版本 0），在 RP2350 上读取为 1。
- **GPIOBASE** 增加了对每个 PIO 块超过 32 个 GPIO 的支持。
  - 每个 PIO 块仍然限制一次使用 32 个 GPIO，但 GPIOBASE 选择哪 32 个。
- **CTRL.NEXT\_PIO\_MASK** 和 **CTRL.PREV\_PIO\_MASK** 对相邻 PIO 块中的状态机同时应用部分 **CTRL** 寄存器操作。
  - **CTRL.NEXTPREV\_SM\_DISABLE** 同时停止多个 PIO 块中的 PIO 状态机。
  - **CTRL.NEXTPREV\_SM\_ENABLE** 同时启动多个 PIO 块中的 PIO 状态机。
  - **CTRL.NEXTPREV\_CLKDIV\_RESTART** 同步多个 PIO 块中 PIO 状态机的时钟分频器。
- **SM0\_SHIFTCTRL.IN\_COUNT** 将不需要的映射到 IN 的引脚屏蔽为零。
  - 这对于 **MOV x, PINS** 指令非常有用，该指令此前总是返回完整旋转的 32 位值。
- **IRQ0\_INTE** 和 **IRQ1\_INTE** 现在将所有八个 SM 中断标志暴露给系统级中断（不仅限于低四位）。
- 从 RXF0\_PUTGET0 开始的寄存器允许系统对每个 RX FIFO 的内部存储寄存器进行随机读或写访问，
  - 新的 **FJOIN\_RX\_PUTFIFO** 连接模式允许状态机进行随机写入，系统进行随机读取（用于实现状态寄存器）。
  - 新的 **FJOIN\_RX\_GETFIFO** 连接模式允许状态机进行随机读取，系统进行随机写入（用于实现控制寄存器）。
  - 同时设置 **FJOIN\_RX\_PUT** 和 **FJOIN\_RX\_GET** 可使状态机实现随机读写，但系统访问将被禁用。

RP2350 adds the following new instruction features:

- Adds `PINCTRL_JMP_PIN` as a source for the `WAIT` instruction, plus an offset in the range 0-3.
  - This gives `WAIT` pin arguments a per-SM mapping that is independent of the IN-mapped pins.
- Adds `PINDIRS` as a destination for `MOV`.
  - This allows changing the direction of all OUT-mapped pins with a single instruction: `MOV PINDIRS, NULL` or `MOV PINDIRS, ~NULL`
- Adds SM IRQ flags as a source for `MOV x, STATUS`
  - This allows branching (as well as blocking) on the assertion of SM IRQ flags.
- Extends `IRQ` instruction encoding to allow state machines to set, clear and observe IRQ flags from different PIO blocks.
  - There is no delay penalty for cross-PIO IRQ flags: an `IRQ` on one state machine is observable to all state machines on the next cycle.
- Adds the `FJOIN_RX_GET` FIFO mode.
  - A new `MOV` encoding reads any of the four RX FIFO storage registers into `OSR`.
  - This instruction permits random reads of the four FIFO entries, indexed either by instruction bits or the `Y` scratch register.
- Adds the `FJOIN_RX_PUT` FIFO mode.
  - A new `MOV` encoding writes the `ISR` into any of the four RX FIFO storage registers.
  - The registers are indexed either by instruction bits or the `Y` scratch register.

RP2350 adds the following security features:

- Limits Non-secure PIOs (set to via ACCESSCTRL) to observation of only Non-secure GPIOs. Attempting to read a Secure GPIO returns a 0.
- Disables cross-PIO functionality (IRQs, `CTRL_NEXTPREV` operations) between Non-secure PIO blocks (those which permit Non-secure access according to ACCESSCTRL) and Secure-only blocks (those which do not).

RP2350 includes the following general improvements:

- Increased the number of PIO blocks from two to three (8 → 12 state machines).
- Improved GPIO input/output delay and skew.
- Reduced DMA request (DREQ) latency by one cycle vs RP2040.

## 11.2. Programmer's model

The four state machines execute from shared instruction memory. System software loads programs into this memory, configures the state machines and IO mapping, and then sets the state machines running. PIO programs come from various sources: assembled directly by the user, drawn from the PIO library, or generated programmatically by user software.

From this point on, state machines are generally autonomous, and system software interacts through DMA, interrupts and control registers, as with other peripherals on RP2350. For more complex interfaces, PIO provides a small but flexible set of primitives which allow system software to be more hands-on with state machine control flow.

RP2350 新增了以下指令特性：

- 增加了 `PINCTRL_JMP_PIN` 作为 `WAIT` 指令的来源，偏移范围为 0 至 3。
  - 这使得 `WAIT` 针脚参数实现按状态机独立映射，且不依赖于 IN 映射的针脚。
- 增加了 `PINDIRS` 作为 `MOV` 指令的目的操作数。
  - 这允许通过一条指令更改所有 OUT 映射针脚的方向：`MOV PINDIRS, NULL` 或 `MOV PINDIRS, ~NULL`。
- 增加了状态机中断标志作为 `MOV x, STATUS` 指令的来源。
  - 此功能允许基于 SM IRQ 标志的断言进行分支及阻塞。
- 扩展了 `IRQ` 指令编码，支持状态机设置、清除及监测来自不同 PIO 块的 IRQ 标志。
  - 跨 PIO 的 IRQ 标志无延迟惩罚：一个状态机上的 `IRQ` 可于下一周期被所有状态机观察到。
- 新增了 `FJOIN_RX_GET` FIFO 模式。
  - 一种新的 `MOV` 编码，可将任一四个 RX FIFO 存储寄存器的数据读取至 `OSR`。
  - 该指令允许根据指令位或 Y 临时寄存器索引，对四个 FIFO 条目进行随机读取。
- 新增了 `FJOIN_RX_PUT` FIFO 模式。
  - 一种新的 `MOV` 编码，可将 `ISR` 写入任一四个 RX FIFO 存储寄存器。
  - 寄存器索引由指令位或 Y 临时寄存器指定。

RP2350 新增以下安全功能：

- 非安全 PIO（通过 `ACCESSCTRL` 设置）仅限观察非安全 GPIO。尝试读取安全 GPIO 时将返回 0。
- 禁用非安全 PIO 块（根据 `ACCESSCTRL` 允许非安全访问的）与仅限安全块（不允许访问的）之间的跨 PIO 功能（中断，`CTRL_NEXTPREV` 操作）。

RP2350 包含以下一般性改进：

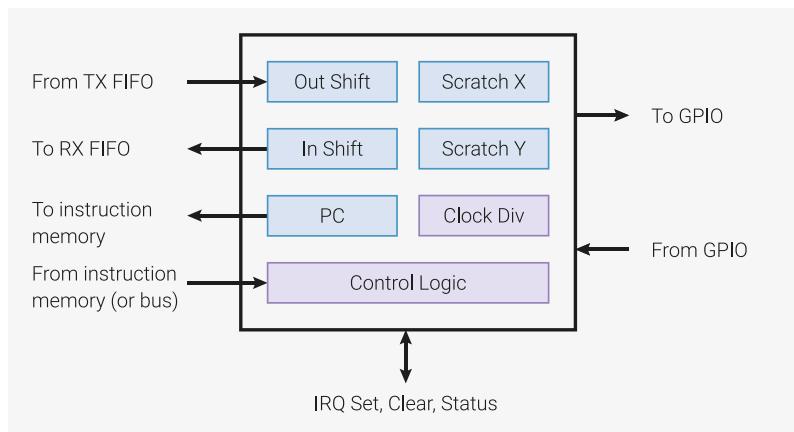

- 将 PIO 块数量从两个增加到三个（8 → 12 个状态机）。
- 改进了 GPIO 输入输出延迟及偏移。
- 相较 RP2040，DMA 请求（DREQ）延迟减少一个周期。

## 11.2. 程序员模型

这四个状态机均从共享指令存储器执行程序。系统软件向该存储器加载程序，配置状态机及 IO 映射，然后启动状态机运行。PIO 程序来源多样：由用户直接汇编、PIO 库提供，或由用户软件程序生成。

从此，状态机通常自治，系统软件通过 DMA、中断和控制寄存器与其交互，类似于 RP2350 上的其他外设。对于更复杂的接口，PIO 提供一组小巧而灵活的原语，允许系统软件更直接控制状态机的控制流。

**Figure 45. State machine overview.**  
 Data flows in and out through a pair of FIFOs. The state machine executes a program which transfers data between these FIFOs, a set of internal registers, and the pins. The clock divider can reduce the state machine's execution speed by a constant factor.

### 11.2.1. PIO programs

PIO state machines execute short binary programs.

Programs for common interfaces, such as UART, SPI, or I2C, are available in the PIO library. In many cases, it is not necessary to write PIO programs. However, the PIO is much more flexible when programmed directly, supporting a wide variety of interfaces which may not have been foreseen by its designers.

The PIO has a total of nine instructions: `JMP`, `WAIT`, `IN`, `OUT`, `PUSH`, `PULL`, `MOV`, `IRQ`, and `SET`. For more information about these instructions, see [Section 11.4](#).

Though the PIO only has a total of nine instructions, it would be difficult to edit PIO program binaries by hand. PIO assembly is a textual format, describing a PIO program, where each command corresponds to one instruction in the output binary. The following code snippet contains an example program written in PIO assembly:

*Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.pio> Lines 8 - 13*

```

8 .program squarewave
9 set pindirs, 1 ; Set pin to output
10 again:
11 set pins, 1 [1] ; Drive pin high and then delay for one cycle
12 set pins, 0 ; Drive pin low
13 jmp again ; Set PC to label `again'

```

The PIO assembler is included with the SDK, and is called `pioasm`. This program processes a PIO assembly input text file, which may contain multiple programs, and writes out the assembled programs ready for use. For the SDK, these assembled programs are emitted as C headers, containing constant arrays.

For more information, see [Section 11.3](#).

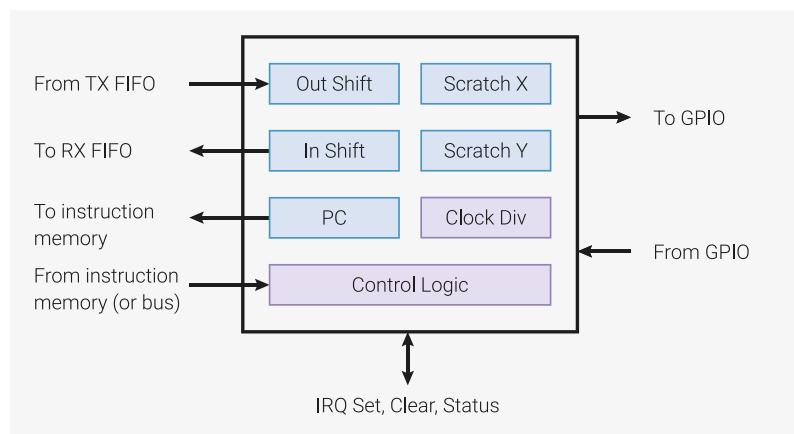

### 11.2.2. Control flow

On every system clock cycle, each state machine fetches, decodes and executes one instruction. Each instruction takes precisely one cycle, unless it explicitly stalls (such as the `WAIT` instruction). Instructions may insert a delay of up to 31 cycles before the next instruction execute, to help write cycle-exact programs.

The program counter, or `PC`, points to the location in the instruction memory being executed on this cycle. Generally, `PC` increments by one each cycle, wrapping at the end of the instruction memory. Jump instructions are an exception and explicitly provide the next value that `PC` will take.

Our example assembly program (listed as `.program squarewave` above) shows both of these concepts in practice. It drives a 50/50 duty cycle square wave with a period of four cycles onto a GPIO. Using some other features (e.g. side-set) this can be made as low as two cycles.

概述  
数据通过一对FIFO流入和流出。  
状态机执行的程序在这些FIFO、一组内部寄存器与引脚之间传输数据。  
时钟分频器可以将状态机的执行速度按固定倍数降低。

### 11.2.1. PIO 程序

PIO状态机执行简短的二进制程序。

常见接口（如UART、SPI或I2C）的程序可在PIO库中获得。在许多情况下，无需编写PIO程序。然而，直接编程PIO更具灵活性，能够支持设计者可能未预见的多种接口。

PIO共有九条指令：`JMP`、`WAIT`、`IN`、`OUT`、`PUSH`、`PULL`、`MOV`、`IRQ`和`SET`。有关这些指令的详细信息，请参见第11.4节。

虽然PIO总共仅有九条指令，但手动编辑PIO程序二进制文件仍极为困难。PIO汇编是一种文本格式，用于描述PIO程序，其中的每条命令对应于输出二进制文件中的一条指令。以下代码片段展示了一个用PIO汇编语言编写的示例程序：

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.pio> 第8至13行

```

8 .program squarewave
9 set pindirs, 1 ; 将引脚方向设置为输出
10 again:
11 set pins, 1 [1] ; 驱动引脚为高电平，然后延迟一个周期
12 set pins, 0 ; 驱动引脚为低电平
13 jmp again ; 程序计数器跳转至标签`again`
```

PIO汇编器包含于SDK中，名称为 `pioasm`。该程序处理PIO汇编输入文本文件，文件中可包含多个程序，并将组装好的程序写出以供使用。对于SDK，这些组装程序以C头文件的形式输出，包含常量数组。

更多信息，请参见第11.3节。

### 11.2.2. 控制流

在每个系统时钟周期内，每个状态机均取指、译码并执行一条指令。除非明确发生停顿（例如 `WAIT` 指令），否则每条指令恰占用一个周期。指令可在下一条指令执行前插入最长31个周期的延迟，以便编写精确到周期的程序。

程序计数器，简称 `PC`，指向当前周期正在执行的指令存储位置。一般情况下，`PC` 每个周期递增1，并在指令存储末尾回绕。跳转指令为例外，明确指定 `PC` 将取的下一值。

我们的示例汇编程序（上述列出的 `.program squarewave`）演示了这些概念的实际应用。此程序在GPIO引脚上输出占空比为50%、周期为四个时钟周期的方波。利用其他功能（如side-set），周期可缩短至两个时钟周期。

**NOTE**

Side-set is where a state machine drives a small number of GPIOs *in addition to* the main side effects of the instruction it executes. It's described fully in [Section 11.5.1](#).

The system has write-only access to the instruction memory, which is used to load programs. The clock divider slows the state machine's execution by a constant factor, represented as a 16.8 fixed-point fractional number. In the following example, if a clock division of `2.5` were programmed, the square wave would have a period of  $4 \times 2.5 = 10$  cycles. This is useful for setting a precise baud rate for a serial interface, such as a UART.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> Lines 34 - 38

```
34 // Load the assembled program directly into the PIO's instruction memory.
35 // Each PIO instance has a 32-slot instruction memory, which all 4 state
36 // machines can see. The system has write-only access.
37 for (uint i = 0; i < count_of(squarewave_program_instructions); ++i)
38 pio->instr_mem[i] = squarewave_program_instructions[i];
```

The following code fragments are part of a complete code example which drives a 12.5 MHz square wave out of GPIO 0 (or any other pins we might choose to map). We can also use pins `WAIT PIN` instruction to stall a state machine's execution for some amount of time, or a `JMP PIN` instruction to branch on the state of a pin, so control flow can vary based on pin state.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> Lines 42 - 47

```
42 // Configure state machine 0 to run at sysclk/2.5. The state machines can
43 // run as fast as one instruction per clock cycle, but we can scale their
44 // speed down uniformly to meet some precise frequency target, e.g. for a
45 // UART baud rate. This register has 16 integer divisor bits and 8
46 // fractional divisor bits.
47 pio->sm[0].clkdiv = (uint32_t) (2.5f * (1 << 16));
```

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> Lines 51 - 59

```
51 // There are five pin mapping groups (out, in, set, side-set, jmp pin)
52 // which are used by different instructions or in different circumstances.
53 // Here we're just using SET instructions. Configure state machine 0 SETs
54 // to affect GPIO 0 only; then configure GPIO0 to be controlled by PI00,
55 // as opposed to e.g. the processors.
56 pio->sm[0].pinctrl =
57 (1 << PIO_SM0_PINCTRL_SET_COUNT_LSB) |
58 (0 << PIO_SM0_PINCTRL_SET_BASE_LSB);
59 gpio_set_function(0, pio_get_funcsel(pio));
```

The system can start and stop each state machine at any time, via the CTRL register. Multiple state machines can be started simultaneously, and the deterministic nature of PIO means they can stay perfectly synchronised.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> Lines 63 - 67

```
63 // Set the state machine running. The PIO CTRL register is global within a
64 // PIO instance, so you can start/stop multiple state machines
65 // simultaneously. We're using the register's hardware atomic set alias to
66 // make one bit high without doing a read-modify-write on the register.
67 hw_set_bits(&pio->ctrl, 1 << (PIO_CTRL_SM_ENABLE_LSB + 0));
```

### ⓘ 注意

Side-set 指的是状态机在执行指令的主要副作用之外，驱动少量 GPIO 的操作。详见第11.5.1节。

系统对指令存储器具有写入权限，用以加载程序。时钟分频器以16.8固定点小数形式表示的常数因子，恒定地减缓状态机的执行速度。在下述示例中，若设定了 2.5的时钟分频，方波的周期将为

$4 \times 2.5$  全时钟周期。

此功能对于为串口接口（如UART）设定精确波特率十分有用。

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> 第34至38行

```

34 // 直接将汇编程序加载至 PIO 指令存储器。
35 // 每个 PIO 实例配备一个32槽的指令存储器，供所有4个状态
36 // 机器可见。系统具有写入权限。
37 for (uint i = 0; i < count_of(squarewave_program_instructions); ++i)
38 pio->instr_mem[i] = squarewave_program_instructions[i];

```

以下代码片段为完整代码示例的一部分，该示例驱动GPIO 0（或我们可能选择映射的其它引脚）输出12.5 MHz方波。我们还可使用引脚 WAIT PIN 指令使状态机执行暂停一段时间，或使用 JMP PIN 指令根据引脚状态进行跳转，从而使控制流依据引脚状态发生变化。

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> 第42至47行

```

42 // 配置状态机0以sysclk/2.5的频率运行。状态机可
43 // 运作速度最快每个时钟周期可执行一条指令，但我们可以将其
44 // 速度均匀降低，以满足某一精确频率目标，例如
45 // UART 波特率。该寄存器包含 16 位整数除数位和8位
46 // 分数除数位。
47 pio->sm[0].clkdiv = (uint32_t) (2.5f * (1 << 16));

```

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> 第51至59行

```

51 // 共有五组引脚映射 (out、in、set、side-set、jmp pin)
52 // 不同指令或不同情况下使用这些映射。
53 // 此处仅使用SET指令。配置状态机0的SET指令
54 // 仅作用于GPIO 0；然后配置GPIO0由PIO0控制，
55 // 而不是例如处理器。
56 pio->sm[0].pinctrl =
57 (1 << PIO_SM0_PINCTRL_SET_COUNT_LSB) |
58 (0 << PIO_SM0_PINCTRL_SET_BASE_LSB);
59 gpio_set_function(0, pio_get_funcsel(pio));

```

系统可通过CTRL寄存器随时启动或停止任一状态机。多个状态机可同时启动，且PIO的确定性特性确保其保持完全同步。

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.c> 第63至67行

```

63 // 启动状态机。PIO CTRL 寄存器在
64 // 一个PIO实例内为全局寄存器，因此可同时启动/停止多个状态机
65 // 。我们使用该寄存器的硬件原子设置别名来
66 // 在不进行读-改-写操作的情况下，将一个比特位设置为高电平。
67 hw_set_bits(&pio->ctrl, 1 << (PIO_CTRL_SM_ENABLE_LSB + 0));

```

Most instructions are executed from instruction memory, but there are other sources which can be freely mixed:

- Instructions written to a special configuration register (`SMx INSTR`) are immediately executed, momentarily interrupting other execution. For example, a `JMP` instruction written to `SMx INSTR` causes the state machine to start executing from a different location.
- Instructions can be executed from a register, using the `MOV EXEC` instruction.
- Instructions can be executed from the output shifter, using the `OUT EXEC` instruction

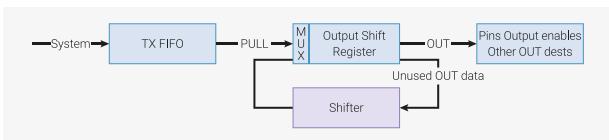

The last of these is particularly versatile: instructions can be embedded in the stream of data passing through the FIFO. The I2C example uses this to embed e.g. `STOP` and `RESTART` line conditions alongside normal data. In the case of `MOV` and `OUT EXEC`, the `MOV/OUT` itself executes in one cycle, and the executee on the next.

### 11.2.3. Registers

Each state machine possesses a small number of internal registers. These hold input or output data, and temporary values such as loop counter variables.

#### 11.2.3.1. Output Shift Register (OSR)

*Figure 46. Output Shift Register (OSR). Data is parcelled out 1...32 bits at a time, and unused data is recycled by a bidirectional shifter. Once empty, the OSR is reloaded from the TX FIFO.*

The Output Shift Register (OSR) holds and shifts output data between the TX FIFO and the pins or other destinations, such as the scratch registers.

- `PULL` instructions: remove a 32-bit word from the TX FIFO and place into the OSR.
- `OUT` instructions shift data from the OSR to other destinations, 1...32 bits at a time.
- The OSR fills with zeroes as data is shifted out
- The state machine will automatically refill the OSR from the FIFO on an `OUT` instruction, once some total shift count threshold is reached, if autopull is enabled
- Shift direction can be left/right, configurable by the processor via configuration registers

For example, to stream data through the FIFO and output to the pins at a rate of one byte per two clocks:

```

1 .program pull_example1
2 loop:
3 out pins, 8
4 public entry_point:
5 pull
6 out pins, 8 [1]
7 out pins, 8 [1]
8 out pins, 8
9 jmp loop

```

### 11.2.4. Autopull

**Autopull** (see [Section 11.5.4](#)) allows the hardware to automatically refill the OSR in the majority of cases, with the state machine stalling if it tries to `OUT` from an empty OSR. This has two benefits:

大多数指令从指令存储器执行，但也有其他来源，可以自由混合使用：

- 写入特殊配置寄存器 (**SM<sub>x</sub> INSTR**) 的指令会被立即执行，短暂中断其他指令的执行。例如，向**SM<sub>x</sub> INSTR**写入的**JMP**指令会使状态机从不同位置开始执行。

- 指令可以通过**MOV EXEC**指令从寄存器中执行。
- 指令可以通过**OUT EXEC**指令从输出移位寄存器执行。

最后一种用法极其灵活：指令可以嵌入通过FIFO传输的数据流中。

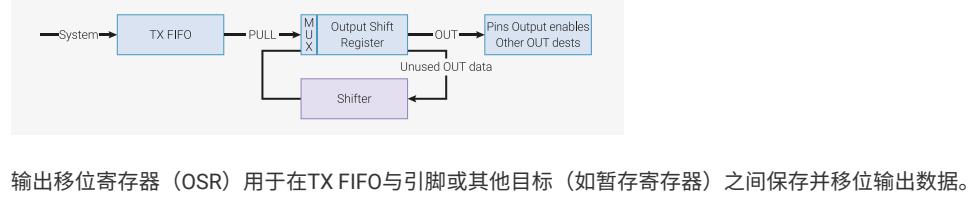

I2C示例利用此功能，嵌入例如 **STOP**和**RESTART**线路状态，与正常数据并存。在 **MOV**和**OUT EXEC**的情况下，**MOV/OUT**自身在一个周期内执行，而被执行的指令在下一个周期执行。

### 11.2.3. 寄存器

每个状态机拥有少量内部寄存器。这些寄存器保存输入或输出数据以及临时值，例如循环计数变量。

#### 11.2.3.1. 输出移位寄存器 (OSR)

图46。输出移位寄存器 (OSR)。数据一次分配1至32位，未使用的数据通过双向移位器回收利用。一旦清空，OSR将从TX FIFO重新加载。

输出移位寄存器 (OSR) 用于在TX FIFO与引脚或其他目标（如暂存寄存器）之间保存并移位输出数据。

- PULL** 指令：从TX FIFO取出一个32位字，放入OSR。
- OUT** 指令将数据从OSR移位至其他目标，每次移位1至32位。
- 数据移出时，OSR内自动用零填充。
- 启用自动拉取功能时，状态机会在执行**OUT**指令且达到总移位计数阈值后，自动从FIFO重新填充OSR。
- 移位方向可以是左或右，由处理器通过配置寄存器进行设置

例如，要通过FIFO流式传输数据并以每两个时钟周期输出一个字节到引脚：

```

1 .program pull_example1
2 loop:
3 out pins, 8
4 public entry_point:
5 pull
6 out pins, 8 [1]
7 out pins, 8 [1]
8 out pins, 8
9 jmp loop

```

### 11.2.4. 自动拉取

自动拉取（参见第11.5.4节）允许硬件在大多数情况下自动补充OSR，若状态机尝试从空的OSR **OUT**时将暂停执行。此功能具有两个优点：

- No instructions spent on explicitly pulling from FIFO at the right time
- Higher throughput: can output up to 32 bits on every single clock cycle, if the FIFO stays topped up

After configuring autopull, the above program can be simplified to the following, which behaves identically:

```
1 .program pull_example2
2
3 loop:
4 out pins, 8
5 public entry_point:
6 jmp loop
```

Program wrapping ([Section 11.5.2](#)) allows further simplification and, if desired, an output of 1 byte every system clock cycle.

```
1 .program pull_example3
2
3 public entry_point:
4 .wrap_target
5 out pins, 8 [1]
6 .wrap
```

#### 11.2.4.1. Input Shift Register (ISR)

*Figure 47. Input Shift Register (ISR). Data enters 1...32 bits at a time, and current contents is shifted left or right to make room. Once full, contents is written to the RX FIFO.*

- **IN** instructions shift 1...32 bits at a time into the register.
- **PUSH** instructions write the ISR contents to the RX FIFO.
- The ISR is cleared to all-zeroes when pushed.
- The state machine will automatically push the ISR on an **IN** instruction, once some shift threshold is reached, if autopush is enabled.
- Shift direction is configurable by the processor via configuration registers

Some peripherals, like UARTs, must shift in from the left to get correct bit order, since the wire order is LSB-first; however, the processor may expect the resulting byte to be right-aligned. This is solved by the special **null** input source, which allows the programmer to shift some number of zeroes into the ISR, following the data.

#### 11.2.4.2. Shift counters

State machines remember how many bits, in total, have been shifted out of the OSR via **OUT** instructions, and into the **ISR** via **IN** instructions. This information is tracked at all times by a pair of hardware counters: the output shift counter and the input shift counter. Each is capable of holding values from 0 to 32 inclusive. With each shift operation, the relevant counter increments by the shift count, up to the maximum value of 32 (equal to the width of the shift register). The state machine can be configured to perform certain actions when a counter reaches a configurable threshold:

- The OSR can be automatically refilled once some number of bits have been shifted out (see [Section 11.5.4](#)).
- The ISR can be automatically emptied once some number of bits have been shifted in (see [Section 11.5.4](#)).

- 无需使用指令在恰当时机显式从FIFO拉取数据
- 更高吞吐量：只要FIFO保持填充状态，每个时钟周期可输出最多32位

在配置自动拉取后，上述程序可简化为以下形式，且行为完全一致：

```
1 .program pull_example2
2
3 loop:
4 out pins, 8
5 public entry_point:
6 jmp loop
```

程序包裹（第11.5.2节）允许进一步简化，且如有需要，可每个系统时钟周期输出1字节。

```
1 .program pull_example3
2
3 public entry_point:
4 .wrap_target
5 out pins, 8 [1]
6 .wrap
```

#### 11.2.4.1 输入移位寄存器 (ISR)

图47。输入移位寄存器 (ISR)。  
数据每次输入1至32位，当前内容向左或向右移位以腾出空间。  
寄存器内容满后会写入RX FIFO。

- **IN** 指令每次向寄存器移入1至32位数据。
- **PUSH** 指令将ISR内容写入RX FIFO。
- 推送时ISR内容被清零。
- 若启用自动推送，状态机将在达到移位阈值后，于 **IN** 指令时自动推送ISR。
- 移位方向由处理器通过配置寄存器进行配置。

某些外设，如 UART，必须从左侧移位以获得正确的位序，因为线路顺序为最低有效位优先；但处理器可能期望得到的是右对齐的字节。该问题通过特殊的空输入源得到解决，该输入源允许程序员在数据后将一定数量的零移入ISR。

#### 11.2.4.2. 移位计数器

状态机记录通过 **OUT** 指令从OSR移出的位数总和，以及通过 **IN** 指令移入ISR的位数总和。此信息由一对硬件计数器实时跟踪：输出移位计数器和输入移位计数器。每个计数器均可保存0至32（含）之间的值。每次移位操作时，相关计数器按移位数递增，最大值为32（即移位寄存器的宽度）。当计数器达到可配置阈值时，状态机可被配置以执行特定操作：

- 当部分位已被移出后，OSR可自动重新填充（参见第11.5.4节）。
- 当部分位已被移入后，ISR可自动清空（参见第11.5.4节）。

- **PUSH** or **PULL** instructions can be conditioned on the input or output shift counter, respectively.

On PIO reset, or the assertion of **CTRL\_SM\_RESTART**, the input shift counter is cleared to 0 (nothing yet shifted in), and the output shift counter is initialised to 32 (nothing remaining to be shifted out; fully exhausted). Some other instructions affect the shift counters:

- A successful **PULL** clears the output shift counter to 0
- A successful **PUSH** clears the input shift counter to 0
- **MOV OSR, ...** (i.e. any **MOV** instruction that writes **OSR**) clears the output shift counter to 0
- **MOV ISR, ...** (i.e. any **MOV** instruction that writes **ISR**) clears the input shift counter to 0
- **OUT ISR, count** sets the input shift counter to **count**

### 11.2.4.3. Scratch registers

Each state machine has two 32-bit internal scratch registers, called **X** and **Y**.

They are used as:

- Source/destination for **IN/OUT/SET/MOV**
- Source for branch conditions

For example, suppose we wanted to produce a long pulse for "1" data bits, and a short pulse for "0" data bits:

```

1 .program ws2812_led
2
3 public entry_point:
4 pull
5 set x, 23 ; Loop over 24 bits
6 bitloop:
7 set pins, 1 ; Drive pin high
8 out y, 1 [5] ; Shift 1 bit out, and write it to y
9 jmp !y skip ; Skip the extra delay if the bit was 0
10 nop [5]
11 skip:
12 set pins, 0 [5]
13 jmp x-- bitloop ; Jump if x nonzero, and decrement x
14 jmp entry_point

```

Here **X** is used as a loop counter, and **Y** is used as a temporary variable for branching on single bits from the OSR. This program can be used to drive a WS2812 LED interface, although more compact implementations are possible (as few as 3 instructions).

**MOV** allows the use of the scratch registers to save/restore the shift registers if, for example, you would like to repeatedly shift out the same sequence.

**i NOTE**

A much more compact WS2812 example (4 instructions total) is shown in [Section 11.6.2](#).

### 11.2.4.4. FIFOs

Each state machine has a pair of 4-word deep FIFOs, one for data transfer from system to state machine (TX), and the other for state machine to system (RX). The TX FIFO is written to by system bus masters, such as a processor or DMA controller, and the RX FIFO is written to by the state machine. FIFOs decouple the timing of the PIO state machines and the system bus, allowing state machines to go for longer periods without processor intervention.

- **PUSH** 或 **PULL** 指令可分别根据输入或输出移位计数器的状态进行条件执行。

在PIO复位或`CTRL_SM_RESTART`信号触发时，输入移位计数器清零（尚未移入任何位），输出移位计数器初始化为32（无剩余位需移出；完全耗尽）。其他若干指令会影响移位计数器：

- 成功执行的 **PULL** 操作将输出移位计数器清零。
- 成功执行的 **PUSH** 操作将输入移位计数器清零。
- `MOV OSR, ...` （即任何写入 `OSR` 的 `MOV` 指令）将输出移位计数器清零。
- `MOV ISR, ...` （即任何写入 `ISR` 的 `MOV` 指令）将输入移位计数器清零。
- `OUT ISR, count` 将输入移位计数器设为 `count`

#### 11.2.4.3. 临时寄存器

每个状态机具有两个32位内部临时寄存器，分别称为 `X` 和 `Y`。

它们的用途如下：

- 作为 `IN/OUT/SET/MOV` 的源或目的地
- 跳转条件的源

例如，假设我们希望为“1”数据位产生长脉冲，为“0”数据位产生短脉冲：

```

1 .program ws2812_led
2
3 public entry_point:
4 pull
5 set x, 23 ; 遍历24位
6 bitloop:
7 set pins, 1 ; 将引脚设为高电平
8 out y, 1 [5] ; 移出1位，并写入y
9 jmp !y skip ; 若该位为0，则跳过额外延迟
10 nop [5]
11 跳过:
12 设置引脚, 0 [5]
13 jmp x-- bitloop ; 如果x非零则跳转，并将x递减
14 jmp entry_point

```

这里 `X` 用作循环计数器，`Y` 用作临时变量，用以基于 `OSR` 中的单个位进行分支。该程序可用于驱动 WS2812 LED 接口，虽然存在更紧凑的实现（最少3条指令）。

`MOV` 允许使用临时寄存器保存/恢复移位寄存器，例如当您希望重复输出相同序列时。

##### **i 注意**

一个更紧凑的WS2812示例（共4条指令）见第11.6.2节。

#### 11.2.4.4. 队列 (FIFOs)

每个状态机配备一对深度为4字的队列，一用于系统向状态机的数据传输（TX），另一用于状态机向系统的数据传输（RX）。TX队列由系统总线主控设备写入，如处理器或DMA控制器，RX队列则由状态机写入。FIFO缓冲区解耦了PIO状态机与系统总线的时序，使状态机能够在更长时间内无需处理器干预而运行。

FIFOs also generate data request (DREQ) signals, which allow a system DMA controller to pace its reads/writes based on the presence of data in an RX FIFO, or space for new data in a TX FIFO. This allows a processor to set up a long transaction, potentially involving many kilobytes of data, which will proceed with no further processor intervention.

Often, a state machine only transfers data in one direction. In this case, the `SHIFTCTRL_FJOIN` option can merge the two FIFOs into a single 8-entry FIFO that only goes in one direction. This is useful for high-bandwidth interfaces such as DPI.

### 11.2.5. Stalling

State machines may momentarily pause execution for a number of reasons:

- A `WAIT` instruction's condition is not yet met
- A blocking `PULL` when the TX FIFO is empty, or a blocking `PUSH` when the RX FIFO is full
- An `IRQ_WAIT` instruction which has set an `IRQ` flag, and is waiting for it to clear
- An `OUT` instruction when autopull is enabled, and OSR has already reached its shift threshold
- An `IN` instruction when autopush is enabled, ISR reaches its shift threshold, and the RX FIFO is full

In this case, the program counter does not advance, and the state machine will continue executing this instruction on the next cycle. If the instruction specifies some number of delay cycles before the next instruction starts, these do not begin until after the stall clears.

**i NOTE**

Side-set (Section 11.5.1) is not affected by stalls, and always takes place on the first cycle of the attached instruction.

### 11.2.6. Pin mapping

PIO controls the output level and direction of up to 32 GPIOs, and can observe their input levels. On every system clock cycle, each state machine may do none, one, or both of the following:

- Change the level or direction of some GPIOs via an `OUT` or `SET` instruction, or read some GPIOs via an `IN` instruction
- Change the level or direction of some GPIOs via a side-set operation

Each of these operations uses one of four contiguous ranges of GPIOs, with the base and count of each range configured via each state machine's `PINCTRL` register. There is a range for each of `OUT`, `SET`, `IN` and side-set operations. Each range can cover any of the GPIOs accessible to a given PIO block (on RP2350 this is the 30 user GPIOs), and the ranges can overlap.

For each individual GPIO output (level and direction separately), PIO considers all 8 writes that may have occurred on that cycle, and applies the write from the highest-numbered state machine. If the same state machine performs a `SET` /`OUT` and a side-set on the same GPIO simultaneously, the side-set is used. If no state machine writes to this GPIO output, its value does not change from the previous cycle.

Generally each state machine's outputs are mapped to a distinct group of GPIOs, implementing some peripheral interface.

### 11.2.7. IRQ flags

IRQ flags are state bits which can be set or cleared by state machines or the system. There are 8 in total: all 8 are visible to all state machines, and the lower 4 can also be masked into one of PIO's interrupt request lines, via the `IRQ0_INTE` and `IRQ1_INTE` control registers.

They have two main uses:

FIFO缓冲区还会产生数据请求（DREQ）信号，允许系统DMA控制器根据RX FIFO中数据的存在情况或TX FIFO中新数据的可用空间调整其读写速率。这样处理器即可设定一个涉及数千字节数据的长事务，并在无须后续处理器干预的情况下继续执行。

通常，状态机仅在单一方向上传输数据。在此情况下，`SHIFTCTRL_FJOIN`选项可将两个FIFO合并为单向传输的8条目FIFO。这对于如DPI等高带宽接口非常有用。

### 11.2.5. 停滞

状态机可能因多种原因暂时暂停执行：

- 等待（`WAIT`）指令的条件尚未满足
- 当TX FIFO为空时的阻塞型拉取（`PULL`），或当RX FIFO已满时的阻塞型推送（`PUSH`）
- 一条`IRQ_WAIT`指令已设置`IRQ`标志，且正在等待该标志被清除
- 启用自动拉取（`autopull`）且OSR已达到移位阈值时的`OUT`指令
- 启用自动推送（`autopush`），ISR达到移位阈值且RX FIFO已满时的`IN`指令

在此情况下，程序计数器不会前进，状态机将在下一周期继续执行该指令。若指令指定了下一条指令开始前的延迟周期数，则该延迟将在stall解除之后才开始。

#### 注意

附加操作（第11.5.1节）不受停顿影响，且始终在所附指令的第一个周期执行。

### 11.2.6. 引脚映射

PIO控制多达32个GPIO的输出电平和方向，并可监测其输入电平。每个系统时钟周期内，每个状态机可选择不执行、执行一项或执行两项以下操作：

- 通过`OUT`或`SET`指令改变部分GPIO的电平或方向，或通过`IN`指令读取部分GPIO
- 通过副设置操作更改部分GPIO的电平或方向

每个操作使用四个连续GPIO范围之一，每个范围的基址和数量通过各状态机的`PINCTRL`寄存器进行配置。分别为`OUT`、`SET`、`IN`以及副设置操作各设有一个范围。

每个范围可覆盖特定PIO模块可访问的任意GPIO（RP2350上为30个用户GPIO），且这些范围之间可相互重叠。

对于每个单独GPIO输出（电平和方向分别计算），PIO会参考该周期内可能发生的所有8次写操作，并采用编号最高状态机的写入。若同一状态机在同一GPIO上同时执行`SET`/`OUT`与副设置，则以副设置为准。若无任何状态机对该GPIO输出进行写入，其值则沿用上一周期的状态，保持不变。

通常，每个状态机的输出映射至一组独立GPIO，用以实现某种外设接口。

### 11.2.7. IRQ 标志

IRQ标志是状态位，可由状态机或系统设置或清除。共有8个：全部8个对所有状态机可见，且低4位可通过`IRQ0_INTE`和`IRQ1_INTE`控制寄存器屏蔽为PIO的中断请求线路之一。

它们有两个主要用途：

- Asserting system level interrupts from a state machine program, and optionally waiting for the interrupt to be acknowledged
- Synchronising execution between two state machines

State machines interact with the flags via the `IRQ` and `WAIT` instructions.

### 11.2.8. Interactions between state machines

Instruction memory is implemented as a 1-write, 4-read register file, allowing all four state machines to read an instruction on the same cycle without stalling.

There are three ways to apply the multiple state machines:

- Pointing multiple state machines at the same program
- Pointing multiple state machines at different programs
- Using multiple state machines to run different parts of the same interface, e.g. TX and RX side of a UART, or clock/hsync and pixel data on a DPI display

State machines cannot communicate data, but they can synchronise with one another by using the `IRQ` flags. There are 8 flags total. Each state machine can set or clear any flag using the `IRQ` instruction, and can wait for a flag to go high or low using the `WAIT IRQ` instruction. This allows cycle-accurate synchronisation between state machines.

## 11.3. PIO assembler (pioasm)

The PIO Assembler parses a PIO source file and outputs the assembled version ready for inclusion in an RP2350 application. This includes C and C++ applications built against the SDK, and Python programs running on the RP2350 MicroPython port.

This section briefly introduces the directives and instructions that can be used in `pioasm` input. For a deeper discussion of how to use `pioasm`, how it is integrated into the SDK build system, extended features such as code pass through, and the various output formats it can produce, see [Raspberry Pi Pico-series C/C++ SDK](#).

### 11.3.1. Directives

The following directives control the assembly of PIO programs:

`.define (PUBLIC) <symbol> <value>`

Define an integer symbol named `<symbol>` with the value `<value>` (see [Section 11.3.2](#)). If this `.define` appears before the first program in the input file, then this define is global to all programs, otherwise it is local to the program in which it occurs. If `PUBLIC` is specified, the symbol will be emitted into the assembled output for use by user code. For the SDK this takes the following forms:

- `#define <program_name> <symbol> value`: for program symbols
- `#define <symbol> value`: for global symbols

`.clock_div <divider>`

If this directive is present, `<divider>` is the state machine clock divider for the program. Note, that divider is a floating point value, but *may not* currently use arithmetic expressions or defined values. This directive affects the default state machine configuration for a program. This directive is only valid within a program before the first instruction.

`.fifo <fifo_config>`

If this directive is present, it is used to specify the FIFO configuration for the program. It affects the default state machine configuration for a program, but also restricts what instructions may be used (for example PUSH makes

- 由状态机程序发出系统级中断，且可选择等待中断被确认
- 实现两个状态机之间的执行同步

状态机通过 `IRQ` 和 `WAIT` 指令与这些标志交互。

### 11.2.8. 状态机之间的交互

指令存储器实现为1写4读寄存器文件，允许四个状态机在同一周期内同时读取指令而不发生阻塞。  
允许在同一周期内读取指令而无阻塞。

应用多个状态机有三种方式：

- 多个状态机指向相同程序
- 多个状态机指向不同程序
- 使用多个状态机运行同一接口的不同部分，例如UART的发送（TX）和接收（RX）端，或DPI显示的时钟/行同步与像素数据

状态机无法传递数据，但可以通过使用 `IRQ` 标志实现相互同步。总共有8个标志。每个状态机可以使用 `IRQ` 指令设置或清除任意标志，也可以使用 `WAIT IRQ` 指令等待标志变为高电平或低电平。这实现了状态机之间的周期级精确同步。

## 11.3. PIO汇编器（pioasm）

PIO汇编器解析PIO源文件，并生成可供RP2350应用程序包含的汇编版本。此处包括针对SDK构建的C及C++应用程序，以及运行在RP2350 MicroPython移植版上的Python程序。

本节简要介绍可用于 `pioasm` 输入的指令和指令集。有关如何使用 `pioasm`、其在SDK构建系统中的集成、代码透传等扩展功能，以及它支持生成的各种输出格式的详细说明，请参阅Raspberry Pi Pico系列C/C++ SDK。

### 11.3.1. 指令

以下指令用于控制PIO程序的汇编：

`.define (PUBLIC) <symbol> <value>`

定义一个名为 `<symbol>` 的整数符号，值为 `<value>`（参见第11.3.2节）。如果该 `.define` 出现在输入文件中第一个程序之前，则此定义对所有程序全局有效，否则仅对其所在程序局部有效。如指定了 `PUBLIC`，符号将被输出至组装结果，供用户代码使用。对于SDK，其形式如下：

- `#define <program_name> <symbol> value`：用于程序符号
- `#define <symbol> value`：用于全局符号

`.clock_div <divider>`

如果存在该指令，`<divider>` 为该程序状态机的时钟分频器。注意，`divider` 为浮点数值，但当前可能不支持使用算术表达式或定义值。该指令影响程序默认的状态机配置。该指令仅在程序第一条指令之前有效。

`.fifo <fifo_config>`

如果存在该指令，则用于指定程序的FIFO配置。它影响程序的默认状态机配置，但也限制可使用的指令（例如若未配置IN FIFO，则PUSH指令

no sense if there is no IN FIFO configured).

This directive supports the following configuration values:

- **txrx**: 4 FIFO entries for each of TX and RX; this is the default.
- **tx**: All 8 FIFO entries for TX.
- **rx**: All 8 FIFO entries for RX.
- **txput**: 4 FIFO entries for TX, and 4 FIFO entries for `mov rxfifo[index], isr` aka `put`. This value is not supported on PIO version 0.
- **txget**: 4 FIFO entries for TX, and 4 FIFO entries for `mov osr, rxfifo[index]` aka `get`. This value is not supported on PIO version 0.
- **putget**: 4 FIFO entries for `mov rxfifo[index], isr` aka `put`, and 4 FIFO entries for `mov osr, rxfifo[index]` aka `get`. This value is not supported on PIO version 0.

This directive is only valid within a program before the first instruction.

```
.mov_status rxfifo < <n>
.mov_status txfifo < <n>
.mov_status irq <(prev|next)> set <n>
```

This directive configures the source for the `mov , STATUS`. One of the three syntaxes can be used to set the status based on the RXFIFO level being below a value N, the TXFIFO level being below a value N, or an IRQ flag N being set on this PIO instance (or the next lower numbered, or higher numbered PIO instance if `prev` or `next` or specified). Note, that the IRQ option requires PIO version 1.

This directive affects the default state machine configuration for a program. This directive is only valid within a program before the first instruction.

```
.in <count> (left|right) (auto) (<threshold>)
```

If this directive is present, `<count>` indicates the number of IN bits to be used. 'left' or 'right' if specified, control the ISR shift direction; 'auto', if present, enables "auto-push"; `<threshold>`, if present, specifies the "auto-push" threshold. This directive affects the default state machine configuration for a program.

This directive is only valid within a program before the first instruction. When assembling for PIO version 0, `<count>` must be 32.

```
.program <name>
```

Start a new program with the name `<name>`. Note that that name is used in code so should be alphanumeric/underscore not starting with a digit. The program lasts until another `.program` directive or the end of the source file. PIO instructions are only allowed within a program.

```
.origin <offset>
```

Optional directive to specify the PIO instruction memory offset at which the program *must* load. Most commonly this is used for programs that must load at offset 0, because they use data based JMPs with the (absolute) jmp target being stored in only a few bits. This directive is invalid outside a program.

```
.out <count> (left|right) (auto) (<threshold>)
```

If this directive is present, `<count>` indicates the number of OUT bits to be used. 'left' or 'right' if specified control the OSR shift direction; 'auto', if present, enables "auto-pull"; `<threshold>`, if present, specifies the "auto-pull" threshold. This directive affects the default state machine configuration for a program. This directive is only valid within a program before the first instruction.

```
.pio_version <version>
```

This directive sets the target PIO hardware version. The version for RP2350 is 1 or `RP2350`, and is also the default version number. For backwards compatibility with RP2040, 0 or `RP2040` may be used.

If this directive appears before the first program in the input file, then this define is the default for all programs, otherwise it specifies the version for the program in which it occurs. If specified for a program, it must occur before the first instruction.

无意义)。

该指令支持以下配置值：

- **txrx**: TX和RX各有4个FIFO条目；此为默认配置。
- **tx**: 所有8个FIFO条目均分配给TX。
- **rx**: 所有8个FIFO条目均分配给RX。
- **txput**: TX有4个FIFO条目，且有4个FIFO条目用于`mov rxfifo[index], isr`，亦称为 `put`。该值在PIO版本0中不受支持。
- **txget**: TX有4个FIFO条目，且有4个FIFO条目用于`mov osr, rxfifo[index]`，亦称为 `get`。该值在PIO版本0中不受支持。
- **putget**: 4个FIFO条目用于`mov rxfifo[index], isr`亦称为 `put`，另4个FIFO条目用于`mov osr, rxfifo[index]`亦称为 `get`。该值在PIO版本0中不受支持。

该指令仅在程序第一条指令之前有效。

```
.mov_status rxfifo < <n>
.mov_status txfifo < <n>
.mov_status irq <(prev|next)> set <n>
```

该指令配置 `mov` 的 **STATUS** 源。可使用以下三种语法之一设置状态：基于RX FIFO 级别低于值N、TX FIFO 级别低于值N，或在该 PIO 实例（或若指定了 `prev` 或 `next`，则为编号较低或较高的 PIO 实例）上 IRQ 标志 N 被设置。

注意，IRQ 选项要求 PIO 版本为 1。

该指令影响程序默认的状态机配置。该指令仅在程序第一条指令之前有效。

```
.in <count> (left|right) (auto) (<threshold>)
```

若包含此指令，`<count>` 表示使用的 IN 位数。若指定，'left' 或 'right' 控制 ISR 的移位方向；若存在，'auto' 启用“自动推送”；若存在，`<threshold>` 指定“自动推送”阈值。

该指令影响程序的默认状态机配置。

该指令仅在程序中的第一条指令之前有效。当为 PIO 版本 0 汇编时，`<count>` 必须为 32。

```
.program <name>
```

以名称 `<name>` 启动一个新程序。请注意，该名称用于代码中，应为字母数字字符或下划线，且不得以数字开头。程序持续有效，直到遇到另一个 `.program` 指令或源文件结束。PIO 指令仅允许在程序内部使用。

```
.origin <offset>
```

该可选指令用于指定程序必须加载的 PIO 指令内存偏移地址。此指令最常用于必须加载到偏移量 0 的程序，因为它们使用基于数据的 JMP，且（绝对）jmp 目标仅存储在少数几位中。该指令在程序外无效。

```
.out <count> (left|right) (auto) (<threshold>)
```

若存在此指令，`<count>` 表示使用的 OUT 位数。如指定，“left” 或 “right” 控制 OSR 移位方向；如存在，“auto” 启用“自动拉取”；如存在，`<threshold>` 指定“自动拉取”阈值。

该指令影响程序默认的状态机配置。该指令仅在程序第一条指令之前有效。

```
.pio_version <version>
```

该指令设置目标 PIO 硬件版本。RP2350 版本为 1 或 RP2350，且为默认版本号。为兼容 RP2040，可使用 0 或 RP2040。

若该指令出现在输入文件首个程序之前，则该定义为所有程序默认版本，否则指定其所在程序版本。若指定于某程序，须位于该程序首条指令之前。

**.set <count>**

If this directive is present, `<count>` indicates the number of SET bits to be used. This directive affects the default state machine configuration for a program. This directive is only valid within a program before the first instruction.

**.side\_set <count> (opt) (pindirs)**

If this directive is present, `<count>` indicates the number of side-set bits to be used. Additionally, `opt` may be specified to indicate that a `side <value>` is optional for instructions (note this requires stealing an extra bit – in addition to the `<count>` bits – from those available for the instruction delay). Finally, `pindirs` may be specified to indicate that the side set values should be applied to the PINDIRs and not the PINs. This directive is only valid within a program before the first instruction.

**.wrap\_target**

Place prior to an instruction, this directive specifies the instruction where execution continues due to program wrapping. This directive is invalid outside of a program, may only be used once within a program, and if not specified defaults to the start of the program.

**.wrap**

Placed after an instruction, this directive specifies the instruction after which, in normal control flow (i.e. `jmp` with false condition, or no `jmp`), the program wraps (to `.wrap_target` instruction). This directive is invalid outside of a program, may only be used once within a program, and if not specified defaults to after the last program instruction.

**.lang\_opt <lang> <name> <option>**

Specifies an option for the program related to a particular language generator. (See Language Generators in [Raspberry Pi Pico-series C/C++ SDK](#)). This directive is invalid outside of a program.

**.word <value>**

Stores a raw 16-bit value as an instruction in the program. This directive is invalid outside of a program.

### 11.3.2. Values

The following types of values can be used to define integer numbers or branch targets:

*Table 978. Values in pioasm, i.e. <value>*

<code>integer</code>	An integer value, e.g. 3 or -7.
<code>hex</code>	A hexadecimal value, e.g. <code>0xf</code> .
<code>binary</code>	A binary value, e.g. <code>0b1001</code> .
<code>symbol</code>	A value defined by a <code>.define</code> (see <a href="#">pioasm_define</a> ).
<code>&lt;label&gt;</code>	The instruction offset of the label within the program. Typically used with a JMP instruction (see <a href="#">Section 11.4.2</a> ).
<code>(&lt;expression&gt;)</code>	An expression to be evaluated; see <a href="#">expressions</a> . Note that the parentheses are necessary.

### 11.3.3. Expressions

Expressions may be freely used within pioasm values.

*Table 979. Expressions in pioasm i.e. <expression>*

<code>&lt;expression&gt; + &lt;expression&gt;</code>	The sum of two expressions
<code>&lt;expression&gt; - &lt;expression&gt;</code>	The difference of two expressions
<code>&lt;expression&gt; * &lt;expression&gt;</code>	The multiplication of two expressions
<code>&lt;expression&gt; / &lt;expression&gt;</code>	The integer division of two expressions
<code>- &lt;expression&gt;</code>	The negation of another expression

**.set <count>**

若存在该指令，`<count>`指示 SET 位数。该指令影响程序默认的状态机配置。该指令仅在程序第一条指令之前有效。

**.side\_set <count> (opt) (pindirs)**

若存在该指令，`<count>`指示旁路设置位数。此外，`opt`可被指定以表示指令的某一侧`<value>`为可选（请注意，这需要从指令延迟可用的`<count>`位中额外占用一位）。最后，`pindirs`可被指定以指示侧边设置值应应用于 PINDIRs 而非 PINs。该指令仅在程序中且位于首条指令之前有效。

**.wrap\_target**

该指令置于某条指令之前，指定程序因环绕而继续执行的指令位置。该指令在程序外无效，且程序内仅能使用一次，若未指定，默认指向程序起始位置。

**.wrap**

该指令置于某条指令之后，指定在正常控制流中（即条件跳转`jmp`失败，或无跳转`jmp`情形下）程序环绕至`.wrap_target`指令的位置。该指令在程序外无效，且程序内仅能使用一次，若未指定，默认指向最后一条程序指令之后。

**.lang\_opt <lang> <name> <option>**

指定与特定语言生成器相关的程序选项。（参见Raspberry Pi Pico系列C/C++ SDK中的语言生成器部分）。该指令仅在程序内部有效。

**.word <value>**

将原始16位值作为程序中的指令存储。该指令仅在程序内部有效。

### 11.3.2. 值

以下类型的值可用于定义整数或分支目标：

表978。pioasm中的值，即`<value>`

<b>整数</b>	一个整数值，例如3或-7。
<b>十六进制</b>	一个十六进制值，例如 <code>0xf</code> 。
<b>二进制</b>	一个二进制值，例如 <code>0b1001</code> 。
<b>符号</b>	由 <code>.define</code> 定义的值（参见 <code>pioasm_define</code> ）。
<b>&lt;label&gt;</b>	程序中该标签的指令偏移量。通常与JMP指令配合使用（参见第11.4.2节）。
<b>(&lt;expression&gt;)</b>	一个需求值的表达式；参见表达式部分。请注意括号是必需的。

### 11.3.3. 表达式

表达式可自由用于pioasm值中。

表979。pioasm中的表达式  
i.e. `<expression>`

<code>&lt;expression&gt; + &lt;expression&gt;</code>	两个表达式的和
<code>&lt;expression&gt; - &lt;expression&gt;</code>	两个表达式的差
<code>&lt;expression&gt; * &lt;expression&gt;</code>	两个表达式的乘积
<code>&lt;expression&gt; / &lt;expression&gt;</code>	两个表达式的整数除法
<code>- &lt;expression&gt;</code>	表达式的取负

<code>&lt;expression&gt; &lt;&lt; &lt;expression&gt;</code>	One expression shifted left by another expression
<code>&lt;expression&gt; &gt;&gt; &lt;expression&gt;</code>	One expression shifted right by another expression
<code>:: &lt;expression&gt;</code>	The bit reverse of another expression
<code>&lt;value&gt;</code>	Any value (see <a href="#">Section 11.3.2</a> )

### 11.3.4. Comments

To create a line comment that ignores all content on a certain line following a certain symbol, use `//` or `;`.

To create a C-style block comment that ignores all content across multiple lines until after a start symbol until an end symbol appears, use `/*` to begin the comment and `*/` to end the comment.

### 11.3.5. Labels

Labels use the following forms at the start of a line:

```
<symbol>:
```

```
PUBLIC <symbol>:
```

 **TIP**

A label is really just an automatic `.define` with a value set to the current program instruction offset. A `PUBLIC` label is exposed to the user code in the same way as a `PUBLIC .define`.

### 11.3.6. Instructions

All pioasm instructions follow a common pattern:

```
<instruction> (side <side_set_value>) ([<delay_value>])
```

where:

- `<instruction>` An assembly instruction detailed in the following sections. (see [Section 11.4](#))
- `<side_set_value>` A value (see [Section 11.3.2](#)) to apply to the side\_set pins at the start of the instruction. Note that the rules for a side-set value via `side <side_set_value>` are dependent on the `.side_set` (see `pioasm_side_set`) directive for the program. If no `.side_set` is specified then the `side <side_set_value>` is invalid, if an optional number of sideset pins is specified then `side <side_set_value>` may be present, and if a non-optional number of sideset pins is specified, then `side <side_set_value>` is required. The `<side_set_value>` must fit within the number of side-set bits specified in the `.side_set` directive.

<expression> << <expression>	一个表达式左移另一个表达式
<expression> >> <expression>	一个表达式右移另一个表达式
:: <expression>	另一个表达式的位反转
<value>	任何值（参见第11.3.2节）

### 11.3.4. 注释

要创建一行注释以忽略某一行中特定符号之后的所有内容，请使用 // 或 ;。

要创建C风格块注释以忽略多行内容，直到出现结束符号，请使用 /\* 开始注释，使用 \*/ 结束注释。

### 11.3.5. 标签

标签在行首使用以下格式：

```
<symbol>:
```

```
PUBLIC <symbol>:
```

#### 提示

标签实际上是一个自动生成的 .define，其值设置为当前程序指令偏移量。PUBLIC 标签以与 PUBLIC .define 相同的方式暴露给用户代码。

### 11.3.6. 指令

所有pioasm指令均遵循以下通用模式：

```
<instruction> (side <side_set_value>) ([<delay_value>])
```

位置：

<instruction> 以下章节详述的汇编指令。（参见第11.4节）

<side\_set\_value> 指令开始时应用于 side\_set 引脚的数值（参见第11.3.2节）。请注意，通过 side <side\_set\_value> 设置的 side-set 值的规则依赖于程序中的 .side\_set 指令（参见 pioasm\_side\_set）。若未指定 side\_set，则 side <side\_set\_value> 无效；若指定了可选数量的 side-set 引脚，则可存在 side <side\_set\_value>；若指定了非可选数量的 side-set 引脚，则必须有 side <side\_set\_value>。<side\_set\_value> 必须在 .side\_set 中指定的 side-set 位数范围内。

指令。

`<delay_value>` Specifies the number of cycles to delay after the instruction completes. The `delay_value` is specified as a value (see [Section 11.3.2](#)), and in general is between 0 and 31 inclusive (a 5-bit value), however the number of bits is reduced when sideset is enabled via the `.side_set` (see `pioasm_side_set`) directive. If the `<delay_value>` is not present, then the instruction has no delay.

#### **NOTE**

pioasm instruction names, keywords and directives are case insensitive; lower case is used in the *Assembly Syntax* sections below, as this is the style used in the SDK.

#### **NOTE**

Commas appear in some *Assembly Syntax* sections below, but are entirely optional, e.g. `out pins, 3` may be written `out pins 3`, and `jmp x-- label` may be written as `jmp x--, label`. The *Assembly Syntax* sections below uses the first style in each case as this is the style used in the SDK.

### 11.3.7. Pseudo-instructions

pioasm provides aliases for certain instructions, as a convenience:

`nop` Assembles to `mov y, y`. No side effect, but a useful vehicle for a side-set operation or an extra delay.

## 11.4. Instruction Set

### 11.4.1. Summary

PIO instructions are 16 bits long, and use the following encoding:

Table 980. PIO instruction encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
<code>JMP</code>	0	0	0	Delay/side-set					Condition			Address					
<code>WAIT</code>	0	0	1	Delay/side-set					<code>Pol</code>	<code>Source</code>		Index					
<code>IN</code>	0	1	0	Delay/side-set					<code>Source</code>			Bit count					
<code>OUT</code>	0	1	1	Delay/side-set					<code>Destination</code>			Bit count					
<code>PUSH</code>	1	0	0	Delay/side-set					0	<code>IfF</code>	<code>Blk</code>	0	0	0	0		
<code>MOV</code>	1	0	0	Delay/side-set					0	0	0	1	<code>IdxI</code>	0	Index		
<code>PULL</code>	1	0	0	Delay/side-set					1	<code>IfE</code>	<code>Blk</code>	0	0	0	0		
<code>MOV</code>	1	0	0	Delay/side-set					1	0	0	1	<code>IdxI</code>	0	Index		
<code>MOV</code>	1	0	1	Delay/side-set					<code>Destination</code>			<code>Op</code>	Source				
<code>IRQ</code>	1	1	0	Delay/side-set					0	<code>Clr</code>	<code>Wait</code>	<code>IdxMode</code>		Index			
<code>SET</code>	1	1	1	Delay/side-set					<code>Destination</code>			Data					

All PIO instructions execute in one clock cycle.

The function of the 5-bit `Delay/side-set` field depends on the state machine's `SIDESET_COUNT` configuration:

- Up to 5 LSBs (5 minus `SIDESET_COUNT`) encode a number of idle cycles inserted between this instruction and the next.

<delay\_value> 指定指令完成后要延迟的周期数。delay\_value 指定为一个数值（参见第11.3.2节），通常取值范围为0至31（含端点）（5位值），但当通过 .side\_set（参见 pioasm\_side\_set）指令启用 sideset 时，位数将减少。如果<delay\_value>未出现，则该指令无延迟。

### ① 注意

pioasm 指令名称、关键字及指令对大小写不敏感；以下汇编语法章节中均使用小写字母，这是 SDK 采用的风格。

### ① 注意

逗号在部分汇编语法章节中出现，但完全可选，例如：out pins, 3 可写作 out pins 3，jmp x-- /label/ 可写成 jmp x--, /label/。以下汇编语法章节均采用每种情况中的第一种风格，因为这符合 SDK 的用法。

## 11.3.7. 伪指令

pioasm 为部分指令提供了别名，以便于使用：

**nop** 汇编为 mov y, y。无副作用，但可作为 side-set 操作或额外延迟的有效手段。

## 11.4. 指令集

### 11.4.1. 概要

PIO 指令长度为 16 位，采用如下编码：

表 980. PIO  
指令编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
跳转	0	0	0	延迟/side-set					条件			地址					
等待	0	0	1	延迟/side-set					极性	源		索引					
输入	0	1	0	延迟/side-set					源			位数					
输出	0	1	1	延迟/side-set					目标			位数					
PUSH	1	0	0	延迟/side-set					0	IfF	块	0	0	0	0		
MOV	1	0	0	延迟/side-set					0	0	0	1	IdxI	0	索引		
PULL	1	0	0	延迟/side-set					1	IfE	块	0	0	0	0		
MOV	1	0	0	延迟/side-set					1	0	0	1	IdxI	0	索引		
MOV	1	0	1	延迟/side-set					目标			Op			源		
IRQ	1	1	0	延迟/side-set					0	Clr	等待	IdxMode		索引			
设置	1	1	1	延迟/side-set					目标			数据					

所有PIO指令均在一个时钟周期内执行。

5位延迟/旁路设置字段的功能取决于状态机的SIDESET\_COUNT配置：

- 最多5位最低有效位（5减SIDESET\_COUNT）编码在本指令与下一指令之间插入的空闲周期数。

- Up to 5 MSBs, set by `SIDESET_COUNT`, encode a side-set (Section 11.5.1), which can assert a constant onto some GPIOs, concurrently with main instruction execution.

## 11.4.2. JMP

### 11.4.2.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JMP	0	0	0	Delay/side-set				Condition			Address					

### 11.4.2.2. Operation

Set program counter to `Address` if `Condition` is true, otherwise no operation.

Delay cycles on a `JMP` always take effect, whether `Condition` is true or false, and they take place after `Condition` is evaluated and the program counter is updated.

- Condition:
  - 000: (*no condition*): Always
  - 001: `!X`: scratch X zero
  - 010: `X--`: scratch X non-zero, prior to decrement
  - 011: `!Y`: scratch Y zero
  - 100: `Y--`: scratch Y non-zero, prior to decrement
  - 101: `X!=Y`: scratch X not equal scratch Y
  - 110: `PIN`: branch on input pin
  - 111: `!OSRE`: output shift register not empty
- Address: Instruction address to jump to. In the instruction encoding this is an absolute address within the PIO instruction memory

`JMP PIN` branches on the GPIO selected by `EXECCTRL_JMP_PIN`, a configuration field which selects one out of the maximum of 32 GPIO inputs visible to a state machine, independently of the state machine's other input mapping. The branch is taken if the GPIO is high.

`!OSRE` compares the bits shifted out since the last `PULL` with the shift count threshold configured by `SHIFTCTRL_PULL_THRESH`. This is the same threshold used by autopull (Section 11.5.4).

`JMP X--` and `JMP Y--` always decrement scratch register X or Y, respectively. The decrement is not conditional on the current value of the scratch register. The branch is conditioned on the *initial* value of the register, i.e. before the decrement took place: if the register is initially nonzero, the branch is taken.

### 11.4.2.3. Assembler syntax

```
jmp (<cond>) <target>
```

where:

- 最多5位最高有效位，由`SIDESET_COUNT`设置，编码旁路设置（第11.5.1节），可在主指令执行的同时将常量置于部分GPIO引脚上。

## 11.4.2. JMP

### 11.4.2.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
跳转	0	0	0	延迟/side-set				条件				地址				

### 11.4.2.2. 操作

如果条件为真，则将程序计数器设置为地址，否则不执行任何操作。

`JMP`指令的延迟周期始终生效，无论条件为真还是假，且在评估条件并更新程序计数器之后发生。

- 条件：

- 000: (无条件)：始终
- 001: `!X`: 寄存器 X 值为零
- 010: `X--`: 寄存器 X 非零，递减前
- 011: `!Y`: 寄存器 Y 值为零
- 100: `Y--`: 寄存器 Y 非零，递减前
- 101: `X!=Y`: 寄存器 X 不等于寄存器 Y
- 110: `PIN`: 基于输入引脚的分支
- 111: `!OSRE`: 输出移位寄存器非空

- 地址：跳转的指令地址。在指令编码中，该地址为 PIO 指令存储器中的绝对地址。

`JMP PIN`根据配置字段`EXECCTRL_JMP_PIN`所选择的 GPIO 引脚进行分支，该字段在最多 32 个可见于状态机的 GPIO 输入中选择一个，独立于状态机的其他输入映射。当该 GPIO 引脚为高电平时，分支跳转将被执行。

`!OSRE` 将自上次执行 `PULL`以来移出的位与由`SHIFTCTRL_PULL_THRESH`配置的移位计数阈值进行比较。这是 autopull（第11.5.4节）使用的相同阈值。

`JMP X--`和`JMP Y--`始终分别递减临时寄存器X或Y。递减操作不依赖于临时寄存器的当前值。分支以寄存器的初始值为条件，即递减发生之前：若寄存器初始值非零，则执行分支。

### 11.4.2.3. 汇编器语法

```
jmp (<cond>) <target>
```

位置：

<cond>	An optional condition listed above (e.g. <code>!x</code> for scratch X zero). If a condition code is not specified, the branch is always taken.
<target>	A program label or value (see <a href="#">Section 11.3.2</a> ) representing instruction offset within the program (the first instruction being offset 0). Because the PIO JMP instruction uses absolute addresses in the PIO instruction memory, JMPs need to be adjusted based on the program load offset at runtime. This is handled for you when loading a program with the SDK, but care should be taken when encoding JMP instructions for use by <code>OUT EXEC</code> .

### 11.4.3. WAIT

#### 11.4.3.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>WAIT</code>	0	0	1	Delay/side-set				Pol	Source	Index						

#### 11.4.3.2. Operation

Stall until some condition is met.

Like all stalling instructions ([Section 11.2.5](#)), delay cycles begin after the instruction completes. That is, if any delay cycles are present, they do not begin counting until after the wait condition is met.

- Polarity:
  - 1: wait for a 1.
  - 0: wait for a 0.
- Source: what to wait on. Values are:
  - 00: `GPIO`: System GPIO input selected by `Index`. This is an absolute GPIO index, and is not affected by the state machine's input IO mapping.
  - 01: `PIN`: Input pin selected by `Index`. This state machine's input IO mapping is applied first, and then `Index` selects which of the mapped bits to wait on. In other words, the pin is selected by adding `Index` to the `PINCTRL_IN_BASE` configuration, modulo 32.
  - 10: `IRQ`: PIO IRQ flag selected by `Index`
  - 11: `JMPPIN`: wait on the pin indexed by the `PINCTRL_JMP_PIN` configuration, plus an `Index` in the range 0-3, all modulo 32. Other values of `Index` are reserved.
- Index: which pin or bit to check.

`WAIT x IRQ` behaves slightly differently from other `WAIT` sources:

- If `Polarity` is 1, the selected IRQ flag is cleared by the state machine upon the wait condition being met.
- The flag index is decoded in the same way as the `IRQ` index field, decoding down from the two MSBs (aligning with the `IRQ` instruction `IdxMode` field):
  - 00: the three LSBs are used directly to index the IRQ flags in this PIO block.
  - 01 (`PREV`), the instruction references an IRQ from the next-lower-numbered PIO in the system, wrapping to the highest-numbered PIO if this is PIO0.
  - 10 (`REL`), the state machine ID (0...3) is added to the IRQ index, by way of modulo-4 addition on the two LSBs. For example, state machine 2 with a flag value of `0x11` will wait on flag 3, and a flag value of `0x13` will wait on flag 1. This allows multiple state machines running the same program to synchronise with each other.

<cond> 上述可选条件（例如 `!x` 表示临时寄存器X为零）。若未指定条件码，则总执行分支。

<target> 程序标签或数值（参见第11.3.2节），表示程序中指令的偏移量（首条指令偏移量为0）。由于PIO JMP指令在PIO指令存储器中使用绝对地址，JMP需根据程序运行时加载的偏移进行调整。当使用SDK加载程序时，此操作由系统自动处理，但在为`OUT EXEC`编码JMP指令时应格外注意。

### 11.4.3. WAIT

#### 11.4.3.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
等待	0	0	1	延迟侧置				极性	源		索引					

#### 11.4.3.2. 操作

挂起，直到满足指定条件。

与所有挂起指令（第11.2.5节）一样，延迟周期从指令完成之后开始计算。也就是说，若存在任何延迟周期，则延迟计数直到等待条件满足后才开始。

- 极性：

- 1：等待信号为1。
- 0：等待信号为0。

- 源：等待的对象，取值为：

- 00: `GPIO`: 由 `Index` 选择的系统GPIO输入。这是绝对GPIO索引，不受状态机输入IO映射影响。
- 01: `PIN`: 由 `Index` 选择的输入引脚。该状态机先应用输入IO映射，然后由 `Index` 选择映射位中具体等待的位置。换言之，所选引脚为 `PINCTRL_IN_BASE` 配置加上 `Index` 后对32取模所得值。
- 10: `IRQ`: 由 `Index` 选择的PIO IRQ标志
- 11: `JMPPIN`: 等待由 `PINCTRL_JMP_PIN` 配置且索引位于0-3范围内的引脚，均按32取模。`Index` 的其他值保留。

- `Index`: 指定要检查的引脚或位。

`WAIT x IRQ` 的行为与其他 `WAIT` 源略有不同：

- 当 `Polarity` 为1时，状态机在等待条件满足后会清除所选IRQ标志。
- 标志索引的解码方式与 `IRQ` 索引字段相同，从两个最高有效位开始解码（与 `IRQ` 指令中的 `IdxMode` 字段对应）：

- 00: 最低三位用于直接索引该PIO块中的IRQ标志。
- 01 (`PREV`): 该指令引用系统中编号较低的下一个PIO中的IRQ，若当前为PIO0，则回绕至编号最高的PIO。
- 10 (`REL`), 状态机ID (0..3) 通过对两个最低有效位执行模4加法，加入到IRQ索引中。例如，状态机2的标志值为 `0x11` 时，将等待标志3，标志值为 `0x13` 时，将等待标志1。此机制允许多个运行相同程序的状态机相互同步。

- o 11 (NEXT), the instruction references an IRQ from the next-higher-numbered PIO in the system, wrapping to PIO0 if this is the highest-numbered PIO.

### **⚠ CAUTION**

`WAIT 1 IRQ x` should not be used with IRQ flags presented to the interrupt controller, to avoid a race condition with a system interrupt handler

#### 11.4.3.3. Assembler syntax

```
wait <polarity> gpio <gpio_num>
```

```
wait <polarity> pin <pin_num>
```

```
wait <polarity> irq (prev | next) <irq_num> (rel)
```

```
wait <polarity> jmppin (+ <pin_offset>)
```

where:

<polarity>	A value (see <a href="#">Section 11.3.2</a> ) specifying the polarity (either 0 or 1).
<pin_num>	A value (see <a href="#">Section 11.3.2</a> ) specifying the input pin number (as mapped by the SM input pin mapping).
<gpio_num>	A value (see <a href="#">Section 11.3.2</a> ) specifying the actual GPIO pin number.
<irq_num> (rel)	A value (see <a href="#">Section 11.3.2</a> ) specifying The IRQ number to wait on (0-7). If <code>rel</code> is present, then the actual IRQ number used is calculating by replacing the low two bits of the IRQ number ( <code>irq_num<sub>10</sub></code> ) with the low two bits of the sum ( <code>irq_num<sub>10</sub> + sm_num<sub>10</sub></code> ) where <code>sm_num<sub>10</sub></code> is the state machine number.
<code>prev</code>	To wait on the IRQ on the next lower numbered PIO block instead of on the current PIO block
<code>next</code>	To wait on the IRQ on the next higher numbered PIO block instead of on the current PIO block
<pin_offset>	A value (see <a href="#">Section 11.3.2</a> ) added to the <code>jmp_pin</code> to get the actual pin number.

#### 11.4.4. IN

##### 11.4.4.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IN	0	1	0	Delay/side-set				Source			Bit count					

- 11 (NEXT)，该指令引用系统中编号紧接其后的PIO的IRQ，若为最高编号的PIO，则回绕至PIO0。

### ⚠ 警告

**WAIT 1 IRQ x**不应与提交给中断控制器的IRQ标志一起使用，以避免与系统中断处理程序发生竞态条件。

#### 11.4.3.3. 汇编语法

```
wait <polarity> gpio <gpio_num>
```

```
wait <polarity> pin <pin_num>
```

```
wait <polarity> irq (prev | next) <irq_num> (rel)
```

```
wait <polarity> jmpin (+ <pin_offset>)
```

位置：

<polarity> 一个数值（参见第11.3.2节），用于指定极性（0或1）。

<pin\_num> 一个数值（参见第11.3.2节），用于指定输入引脚编号（根据SM输入引脚映射）。

<gpio\_num> 一个数值（参见第11.3.2节），用于指定实际GPIO引脚编号。

<irq\_num> (rel) 一个数值（参见第11.3.2节），用于指定待等待的IRQ编号（0-7）。若存在 rel，则实际使用的IRQ编号通过将IRQ编号 ( $irq\_num_{10}$ ) 的低两位替换为IRQ编号与状态机编号之和 ( $irq\_num_{10} + sm\_num_{10}$ ) 的低两位计算得出， $sm\_num_{10}$  为状态机编号。

prev 等待编号较低的下一个PIO模块的IRQ，而非当前PIO模块的IRQ

下一个 等待下一编号的PIO模块上的IRQ，而非当前PIO模块上的IRQ

<pin\_offset> 一个值（参见第11.3.2节），加至 jmp\_pin 以获得实际引脚编号。

#### 11.4.4. IN

##### 11.4.4.1 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
输入	0	1	0	延迟/side-set				源				位数				

#### 11.4.4.2. Operation

Shift `Bit count` bits from `Source` into the Input Shift Register (ISR). Shift direction is configured for each state machine by `SHIFTCTRL_IN_SHIFTDIR`. Additionally, increase the input shift count by `Bit count`, saturating at 32.

- Source:
  - 000: `PINS`
  - 001: `X` (scratch register X)
  - 010: `Y` (scratch register Y)
  - 011: `NULL` (all zeroes)
  - 100: Reserved
  - 101: Reserved
  - 110: `ISR`
  - 111: `OSR`
- Bit count: How many bits to shift into the ISR. 1...32 bits, 32 is encoded as `00000`

If automatic push is enabled, `IN` will also push the ISR contents to the RX FIFO if the push threshold is reached (`SHIFTCTRL_PUSH_THRESH`). `IN` still executes in one cycle, whether an automatic push takes place or not. The state machine will stall if the RX FIFO is full when an automatic push occurs. An automatic push clears the ISR contents to all-zeroes, and clears the input shift count. See [Section 11.5.4](#).

`IN` always uses the least significant `Bit count` bits of the source data. For example, if `PINCTRL_IN_BASE` is set to 5, the instruction `IN PINS, 3` will take the values of pins 5, 6 and 7, and shift these into the ISR. First the ISR is shifted to the left or right to make room for the new input data, then the input data is copied into the gap this leaves. The bit order of the input data is not dependent on the shift direction.

`NULL` can be used for shifting the ISR's contents. For example, UARTs receive the LSB first, so must shift to the right. After 8 `IN PINS, 1` instructions, the input serial data will occupy bits 31...24 of the ISR. An `IN NULL, 24` instruction will shift in 24 zero bits, aligning the input data at ISR bits 7...0. Alternatively, the processor or DMA could perform a byte read from FIFO address + 3, which would take bits 31...24 of the FIFO contents.

#### 11.4.4.3. Assembler syntax

```
in <source>, <bit_count>
```

where:

`<source>` One of the sources specified above.

`<bit_count>` A value (see [Section 11.3.2](#)) specifying the number of bits to shift (valid range 1-32).

### 11.4.5. OUT

#### 11.4.5.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>OUT</code>	0	1	1	Delay/side-set				Destination			Bit count					

#### 11.4.4.2 操作

将Bit count位从 Source移位至输入移位寄存器（ISR）。通过SHIFTCTRL\_IN\_SHIFTDIR为每个状态机配置移位方向。此外，将输入移位计数增加Bit count，最大饱和至32。

- 来源：
  - 000: 引脚
  - 001: X (临时寄存器X)
  - 010: Y (临时寄存器Y)
  - 011: NULL (全零)
  - 100: 保留
  - 101: 保留
  - 110: ISR
  - 111: OSR
- 位计数：要移入ISR的位数。1至32位，其中32编码为 00000

如果启用自动推送，IN在达到推送阈值时也会将ISR内容推入RX FIFO。

(SHIFTCTRL\_PUSH\_THRESH)。IN无论是否发生自动推送，均在一个周期内执行。如果自动推送发生时RX FIFO已满，状态机将暂停。自动推送会将ISR内容清零并重置输入移位计数。详见11.5.4节。

IN始终使用源数据的最低有效位数。例如，若PINCTRL\_IN\_BASE设置为5，指令IN PINS, 3将读取引脚5、6和7的值，并将其移入ISR。首先，ISR向左或向右移位以腾出新输入数据的位置，然后将输入数据复制至该空隙。输入数据的位顺序不依赖于移位方向。

NULL 可用于移位ISR的内容。例如，UART接收最低有效位（LSB）优先，因此必须向右移位。

经过8个输入引脚、1条指令后，输入的串行数据将占据ISR的第31至24位。一条IN NULL, 24条指令会移入24个位的零，使输入数据对齐于ISR的第7至0位。或者，处理器或DMA可以从FIFO地址+3执行字节读取，该操作将获取FIFO内容的第31至24位。

#### 11.4.4.3. 汇编语法

```
in <source>, <bit_count>
```

位置：

<source>

上述指定的源之一。

<bit\_count>

一个值（参见第11.3.2节），指定移位位数（有效范围为1至32）。

#### 11.4.5. OUT

##### 11.4.5.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
输出	0	1	1	延迟侧集				目标			位数					

### 11.4.5.2. Operation

Shift `Bit count` bits out of the Output Shift Register (OSR), and write those bits to `Destination`. Additionally, increase the output shift count by `Bit count`, saturating at 32.

- Destination:
  - 000: `PINS`
  - 001: `X` (scratch register X)
  - 010: `Y` (scratch register Y)
  - 011: `NULL` (discard data)
  - 100: `PINDIRS`
  - 101: `PC`
  - 110: `ISR` (also sets ISR shift counter to `Bit count`)
  - 111: `EXEC` (Execute OSR shift data as instruction)
- Bit count: how many bits to shift out of the OSR. 1...32 bits, 32 is encoded as `00000`

A 32-bit value is written to `Destination`: the lower `Bit count` bits come from the OSR, and the remainder are zeroes. This value is the least significant `Bit count` bits of the OSR if `SHIFTCTRL_OUT_SHIFTDIR` is to the right, otherwise it is the most significant bits.

`PINS` and `PINDIRS` use the `OUT` pin mapping, as described in [Section 11.5.6](#).

If automatic pull is enabled, the OSR is automatically refilled from the TX FIFO if the pull threshold, `SHIFTCTRL_PULL_THRESH`, is reached. The output shift count is simultaneously cleared to 0. In this case, the `OUT` will stall if the TX FIFO is empty, but otherwise still executes in one cycle. The specifics are given in [Section 11.5.4](#).

`OUT EXEC` allows instructions to be included inline in the FIFO datastream. The `OUT` itself executes on one cycle, and the instruction from the OSR is executed on the next cycle. There are no restrictions on the types of instructions which can be executed by this mechanism. Delay cycles on the initial `OUT` are ignored, but the executee may insert delay cycles as normal.

`OUT PC` behaves as an unconditional jump to an address shifted out from the OSR.

### 11.4.5.3. Assembler syntax

```
out <destination>, <bit_count>
```

where:

- |                                  |                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>&lt;destination&gt;</code> | One of the destinations specified above.                                                                 |
| <code>&lt;bit_count&gt;</code>   | A value (see <a href="#">Section 11.3.2</a> ) specifying the number of bits to shift (valid range 1-32). |

## 11.4.6. PUSH

### 11.4.6.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>PUSH</code>	1	0	0	Delay/side-set				0	IfF	Blk	0	0	0	0	0	0

### 11.4.5.2. 操作

Shift位计数表示从输出移位寄存器（OSR）移出的位数，并将这些位写入目标。此外，将输出移位计数增加位计数，最大饱和至32。

- 目标：
  - 000: 引脚
  - 001: X (临时寄存器X)
  - 010: Y (临时寄存器Y)
  - 011: NULL (丢弃数据)
  - 100: PINDIRS
  - 101: PC
  - 110: ISR (同时将ISR移位计数器设置为位计数 )
  - 111: EXEC (将OSR移位数据作为指令执行)
- 位计数：表示要从OSR移出的位数，范围为1至32位，32编码为00000

向目标写入一个32位值：低位计数位来自OSR，剩余位填充为零。如果SHIFTCTRL\_OUT\_SHIFTDIR为向右，则该值为OSR的最低有效位计数位，否则为最高有效位。

PINS 和 PINDIRS 使用 OUT 引脚映射，详见第11.5.6节。

若启用自动拉取，当拉取阈值SHIFTCTRL\_PULL\_THRESH达到时，OSR会自动从TX FIFO重新填充。输出移位计数同时被清零为0。在此情况下，如TX FIFO为空，OUT将阻塞，但其他情况下仍在周期内执行。具体内容详见第11.5.4节。

OUT EXEC 允许指令以内联形式包含在FIFO数据流中。OUT本身在一个周期内执行，来自OSR的指令在下一周期执行。该机制执行的指令类型没有限制。初始OUT的延迟周期将被忽略，但执行体可按常规插入延迟周期。

OUT PC 表现为对从OSR移出的地址的无条件跳转。

### 11.4.5.3. 汇编语法

```
out <destination>, <bit_count>
```

位置：

<destination> 上述指定的目标之一。

<bit\_count> 一个值（参见第11.3.2节），指定移位位数（有效范围为1至32）。

## 11.4.6. PUSH

### 11.4.6.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PUSH	1	0	0	延迟/side-set				0	IfF	块	0	0	0	0	0	

### 11.4.6.2. Operation

Push the contents of the ISR into the RX FIFO, as a single 32-bit word. Clear ISR to all-zeroes.

- **IfFull:** If 1, do nothing unless the total input shift count has reached its threshold, `SHIFTCTRL_PUSH_THRESH` (the same as for autopush; see [Section 11.5.4](#)).
- **Block:** If 1, stall execution if RX FIFO is full.

`PUSH IFFULL` helps to make programs more compact, like autopush. It is useful in cases where the `IN` would stall at an inappropriate time if autopush were enabled, e.g. if the state machine is asserting some external control signal at this point.

The PIO assembler sets the `Block` bit by default. If the `Block` bit is not set, the `PUSH` does not stall on a full RX FIFO, instead continuing immediately to the next instruction. The FIFO state and contents are unchanged when this happens. The ISR is still cleared to all-zeroes, and the `FDEBUG_RXSTALL` flag is set (the same as a blocking `PUSH` or autopush to a full RX FIFO) to indicate data was lost.

#### ⓘ NOTE

The operation of the `PUSH` instruction is undefined when `SM0_SHIFTCTRL.FJOIN_RX_PUT` or `FJOIN_RX_GET` is set – see [Section 11.4.8](#) and [Section 11.4.9](#) for details of the `PUT` and `GET` instruction which can be used in this state.

### 11.4.6.3. Assembler syntax

```
push (iffull)
```

```
push (iffull) block
```

```
push (iffull) noblock
```

where:

- |                      |                                                                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>iffull</code>  | Equivalent to <code>IfFull == 1</code> above. i.e. the default if this is not specified is <code>IfFull == 0</code> .                 |
| <code>block</code>   | Equivalent to <code>Block == 1</code> above. This is the default if neither <code>block</code> nor <code>noblock</code> is specified. |
| <code>noblock</code> | Equivalent to <code>Block == 0</code> above.                                                                                          |

### 11.4.7. PULL

#### 11.4.7.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>PULL</code>	1	0	0	Delay/side-set				1	IfE	Blk	0	0	0	0	0	0

### 11.4.6.2. 操作

将 ISR 内容作为一个单独的 32 位字推入 RX FIFO，并将 ISR 清零为全零。

- **Iffull**: 如果为 1，除非总输入移位计数达到阈值SHIFTCTRL\_PUSH\_THRESH（与自动推送相同，参见第 11.5.4 节），否则不执行任何操作。
- **Block**: 如果为 1，当 RX FIFO 满时阻止执行。

**PUSH IFFULL**有助于使程序更紧凑，类似自动推送。当启用自动推送会导致 IN在不适当的时间阻塞时，此功能非常有用，例如状态机此时正在断言某些外部控制信号。

PIO 汇编器默认设置 **Block**位。若 **Block**位未设置，**PUSH**指令在RX FIFO已满时不会阻塞，而是立即继续执行下一条指令。此时，FIFO的状态及内容保持不变。ISR依然被清零，且设置了**FDEBUG\_RXSTALL**标志（与阻塞的 **PUSH**或自动推送至满的RX FIFO相同），以指示数据丢失。

#### ① 注意

当SM0\_SHIFTCTRL.FJOIN\_RX\_PUT或FJOIN\_RX\_GET被设置时，**PUSH**指令的操作行为未定义——有关此状态下可使用的 **PUT**和 **GET**指令的详细信息，请参见第11.4.8节和第11.4.9节。

### 11.4.6.3. 汇编语法

```
push (iffull)
```

```
push (iffull) block
```

```
push (iffull) noblock
```

位置：

**iffull** 等同于上述的**IfFull == 1**。即默认情况下，若未指明，则为**IfFull == 0**。

**块** 等同于**Block == 1**如上。如果既未指定 **block**也未指定 **noblock**，则采用此默认设置。

**noblock** 等同于**Block == 0**如上。

### 11.4.7. PULL

#### 11.4.7.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>PULL</b>	1	0	0	延迟/side-set				1	IfE	块	0	0	0	0	0	0

### 11.4.7.2. Operation

Load a 32-bit word from the TX FIFO into the OSR.

- **IfEmpty:** If 1, do nothing unless the total output shift count has reached its threshold, `SHIFTCTRL_PULL_THRESH` (the same as for autopull; see [Section 11.5.4](#)).
- **Block:** If 1, stall if TX FIFO is empty. If 0, pulling from an empty FIFO copies scratch X to OSR.

Some peripherals (UART, SPI, etc.) should halt when no data is available, and pick it up as it comes in; others (I2S) should clock continuously, and it is better to output placeholder or repeated data than to stop clocking. This can be achieved with the `Block` parameter.

A non-blocking `PULL` on an empty FIFO has the same effect as `MOV OSR, X`. The program can either preload scratch register X with a suitable default, or execute a `MOV X, OSR` after each `PULL NOBLOCK`, so that the last valid FIFO word will be recycled until new data is available.

`PULL IFEMPTY` is useful if an `OUT` with autopull would stall in an inappropriate location when the TX FIFO is empty. `IfEmpty` permits some of the same program simplifications as autopull: for example, the elimination of an outer loop counter. However, the stall occurs at a controlled point in the program.

#### NOTE

When autopull is enabled, any `PULL` instruction is a no-op when the OSR is full, so that the `PULL` instruction behaves as a barrier. `OUT NULL, 32` can be used to explicitly discard the OSR contents. See [Section 11.5.4.2](#) for more detail.

### 11.4.7.3. Assembler syntax

```
pull (ifempty)
```

```
pull (ifempty) block
```

```
pull (ifempty) noblock
```

where:

- |                      |                                                                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>ifempty</code> | Equivalent to <code>IfEmpty == 1</code> above. i.e. the default if this is not specified is <code>IfEmpty == 0</code> .               |
| <code>block</code>   | Equivalent to <code>Block == 1</code> above. This is the default if neither <code>block</code> nor <code>noblock</code> is specified. |
| <code>noblock</code> | Equivalent to <code>Block == 0</code> above.                                                                                          |

### 11.4.8. MOV (to RX)

#### 11.4.8.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>MOV</code>	1	0	0	Delay/side-set				0	0	0	1	IdxI	Index			

### 11.4.7.2. 操作

从 TX FIFO 中加载一个 32 位字到 OSR。

- **IfEmpty**: 若为 1，则除非总输出移位计数达到阈值 **SHIFTCTRL\_PULL\_THRESH**（与 autopull 相同；参见第 11.5.4 节），否则不执行任何操作。
- **Block**: 若为 1，在 TX FIFO 为空时阻塞。若为 0，从空 FIFO 拉取时将暂存 X 复制至 OSR。

某些外设（UART、SPI 等）在无数据可用时应暂停，并在数据到达时继续处理；其他外设（如 I2S）应持续时钟输出，且输出占位数据或重复数据优于停止时钟。这可以通过 **Block** 参数实现。

对空 FIFO 执行非阻塞的 **PULL**，其效果等同于 **MOV OSR, X**。程序可以预先用适当默认值加载临时寄存器 X，或在每次 PULL N **BLOCK** 后执行 **MOV X, OSR**，以便在新数据可用前重复使用最后一个有效的 FIFO 字。

当 TX FIFO 为空且带自动拉取的 OUT 指令会在不当位置停顿时，PULL IFEMPTY 指令非常有用。IfEmpty 允许进行某些与自动拉取相同的程序简化，例如省略外层循环计数器。

但程序中的停顿发生在可控的位置。

#### ① 注意

启用自动拉取时，当 OSR 已满，任何 **PULL** 指令均为无操作，因此 **PULL** 指令表现为屏障。**OUT NULL, 32** 可用于显式丢弃 OSR 内容。详见第 11.5.4.2 节。

### 11.4.7.3. 汇编语法

**pull (ifempty)**

**pull (ifempty) 块**

**pull (ifempty) 非阻塞**

位置：

**ifempty** 等同于 **IfEmpty == 1**。即默认情况下如果未指定，则为 **IfEmpty == 0**。

**块** 等同于 **Block == 1** 如上。如果既未指定 **block** 也未指定 **noblock**，则采用此默认设置。

**noblock** 等同于 **Block == 0** 如上。

### 11.4.8. MOV (至RX)

#### 11.4.8.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>MOV</b>	1	0	0	延迟/side-set				0	0	0	1	IdxI	索引			

### 11.4.8.2. Operation

Write the ISR to a selected RX FIFO entry. The state machine can write the RX FIFO entries in any order, indexed either by the Y register, or an immediate Index in the instruction. Requires the `SHIFTCTRL_FJOIN_RX_PUT` configuration field to be set, otherwise its operation is undefined. The FIFO configuration can be specified for the program via the `.fifo` directive (see `pioasm_fifo`).

If `Idxl` (index by immediate) is set, the RX FIFO's registers are indexed by the two least-significant bits of the Index operand. Otherwise, they are indexed by the two least-significant bits of the Y register. When `Idxl` is clear, all non-zero values of Index are reserved encodings, and their operation is undefined.

When only `SHIFTCTRL_FJOIN_RX_PUT` is set (in `SM0_SHIFTCTRL` through `SM3_SHIFTCTRL`), the system can also read the RX FIFO registers with random access via `RXF0_PUTGET0` through `RXF0_PUTGET3` (where `RXFx` indicates which state machine's FIFO is being accessed). In this state, the FIFO register storage is repurposed as status registers, which the state machine can update at any time and the system can read at any time. For example, a quadrature decoder program could maintain the current step count in a status register at all times, rather than pushing to the RX FIFO and potentially blocking.

When both `SHIFTCTRL_FJOIN_RX_PUT` and `SHIFTCTRL_FJOIN_RX_GET` are set, the system can no longer access the RX FIFO storage registers, but the state machine can now put/get the registers in arbitrary order, allowing them to be used as additional scratch storage.

**i NOTE**

The RX FIFO storage registers have only a single read port and write port, and access through each port is assigned to only one of (system, state machine) at any time.

### 11.4.8.3. Assembler syntax

```
mov rxfifo[y], isr
```

```
mov rxfifo[<index>], isr
```

where:

`y` The literal token "y", indicating the RX FIFO entry is indexed by the Y register.

`<index>` A value (see [Section 11.3.2](#)) specifying the RX FIFO entry to write (valid range 0-3).

## 11.4.9. MOV (from RX)

### 11.4.9.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>MOV</code>	1	0	0	Delay/side-set				1	0	0	1	<code>Idxl</code>	Index			

### 11.4.8.2. 操作

将 ISR 写入所选的 RX FIFO 条目。状态机可以以任意顺序写入 RX FIFO 条目，索引可通过 Y 寄存器或指令中的立即数索引确定。要求设置 SHIFTCTRL\_FJOIN\_RX\_PUT 配置字段，否则其操作未定义。可以通过 .fifo 指令为程序指定 FIFO 配置（参见 pio\_asm\_fifo）。

如果设置了 **IdxI**（立即数索引），RX FIFO 的寄存器由 Index 操作数的最低两位索引。否则，它们由 Y 寄存器的两个最低有效位进行索引。当 IdxI 位清除时，Index 的所有非零值均为保留编码，其操作未定义。

当仅设置 SHIFTCTRL\_FJOIN\_RX\_PUT（位于 SM0\_SHIFTCTRL 至 SM3\_SHIFTCTRL 寄存器中）时，系统还可以通过 RXF0\_PUTGET0 至 RXF0\_PUTGET3 寄存器随机访问 RX FIFO（其中 RXFx 表示访问的是哪个状态机的 FIFO）。在此状态下，FIFO 寄存器存储被重新用作状态寄存器，状态机可随时更新，系统亦可随时读取。例如，正交编码器程序可以始终在状态寄存器中维护当前步进计数，而无需推送至 RX FIFO，从而避免潜在阻塞。

当同时设置 SHIFTCTRL\_FJOIN\_RX\_PUT 与 SHIFTCTRL\_FJOIN\_RX\_GET 时，系统将无法访问 RX FIFO 存储寄存器，但状态机可以任意顺序读写这些寄存器，使其可用作额外的临时存储空间。

#### i 注意

RX FIFO 存储寄存器仅设有单个读端口和写端口，且每个端口在任一时刻仅分配给（系统、状态机）之一。

### 11.4.8.3. 汇编语法

```
mov rxfifo[y], isr
```

```
mov rxfifo[<index>], isr
```

位置：

**y** 字面标记 "y"，表示 RX FIFO 条目通过 Y 寄存器索引。

**<index>** 一个值（参见第 11.3.2 节），指定要写入的 RX FIFO 条目（有效范围为 0-3）。

## 11.4.9. MOV (来自 RX)

### 11.4.9.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOV	1	0	0	延迟/side-set				1	0	0	1	IdxI	索引			

### 11.4.9.2. Operation

Read the selected RX FIFO entry into the OSR. The PIO state machine can read the FIFO entries in any order, indexed either by the Y register, or an immediate Index in the instruction. Requires the `SHIFTCTRL_FJOIN_RX_GET` configuration field to be set, otherwise its operation is undefined.

If `Idxl` (index by immediate) is set, the RX FIFO's registers are indexed by the two least-significant bits of the Index operand. Otherwise, they are indexed by the two least-significant bits of the Y register. When `Idxl` is clear, all non-zero values of Index are reserved encodings, and their operation is undefined.

When only `SHIFTCTRL_FJOIN_RX_GET` is set, the system can also write the RX FIFO registers with random access via `RXF0_PUTGET0` through `RXF0_PUTGET3` (where RXFx indicates which state machine's FIFO is being accessed). In this state, the RX FIFO register storage is repurposed as additional configuration registers, which the system can update at any time and the state machine can read at any time. For example, a UART TX program might use these registers to configure the number of data bits, or the presence of an additional stop bit.

When both `SHIFTCTRL_FJOIN_RX_PUT` and `SHIFTCTRL_FJOIN_RX_GET` are set, the system can no longer access the RX FIFO storage registers, but the state machine can now put/get the registers in arbitrary order, allowing them to be used as additional scratch storage.

**NOTE**

The RX FIFO storage registers have only a single read port and write port, and access through each port is assigned to only one of (system, state machine) at any time.

### 11.4.9.3. Assembler syntax

```
mov osr, rxfifo[y]
```

```
mov osr, rxfifo[<index>]
```

where:

`y` The literal token "y", indicating the RX FIFO entry is indexed by the Y register.

`<index>` A value (see [Section 11.3.2](#)) specifying the RX FIFO entry to read (valid range 0-3).

## 11.4.10. MOV

### 11.4.10.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>MOV</code>	1	0	1	Delay/side-set				Destination			Op		Source			

### 11.4.10.2. Operation

Copy data from `Source` to `Destination`.

- Destination:

### 11.4.9.2. 操作

将所选 RX FIFO 条目读取至 OSR。PIO 状态机可按任意顺序读取 FIFO 条目，其索引可由 Y 寄存器或指令中的立即数 `Indx` 指定。必须设置`SHIFTCTRL_FJOIN_RX_GET`配置字段，否则其操作未定义。

如果设置了 `Indx`（立即数索引），RX FIFO 的寄存器由 Index 操作数的最低两位索引。否则，它们由Y寄存器的两个最低有效位进行索引。当`Indx`位清除时，Index的所有非零值均为保留编码，其操作未定义。

仅当设置`SHIFTCTRL_FJOIN_RX_GET`时，系统方可通过 RXF0\_PUTGET0 至 RXF0\_PUTGET3（其中 RXFx 表示访问对应状态机的 FIFO）对 RX FIFO 寄存器进行随机访问写入。在此状态下，RX FIFO寄存器存储被重新用作附加配置寄存器，系统可随时更新，状态机亦可随时读取。例如，[UART TX](#)程序可能使用这些寄存器来配置数据位数或额外停止位的存在。

当同时设置`SHIFTCTRL_FJOIN_RX_PUT`与`SHIFTCTRL_FJOIN_RX_GET`时，系统将无法访问RX FIFO存储寄存器，但状态机可以任意顺序读写这些寄存器，使其可用作额外的临时存储空间。

#### ① 注意

RX FIFO 存储寄存器仅设有单个读端口和写端口，且每个端口在任一时刻仅分配给（系统、状态机）之一。

### 11.4.9.3. 汇编语法

```
mov osr, rxfifo[y]
```

```
mov osr, rxfifo[<index>]
```

位置：

`y` 字面标记 "y"，表示 RX FIFO 条目通过 Y 寄存器索引。

`<index>` 一个值（参见第11.3.2节），指定要读取的RX FIFO条目（有效范围0-3）。

## 11.4.10. MOV

### 11.4.10.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<code>MOV</code>	1	0	1	延迟侧集				目标				Op		源		

### 11.4.10.2. 操作

从源复制数据至目的地。

- 目标：

- 000: **PINS** (Uses same pin mapping as **OUT**)
- 001: **X** (Scratch register X)
- 010: **Y** (Scratch register Y)
- 011: **PINDIRS** (Uses same pin mapping as **OUT**)
- 100: **EXEC** (Execute data as instruction)
- 101: **PC**
- 110: **ISR** (Input shift counter is reset to 0 by this operation, i.e. empty)
- 111: **OSR** (Output shift counter is reset to 0 by this operation, i.e. full)
- Operation:
- 00: None
- 01: Invert (bitwise complement)
- 10: Bit-reverse
- 11: Reserved
- Source:
- 000: **PINS** (Uses same pin mapping as **IN**)
- 001: **X**
- 010: **Y**
- 011: **NULL**
- 100: Reserved
- 101: **STATUS**
- 110: **ISR**
- 111: **OSR**

**MOV PC** causes an unconditional jump. **MOV EXEC** has the same behaviour as **OUT EXEC** (Section 11.4.5), and allows register contents to be executed as an instruction. The **MOV** itself executes in 1 cycle, and the instruction in **Source** on the next cycle. Delay cycles on **MOV EXEC** are ignored, but the executee may insert delay cycles as normal.

The **STATUS** source has a value of all-ones or all-zeroes, depending on some state machine status such as FIFO full/empty, configured by **EXECCTRL\_STATUS\_SEL**.

**MOV** can manipulate the transferred data in limited ways, specified by the **Operation** argument. Invert sets each bit in **Destination** to the logical NOT of the corresponding bit in **Source**, i.e. 1 bits become 0 bits, and vice versa. Bit reverse sets each bit **n** in **Destination** to bit  $31 - n$  in **Source**, assuming the bits are numbered 0 to 31.

**MOV dst, PINS** reads pins using the **IN** pin mapping, masked to the number of bits specified by **SHIFTCTRL\_IN\_COUNT**. The LSB of the read value is the pin indicated by **PINCTRL\_IN\_BASE**, and each successive bit comes from a higher-numbered pin, wrapping after 31. Result bits greater than the width specified by **SHIFTCTRL\_IN\_COUNT** configuration are 0.

**MOV PINDIRS, src** is not supported on PIO version 0.

### 11.4.10.3. Assembler syntax

```
mov <destination>, (op) <source>
```

where:

- 000: PINS (使用与 OUT 相同的引脚映射)
- 001: X (临时寄存器X)
- 010: Y (临时寄存器Y)
- 011: PINDIRS (使用与 OUT 相同的引脚映射)
- 100: EXEC (将数据作为指令执行)
- 101: PC
- 110: ISR (该操作将输入移位计数器复位为0, 即清空)
- 111: OSR (该操作将输出移位计数器复位为0, 即填写满)

• 操作:

- 00: 无
- 01: 取反 (按位取补)
- 10: 位反转
- 11: 保留

• 来源:

- 000: PINS (使用与 IN 相同的引脚映射)
- 001: X
- 010: Y
- 011: NULL
- 100: 保留
- 101: STATUS
- 110: ISR
- 111: OSR

**MOV PC**导致无条件跳转。**MOV EXEC**行为与**OUT EXEC** (第11.4.5节) 相同, 允许将寄存器内容作为指令执行。**MOV**自身执行一个周期, 下一周期执行Source中的指令。**MOV EXEC**的延迟周期被忽略, 但被执行的指令可正常插入延迟周期。

STATUS源的值为全1或全0, 取决于某些状态机状态 (如FIFO满或空), 通过EXECCTRL\_STATUS\_SEL配置。

**MOV**可按有限方式操作所传输的数据, 该操作由 **Operation**参数指定。**Invert**将**Destination**中的每个位设置为对应**Source**位的逻辑非, 即1变0, 0变1。**Bit reverse**将**Destination**中的每个位 n设置为**Source**中第31 - n位, 假设位编号从0至31。

**MOV dst, PINS**通过 **IN**引脚映射读取引脚信号, 掩码位数由**SHIFTCTRL\_IN\_COUNT**指定。读取值的最低有效位对应**PINCTRL\_IN\_BASE**指定的引脚, 后续每个位由编号更高的引脚提供, 超过31后循环。超过**SHIFTCTRL\_IN\_COUNT**配置宽度的结果位将为0。

PIO版本0不支持**MOV PINDIRS, src**指令。

### 11.4.10.3. 汇编语法

```
mov <destination>, (op) <source>
```

位置:

<destination>	One of the destinations specified above.
op	If present, is:
	! or ~ for NOT (Note: this is always a bitwise NOT)
	:: for bit reverse

<source>	One of the sources specified above.
----------	-------------------------------------

## 11.4.11. IRQ

### 11.4.11.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IRQ	1	1	0	Delay/side-set				0	Clr	Wait	IdxMode	Index				

### 11.4.11.2. Operation

Set or clear the IRQ flag selected by [Index](#) argument.

- Clear: if 1, clear the flag selected by [Index](#), instead of raising it. If [Clear](#) is set, the [Wait](#) bit has no effect.
- Wait: if 1, halt until the raised flag is lowered again, e.g. if a system interrupt handler has acknowledged the flag.
- Index: specifies an IRQ index from 0-7. This IRQ flag will be set/cleared depending on the Clear bit.
- IdxMode: modify the behaviour if the Index field, either modifying the index, or indexing IRQ flags from a different PIO block:
  - 00: the three LSBs are used directly to index the IRQ flags in this PIO block.
  - 01 ([PREV](#)): the instruction references an IRQ flag from the next-lower-numbered PIO in the system, wrapping to the highest-numbered PIO if this is PIO0.
  - 10 ([REL](#)): the state machine ID (0...3) is added to the IRQ flag index, by way of modulo-4 addition on the two LSBs. For example, state machine 2 with a flag value of '0x11' will wait on flag 3, and a flag value of '0x13' will wait on flag 1. This allows multiple state machines running the same program to synchronise with each other.
  - 11 ([NEXT](#)): the instruction references an IRQ flag from the next-higher-numbered PIO in the system, wrapping to PIO0 if this is the highest-numbered PIO.

All IRQ flags 0-7 can be routed out to system level interrupts, on either of the PIO's two external interrupt request lines, configured by [IRQ0\\_INTE](#) and [IRQ1\\_INTE](#).

The modulo addition mode ([REL](#)) allows relative addressing of 'IRQ' and 'WAIT' instructions, for synchronising state machines which are running the same program. Bit 2 (the third LSB) is unaffected by this addition.

The [NEXT/PREV](#) modes can be used to synchronise between state machines in different PIO blocks. If these state machines' clocks are divided, their clock dividers must be the same, and must have been synchronised by writing [CTRL.NEXTPREV\\_CLKDIV\\_RESTART](#) in addition to the relevant [NEXT\\_PIO\\_MASK](#)/[PREV\\_PIO\\_MASK](#) bits. Note that the cross-PIO connection is severed between PIOs with different accessibility to Non-secure code, as per [ACCESSCTRL](#).

If [Wait](#) is set, [Delay](#) cycles do not begin until after the wait period elapses.

<destination>	上述指定的目标之一。

	:: 表示位反转

## 11.4.11. IRQ

### 11.4.11.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IRQ	1	1	0	延迟/side-set				0	Clr	等待	IdxMode	索引				

### 11.4.11.2. 操作

根据参数 Index 设置或清除所选的 IRQ 标志。

- Clear：若为 1，则清除由 Index 选定的标志，而非置位该标志。若设置了 Clear，则 Wait 位无效。
- Wait：若为 1，则挂起直到置位的标志被清除，例如当系统中断处理程序已确认该标志时。
- Index：指定一个 0 到 7 范围内的 IRQ 索引。该 IRQ 标志将根据 Clear 位被置位或清除。
- IdxMode：修改 Index 字段的行为，可修改索引或从不同 PIO 模块索引 IRQ 标志：
  - 00：最低三位用于直接索引该 PIO 块中的 IRQ 标志。
  - 01 (PREV)：指令引用系统中编号更低的 PIO 的 IRQ 标志，若为 PIO0 则循环至编号最高的 PIO。
  - 10 (REL)：状态机 ID (0...3) 通过对两个最低有效位进行模4加法，添加到 IRQ 标志索引中。例如，状态机 2 的标志值为 '0x11' 时，将等待标志 3；标志值为 '0x13' 时，将等待标志 1。此机制允许多个运行相同程序的状态机相互同步。
  - 11 (NEXT)：指令引用系统中编号次高的 PIO 的 IRQ 标志，若该 PIO 为最高编号，则回绕至 PIO0。

所有 IRQ 标志 0-7 均可路由至系统级中断，连接至 PIO 的两个外部中断请求线之一，由 IRQ0\_INTE 和 IRQ1\_INTE 配置。

模加法模式 (REL) 允许对“IRQ”和“WAIT”指令进行相对寻址，以实现运行同一程序的状态机间同步。第 2 位（第三个最低有效位）不受此加法影响。

NEXT/PREV 模式可用于不同 PIO 模块中的状态机之间同步。如果这些状态机的时钟被分频，则其时钟分频器必须相同，且必须通过写入 CTRL\_NEXTPREV\_CLKDIV\_RESTART 以及相关的 NEXT\_PIO\_MASK/PREV\_PIO\_MASK 位实现同步。请注意，根据 ACCESSCTRL，不同对非安全代码可访问的 PIO 之间的跨 PIO 连接将被切断。

如果设置了 Wait，Delay 周期将在等待期结束后才开始。

### 11.4.11.3. Assembler syntax

```
irq (prev | next) <irq_num> (rel)
```

```
irq (prev | next) set <irq_num> (rel)
```

```
irq (prev | next) nowait <irq_num> (rel)
```

```
irq (prev | next) wait <irq_num> (rel)
```

```
irq (prev | next) clear <irq_num> (rel)
```

where:

<irq_num> (rel)	A value (see <a href="#">Section 11.3.2</a> ) specifying the IRQ number to target (0-7). If <b>rel</b> is present, then the actual IRQ number used is calculated by replacing the low two bits of the IRQ number ( $\text{irq\_num}_{10}$ ) with the low two bits of the sum ( $\text{irq\_num}_{10} + \text{sm\_num}_{10}$ ) where $\text{sm\_num}_{10}$ is the state machine number.
irq	Set the IRQ without waiting.
irq set	Set the IRQ without waiting.
irq nowait	Set the IRQ without waiting.
irq wait	Set the IRQ and wait for it to be cleared before proceeding.
irq clear	Clear the IRQ.
prev	To target the IRQ on the next lower numbered PIO block instead of the current PIO block
next	To target the IRQ on the next higher numbered PIO block instead of the current PIO block

### 11.4.12. SET

#### 11.4.12.1. Encoding

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SET	1	1	1	Delay/side-set				Destination			Data					

#### 11.4.12.2. Operation

Write immediate value **Data** to **Destination**.

- Destination:

### 11.4.11.3. 汇编语法

```
irq (prev | next) <irq_num> (rel)
```

```
irq (prev | next) set <irq_num> (rel)
```

```
irq (prev | next) nowait <irq_num> (rel)
```

```
irq (prev | next) wait <irq_num> (rel)
```

```
irq (prev | next) clear <irq_num> (rel)
```

位置：

**<irq\_num> (rel)** 一个值（参见第11.3.2节），指定要定位的IRQ号（0-7）。如果 **rel** 存在，则实际使用的IRQ号通过将IRQ号的最低两位 ( $\text{irq\_num}_{10}$ ) 替换为和的最低两位 ( $\text{irq\_num}_{10} + \text{sm\_num}_{10}$ ) 计算得出，其中  $\text{sm\_n}_{10}$  为状态机编号。

<b>irq</b>	设置IRQ且不等待。
<b>irq 设置</b>	设置IRQ且不等待。
<b>irq 不等待</b>	设置IRQ且不等待。
<b>irq 等待</b>	设置IRQ并等待其被清除后再继续。
<b>irq 清除</b>	清除IRQ。
<b>prev</b>	定位至下一个编号较低的PIO块上的IRQ，而非当前PIO块。
<b>下一个</b>	定位至下一个编号较高的PIO块上的IRQ，而非当前PIO块。

### 11.4.12. SET

#### 11.4.12.1. 编码

位	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>设置</b>	1	1	1	延迟/side-set				目标			数据					

#### 11.4.12.2. 操作

将立即数数据写入目标。

- 目标：

- 000: PINS
- 001: X (scratch register X) 5 LSBs are set to Data, all others cleared to 0.
- 010: Y (scratch register Y) 5 LSBs are set to Data, all others cleared to 0.
- 011: Reserved
- 100: PINDIRS
- 101: Reserved
- 110: Reserved
- 111: Reserved
- Data: 5-bit immediate value to drive to pins or register.

This can be used to assert control signals such as a clock or chip select, or to initialise loop counters. As Data is 5 bits in size, scratch registers can be SET to values from 0-31, which is sufficient for a 32-iteration loop.

The mapping of SET and OUT onto pins is configured independently. They may be mapped to distinct locations, for example if one pin is to be used as a clock signal, and another for data. They may also be overlapping ranges of pins: a UART transmitter might use SET to assert start and stop bits, and OUT instructions to shift out FIFO data to the same pins.

#### 11.4.12.3. Assembler syntax

```
set <destination>, <value>
```

where:

- |               |                                                                            |
|---------------|----------------------------------------------------------------------------|
| <destination> | Is one of the destinations specified above.                                |
| <value>       | The value (see <a href="#">Section 11.3.2</a> ) to set (valid range 0-31). |

## 11.5. Functional details

### 11.5.1. Side-set

Side-set is a feature that allows state machines to change the level or direction of up to 5 pins, concurrently with the main execution of the instruction.

One example where this is necessary is a fast SPI interface: here a clock transition (toggling 1→0 or 0→1) must be simultaneous with a data transition, where a new data bit is shifted from the OSR to a GPIO. In this case an OUT with a side-set would achieve both of these at once.

This makes the timing of the interface more precise, reduces the overall program size (as a separate SET instruction is not needed to toggle the clock pin), and also increases the maximum frequency the SPI can run at.

Side-set also makes GPIO mapping much more flexible, as its mapping is independent from SET. The example I2C code allows SDA and SCL to be mapped to any two arbitrary pins, if clock stretching is disabled. Normally, SCL toggles to synchronise data transfer, and SDA contains the data bits being shifted out. However, some particular I2C sequences such as Start and Stop line conditions, need a fixed pattern to be driven on SDA as well as SCL. The mapping I2C uses to achieve this is:

- Side-set → SCL

- 000: 引脚
- 001: X (暂存寄存器X) 其最低5位被设置为 Data，其他位全部清零。
- 010: Y (暂存寄存器Y) 其最低5位被设置为 Data，其他位全部清零。
- 011: 保留
- 100: PINDIRS
- 101: 保留
- 110: 保留
- 111: 保留
- Data: 用于驱动引脚或寄存器的5位立即数。

此数值可用于断言控制信号，例如时钟或芯片选择信号，或初始化循环计数器。鉴于 Data 大小为5位，暂存寄存器可以被 SET 为0至31之间的值，足以支持32次迭代的循环。

对 SET 和 OUT 映射至引脚的配置是相互独立的。它们可以映射至不同的引脚位置，例如某引脚用作时钟信号，另一引脚用于数据信号。它们也可以映射至部分重叠的引脚范围：UART发送器可能利用 SET 断言起始位和停止位，同时使用 OUT 指令将FIFO数据发送至同一引脚。

#### 11.4.12.3. 汇编语法

```
set <destination>, <value>
```

位置：

- |               |                              |
|---------------|------------------------------|
| <destination> | 是上述所指定的目标之一。                 |
| <value>       | 设置的值（参见第11.3.2节）（有效范围为0至31）。 |

## 11.5. 功能细节

### 11.5.1. Side-set

侧置功能允许状态机在指令主执行的同时，改变最多5个引脚的电平或方向。

一个必要的例子是高速SPI接口：时钟跳变（切换1→0或0→1）必须与数据跳变同步，新的数据位从OSR移入GPIO。在此情况下，带侧置功能的 OUT 指令能够同时完成这两项操作。

这使接口的时序更加精准，减少整体程序大小（无需单独的 SET 指令切换时钟引脚），并提升SPI的最大运行频率。

侧置功能还使GPIO映射更为灵活，因为其映射独立于 SET 指令。示例 I2C 代码允许将 SDA 和 SCL 映射到任意两个引脚，前提是禁用时钟拉伸功能。通常，SCL 切换以同步数据传输，而 SDA 包含被移出的数据位。然而，某些特定的 I2C 序列，如 Start 和 Stop 线条件，需要在 SDA 和 SCL 上驱动固定模式。I2C 用于实现此目的的映射如下：

- Side-set → SCL

- OUT → SDA
- SET → SDA

This lets the state machine serve the two use cases of data on SDA and clock on SCL, or fixed transitions on both SDA and SCL, while still allowing SDA and SCL to be mapped to any two GPIOs of choice.

The side-set data is encoded in the `Delay/side-set` field of each instruction. Any instruction can be combined with side-set, including instructions which write to the pins, such as `OUT PINS` or `SET PINS`. Side-set's pin mapping is independent from `OUT` and `SET` mappings, though it may overlap. If side-set and an `OUT` or `SET` write to the same pin simultaneously, the side-set data is used.

### NOTE

If an instruction stalls, the side-set still takes effect immediately.

```

1 .program spi_tx_fast
2 .side_set 1
3
4 loop:
5 out pins, 1 side 0
6 jmp loop side 1

```

The `spi_tx_fast` example shows two benefits of this: data and clock transitions can be more precisely co-aligned, and programs can be made faster overall, with an output of one bit per two system clock cycles in this case. Programs can also be made smaller.

There are four things to configure when using side-set:

- The number of MSBs of the `Delay/side-set` field to use for side-set rather than delay. This is configured by `PINCTRL_SIDESET_COUNT`. If this is set to 5, delay cycles are not available. If set to 0, no side-set will take place.
- Whether to use the most significant of these bits as an enable. Side-set takes place on instructions where the enable is high. If there is no enable bit, `every` instruction on that state machine will perform a side-set, if `SIDESET_COUNT` is nonzero. This is configured by `EXECCTRL_SIDE_EN`.
- The GPIO number to map the least-significant side-set bit to. Configured by `PINCTRL_SIDESET_BASE`.
- Whether side-set writes to GPIO levels or GPIO directions. Configured by `EXECCTRL_SIDE_PINDIR`

In the above example, we have only one side-set data bit, and every instruction performs a side-set, so no enable bit is required. `SIDESET_COUNT` would be 1, `SIDE_EN` would be false. `SIDE_PINDIR` would also be false, as we want to drive the clock high and low, not high- and low-impedance. `SIDESET_BASE` would select the GPIO the clock is driven from.

## 11.5.2. Program wrapping

PIO programs often have an "outer loop": they perform the same sequence of steps, repetitively, as they transfer a stream of data between the FIFOs and the outside world. The square wave program from the introduction is a minimal example of this:

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.pio> Lines 8 - 13

```

8 .program squarewave
9 set pindirs, 1 ; Set pin to output
10 again:
11 set pins, 1 [1] ; Drive pin high and then delay for one cycle
12 set pins, 0 ; Drive pin low
13 jmp again ; Set PC to label `again`

```

- OUT → SDA
- SET → SDA

这使状态机能够满足两种应用场景：SDA 上传输数据且 SCL 上传输时钟，或在 SDA 和 SCL 上产生固定跳变，同时仍允许将 SDA 和 SCL 映射到任意两个所选 GPIO。

side-set 数据编码于每条指令的Delay/side-set字段内。任意指令均可与 side-set 结合使用，包括写入引脚的指令，如 OUT PINS 或 SET PINS。侧置设置的引脚映射独立于 OUT 和 SET 映射，但可能存在重叠。如果侧置设置与 OUT 或 SET 同时写入同一引脚，将采用侧置设置的数据。

### ① 注意

即使指令停顿，侧置设置仍会立即生效。

```

1 .program spi_tx_fast
2 .side_set 1
3
4 loop:
5 输出引脚, 1位侧置, 0位无
6 jmp loop 侧置 1

```

spi\_tx\_fast示例展示了两个优势：数据与时钟转换可更精确地协同对齐，且程序整体更快速，在本例中每两个系统时钟周期输出一位。程序也可更小。

使用侧置设置时需配置以下四项：

- 用于侧置而非延迟的Delay/side-set字段最高有效位（MSB）的数量。通过设置PINCTRL\_SIDESET\_COUNT进行配置。若设置为5，则无延迟周期可用。如果设置为0，则不会执行side-set。
- 是否使用这些位中的最高有效位作为使能位。仅在使能位为高时执行side-set操作。如果无使能位，且SIDESET\_COUNT非零，则该状态机上的每条指令均执行side-set。此配置由EXECCTRL\_SIDE\_EN参数控制。
- 映射最不重要的side-set位对应的GPIO编号，由PINCTRL\_SIDESET\_BASE配置。
- 确定side-set是写入GPIO电平还是GPIO方向。由EXECCTRL\_SIDE\_PINDIR进行配置。

在上述示例中，我们仅有一个side-set数据位，且每条指令均执行side-set，因此无需使能位。SIDESET\_COUNT为1，SIDE\_EN为false。SIDE\_PINDIR亦为false，因为我们希望驱动时钟的高低电平，而非高低阻抗。SIDESET\_BASE用于选择时钟驱动的GPIO。

## 11.5.2. 程序包装

PIO程序通常包含一个“外循环”：它们重复执行相同的步骤序列，在FIFO与外部世界之间传输数据流。引言中的方波程序是这一概念的最简示例：

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave.pio> 第8至13行

```

8 .program squarewave
9 set pindirs, 1 ; 将引脚方向设置为输出
10 again:
11 set pins, 1 [1] ; 驱动引脚为高电平，然后延迟一个周期
12 set pins, 0 ; 驱动引脚为低电平
13 jmp again ; 程序计数器跳转至标签`again`

```

The main body of the program drives a pin high, and then low, producing one period of a square wave. The entire program then loops, driving a periodic output. The jump itself takes one cycle, as does each `set` instruction, so to keep the high and low periods of the same duration, the `set pins, 1` has a single delay cycle added, which makes the state machine idle for one cycle before executing the `set pins, 0` instruction. In total, each loop takes four cycles. There are two frustrations here:

- The `JMP` takes up space in the instruction memory that could be used for other programs
- The extra cycle taken to execute the `JMP` ends up *halving* the maximum output rate

As the Program Counter (`PC`) naturally wraps to 0 when incremented past 31, we could solve the second of these by filling the entire instruction memory with a repeating pattern of `set pins, 1` and `set pins, 0`, but this is wasteful. State machines have a hardware feature, configured via their `EXECCTRL` control register, which solves this common case.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave\\_wrap.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave_wrap.pio) Lines 12 - 20

```

12 .program squarewave_wrap
13 ; Like squarewave, but use the state machine's .wrap hardware instead of an
14 ; explicit jmp. This is a free (0-cycle) unconditional jump.
15
16 set pindirs, 1 ; Set pin to output
17 .wrap_target
18 set pins, 1 [1] ; Drive pin high and then delay for one cycle
19 set pins, 0 [1] ; Drive pin low and then delay for one cycle
20 .wrap

```

After executing an instruction from the program memory, state machines use the following logic to update `PC`:

1. If the current instruction is a `JMP`, and the `Condition` is true, set `PC` to the `Target`
2. Otherwise, if `PC` matches `EXECCTRL_WRAP_TOP`, set `PC` to `EXECCTRL_WRAP_BOTTOM`
3. Otherwise, increment `PC`, or set to 0 if the current value is 31.

The `.wrap_target` and `.wrap` assembly directives in `pioasm` are essentially labels. They export constants which can be written to the `WRAP_BOTTOM` and `WRAP_TOP` control fields, respectively:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/generated/squarewave\\_wrap.pio.h](https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/generated/squarewave_wrap.pio.h)

```

1 // -----
2 // This file is autogenerated by pioasm; do not edit! //
3 // -----
4
5 #pragma once
6
7 #include "hardware/pio.h"
8
9 // -----
10 // squarewave_wrap //
11 // -----
12
13 #define squarewave_wrap_target 1
14 #define squarewave_wrap_wrap 2
15 #define squarewave_wrap_pio_version 0
16
17 static const uint16_t squarewave_wrap_program_instructions[] = {
18 0xe081, // 0: set pindirs, 1
19 // .wrap_target
20 0xe101, // 1: set pins, 1 [1]
21 0xe100, // 2: set pins, 0 [1]
22 // .wrap
23 };
24

```

程序主体驱动一个引脚先置为高电平，再置为低电平，产生一个方波周期。整个程序随后循环执行，输出周期性信号。跳转指令本身占用一个周期，每条 `set` 指令也占用一个周期，因此为保持高低电平时长相等，`set pins, 1` 指令增加了一个延迟周期，使状态机在执行 `set pins, 0` 指令前空闲一个周期。总计，每次循环耗时四个周期。这里存在两个缺憾：

- `JMP` 指令占用了指令存储器空间，本应用于其他程序。
- 执行 `JMP` 的额外周期最终导致最大输出速率减半。

由于程序计数器（`PC`）在递增超过31后自然回绕至0，我们可以通过填充整个指令存储器为重复的 `set pins, 1` 和 `set pins, 0` 模式来解决第二个问题，但这样做非常浪费。状态机配备有通过其 `EXECCTRL` 控制寄存器配置的硬件功能，可解决这一常见情况。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave\\_wrap.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave_wrap.pio) 第12至20行

```

12 .program squarewave_wrap
13 ; 类似于squarewave，但使用状态机的.wrap硬件功能替代
14 ; 显式jmp。这是一个免费（0周期）的无条件跳转。
15
16 set pindirs, 1 ; 设置引脚为输出
17 .wrap_target
18 set pins, 1 [1] ; 驱动引脚为高电平，然后延迟一个周期
19 set pins, 0 [1] ; 先驱动引脚为低电平，然后延迟一个周期
20 .wrap

```

执行程序存储器中的指令后，状态机依据以下逻辑更新 `PC`：

1. 若当前指令为 `JMP`，且 `Condition` 为真，则将 `PC` 设置为 `Target`
2. 否则，若 `PC` 等于 `EXECCTRL_WRAP_TOP`，则将 `PC` 设置为 `EXECCTRL_WRAP_BOTTOM`
3. 否则，递增 `PC`；若当前值为31，则将其重置为0。

在 `pioasm` 中，`.wrap_target` 和 `.wrap` 汇编指令实质为标签。该标签导出常量，可分别写入 `WRAP_BOTTOM` 和 `WRAP_TOP` 控制字段：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/generated/squarewave\\_wrap.pio.h](https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/generated/squarewave_wrap.pio.h)

```

1 // -----
2 // 此文件由 pioasm 自动生成；请勿修改！ //
3 // -----
4
5 #pragma once
6
7 #include "hardware/pio.h"
8
9 // -----
10 // squarewave_wrap //
11 // -----
12
13 #define squarewave_wrap_target 1
14 #define squarewave_wrap 2
15 #define squarewave_wrap_pio_version 0
16
17 static const uint16_t squarewave_wrap_program_instructions[] = {
18 0xe081, // 0: 设置 pindirs, 1
19 // .wrap_target
20 0xe101, // 1: 设置 pins, 1
21 0xe100, // 2: 设置 pins, 0
22 // .wrap
23 };
24

```

```

25 static const struct pio_program squarewave_wrap_program = {
26 .instructions = squarewave_wrap_program_instructions,
27 .length = 3,
28 .origin = -1,
29 .pio_version = squarewave_wrap_pio_version,
30 .used_gpio_ranges = 0x0
31 #endif
32 };
33
34 static inline pio_sm_config squarewave_wrap_program_get_default_config(uint offset) {
35 pio_sm_config c = pio_get_default_sm_config();
36 sm_config_set_wrap(&c, offset + squarewave_wrap_wrap_target, offset +
37 squarewave_wrap_wrap);
38 return c;
39 }
```

This is raw output from the PIO assembler, `pioasm`, which has created a default `pio_sm_config` object containing the `WRAP` register values from the program listing. The control register fields could also be initialised directly.

#### NOTE

`WRAP_BOTTOM` and `WRAP_TOP` are absolute addresses in the PIO instruction memory. If a program is loaded at an offset, the wrap addresses must be adjusted accordingly.

The `squarewave_wrap` example has delay cycles inserted, so that it behaves identically to the original `squarewave` program. Thanks to program wrapping, these can now be removed, so that the output toggles twice as fast, while maintaining an even balance of high and low periods.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave\\_fast.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave_fast.pio) Lines 12 - 18

```

12 .program squarewave_fast
13 ; Like squarewave_wrap, but remove the delay cycles so we can run twice as fast.
14 set pindirs, 1 ; Set pin to output
15 .wrap_target
16 set pins, 1 ; Drive pin high
17 set pins, 0 ; Drive pin low
18 .wrap
```

### 11.5.3. FIFO joining

By default, each state machine possesses a 4-entry FIFO in each direction: one for data transfer from system to state machine (TX), the other for the reverse direction (RX). However, many applications do not require bidirectional data transfer between the system and an individual state machine, but may benefit from deeper FIFOs: in particular, high-bandwidth interfaces such as DPI. For these cases, `SHIFTCTRL_FJOIN` can merge the two 4-entry FIFOs into a single 8-entry FIFO.

```

25 static const struct pio_program squarewave_wrap_program = {
26 .instructions = squarewave_wrap_program_instructions,
27 .length = 3,
28 .origin = -1,
29 .pio_version = squarewave_wrap_pio_version,
30 .used_gpio_ranges = 0x0
31 #endif
32 };
33
34 static inline pio_sm_config squarewave_wrap_program_get_default_config(uint offset) {
35 pio_sm_config c = pio_get_default_sm_config();
36 sm_config_set_wrap(&c, offset + squarewave_wrap_wrap_target, offset +
37 squarewave_wrap_wrap);
38 return c;
39 }

```

这是来自PIO汇编器 `pioasm` 的原始输出，它已创建一个默认的 `pio_sm_config` 对象，包含程序列表中的 `WRAP` 寄存器值。控制寄存器字段也可以直接初始化。

### 注意

`WRAP_BOTTOM` 和 `WRAP_TOP` 是 PIO 指令存储器中的绝对地址。如果程序加载时存在偏移，包围地址必须相应调整。

`squarewave_wrap` 示例中插入了延迟周期，因此其行为与原始的 `squarewave` 程序完全相同。  
得益于程序包围机制，这些延迟现在可被移除，从而使输出切换速度加倍，同时保持高低电平周期的平衡。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave\\_fast.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/squarewave/squarewave_fast.pio) 第12至18行

```

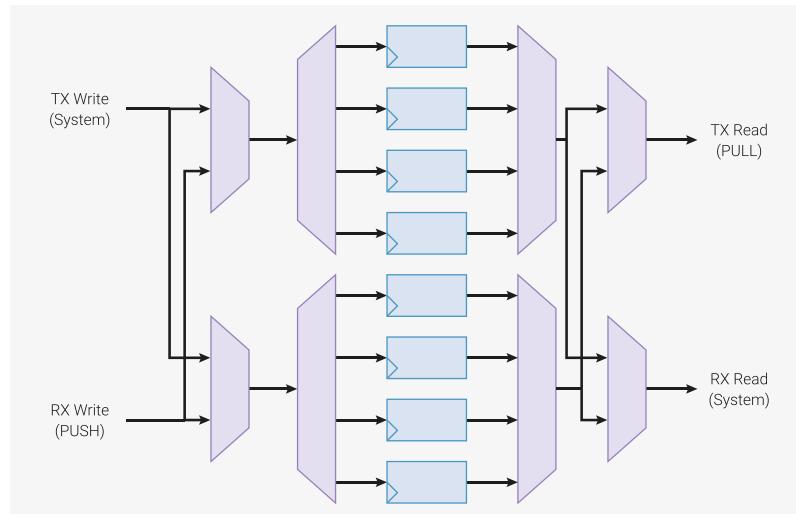

12 .program squarewave_fast
13 ; 类似 squarewave_wrap，但去除了延迟周期，从而使运行速度提升一倍。
14 set pindirs, 1 ; 将引脚设置为输出
15 .wrap_target
16 set pins, 1 ; 使引脚输出高电平
17 set pins, 0 ; 驱动引脚为低电平
18 .wrap

```

### 11.5.3. FIFO 连接

默认情况下，每个状态机在每个方向均配备一个4条目的FIFO：一个用于系统到状态机的数据传输（TX），另一个用于反向传输（RX）。然而，许多应用不需要系统与单个状态机间的双向数据传输，但可能因高带宽接口（如DPI）而受益于更深的FIFO。在这种情况下，`SHIFTCTRL_FJOIN` 可将两个4条目FIFO合并为一个8条目的FIFO。

Figure 48. Joinable dual FIFO. A pair of four-entry FIFOs, implemented with four data registers, a 1:4 decoder and a 4:1 multiplexer. Additional multiplexing allows write data and read data to cross between the TX and RX lanes, so that all 8 entries are accessible from both ports

Another example is a UART: because the TX/CTS and RX/RTS parts of a UART are asynchronous, they are implemented on two separate state machines. It would be wasteful to leave half of each state machine's FIFO resources idle. The ability to join the two halves into just a TX FIFO for the TX/CTS state machine, or just an RX FIFO in the case of the RX/RTS state machine, allows full utilisation. A UART equipped with an 8-deep FIFO can be left alone for twice as long between interrupts as one with only a 4-deep FIFO.

When one FIFO is increased in size (from 4 to 8), the other FIFO on that state machine is reduced to zero. For example, if joining to TX, the RX FIFO is unavailable, and any **PUSH** instruction will stall. The RX FIFO will appear both **RXFULL** and **RXEMPTY** in the **FSTAT** register. The converse is true if joining to RX: the TX FIFO is unavailable, and the **TXFULL** and **TXEMPTY** bits for this state machine will both be set in **FSTAT**. Setting both **FJOIN\_RX** and **FJOIN\_TX** makes both FIFOs unavailable.

8 FIFO entries is sufficient for 1 word per clock through the RP2350 system DMA, provided the DMA is not slowed by contention with other masters.

#### **⚠ CAUTION**

Changing **FJOIN** discards any data present in the state machine's FIFOs. If this data is irreplaceable, it must be drained beforehand.

#### 11.5.4. Autopush and Autopull

With each **OUT** instruction, the OSR gradually empties, as data is shifted out. Once empty, it must be refilled: for example, a **PULL** transfers one word of data from the TX FIFO to the OSR. Similarly, the ISR must be emptied once full. One approach to this is a loop which performs a **PULL** after an appropriate amount of data has been shifted:

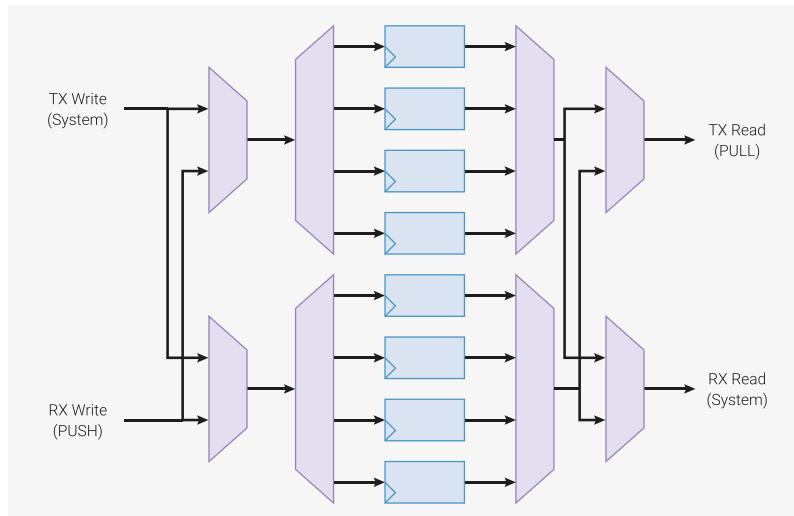

```

1 .program manual_pull
2 .side_set 1 opt
3
4 .wrap_target
5 set x, 2 ; X = bit count - 2
6 pull side 1 [1] ; Stall here if no TX data
7 bitloop:
8 out pins, 1 side 0 [1] ; Shift out data bit and toggle clock low
9 jmp x-- bitloop side 1 [1] ; Loop runs 3 times
10 out pins, 1 side 0 ; Shift out last bit before reloading X
11 .wrap

```

This program shifts out 4 bits from each FIFO word, with an accompanying bit clock, at a constant rate of 1 bit per 4 cycles. When the TX FIFO is empty, it stalls with the clock high (noting that side-set still takes place on cycles where the

图48. 可合并的双FIFO。由一对四条目的FIFO组成，采用四个数据寄存器、一个1:4解码器及一个4:1多路复用器实现。额外的复用允许写数据和读数据在TX和RX通道之间交叉，使所有8个条目均可从两个端口访问。

另一个例子是UART：由于UART的TX/CTS和RX/RTS部分是异步的，它们在两台独立的状态机中实现。让每个状态机一半的FIFO资源闲置是一种浪费。将两半合并为仅供TX/CTS状态机使用的TX FIFO，或仅供RX/RTS状态机使用的RX FIFO，使资源得以充分利用。配备8深度FIFO的UART可使中断间隔时间是配备4深度FIFO的UART的两倍。

当一个FIFO的大小增加（从4增至8）时，该状态机上的另一个FIFO容量将减少为零。例如，如果连接到TX，则RX FIFO不可用，任何 **PUSH** 指令将会阻塞。RX FIFO将在 FSTAT 寄存器中同时显示为 RXFULL 和 RXEMPTY。若连接至RX，则情况相反：TX FIFO不可用，且该状态机的 TXFULL 和 TXEMPTY 位均将在 FSTAT 中被置位。同时设置 FJOIN\_RX 和 FJOIN\_TX 将导致两个FIFO均不可用。

8个FIFO条目足以支持以每时钟1字的速度通过RP2350系统DMA前提是DMA未被其他主设备竞争而减慢。

#### **⚠ 警告**

更改 **FJOIN** 将丢弃状态机 FIFO 中存在的任何数据。如该数据不可替代，必须事先清空。

#### 11.5.4. 自动推送与自动拉取

每执行一次 **OUT** 指令，OSR都会逐渐清空，数据被移出。清空后必须重新填充：例如，**PULL** 指令将 TX FIFO 中的一个字移入 OSR。同理，ISR满后也必须清空。一种做法是循环执行，在适当量数据被移出后执行一次 **PULL** 指令：

```

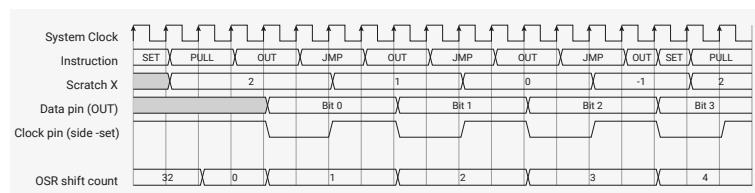

1 .program manual_pull
2 .side_set 1 opt
3
4 .wrap_target
5 set x, 2 ; X = bit count - 2
6 pull side 1 [1] ; 如果无TX数据则在此处暂停
7 bitloop:
8 out pins, 1 side 0 [1] ; 移出数据位并切换时钟信号为低电平
9 jmp x-- bitloop side 1 [1] ; 循环执行3次
10 out pins, 1 side 0 ; 在重新加载X值之前移出最后一位
11 .wrap

```

本程序以每4个周期1位的恒定速率，从每个FIFO字中移出4位数据，并伴随位时钟信号。当TX FIFO为空时，时钟保持高电平暂停（请注意，在指令暂停的周期中侧边设置信号仍然会发生）。

instruction stalls). Figure 49 shows how a state machine would execute this program.

**Figure 49. Execution of manual\_pull program.** X is used as a loop counter. On each iteration, one data bit is shifted out, and the clock is asserted low, then high. A delay cycle on each instruction brings the total up to four cycles per iteration. After the third loop, a fourth bit is shifted out, and the state machine immediately returns to the start of the program to reload the loop counter and pull fresh data, while maintaining the 4 cycles/bit cadence.

This program has some limitations:

- It occupies 5 instruction slots, but only 2 of these are immediately useful (`out pins, 1 set 0` and `... set 1`), for outputting serial data and a clock.
- Throughput is limited to system clock over 4, due to the extra cycles required to pull in new data, and reload the loop counter.

This is a common type of problem for PIO, so each state machine has some extra hardware to handle it. State machines keep track of the total shift count `OUT` of the OSR and `IN` to the ISR, and trigger certain actions once these counters reach a programmable threshold.

- On an `OUT` instruction which reaches or exceeds the pull threshold, the state machine can simultaneously refill the OSR from the TX FIFO, if data is available.
- On an `IN` instruction which reaches or exceeds the push threshold, the state machine can write the shift result directly to the RX FIFO, and clear the ISR.

The `manual_pull` example can be rewritten to take advantage of automatic pull (autopull):

```

1 .program autopull
2 .side_set 1
3
4 .wrap_target
5 out pins, 1 side 0 [1]
6 nop side 1 [1]
7 .wrap

```

This is shorter and simpler than the original, and can run twice as fast, if the delay cycles are removed, since the hardware refills the OSR "for free". Note that the program does not determine the total number of bits to be shifted before the next pull; the hardware automatically pulls once the programmable threshold, `SHIFCTRL_PULL_THRESH`, is reached, so the same program could also shift out e.g. 16 or 32 bits from each FIFO word.

Finally, note that the above program is not exactly the same as the original, since it stalls with the clock output low, rather than high. We can change the location of the stall, using the `PULL IFEMPTY` instruction, which uses the same configurable threshold as autopull:

```

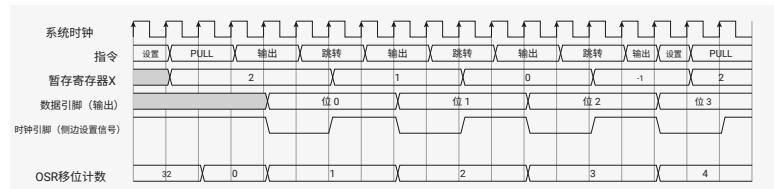

1 .program somewhat_manual_pull
2 .side_set 1
3
4 .wrap_target
5 out pins, 1 side 0 [1]
6 pull ifempty side 1 [1]
7 .wrap

```

Below is a complete example (PIO program, plus a C program to load and run it) which illustrates autopull and autopush both enabled on the same state machine. It programs state machine 0 to loopback data from the TX FIFO to the RX FIFO, with a throughput of one word per two clocks. It also demonstrates how the state machine will stall if it tries to `OUT` when both the OSR and TX FIFO are empty.

图49展示了状态机执行该程序的过程。

图 49。 manual\_pul  
I 程序的执行。  
。X 用作循环计数器。每次迭代时，移出一位数据，时钟先拉低，然后拉高。每条指令的延迟周期使得每次迭代总共消耗四个周期。  
。第三次循环后，移出第四位数据，状态机立即返回程序起始处，重新加载循环计数器并拉取新数据，同时保持每位四周期的节奏。

该程序存在若干限制：

- 程序占用 5 个指令槽，但只有 2 个指令立即有效（out 引脚指令，1 个置 0 和 1 个置 1），用于输出串行数据和时钟。
- 由于拉取新数据和重新加载循环计数器所需的额外周期，吞吐量限制为系统时钟频率的四分之一。

这是PIO常见的一类问题，因此每个状态机配备了额外硬件以应对。状态机会跟踪OSR的总移位计数 OUT和ISR的 IN，并在这些计数器达到可编程阈值时触发相应操作。

- 在达到或超过拉取阈值的 OUT 指令执行时，若数据可用，状态机可同时从 TX FIFO 重新填充 OSR。
- 在达到或超过推进阈值的 IN 指令执行时，状态机可以将移位结果直接写入 RX FIFO，并清除 ISR。

manual\_pull示例可重写为利用自动拉取（autopull）：

```
1 .program autopull
2 .side_set 1
3
4 .wrap_target
5 out pins, 1 side 0 [1]
6 nop side 1 [1]
7 .wrap
```

该版本比原版更短、更简洁，且若去除延迟周期，运行速度可提高 twice，因为硬件“免费”为OSR完成重新填充。请注意，该程序并不确定下一次拉取前要移位的总位数；硬件在达到可编程阈值 SHIFCTRL\_PULL\_THRESH 时会自动拉取，因此该程序也可从每个FIFO字中移位输出例如16位或32位。

最后，请注意，上述程序与原程序不完全相同，因为它在时钟输出为低电平时暂停，而不是高电平。我们可以通过 PULL I FEMPTY 指令更改暂停位置，该指令使用与自动拉取相同的可配置阈值：

```
1 .program somewhat_manual_pull
2 .side_set 1
3
4 .wrap_target
5 out pins, 1 side 0 [1]
6 pull ifempty side 1 [1]
7 .wrap
```

以下是一个完整示例（PIO程序及用于加载运行该程序的C程序），演示了同一状态机上同时启用自动拉取和自动推送。该程序将状态机0配置为将数据从TX FIFO回环至RX FIFO，吞吐量为每两个时钟周期传输一个字。该示例还展示了当 OSR 和 TX FIFO 均为空时，状态机尝试执行 OUT 操作将会阻塞的情况。

```

1 .program auto_push_pull
2
3 .wrap_target
4 out x, 32
5 in x, 32
6 .wrap

```

```

1 #include "tb.h" // TODO this is built against existing sw tree, so that we get printf etc
2
3 #include "platform.h"
4 #include "pio_regs.h"
5 #include "system.h"
6 #include "hardware.h"
7
8 #include "auto_push_pull.pio.h"
9
10 int main()
11 {
12 tb_init();
13
14 // Load program and configure state machine 0 for autopush/pull with
15 // threshold of 32, and wrapping on program boundary. A threshold of 32 is
16 // encoded by a register value of 00000.
17 for (int i = 0; i < count_of(auto_push_pull_program); ++i)
18 mm_pio->instr_mem[i] = auto_push_pull_program[i];
19 mm_pio->sm[0].shiftctrl =
20 (1u << PIO_SM0_SHIFTCTRL_AUTOPUSH_LSB) |
21 (1u << PIO_SM0_SHIFTCTRL_AUTOPULL_LSB) |
22 (0u << PIO_SM0_SHIFTCTRL_PUSH_THRESH_LSB) |
23 (0u << PIO_SM0_SHIFTCTRL_PULL_THRESH_LSB);
24 mm_pio->sm[0].execctrl =
25 (auto_push_pull_wrap_target << PIO_SM0_EXECCTRL_WRAP_BOTTOM_LSB) |
26 (auto_push_pull_wrap << PIO_SM0_EXECCTRL_WRAP_TOP_LSB);
27
28 // Start state machine 0
29 hw_set_bits(&mm_pio->ctrl, 1u << (PIO_CTRL_SM_ENABLE_LSB + 0));
30
31 // Push data into TX FIFO, and pop from RX FIFO
32 for (int i = 0; i < 5; ++i)
33 mm_pio->txf[0] = i;
34 for (int i = 0; i < 5; ++i)
35 printf("%d\n", mm_pio->rx[0]);
36
37 return 0;
38 }

```

Figure 50 shows how the state machine executes the example program. Initially the OSR is empty, so the state machine stalls on the first OUT instruction. Once data is available in the TX FIFO, the state machine transfers this into the OSR. On the next cycle, the OUT can execute using the data in the OSR (in this case, transferring this data to the X scratch register), and the state machine simultaneously refills the OSR with fresh data from the FIFO. Since every IN instruction immediately fills the ISR, the ISR remains empty, and IN transfers data directly from scratch X to the RX FIFO.

```

1 .program auto_push_pull
2
3 .wrap_target
4 out x, 32
5 in x, 32
6 .wrap

```

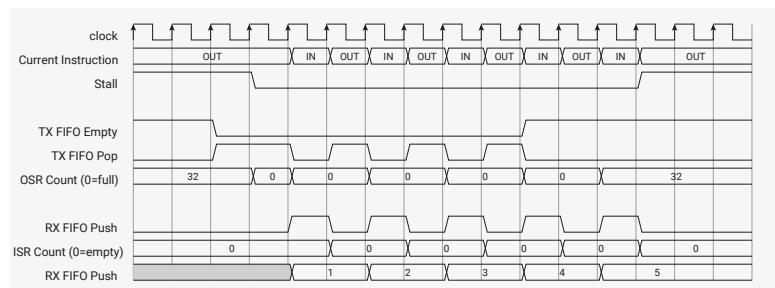

```

1 #include "tb.h" // TODO 该文件基于现有软件树构建, 以支持 printf 等功能
2
3 #include "platform.h"
4 #include "pio_regs.h"
5 #include "system.h"
6 #include "hardware.h"
7
8 #include "auto_push_pull.pio.h"
9
10 int main()
11 {
12 tb_init();
13
14 // 加载程序并配置状态机 0 以实现自动推送 / 拉取,
15 // 阈值为 32, 且程序在边界处环绕。阈值 32
16 // 由寄存器值 00000 编码。
17 for (int i = 0; i < count_of(auto_push_pull_program); ++i)
18 mm_pio->instr_mem[i] = auto_push_pull_program[i];
19 mm_pio->sm[0].shiftctrl =
20 (1u << PIO_SM0_SHIFTCTRL_AUTOPUSH_LSB) |
21 (1u << PIO_SM0_SHIFTCTRL_AUTOPULL_LSB) |
22 (0u << PIO_SM0_SHIFTCTRL_PUSH_THRESH_LSB) |
23 (0u << PIO_SM0_SHIFTCTRL_PULL_THRESH_LSB);
24 mm_pio->sm[0].execctrl =
25 (auto_push_pull_wrap_target << PIO_SM0_EXECCTRL_WRAP_BOTTOM_LSB) |
26 (auto_push_pull_wrap << PIO_SM0_EXECCTRL_WRAP_TOP_LSB);
27
28 // 启动状态机 0
29 hw_set_bits(&mm_pio->ctrl, 1u << (PIO_CTRL_SM_ENABLE_LSB + 0));
30
31 // 将数据推入 TX FIFO, 并从 RX FIFO 弹出
32 for (int i = 0; i < 5; ++i)
33 mm_pio->txf[0] = i;
34 for (int i = 0; i < 5; ++i)
35 printf("%d\n", mm_pio->rx[0]);
36
37 return 0;
38 }

```

图50展示了状态机如何执行示例程序。初始时OSR为空，因此状态机在第一条 OUT指令处暂停。一旦TX FIFO中有数据，状态机会将其传输到OSR。下一周期， OUT指令可以使用OSR中的数据执行（在本例中为将数据传输到X scratch寄存器），状态机同时从FIFO重新填充OSR。由于每条 IN指令会立即填充ISR，ISR始终为空， IN指令直接将数据从scratch X传输到RX FIFO。

Figure 50. Execution of auto\_push\_pull program. The state machine stalls on an OUT until data has travelled through the TX FIFO into the OSR. Subsequently, the OSR is refilled simultaneously with each OUT operation (due to bit count of 32), and IN data bypasses the ISR and goes straight to the RX FIFO. The state machine stalls again when the FIFO has drained, and the OSR is once again empty.

To trigger automatic push or pull at the correct time, the state machine tracks the total shift count of the ISR and OSR, using a pair of saturating 6-bit counters.

- At reset, or upon `CTRL_SM_RESTART` assertion, ISR shift counter is set to 0 (nothing shifted in), and OSR to 32 (nothing left to be shifted out)
- An `OUT` instruction increases the OSR shift counter by `Bit count`
- An `IN` instruction increases the ISR shift counter by `Bit count`
- A `PULL` instruction or autopull clears the OSR counter to 0
- A `PUSH` instruction or autopush clears the ISR counter to 0
- A `MOV OSR, x` or `MOV ISR, x` clears the OSR or ISR shift counter to 0, respectively
- A `OUT ISR, n` instruction sets the ISR shift counter to `n`

On any `OUT` or `IN` instruction, the state machine compares the shift counters to the values of `SHIFTCTRL_PULL_THRESH` and `SHIFTCTRL_PUSH_THRESH` to decide whether action is required. Autopull and autopush are individually enabled by the `SHIFTCTRL_AUTOPULL` and `SHIFTCTRL_AUTOPUSH` fields.

#### 11.5.4.1. Autopush details

Pseudocode for an `IN` with autopush enabled:

```

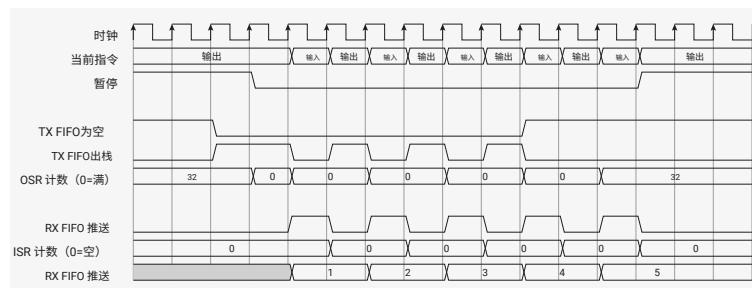

1 isr = shift_in(isr, input())
2 isr count = saturate(isr count + in count)
3
4 if rx count >= threshold:
5 if rx fifo is full:
6 stall
7 else:
8 push(isr)
9 isr = 0
10 isr count = 0

```

The hardware performs the above steps in a single machine clock cycle, unless there is a stall.

Threshold is configurable from 1 to 32.

图 50。执行 auto\_push\_pull 程序。  
状态机在一个 OUT 指令上停滞，直到数据通过 TX FIFO 进入 OSR。  
随后，OSR 在每次 0 UT 操作时同时被重新填充（由于位数为 32），而 IN 数据绕过 ISR 直接进入 RX FIFO。当 FIFO 被耗尽时，状态机再次停滞，OSR 也再次为空。

为了在正确时机触发自动推送或拉取，状态机使用一对饱和6位计数器来跟踪 ISR 和 OSR 的总移位计数。

- 复位时或在 **CTRL\_SM\_RESTART** 断言时，ISR 移位计数器设为 0（无数据移入），OSR 设为 32（无数据待移出）。
- 一次 **OUT** 指令会将 OSR 移位计数器增加位数。
- 一条 **IN** 指令将 ISR 移位计数器增加位数
- 一条 **PULL** 指令或自动拉取将 OSR 计数器清零
- 一条 **PUSH** 指令或自动推送将 ISR 计数器清零
- 一条 **MOV OSR, n** 或 **MOV ISR, n** 指令分别将 OSR 或 ISR 移位计数器清零
- 一条 **OUT ISR, n** 指令将 ISR 移位计数器设置为 n

执行任何 **OUT** 或 **IN** 指令时，状态机将移位计数器与 **SHIFTCTRL\_PULL\_THRESH** 和 **SHIFTCTRL\_PUSH\_THRESH** 值进行比较，以决定是否应采取操作。自动拉取和自动推送由 **SHIFTCTRL\_AUTO\_PULL** 和 **SHIFTCTRL\_AUTO\_PUSH** 字段分别启用。

#### 11.5.4.1. 自动推送详细说明

启用自动推送的 **IN** 指令伪代码如下：

```

1 isr = shift_in(isr, input())
2 isr count = saturate(isr count + in count)
3
4 如果 rx count >= 阈值:
5 如果 rx fifo 已满:
6 暂停
7 else:
8 push(isr)
9 isr = 0
10 isr 计数 = 0

```

硬件在单个机器时钟周期内完成上述步骤，除非发生暂停。

阈值可配置，范围为 1 至 32。

## ⚠️ IMPORTANT

Autopush must not be enabled when `SHIFTCTRL_FJOIN_RX_PUT` or `SHIFTCTRL_FJOIN_RX_GET` is set. Its operation in this state is undefined.

### 11.5.4.2. Autopull Details

On non-`OUT` cycles, the hardware performs the equivalent of the following pseudocode:

```

1 if MOV or PULL:
2 osr count = 0
3
4 if osr count >= threshold:
5 if tx fifo not empty:
6 osr = pull()
7 osr count = 0

```

An autopull can therefore occur at any point between two `OUT`s, depending on when the data arrives in the FIFO.

On `OUT` cycles, the sequence is a little different:

```

1 if osr count >= threshold:
2 if tx fifo not empty:
3 osr = pull()
4 osr count = 0
5 stall
6 else:
7 output(osr)
8 osr = shift(osr, out count)
9 osr count = saturate(osr count + out count)
10
11 if osr count >= threshold:
12 if tx fifo not empty:
13 osr = pull()
14 osr count = 0

```

The hardware is capable of refilling the OSR simultaneously with shifting out the last of the shift data, as these two operations can proceed in parallel. However, it cannot fill an empty OSR and `OUT` it on the same cycle, due to the long logic path this would create.

The refill is somewhat asynchronous to your program, but an `OUT` behaves as a data fence, and the state machine will never `OUT` data which you didn't write into the FIFO.

Note that a `MOV` from the OSR is undefined whilst autopull is enabled; you will read either any residual data that has not been shifted out, or a fresh word from the FIFO, depending on a race against system DMA. Likewise, a `MOV` to the OSR may overwrite data which has just been autopulled. However, data which you `MOV` into the OSR will never be overwritten, since `MOV` updates the shift counter.

If you **do** need to read the OSR contents, you should perform an explicit `PULL` of some kind. The nondeterminism described above is the cost of the hardware managing pulls automatically. When autopull is enabled, the behaviour of `PULL` is altered: it becomes a no-op if the OSR is full. This is to avoid a race condition against the system DMA. It behaves as a fence: either an autopull has already taken place, in which case the `PULL` has no effect, or the program will stall on the `PULL` until data becomes available in the FIFO.

`PULL` does not require similar behaviour, because autopush does not have the same nondeterminism.

## ❗ 重要

当设置了`SHIFTCTRL_FJOIN_RX_PUT`或`SHIFTCTRL_FJOIN_RX_GET`时，禁止启用自动推送功能。其在该状态下的行为未定义。

### 11.5.4.2. 自动拉取详情

在非`OUT`周期，硬件执行相当于以下伪代码的操作：

```

1 如果是 MOV 或 PULL:
2 osr 计数 = 0
3
4 如果 osr 计数 >= 阈值:
5 如果 tx fifo 非空:
6 osr = pull()
7 osr 计数 = 0

```

因此，自动拉取可在两次 `OUT` 周期之间的任意时刻发生，具体取决于数据何时到达 FIFO。

在 `OUT` 周期，操作序列稍有区别：

```

1 如果 osr 计数 >= 阈值:
2 如果 tx fifo 非空:
3 osr = pull()
4 osr 计数 = 0
5 暂停
6 else:
7 output(osr)
8 osr = shift(osr, out count)
9 osr count = saturate(osr count + out count)
10
11 if osr count >= threshold:
12 如果 tx fifo 非空:
13 osr = pull()
14 osr 计数 = 0

```

硬件能够在移出最后的移位数据的同时重新填充OSR，因为这两个操作可以并行进行。然而，由于这会导致较长的逻辑路径，硬件无法在同一时钟周期内填充空的OSR并 `OUT` 它。

重新填充在某种程度上与您的程序异步，但 `OUT` 操作表现为数据屏障，状态机绝不会 `OUT` 尚未写入 FIFO 的数据。

请注意，当启用自动拉取时，从OSR执行 `MOV` 操作是未定义的；您将根据与系统DMA的竞争情况，读取尚未移出的残余数据或来自FIFO的新字。同样，向OSR执行 `MOV` 操作可能会覆盖刚刚自动拉取的数据。然而，您通过 `MOV` 写入OSR的数据永远不会被覆盖，因为 `MOV` 会更新移位计数器。

如果您确实需要读取OSR内容，应执行某种显式的`PULL`操作。上述所描述的非确定性是硬件自动管理`pull`操作所付出的代价。启用自动`pull`时，`PULL`的行为会改变：若OSR已满，`PULL`将成为无效操作。此举旨在避免与系统DMA的竞争条件。它表现为一个屏障：自动`pull`要么已经发生，此时 `PULL` 无效；要么程序将在`PULL`处阻塞，直到FIFO中出现可用数据。

`PULL`不需类似行为，因为自动`push`不具有相同的非确定性。

### 11.5.5. Clock Dividers

PIO runs off the system clock, but this is too fast for many interfaces, and the number of **Delay** cycles which can be inserted is limited. Some devices, such as UART, require the signalling rate to be precisely controlled and varied, and ideally multiple state machines can be varied independently while running identical programs. Each state machine is equipped with a clock divider, for this purpose.

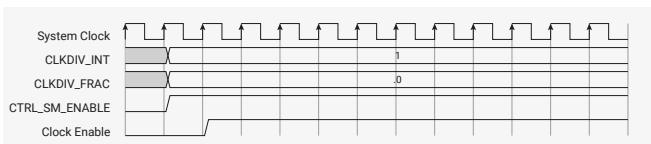

Rather than slowing the system clock itself, the clock divider redefines how many system clock periods are considered to be "one cycle", for execution purposes. It does this by generating a clock enable signal, which can pause and resume execution on a per-system-clock-cycle basis. The clock divider generates clock enable pulses at regular intervals, so that the state machine runs at some steady pace, potentially much slower than the system clock.

Implementing the clock dividers in this way allows interfacing between the state machines and the system to be simpler, lower-latency, and with a smaller footprint. The state machine is completely idle on cycles where clock enable is low, though the system can still access the state machine's FIFOs and change its configuration.

The clock dividers are 16-bit integer, 8-bit fractional, with first-order delta-sigma for the fractional divider. The clock divisor can vary between 1 and 65536, in increments of  $1 / 256$ .

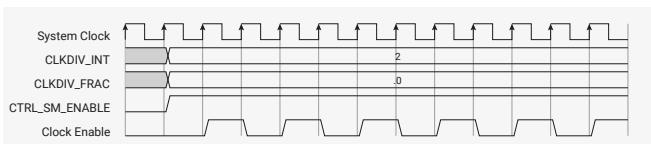

If the clock divisor is set to 1, the state machine runs on every cycle, i.e. full speed:

**Figure 51.** State machine operation with a clock divisor of 1. Once the state machine is enabled via the CTRL register, its clock enable is asserted on every cycle.

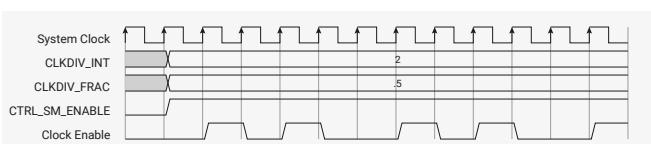

In general, an integer clock divisor of  $n$  will cause the state machine to run 1 cycle in every  $n$ , giving an effective clock speed of  $f_{sys} / n$ .

**Figure 52.** Integer clock divisors yield a periodic clock enable. The clock divider repeatedly counts down from  $n$ , and emits an enable pulse when it reaches 1.

Fractional division will maintain a steady state division rate of  $n + f / 256$ , where  $n$  and  $f$  are the integer and fractional fields of this state machine's **CLKDIV** register. It does this by selectively extending some division periods from  $n$  cycles to  $n + 1$ .

**Figure 53.** Fractional clock division with an average divisor of 2.5. The clock divider maintains a running total of the fractional value from each division period, and every time this value wraps through 1, the integer divisor is increased by one for the next division period.

For small  $n$ , the jitter introduced by a fractional divider may be unacceptable. However, for larger values, this effect is much less apparent.

#### **NOTE**

For fast asynchronous serial, it is recommended to use even divisions or multiples of 1 Mbaud where possible, rather than the traditional multiples of 300, to avoid unnecessary jitter.

### 11.5.6. GPIO mapping

Internally, PIO has a 32-bit register for the output levels of each GPIO it can drive, and another register for the output enables (Hi/Lo-Z). On every system clock cycle, each state machine can write to some or all of the GPIOs in each of these registers.

### 11.5.5. 时钟分频器

PIO基于系统时钟运行，但该时钟速度对于许多接口而言过快，且可插入的 Delay 周期数有限。某些设备，如UART，要求精确控制和调整信号速率，且理想情况下多个状态机能够在运行相同程序时独立变化。为此，每个状态机都配备了时钟分频器。

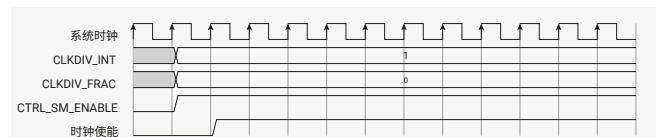

时钟分频器并非降低系统时钟本身的速度，而是重新定义多少个系统时钟周期被视为“一个周期”以便于执行。其通过生成时钟使能信号来实现，该信号可在每个系统时钟周期基础上暂停和恢复执行。时钟分频器以规律的间隔产生时钟使能脉冲，使状态机以某一稳定速度运行，可能远低于系统时钟频率。

通过这种方式实现时钟分频器，可以简化状态机与系统之间的接口，降低延迟，并减小占用面积。当时钟使能信号为低时，状态机完全空闲，但系统仍然可以访问状态机的FIFO并更改其配置。

时钟分频器采用16位整数位和8位小数位，且小数分频器采用一阶delta-sigma调制。时钟除数可在1至65536之间变化，变化步长为  $1/256$ 。

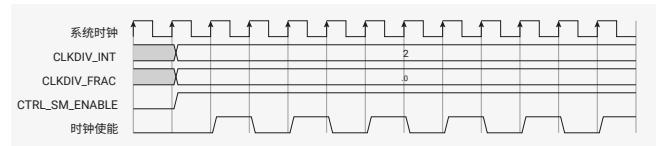

若时钟除数设置为1，状态机将在每个周期运行，即全速运行：

图51。时钟除数为1时状态机的运行情况。一旦通过CTRL寄存器启用状态机，其时钟使能将在每个周期被置位。

通常，整数时钟除数  $n$  将使状态机在每  $n$  个周期运行1次，有效时钟频率为  $f_{sys} / n$ 。

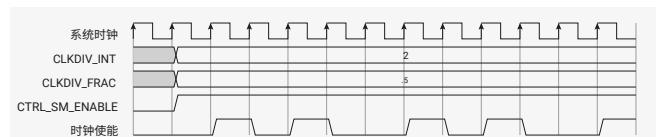

图52。整数时钟除数产生周期性时钟使能信号。时钟分频器不断从  $n$  倒计数，并在

计数至1时发出使能脉冲。小数除法将保持稳定的分频率为  $n + f / 256$ ，其中  $n$  和  $f$  分别是该状态机 CLKDIV 寄存器的整数和小数字段。它通过选择性地将某些分频周期从一个周期延长至下一个周期实现。

$n + 1$

图53。采用平均除数为2.5的分数时钟分频。时钟分频器会累计每个分频周期的分数值，每当该累计值超过1时，下一分频周期的整数除数将增加1。

对于较小的  $n$ ，分数分频器引入的抖动可能无法接受。但对于较大的数值，该效应明显减弱。

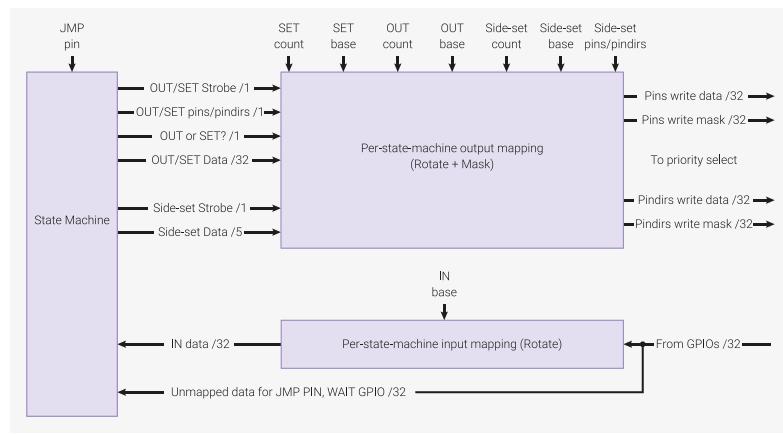

#### 注意

对于高速异步串行通信，建议尽可能使用偶数分频或1 Mbaud的倍数，而非传统的300倍数，以避免不必要的抖动。

### 11.5.6. GPIO 映射

PIO内部设有一个32位寄存器，用于控制其所驱动的每个GPIO的输出电平，另有一个寄存器用于控制输出使能（高电平/高阻抗状态）。在每个系统时钟周期内，每个状态机可向这些寄存器中的部分或全部GPIO输出端口写入数据。

**Figure 54.** The state machine has two independent output channels, one shared by OUT/SET, and another used by side-set (which can happen at any time). Three independent mappings (first GPIO, number of GPIOs) control which GPIOs OUT, SET and side-set are directed to. Input data is rotated according to which GPIO is mapped to the LSB of the IN data.

The write data and write masks for the output level and output enable registers come from the following sources:

- An **OUT** instruction writes to up to 32 bits. Depending on the instruction's **Destination** field, this is applied to either pins or pindirs. The least-significant bit of **OUT** data is mapped to **PINCTRL\_OUT\_BASE**, and this mapping continues for **PINCTRL\_OUT\_COUNT** bits, wrapping after GPIO31.
- A **SET** instruction writes up to 5 bits. Depending on the instruction's **Destination** field, this is applied to either pins or pindirs. The least-significant bit of **SET** data is mapped to **PINCTRL\_SET\_BASE**, and this mapping continues for **PINCTRL\_SET\_COUNT** bits, wrapping after GPIO31.
- A side-set operation writes up to 5 bits. Depending on the register field **EXECCTRL\_SIDE\_PDIR**, this is applied to either pins or pindirs. The least-significant bit of side-set data is mapped to **PINCTRL\_SIDESET\_BASE**, continuing for **PINCTRL\_SIDESET\_COUNT** pins, minus one if **EXECCTRL\_SIDE\_EN** is set.

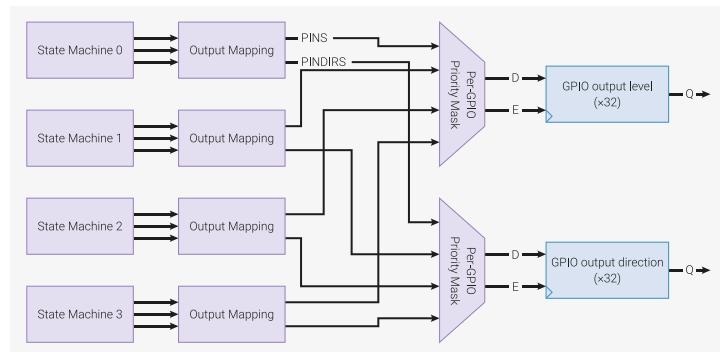

Each **OUT/SET**/side-set operation writes to a contiguous range of pins, but each of these ranges is independently sized and positioned in the 32-bit GPIO space. This is sufficiently flexible for many applications. For example, if one state machine is implementing some interface such as an SPI on a group of pins, another state machine can run the same program, mapped to a different group of pins, and provide a second SPI interface.

On any given clock cycle, the state machine may perform an **OUT** or a **SET**, and may simultaneously perform a side-set. The pin mapping logic generates a 32-bit write mask and write data bus for the output level and output enable registers, based on this request, and the pin mapping configuration.

If a side-set overlaps with an **OUT/SET** performed by that state machine on the same cycle, the side-set takes precedence in the overlapping region.

### 11.5.6.1. Output priority

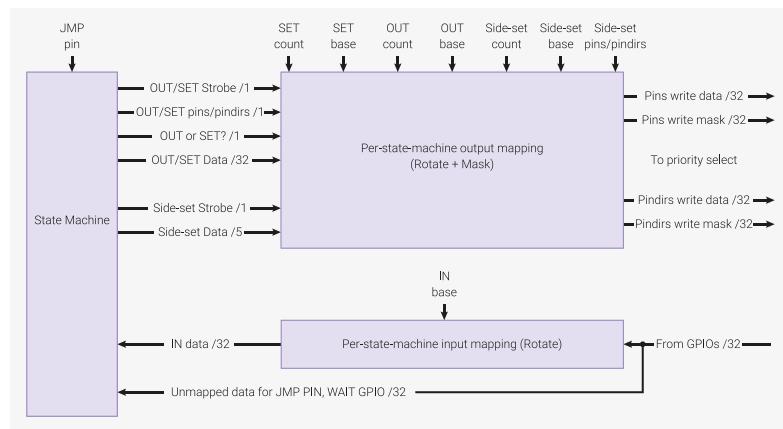

**Figure 55.** Per-GPIO priority select of write masks from each state machine. Each GPIO considers level and direction writes from each of the four state machines, and applies the value from the highest-numbered state machine.

Each state machine may assert an **OUT/SET** and a side-set through its pin mapping hardware on each cycle. This generates 32 bits of write data and write mask for the GPIO output level and output enable registers, from each state machine.

For each GPIO, PIO collates the writes from all four state machines, and applies the write from the highest-numbered

图54。该状态机具有两个独立的输出通道，一个由OUT/SET共享，另一个用于侧置(side-set)（可在任意时刻发生）。三个独立映射（首个GPIO编号及GPIO数量）控制OUT、SET及侧置信号所指向的GPIO。输入数据根据映射至IN数据最低有效位的GPIO进行循环轮换。

输出电平与输出使能寄存器的写入数据及写入掩码来自以下来源：

- 一条 **OUT** 指令可写入最多32位数据。根据指令的 **Destination** 字段，该数据被应用于引脚或引脚方向寄存器 (pindir s)。 **OUT** 数据的最低有效位映射至 **PINCTRL\_OUT\_BASE**，随后映射持续覆盖 **PINCTRL\_OUT\_COUNT** 位，至 **GPIO31** 后循环回绕。
- 一条 **SET** 指令可写入最多5位数据。根据指令的 **Destination** 字段，该数据被应用于引脚或引脚方向寄存器 (pindirs)。 **SET** 数据的最低有效位映射至 **PINCTRL\_SET\_BASE**，随后映射持续覆盖 **PINCTRL\_SET\_COUNT** 位，至 **GPIO31** 后循环回绕。
- 侧置操作可写入最多 5 位。根据寄存器字段 **EXECCTRL\_SIDE\_PINDIR**，此操作应用于引脚或引脚方向。侧置数据的最低有效位映射至 **PINCTRL\_SIDESET\_BASE**，继续映射至 **PINCTRL\_SIDESET\_COUNT** 个引脚；若 **EXECCTRL\_SIDE\_EN** 被设置，则减少一个。

每个 **OUT/SET**/侧置操作写入一段连续的引脚范围，但这些范围在 32 位 GPIO 空间中大小和位置均相互独立。该设计对多种应用均具备足够的灵活性。例如，若一个状态机在一组引脚上实现诸如 SPI 的接口，另一状态机可运行相同程序，映射至不同引脚组，从而提供第二个 SPI 接口。

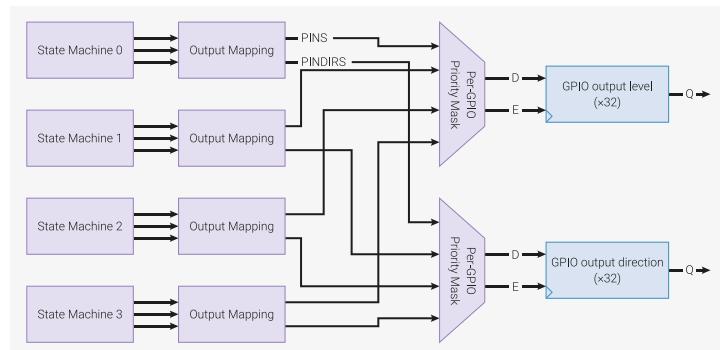

在任一时钟周期中，状态机可执行 **OUT** 或 **SET** 操作，同时进行侧置操作。

引脚映射逻辑为输出电平及输出使能寄存器生成 32 位写掩码与写数据总线，基于该请求及引脚映射配置。

如果侧置组 (side-set) 与同一状态机在同一周期内执行的 **OUT/SET** 操作发生重叠，则侧置组在重叠区域内具有优先权。

### 11.5.6.1. 输出优先级

图55。每个GPIO按状态机优先级选择写掩码。每个GPIO考虑来自四个状态机的电平和方向写入，并应用最高编号状态机的值。

每个状态机可通过其引脚映射硬件，在每个周期内断言一个 **OUT/SET** 和一个侧置组。这为每个状态机生成32位写入数据及写掩码，用于GPIO输出电平和输出使能寄存器。

对于每个GPIO，PIO汇总所有四个状态机的写入操作，并应用最高编号状态机的写入。

state machine. This occurs separately for output levels and output values – it is possible for a state machine to change both the level and direction of the same pin on the same cycle (e.g. via simultaneous `SET` and side-set), or for one state machine to change a GPIO’s direction while another changes that GPIO’s level. If no state machine asserts a write to a GPIO’s level or direction, the value does not change.

### 11.5.6.2. Input mapping

The data observed by `IN` instructions is mapped such that the LSB is the GPIO selected by `PINCTRL_IN_BASE`, and successively more-significant bits come from successively higher-numbered GPIOs, wrapping after 31.

In other words, the `IN` bus is a right-rotate of the GPIO input values, by `PINCTRL_IN_BASE`. If fewer than 32 GPIOs are present, the PIO input is padded with zeroes up to 32 bits.

Some instructions, such as `WAIT GPIO`, use an absolute GPIO number, rather than an index into the `IN` data bus. In this case, the right-rotate is not applied.

### 11.5.6.3. Input synchronisers

To protect PIO from metastabilities, each GPIO input is equipped with a standard 2-flipflop synchroniser. This adds two cycles of latency to input sampling, but the benefit is that state machines can perform an `IN PINS` at any point, and will see only a clean high or low level, not some intermediate value that could disturb the state machine circuitry. This is absolutely necessary for asynchronous interfaces such as UART RX.

It is possible to bypass these synchronisers, on a per-GPIO basis. This reduces input latency, but it is then up to the user to guarantee that the state machine does not sample its inputs at inappropriate times. Generally this is only possible for synchronous interfaces such as SPI. Synchronisers are bypassed by setting the corresponding bit in `INPUT_SYNC_BYPASS`.

#### WARNING

Sampling a metastable input can lead to unpredictable state machine behaviour. This should be avoided.

### 11.5.7. Forced and EXEC’d instructions

Besides the instruction memory, state machines can execute instructions from 3 other sources:

- `MOV EXEC` which executes an instruction from some register `Source`
- `OUT EXEC` which executes data shifted out from the OSR
- The `SMx_INSTR` control registers, to which the system can write instructions for immediate execution

```

1 .program exec_example
2
3 hang:
4 jmp hang
5 execute:
6 out exec, 32
7 jmp execute
8
9 .program instructions_to_push
10
11 out x, 32
12 in x, 32
13 push

```

状态机。此过程分别针对输出电平和输出值进行——状态机可在同一周期内同时更改同一引脚的电平和方向（例如通过同时执行SET和侧置组），或一个状态机更改GPIO的方向，而另一个状态机更改该GPIO的电平。如果没有状态机声明对GPIO的电平或方向进行写操作，则该值保持不变。

### 11.5.6.2 输入映射

由 **IN** 指令读取的数据映射方式为：最低有效位对应由 **PINCTRL\_IN\_BASE** 选择的 GPIO，随后更高有效位依次对应编号递增的 GPIO，编号超过31时循环回绕。

换言之，**IN** 总线是GPIO输入值向右旋转 **PINCTRL\_IN\_BASE** 位后的结果。若GPIO数量少于32个，则PIO输入信号以零进行补齐，直至32位。

部分指令，如 **WAIT GPIO**，使用绝对GPIO编号而非 **IN** 总线索引，此时不进行右旋转操作。

### 11.5.6.3 输入同步器

为防止PIO出现亚稳态，每个GPIO输入均配备标准的双触发器同步器。这会在输入采样上增加两个周期的延迟，但其优点是状态机可以在任意时刻执行 **IN PINS** 操作，并且只会看到清晰的高电平或低电平，而不会看到可能干扰状态机电路的中间电平。这对于诸如 UART RX 这样的异步接口而言绝对必要。

可以针对每个 GPIO 端口绕过这些同步器。这可以减少输入延迟，但用户必须保证状态机不会在不适当的时间采样其输入。通常这仅适用于诸如 SPI 这类同步接口。通过设置 **INPUT\_SYNC\_BYPASS** 中的相应位可以绕过同步器。

#### ● 警告

采样处于亚稳态的输入可能导致状态机行为不可预测，应当避免。

### 11.5.7. 强制执行及 EXEC 指令

除了指令存储器之外，状态机还可以从另外三种来源执行指令：

- **MOV EXEC** 执行来自某寄存器 **Source** 的指令
- **OUT EXEC** 执行从 OSR 移出的数据
- **SMx\_INSTR** 控制寄存器，系统可向其写入指令以实现即时执行

```

1 .program exec_example
2
3 hang:
4 jmp hang
5 execute:
6 out exec, 32
7 jmp execute
8
9 .program instructions_to_push
10
11 out x, 32
12 in x, 32
13 push

```

```

1 #include "tb.h" // TODO this is built against existing sw tree, so that we get printf etc
2
3 #include "platform.h"
4 #include "pio_regs.h"
5 #include "system.h"
6 #include "hardware.h"
7
8 #include "exec_example.pio.h"
9
10 int main()
11 {
12 tb_init();
13
14 for (int i = 0; i < count_of(exec_example_program); ++i)
15 mm_pio->instr_mem[i] = exec_example_program[i];
16
17 // Enable autopull, threshold of 32
18 mm_pio->sm[0].shiftctrl = (1u << PIO_SM0_SHIFTCTRL_AUTOPULL_LSB);
19
20 // Start state machine 0 -- will sit in "hang" loop
21 hw_set_bits(&mm_pio->ctrl, 1u << (PIO_CTRL_SM_ENABLE_LSB + 0));
22
23 // Force a jump to program location 1
24 mm_pio->sm[0].instr = 0x0000 | 0x1; // jmp execute
25
26 // Feed a mixture of instructions and data into FIFO
27 mm_pio->txf[0] = instructions_to_push_program[0]; // out x, 32
28 mm_pio->txf[0] = 12345678; // data to be OUTed
29 mm_pio->txf[0] = instructions_to_push_program[1]; // in x, 32
30 mm_pio->txf[0] = instructions_to_push_program[2]; // push
31
32 // The program pushed into TX FIFO will return some data in RX FIFO
33 while (mm_pio->fstat & (1u << PIO_FSTAT_RXEMPTY_LSB))
34 ;
35
36 printf("%d\n", mm_pio->rx[0]);
37
38 return 0;
39 }

```

Here we load an example program into the state machine, which does two things:

- Enters an infinite loop
- Enters a loop which repeatedly pulls 32 bits of data from the TX FIFO, and executes the lower 16 bits as an instruction

The C program sets the state machine running, at which point it enters the `hang` loop. While the state machine is still running, the C program forces in a `jmp` instruction, which causes the state machine to break out of the loop.

When an instruction is written to the `INSTR` register, the state machine immediately decodes and executes that instruction, rather than the instruction it would have fetched from the PIO's instruction memory. The program counter does not advance, so on the next cycle (assuming the instruction forced into the `INSTR` interface did not stall) the state machine continues to execute its current program from the point where it left off, unless the written instruction itself manipulated `PC`.

Delay cycles are ignored on instructions written to the `INSTR` register, and execute immediately, ignoring the state machine clock divider. This interface is provided for performing initial setup and effecting control flow changes, so it executes instructions in a timely manner, no matter how the state machine is configured.

Instructions written to the `INSTR` register are permitted to stall, in which case the state machine will latch this instruction internally until it completes. This is signified by the `EXECCTRL_EXEC_STALLED` flag. This can be cleared by restarting the state

```

1 #include "tb.h" // TODO 该文件基于现有软件树构建, 以支持 printf 等功能
2
3 #include "platform.h"
4 #include "pio_regs.h"
5 #include "system.h"
6 #include "hardware.h"
7
8 #include "exec_example.pio.h"
9
10 int main()
11 {
12 tb_init();
13
14 for (int i = 0; i < count_of(exec_example_program); ++i)
15 mm_pio->instr_mem[i] = exec_example_program[i];
16
17 // 启用自动拉取功能, 阈值设置为32
18 mm_pio->sm[0].shiftctrl = (1u << PIO_SM0_SHIFTCTRL_AUTOPULL_LSB);
19
20 // 启动状态机0 —— 程序将停留于 “hang” 循环
21 hw_set_bits(&mm_pio->ctrl, 1u << (PIO_CTRL_SM_ENABLE_LSB + 0));
22
23 // 强制跳转至程序位置 1
24 mm_pio->sm[0].instr = 0x0000 | 0x1; // jmp 执行
25
26 // 向 FIFO 中加载指令和数据混合
27 mm_pio->txf[0] = instructions_to_push_program[0]; // out x, 32
28 mm_pio->txf[0] = 12345678; // 待输出的数据
29 mm_pio->txf[0] = instructions_to_push_program[1]; // in x, 32
30 mm_pio->txf[0] = instructions_to_push_program[2]; // push
31
32 // 推入 TX FIFO 的程序将在 RX FIFO 中返回部分数据
33 while (mm_pio->fstat & (1u << PIO_FSTAT_RXEMPTY_LSB))
34 ;
35
36 printf("%d\n", mm_pio->rxf[0]);
37
38 return 0;
39 }

```

这里将一个示例程序加载到状态机中，该程序执行两个操作：

- 进入无限循环
- 进入一个循环，反复从TX FIFO拉取32位数据，并执行低16位作为指令

C程序启动状态机，状态机随后进入 `hang` 循环。当状态机仍在运行时，C程序强制注入一条 `jmp` 指令，使状态机跳出循环。

当指令写入 `INSTR` 寄存器时，状态机会立即解码并执行该指令，而非从PIO指令存储器取出的指令。程序计数器不前进，因此在下一周期（假设强制写入 `INSTR` 接口的指令未引起阻塞）状态机从中断点继续执行当前程序，除非写入指令本身修改了 `PC` 寄存器。

写入 `INSTR` 寄存器的指令会忽略延迟周期，并立即执行，忽略状态机时钟分频。该接口用于执行初始配置及控制流程变更，因此无论状态机如何配置，均能及时执行指令。

写入 `INSTR` 寄存器的指令允许停滞，状态机将内部锁存该指令直至其执行完成。此状态由 `EXECCTRL_EXEC_STALLED` 标志表示。可通过重启状态

machine, or writing a `NOP` to `INSTR`.

In the second phase of the example state machine program, the `OUT EXEC` instruction is used. The `OUT` itself occupies one execution cycle, and the instruction which the `OUT` executes is on the next execution cycle. Note that one of the instructions we execute is also an `OUT` – the state machine is only capable of executing one `OUT` instruction on any given cycle.

`OUT EXEC` works by writing the `OUT` shift data to an internal instruction latch. On the next cycle, the state machine remembers it must execute from this latch rather than the instruction memory, and also knows to not advance `PC` on this second cycle.

This program will print "12345678" when run.

#### CAUTION

If an instruction written to `INSTR` stalls, it is stored in the same instruction latch used by `OUT EXEC` and `MOV EXEC`, and will overwrite an in-progress instruction there. If `EXEC` instructions are used, instructions written to `INSTR` must not stall.

## 11.6. Examples

These examples illustrate some of PIO's hardware features, by implementing common I/O interfaces.

#### TIP

**Raspberry Pi Pico-series C/C++ SDK** has a comprehensive PIO chapter that begins with writing and building your first PIO application. Later chapters walk through some programs line-by-line. Finally, it covers broader topics such as using PIO with DMA, and how PIO can integrate into your software.

### 11.6.1. Duplex SPI

机或向 `INSTR` 写入 `NOP` 指令来清除此状态。

在示例状态机程序的第二阶段，使用了 `OUT EXEC` 指令。`OUT` 指令本身占用一个执行周期，而 `OUT` 执行的指令则在下一个执行周期完成。请注意，我们执行的指令之一亦为 `OUT` —— 状态机在任一周期内仅能执行一个 `OUT` 指令。

`OUT EXEC` 通过将 `OUT` 移位数据写入内部指令锁存器来工作。在下一个周期，状态机会记住必须从此锁存器而非指令存储器执行，并且知道在该第二周期不应推进 `PC`。

该程序运行时将打印 “12345678”。

#### ⚠ 警告

如果写入 `INSTR` 的指令发生阻塞，则会存储在 `OUT EXEC` 和 `MOV EXEC` 共用的指令锁存器中，并覆盖正在执行的指令。如果使用 `EXEC` 指令，则写入 `INSTR` 的指令不得发生阻塞。

## 11.6. 示例

这些示例通过实现常见输入输出接口，展示了 PIO 的一些硬件特性。

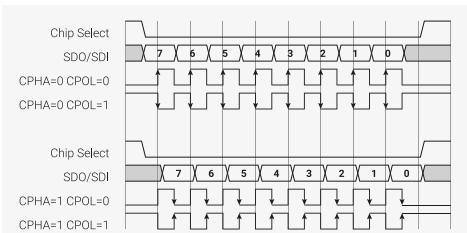

#### 💡 提示

**Raspberry Pi Pico** 系列 **C/C++ SDK** 拥有详尽的 **PIO** 章节，从编写和构建第一个 **PIO** 应用程序开始。后续章节逐行解析部分程序。最后涵盖了更广泛的主题，如结合 **DMA** 使用 **PIO** 及 **PIO** 如何集成到您的软件中。

### 11.6.1. 双工 SPI

Figure 56. In SPI, a host and device exchange data over a bidirectional pair of serial data lines, synchronous with a clock (SCK). Two flags, CPOL and CPHA, specify the clock's behaviour.

CPOL is the idle state of the clock: 0 for low, 1 for high. The clock pulses a number of times, transferring one bit in each direction per pulse, but always returns to its idle state. CPHA determines on which edge of the clock data is captured: 0 for leading edge, and 1 for trailing edge. The arrows in the figure show the clock edge where data is captured by both the host and device.

SPI is a common serial interface with a twisty history. The following program implements full-duplex (i.e. transferring data in both directions simultaneously) SPI, with a CPHA parameter of 0.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi.pio> Lines 14 - 32

```

14 .program spi_cpha0
15 .side_set 1
16
17 ; Pin assignments:
18 ; - SCK is side-set pin 0
19 ; - MOSI is OUT pin 0
20 ; - MISO is IN pin 0
21 ;
22 ; Autopush and autopull must be enabled, and the serial frame size is set by
23 ; configuring the push/pull threshold. Shift left/right is fine, but you must
24 ; justify the data yourself. This is done most conveniently for frame sizes of
25 ; 8 or 16 bits by using the narrow store replication and narrow load byte
26 ; picking behaviour of RP2040's IO fabric.
27
28 ; Clock phase = 0: data is captured on the leading edge of each SCK pulse, and
29 ; transitions on the trailing edge, or some time before the first leading edge.
30
31 out pins, 1 side 0 [1] ; Stall here on empty (sideset proceeds even if
32 in pins, 1 side 1 [1] ; instruction stalls, so we stall with SCK low)

```

This code uses autopush and autopull to continuously stream data from the FIFOs. The entire program runs once for every bit that is transferred, and then loops. The state machine tracks how many bits have been shifted in/out, and automatically pushes/pulls the FIFOs at the correct point. A similar program handles the CPHA=1 case:

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi.pio> Lines 34 - 42

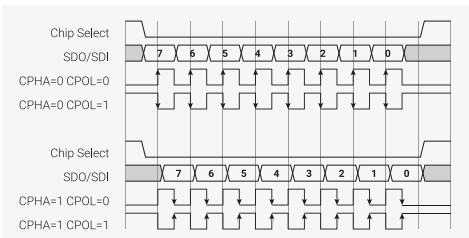

```

34 .program spi_cpha1
35 .side_set 1
36
37 ; Clock phase = 1: data transitions on the leading edge of each SCK pulse, and
38 ; is captured on the trailing edge.
39
40 out x, 1 side 0 ; Stall here on empty (keep SCK deasserted)
41 mov pins, x side 1 [1] ; Output data, assert SCK (mov pins uses OUT mapping)
42 in pins, 1 side 0 ; Input data, deassert SCK

```

图56。在SPI协议中，主机与设备通过一对双向串行数据线交换数据，且同步于时钟（SCK）。两个标志位，CPOL和CPH A，定义了时钟的工作特性。

CPOL表示时钟的空闲状态：0代表低电平，1代表高电平。时钟产生若干脉冲，每个脉冲在两个方向上传输一位数据，但始终返回至其空闲状态。CPH A决定数据采样发生在时钟的哪个边沿：0为前沿，1为后沿。图中箭头指示了主机和设备采样数据时对应的时钟边沿。

SPI是一种常用的串行接口，且拥有复杂的发展历史。以下程序实现了全双工SPI（即数据双向同时传输），CPHA参数设为0。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi.pio> 第14至32行

```

14 .program spi_cpha0
15 .side_set 1
16
17 ; 引脚分配：
18 ; - SCK 是旁路设置引脚 0
19 ; - MOSI 是输出引脚 0
20 ; - MISO 是输入引脚 0
21 ;
22 ; 必须启用 Autopush 和 Autopull，串行帧大小通过
23 ; 配置推送/拉取阈值来设置。允许左/右移位，但您必须
24 ; 自行对齐数据。对于帧大小为
25 ; 8 位或 16 位，最便捷的方法是利用 RP2040 IO 结构中的
26 ; 窄存储复制和窄加载字节的行为。
27
28 ; 时钟相位=0：数据在每个 SCK 脉冲的上升沿捕获，
29 ; 并在下降沿或首个上升沿之前的某个时间完成转换。
30
31 输出引脚，1 旁路 0 [1] ; 空时暂停（即使旁路设置仍在进行）
32 在引脚中，一侧为1 [1] ; 由于指令阻塞，因此我们在SCK保持低电平时阻塞)

```

该代码使用autopush和autopull持续从FIFO流式传输数据。程序针对转移的每个位执行一次，然后循环。状态机跟踪已移入/移出的位数，并在正确时点自动推动/拉取FIFO。类似程序处理CPHA=1的情况：

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi.pio> 第34至42行

```

34 .program spi_cpha1
35 .side_set 1
36
37 ; 时钟相位=1：数据在每个SCK脉冲的上升沿变化，
38 ; 并在下降沿采样。
39
40 out x, 1 side 0 ; FIFO为空时此处阻塞（保持 SCK未置位）
41 mov pins, x side 1 [1] ; 输出数据，断言SCK（mov pins使用OUT映射）
42 in pins, 1 side 0 ; 输入数据，撤销断言SCK

```

**NOTE**

These programs do not control the chip select line; chip select is often implemented as a software-controlled GPIO, due to wildly different behaviour between different SPI hardware. The full `spi.pio` source linked above contains some examples how PIO can implement a hardware chip select line.

A C helper function configures the state machine, connects the GPIOs, and sets the state machine running. Note that the SPI frame size – that is, the number of bits transferred for each FIFO record – can be programmed to any value from 1 to 32, without modifying the program. Once configured, the state machine is set running.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi.pio> Lines 46 - 72

```

46 static inline void pio_spi_init(PIO pio, uint sm, uint prog_offs, uint n_bits,
47 float clkdiv, bool cpha, bool cpol, uint pin_sck, uint pin_mosi, uint pin_miso) {
48 pio_sm_config c = cpha ? spi_cpha1_program_get_default_config(prog_offs) :
49 spi_cpha0_program_get_default_config(prog_offs);
50 sm_config_set_out_pins(&c, pin_mosi, 1);
51 sm_config_set_in_pins(&c, pin_miso);
52 sm_config_set_sideset_pins(&c, pin_sck);
53 // Only support MSB-first in this example code (shift to left, auto push/pull,
54 // threshold=nbits)
55 sm_config_set_out_shift(&c, false, true, n_bits);
56 sm_config_set_in_shift(&c, false, true, n_bits);
57 sm_config_set_clkdiv(&c, clkdiv);
58
59 // MOSI, SCK output are low, MISO is input
60 pio_sm_set_pins_with_mask(pio, sm, 0, (1u << pin_sck) | (1u << pin_mosi));
61 pio_sm_set_pindirs_with_mask(pio, sm, (1u << pin_sck) | (1u << pin_mosi), (1u << pin_sck)
62 | (1u << pin_mosi) | (1u << pin_miso));
63 pio_gpio_init(pio, pin_mosi);
64 pio_gpio_init(pio, pin_miso);
65 pio_gpio_init(pio, pin_sck);
66
67 // The pin muxes can be configured to invert the output (among other things
68 // and this is a cheesy way to get CPOL=1
69 gpio_set_outherver(pin_sck, cpol ? GPIO_OVERRIDE_INVERT : GPIO_OVERRIDE_NORMAL);
70 // SPI is synchronous, so bypass input synchroniser to reduce input delay.
71 hw_set_bits(&pio->input_sync_bypass, 1u << pin_miso);
72
73 pio_sm_init(pio, sm, prog_offs, &c);
74 pio_sm_set_enabled(pio, sm, true);
75 }
```

The state machine will now immediately begin to shift out any data appearing in the TX FIFO, and push received data into the RX FIFO.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/pio\\_spi.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/pio_spi.c) Lines 18 - 34

```

18 void __time_critical_func(pio_spi_write8_blocking)(const pio_spi_inst_t *spi, const uint8_t
 *src, size_t len) {
19 size_t tx_remain = len, rx_remain = len;
20 // Do 8 bit accesses on FIFO, so that write data is byte-replicated. This
21 // gets us the left-justification for free (for MSB-first shift-out)
22 io_rw_8 *txfifo = (io_rw_8 *) &spi->pio->txf[spi->sm];
23 io_rw_8 *rxfifo = (io_rw_8 *) &spi->pio->rx[spi->sm];
24 while (tx_remain || rx_remain) {
25 if (tx_remain && !pio_sm_is_tx_fifo_full(spi->pio, spi->sm)) {
26 *txfifo = *src++;
27 --tx_remain;
28 }
```

### ⓘ 注意

这些程序不控制片选线；由于不同SPI硬件之间行为差异极大，片选线通常作为软件控制的GPIO实现。上述完整的 `spi.pio` 源代码包含一些示例，演示PIO如何实现硬件片选线。

C语言辅助函数负责配置状态机、连接GPIO并启动状态机运行。请注意，SPI帧大小——即每个FIFO记录传输的比特数——可以在1到32之间任意编程，无需修改程序。配置完成后，状态机即启动运行。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi.pio> 第46至72行

```

46 static inline void pio_spi_init(PIO pio, uint sm, uint prog_offs, uint n_bits,
47 float clkdiv, bool cpha, bool cpol, uint pin_sck, uint pin_mosi, uint pin_miso) {
48 pio_sm_config c = cpha ? spi_cpha1_program_get_default_config(prog_offs) :
49 spi_cpha0_program_get_default_config(prog_offs);
50 sm_config_set_out_pins(&c, pin_mosi, 1);
51 sm_config_set_in_pins(&c, pin_miso);
52 sm_config_set_sideset_pins(&c, pin_sck);
53 // 本示例代码仅支持 MSB 优先（左移，自动推送/拉取，阈值=位数）
54
55 sm_config_set_out_shift(&c, false, true, n_bits);
56 sm_config_set_in_shift(&c, false, true, n_bits);
57 sm_config_set_clkdiv(&c, clkdiv);
58
59 // MOSI, SCK 输出为低电平, MISO 为输入
60 pio_sm_set_pins_with_mask(pio, sm, 0, (1u << pin_sck) | (1u << pin_mosi));
61 pio_sm_set_pindirs_with_mask(pio, sm, (1u << pin_sck) | (1u << pin_mosi), (1u << pin_sck)
62 | (1u << pin_mosi) | (1u << pin_miso));
63 pio_gpio_init(pio, pin_mosi);
64 pio_gpio_init(pio, pin_miso);
65 pio_gpio_init(pio, pin_sck);
66
67 // 引脚复用器可配置为反转输出（以及其他功能）
68 // 这是一种实现 CPOL=1 的简易方法
69 gpio_set_outover(pin_sck, cpol ? GPIO_OVERRIDE_INVERT : GPIO_OVERRIDE_NORMAL);
70 // SPI 为同步操作，因此绕过输入同步器以减少输入延迟。
71 hw_set_bits(&pio->input_sync_bypass, 1u << pin_miso);
72
73 pio_sm_init(pio, sm, prog_offs, &c);
74 pio_sm_set_enabled(pio, sm, true);
75 }
```

状态机现将立即开始移出出现在 TX FIFO 中的任何数据，并将接收到的数据推送至 RX FIFO。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/pio\\_spi.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/pio_spi.c) 第18至34行

```

18 void __time_critical_func(pio_spi_write8_blocking)(const pio_spi_inst_t *spi, const uint8_t
 *src, size_t len) {
19 size_t tx_remain = len, rx_remain = len;
20 // 对 FIFO 进行 8 位访问，以保证写入数据为字节复制。该
21 // 对于 MSB 优先的移位输出，实现左对齐
22 io_rw_8 *txfifo = (io_rw_8 *) &spi->pio->txf[spi->sm];
23 io_rw_8 *rxfifo = (io_rw_8 *) &spi->pio->rxr[spi->sm];
24 while (tx_remain || rx_remain) {
25 if (tx_remain && !pio_sm_is_tx_fifo_full(spi->pio, spi->sm)) {
26 *txfifo = *src++;
27 --tx_remain;
28 }
29 }
30 }
```

```

29 if (rx_remain && !pio_sm_is_rx_fifo_empty(spi->pio, spi->sm)) {
30 (void) *rxfifo;
31 --rx_remain;
32 }
33 }
34 }
```

Putting this all together, this complete C program will loop back some data through a PIO SPI at 1 MHz, with all four CPOL/CPHA combinations:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi\\_loopback.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi_loopback.c)

```

6
7 #include <stdlib.h>
8 #include <stdio.h>
9
10 #include "pico/stdlib.h"
11 #include "pio_spi.h"
12
13 // This program instantiates a PIO SPI with each of the four possible
14 // CPOL/CPHA combinations, with the serial input and output pin mapped to the
15 // same GPIO. Any data written into the state machine's TX FIFO should then be
16 // serialised, deserialised, and reappear in the state machine's RX FIFO.
17
18 #define PIN_SCK 18
19 #define PIN_MOSI 16
20 #define PIN_MISO 16 // same as MOSI, so we get loopback
21
22 #define BUF_SIZE 20
23
24 void test(const pio_spi_inst_t *spi) {
25 static uint8_t txbuf[BUF_SIZE];
26 static uint8_t rxbuf[BUF_SIZE];
27 printf("TX:");
28 for (int i = 0; i < BUF_SIZE; ++i) {
29 txbuf[i] = rand() >> 16;
30 rxbuf[i] = 0;
31 printf(" %02x", (int) txbuf[i]);
32 }
33 printf("\n");
34
35 pio_spi_write8_read8_blocking(spi, txbuf, rxbuf, BUF_SIZE);
36
37 printf("RX:");
38 bool mismatch = false;
39 for (int i = 0; i < BUF_SIZE; ++i) {
40 printf(" %02x", (int) rxbuf[i]);
41 mismatch = mismatch || rxbuf[i] != txbuf[i];
42 }
43 if (mismatch)
44 printf("\n Nope\n");
45 else
46 printf("\n OK\n");
47 }
48
49 int main() {
50 stdio_init_all();
```

```

29 if (rx_remain && !pio_sm_is_rx_fifo_empty(spi->pio, spi->sm)) {
30 (void) *rxfifo;
31 --rx_remain;
32 }
33 }
34 }
```

综上所述，此完整 C 程序将在 1 MHz 频率下通过 PIO SPI 进行数据回环，支持所有四种 CPOL/CPHA 组合：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi\\_loopback.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/spi/spi_loopback.c)

```

## 11.6.2. WS2812 LEDs

WS2812 LEDs are driven by a proprietary pulse-width serial format, with a wide positive pulse representing a "1" bit, and narrow positive pulse a "0". Each LED has a serial input and a serial output; LEDs are connected in a chain, with each serial input connected to the previous LED's serial output.

Figure 57. WS2812 line format. Wide positive pulse for 1, narrow positive pulse for 0, very long negative pulse for latch enable

LEDs consume 24 bits of pixel data, then pass any additional input data on to their output. In this way a single serial burst can individually program the colour of each LED in a chain. A long negative pulse latches the pixel data into the LEDs.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/ws2812/ws2812.pio> Lines 8 - 31

```

8 .program ws2812
9 .side_set 1
10
11 ; The following constants are selected for broad compatibility with WS2812,
12 ; WS2812B, and SK6812 LEDs. Other constants may support higher bandwidths for
13 ; specific LEDs, such as (7,10,8) for WS2812B LEDs.

72);
73 test(&spi);
74 sleep_ms(10);
75 }
76 }
77 }
```

## 11.6.2. WS2812 LED

WS2812 LED采用专有的脉宽串行格式驱动，宽正脉冲表示“1”位，窄正脉冲表示“0”位。每个LED均具有串行输入和串行输出；LED以链式连接，每个串行输入连接至前一LED的串行输出。

图57. WS2812线  
路格式。宽正  
脉冲表示1，窄正  
脉冲表示0，超长  
负脉冲用于  
锁存使能

LED消耗24位像素数据，随后将任何额外输入数据传递到其输出。通过该方式，单次串行数据传输可独立设置链中每个LED的颜色。长负脉冲将像素数据锁存至LED。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/ws2812/ws2812.pio> 第8至31行

```

8 .program ws2812
9 .side_set 1
10
11 ; 以下常量选取以广泛兼容WS2812、
12 ; WS2812B及SK6812 LED。其他常量可支持
13 ; 特定LED的更高带宽，例如WS2812B LED的(7, 10, 8)。
14
15 .define public T1 3
16 .define public T2 3
17 .define public T3 4
18
19 .lang_opt python sideset_init = pico.PIO.OUT_HIGH
20 .lang_opt python out_init = pico.PIO.OUT_HIGH
21 .lang_opt python out_shiftdir = 1
22
23 .wrap_target
```

```

24 bitloop:
25 out x, 1 side 0 [T3 - 1] ; Side-set still takes place when instruction stalls
26 jmp !x do_zero side 1 [T1 - 1] ; Branch on the bit we shifted out. Positive pulse
27 do_one:
28 jmp bitloop side 1 [T2 - 1] ; Continue driving high, for a long pulse
29 do_zero:
30 nop side 0 [T2 - 1] ; Or drive low, for a short pulse
31 .wrap

```

This program shifts bits from the OSR into X, and produces a wide or narrow pulse on side-set pin 0, based on the value of each data bit. Autopull must be configured, with a threshold of 24. Software can then write 24-bit pixel values into the FIFO, and these will be serialised to a chain of WS2812 LEDs. The `.pio` file contains a C helper function to set this up:

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/ws2812/ws2812.pio> Lines 36 - 52

```

36 static inline void ws2812_program_init(PIO pio, uint sm, uint offset, uint pin, float freq,
37 bool rgbw) {
38 pio_gpio_init(pio, pin);
39 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
40
41 pio_sm_config c = ws2812_program_get_default_config(offset);
42 sm_config_set_sideset_pins(&c, pin);
43 sm_config_set_out_shift(&c, false, true, rgbw ? 32 : 24);
44 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
45
46 int cycles_per_bit = ws2812_T1 + ws2812_T2 + ws2812_T3;
47 float div = clock_get_hz(clk_sys) / (freq * cycles_per_bit);
48 sm_config_set_clkdiv(&c, div);
49
50 pio_sm_init(pio, sm, offset, &c);
51 pio_sm_set_enabled(pio, sm, true);
52 }

```

Because the shift is MSB-first, and our pixels aren't a power of two size (so we can't rely on the narrow write replication behaviour on RP2350 to fan out the bits for us), we need to preshift the values written to the TX FIFO.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/ws2812/ws2812.c> Lines 43 - 45

```

43 static inline void put_pixel(PIO pio, uint sm, uint32_t pixel_grb) {
44 pio_sm_put_blocking(pio, sm, pixel_grb << 8u);
45 }

```

To DMA the pixels, we could instead set the autopull threshold to 8 bits, set the DMA transfer size to 8 bits, and write a byte at a time into the FIFO. Each pixel would be 3 one-byte transfers. Because of how the bus fabric and DMA on RP2350 work, each byte the DMA transfers will appear replicated four times when written to a 32-bit IO register, so effectively your data is at *both ends* of the shift register, and you can shift in either direction without worry.

```

24 bitloop:
25 out x, 1 side 0 [T3 - 1] ; 即使指令停滞，side-set仍会执行
26 jmp !x do_zero side 1 [T1 - 1] ; 根据移出的位进行分支。正脉冲
27 do_one:
28 jmp bitloop side 1 [T2 - 1] ; 继续将引脚驱动为高电平，产生长脉冲
29 do_zero:
30 nop side 0 [T2 - 1] ; 或将引脚驱动为低电平，产生短脉冲
31 .wrap

```

该程序将只读存储器中的位移入X寄存器，并根据每个位的数据值，在侧置引脚0上产生宽或窄脉冲。必须配置自动拉取，阈值为24。软件随后可将24位像素值写入FIFO，这些值将被串行传输至WS2812 LED链。该 .pio文件包含一个用于配置的C辅助函数：

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/ws2812/ws2812.pio> 第36至52行

```

36 static inline void ws2812_program_init(PIO pio, uint sm, uint offset, uint pin, float freq,
37 bool rgbw) {
38 pio_gpio_init(pio, pin);
39 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
40
41 pio_sm_config c = ws2812_program_get_default_config(offset);
42 sm_config_set_sideset_pins(&c, pin);
43 sm_config_set_out_shift(&c, false, true, rgbw ? 32 : 24);
44 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
45
46 int cycles_per_bit = ws2812_T1 + ws2812_T2 + ws2812_T3;
47 float div = clock_get_hz(clk_sys) / (freq * cycles_per_bit);
48 sm_config_set_clkdiv(&c, div);
49
50 pio_sm_init(pio, sm, offset, &c);
51 pio_sm_set_enabled(pio, sm, true);
52 }

```

由于移位是最高有效位优先，且我们的像素大小不是二的幂（因此无法依赖 RP2350 上的窄写复制行为来扩展比特），我们必须对写入 TX FIFO 的值进行预移位处理。

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/ws2812/ws2812.c> 第43-45行

```

43 static inline void put_pixel(PIO pio, uint sm, uint32_t pixel_grb) {
44 pio_sm_put_blocking(pio, sm, pixel_grb << 8u);
45 }

```

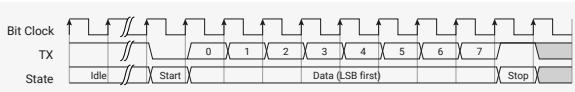

为了通过 DMA 传输像素，我们可以将 autopull 阈值设置为 8 位，将 DMA 传输大小设置为 8 位，并每次向 FIFO 写入一个字节。每个像素将由三个单字节传输组成。由于 RP2350 的总线结构和 DMA 工作方式，DMA 传输的每个字节在写入 32 位 IO 寄存器时会被复制四次，因此数据实际上位于移位寄存器的两端，您可以无忧地向任意方向移位。

 **TIP**

The WS2812 example is the subject of a tutorial in the [Raspberry Pi Pico-series C/C++ SDK](#) document, in the PIO chapter. The tutorial dissects the `ws2812` program line by line, traces through how the program executes, and shows wave diagrams of the GPIO output at every point in the program.

### 11.6.3. UART TX

Figure 58. UART serial format. The line is high when idle. The transmitter pulls the line down for one bit period to signify the start of a serial frame (the "start bit"), and a small, fixed number of data bits follows. The line returns to the idle state for at least one bit period (the "stop bit") before the next serial frame can begin.

This program implements the transmit component of a universal asynchronous receive/transmit (UART) serial peripheral. Perhaps it would be more correct to refer to this as a UAT.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) Lines 8 - 18

```

8 .program uart_tx
9 .side_set 1 opt
10
11 ; An 8n1 UART transmit program.
12 ; OUT pin 0 and side-set pin 0 are both mapped to UART TX pin.
13
14 pull side 1 [7] ; Assert stop bit, or stall with line in idle state
15 set x, 7 side 0 [7] ; Preload bit counter, assert start bit for 8 clocks
16 bitloop: ; This loop will run 8 times (8n1 UART)
17 out pins, 1 ; Shift 1 bit from OSR to the first OUT pin
18 jmp x-- bitloop [6] ; Each loop iteration is 8 cycles.

```

As written, it will:

1. Stall with the pin driven high until data appears (noting that side-set takes effect even when the state machine is stalled)
2. Assert a start bit, for 8 SM execution cycles
3. Shift out 8 data bits, each lasting for 8 cycles
4. Return to the idle line state for at least 8 cycles before asserting the next start bit

If the state machine's clock divider is configured to run at 8 times the desired baud rate, this program will transmit well-formed UART serial frames, whenever data is pushed to the TX FIFO either by software or the system DMA. To extend the program to cover different frame sizes (different numbers of data bits), the `set x, 7` could be replaced with `mov x, y`, so that the `y` scratch register becomes a per-SM configuration register for UART frame size.

The `.pio` file in the SDK also contains this function, for configuring the pins and the state machine, once the program has been loaded into the PIO instruction memory:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) Lines 24 - 51

```

24 static inline void uart_tx_program_init(PIO pio, uint sm, uint offset, uint pin_tx, uint
baud) {
25 // Tell PIO to initially drive output-high on the selected pin, then map PIO
26 // onto that pin with the IO muxes.
27 pio_sm_set_pins_with_mask64(pio, sm, 1ull << pin_tx, 1ull << pin_tx);
28 pio_sm_set_pindirs_with_mask64(pio, sm, 1ull << pin_tx, 1ull << pin_tx);
29 pio_gpio_init(pio, pin_tx);
30
31 pio_sm_config c = uart_tx_program_get_default_config(offset);

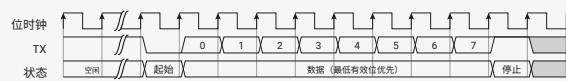

```

### 💡 提示

WS2812 示例是Raspberry Pi Pico 系列 C/C++ SDK 文档中 PIO 章节的教程内容。本教程逐行解析了 ws2812 程序，追踪程序执行流程，并展示了程序各阶段GPIO输出的波形图。

### 11.6.3. UART 发送

图58. UART串行格式。空闲时线路处于高电平。发送器将线路拉低一个位周期以表示串行帧的开始（“起始位”），随后传输一定数量的固定数据位。下一帧串行数据开始前，线路须保持空闲状态至少一个位周期（“停止位”）。

该程序实现了通用异步接收/发送（UART）串行外设的发送功能。更准确地说，可称其为UAT。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) 第8至18行

```

8 .program uart_tx
9 .side_set 1 opt
10
11 ; 一个8n1 UART发送程序。
12 ; OUT引脚0和side-set引脚0均映射至UART TX引脚。
13
14 下拉 side 1 [7] ; 断言停止位，或在线路空闲状态下阻塞
15 set x, 7 side 0 [7] ; 预载位计数器，断言起始位持续8个时钟周期
16 bitloop: ; 此循环将运行8次（8n1 UART）
17 输出引脚, 1 ; 从OSR移出1位至第一个OUT引脚
18 jmp x-- bitloop [6] ; 每次循环迭代为8个周期。

```

按此编写，程序将执行：

1. 在数据出现前，保持引脚高电平阻塞（注意side-set即使状态机阻塞时亦生效）
2. 断言起始位，持续8个状态机执行周期
3. 移出8位数据，每位持续8个周期
4. 在断言下一个起始位之前，至少保持线路空闲状态8个周期

如果状态机的时钟分频器配置为以期望波特率的8倍运行，则每当数据由软件或系统DMA推入TX FIFO时，该程序将发送格式规范的UART串行帧。为支持不同帧大小（不同数据位数），可以将set x, 7 替换为mov x, y，使y临时寄存器成为每个SM的UART帧大小配置寄存器。

SDK中的 .pio文件亦包含该函数，用于程序加载至PIO指令存储器后配置引脚和状态机：

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) 第24至51行

```

24 static inline void uart_tx_program_init(PIO pio, uint sm, uint offset, uint pin_tx, uint
baud) {
25 // 指示 PIO 初始将所选引脚驱动为输出高电平，然后通过 IO 复用器映射 PIO
26 // 到该引脚。
27 pio_sm_set_pins_with_mask64(pio, sm, 1ull << pin_tx, 1ull << pin_tx);
28 pio_sm_set_pindirs_with_mask64(pio, sm, 1ull << pin_tx, 1ull << pin_tx);
29 pio_gpio_init(pio, pin_tx);
30
31 pio_sm_config c = uart_tx_program_get_default_config(offset);

```

```

32
33 // OUT shifts to right, no autopull
34 sm_config_set_out_shift(&c, true, false, 32);
35
36 // We are mapping both OUT and side-set to the same pin, because sometimes
37 // we need to assert user data onto the pin (with OUT) and sometimes
38 // assert constant values (start/stop bit)
39 sm_config_set_out_pins(&c, pin_tx, 1);
40 sm_config_set_sideset_pins(&c, pin_tx);
41
42 // We only need TX, so get an 8-deep FIFO!
43 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
44
45 // SM transmits 1 bit per 8 execution cycles.
46 float div = (float)clock_get_hz(clk_sys) / (8 * baud);
47 sm_config_set_clkdiv(&c, div);
48
49 pio_sm_init(pio, sm, offset, &c);
50 pio_sm_set_enabled(pio, sm, true);
51 }
```

The state machine is configured to shift right in `out` instructions, because UARTs typically send data LSB-first. Once configured, the state machine will print any characters pushed to the TX FIFO.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) Lines 53 - 55

```

53 static inline void uart_tx_program_putc(PIO pio, uint sm, char c) {
54 pio_sm_put_blocking(pio, sm, (uint32_t)c);
55 }
```

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) Lines 57 - 60

```

57 static inline void uart_tx_program_puts(PIO pio, uint sm, const char *s) {
58 while (*s)
59 uart_tx_program_putc(pio, sm, *s++);
60 }
```

The example program in the SDK will configure one PIO state machine as a UART TX peripheral, and use it to print a message on GPIO 0 at 115200 baud once per second.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.c)

```

1 /**

5 */
6
7 #include "pico/stdlib.h"
8 #include "hardware/pio.h"
9 #include "uart_tx.pio.h"
10
11 // We're going to use PIO to print "Hello, world!" on the same GPIO which we
12 // normally attach UART0 to.
13 #define PIO_TX_PIN 0
14
15 // Check the pin is compatible with the platform
16 #error Attempting to use a pin>=32 on a platform that does not support it
```

```

32
33 // 输出右移, 无自动拉取
34 sm_config_set_out_shift(&c, true, false, 32);
35
36 // 我们将 OUT 与侧边设置均映射至同一引脚, 因为有时
37 // 需通过 OUT 驱动用户数据至该引脚, 有时
38 // 需驱动恒定值 (起始位/停止位)
39 sm_config_set_out_pins(&c, pin_tx, 1);
40 sm_config_set_sideset_pins(&c, pin_tx);
41
42 // 我们只需要 TX, 因此使用深度为8的FIFO!
43 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
44
45 // 状态机每执行8个周期传输1位。
46 float div = (float)clock_get_hz(clk_sys) / (8 * baud);
47 sm_config_set_clkdiv(&c, div);
48
49 pio_sm_init(pio, sm, offset, &c);
50 pio_sm_set_enabled(pio, sm, true);
51 }

```

该状态机配置为在 `out` 指令中向右移位, 因为UART通常以LSB优先发送数据。配置完成后, 状态机将打印推送至TX FIFO 的所有字符。

Pico示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) 第53至55行

```

53 static inline void uart_tx_program_putc(PIO pio, uint sm, char c) {
54 pio_sm_put_blocking(pio, sm, (uint32_t)c);
55 }

```

Pico示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.pio) 第57至60行

```

57 static inline void uart_tx_program_puts(PIO pio, uint sm, const char *s) {
58 while (*s)
59 uart_tx_program_putc(pio, sm, *s++);
60 }

```

SDK中的示例程序将配置一个PIO状态机作为UART TX外设, 并利用其以115200波特率每秒在GPIO 0上打印一条消息。

Pico示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_tx/uart\\_tx.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_tx/uart_tx.c)

```

5 */
6
7 #include "pico/stdlib.h"
8 #include "hardware/pio.h"
9 #include "uart_tx.pio.h"
10
11 // 我们将使用PIO在同一GPIO引脚上打印 "Hello, world!"
12 // 通常连接到UART0。
13 #define PIO_TX_PIN 0
14
15 // 检查引脚是否与平台兼容
16 #error 尝试使用平台不支持的 pin >= 32

```

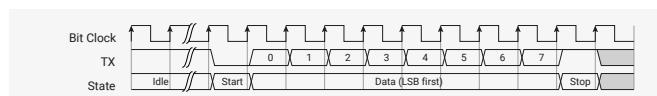

```

17
18 int main() {
19 // This is the same as the default UART baud rate on Pico
20 const uint SERIAL_BAUD = 115200;
21
22 PIO pio;
23 uint sm;
24 uint offset;
25
26 // This will find a free pio and state machine for our program and load it for us
27 // We use pio_claim_free_sm_and_add_program_for_gpio_range (for_gpio_range variant)
28 // so we will get a PIO instance suitable for addressing gpios >= 32 if needed and
29 // supported by the hardware
30 bool success = pio_claim_free_sm_and_add_program_for_gpio_range(&uart_tx_program, &pio,
31 &sm, &offset, PIO_TX_PIN, 1, true);
32 hard_assert(success);
33
34 uart_tx_program_init(pio, sm, offset, PIO_TX_PIN, SERIAL_BAUD);
35
36 while (true) {
37 uart_tx_program_puts(pio, sm, "Hello, world! (from PIO!)\r\n");
38 sleep_ms(1000);
39 }
40
41 // This will free resources and unload our program
42 pio_remove_program_and_unclaim_sm(&uart_tx_program, pio, sm, offset);
43 }
```

With the two PIO instances on RP2350, this could be extended to 8 additional UART TX interfaces, on 8 different pins, with 8 different baud rates.

## 11.6.4. UART RX

Recalling [Figure 58](#) showing the format of an 8n1 UART:

We can recover the data by waiting for the start bit, sampling 8 times with the correct timing, and pushing the result to the RX FIFO. Below is possibly the shortest program which can do this:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.pio) Lines 8 - 19

```

8 .program uart_rx_mini
9
10 ; Minimum viable 8n1 UART receiver. Wait for the start bit, then sample 8 bits
11 ; with the correct timing.
12 ; IN pin 0 is mapped to the GPIO used as UART RX.
13 ; Autopush must be enabled, with a threshold of 8.
14
15 wait 0 pin 0 ; Wait for start bit
16 set x, 7 [10] ; Preload bit counter, delay until eye of first data bit
17 bitloop: ; Loop 8 times
18 in pins, 1 ; Sample data
19 jmp x-- bitloop [6] ; Each iteration is 8 cycles
```

This works, but it has some annoying characteristics, like repeatedly outputting **NUL** characters if the line is stuck low.

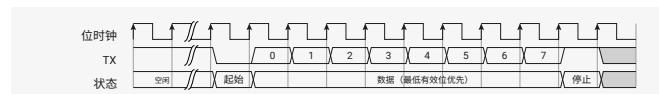

```

17
18 int main() {
19 // 与 Pico 上的默认 UART 波特率相同
20 const uint SERIAL_BAUD = 115200;
21
22 PIO pio;
23 uint sm;
24 uint offset;
25
26 // 此操作将为我们的程序找到一个空闲的 pio 和状态机，并加载它们
27 // 我们使用 pio_claim_free_sm_and_add_program_for_gpio_range (for_gpio_range 变体)
28 // 因此，如果硬件支持，我们将获得适用于地址 gpios >= 32 的 PIO 实例
29
30 bool success = pio_claim_free_sm_and_add_program_for_gpio_range(&uart_tx_program, &pio,
31 &sm, &offset, PIO_TX_PIN, 1, true);
32 hard_assert(success);
33
34 uart_tx_program_init(pio, sm, offset, PIO_TX_PIN, SERIAL_BAUD);
35
36 while (true) {
37 uart_tx_program_puts(pio, sm, "你好，世界！（来自 PIO！）\r\n");
38 sleep_ms(1000);
39 }
40
41 // 这将释放资源并卸载我们的程序
42 pio_remove_program_and_unclaim_sm(&uart_tx_program, pio, sm, offset);
43 }
```

在 RP2350 的两个 PIO 实例基础上，可扩展为 8 个附加 UART 发送接口，分别位于 8 个不同引脚，并使用 8 种不同波特率。

#### 11.6.4. UART 接收

回顾图 58 中显示的 8n1 UART 格式：

我们可以通过等待起始位、以正确时序采样 8 次，并将结果推入 RX FIFO 来恢复数据。以下可能是实现此功能的最简程序：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.pio) 第 8 至 19 行

```

8 .program uart_rx_mini
9
10 ; 最低可行的8n1 UART接收器。等待起始位，然后采样8位数据
11 ; 以正确的时序。
12 ; 将IN引脚0映射至用作UART RX的GPIO。
13 ; 必须启用自动推送功能，阈值设置为8。
14
15 等待0引脚0 ; 等待起始位
16 将x设为7 [10] ; 预加载位计数器，延迟至第一个数据位的采样窗口
17 bitloop: ; 循环8次
18 从引脚读取, 1 ; 采样数据
19 跳转至x-- bitloop [6] ; 每次迭代耗时8个时钟周期
```

该方法可行，但存在一些问题，例如线路持续低电平时会反复输出 NUL 字符。

Ideally, we would want to drop data that is not correctly framed by a start and stop bit (and set some sticky flag to indicate this has happened), and pause receiving when the line is stuck low for long periods. We can add these to our program, at the cost of a few more instructions.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio uart\\_rx uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio uart_rx uart_rx.pio) Lines 44 - 63

```

44 .program uart_rx
45
46 ; Slightly more fleshed-out 8n1 UART receiver which handles framing errors and
47 ; break conditions more gracefully.
48 ; IN pin 0 and JMP pin are both mapped to the GPIO used as UART RX.
49
50 start:
51 wait 0 pin 0 ; Stall until start bit is asserted
52 set x, 7 [10] ; Preload bit counter, then delay until halfway through
53 bitloop: ; the first data bit (12 cycles incl wait, set).
54 in pins, 1 ; Shift data bit into ISR
55 jmp x-- bitloop [6] ; Loop 8 times, each loop iteration is 8 cycles
56 jmp pin good_stop ; Check stop bit (should be high)
57
58 irq 4 rel ; Either a framing error or a break. Set a sticky flag,
59 wait 1 pin 0 ; and wait for line to return to idle state.
60 jmp start ; Don't push data if we didn't see good framing.
61
62 good_stop: ; No delay before returning to start; a little slack is
63 push ; important in case the TX clock is slightly too fast.

```

The second example does not use autopush (Section 11.5.4), preferring instead to use an explicit `push` instruction, so that it can condition the push on whether a correct stop bit is seen. The `.pio` file includes a helper function which configures the state machine and connects it to a GPIO with the pull-up enabled:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio uart\\_rx uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio uart_rx uart_rx.pio) Lines 67 - 85

```

67 static inline void uart_rx_program_init(PIO pio, uint sm, uint offset, uint pin, uint baud) {
68 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
69 pio_gpio_init(pio, pin);
70 gpio_pull_up(pin);
71
72 pio_sm_config c = uart_rx_program_get_default_config(offset);
73 sm_config_set_in_pins(&c, pin); // for WAIT, IN
74 sm_config_set_jmp_pin(&c, pin); // for JMP
75 // Shift to right, autopush disabled
76 sm_config_set_in_shift(&c, true, false, 32);
77 // Deeper FIFO as we're not doing any TX
78 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
79 // SM transmits 1 bit per 8 execution cycles.
80 float div = (float)clock_get_hz(clk_sys) / (8 * baud);
81 sm_config_set_clkdiv(&c, div);
82
83 pio_sm_init(pio, sm, offset, &c);
84 pio_sm_set_enabled(pio, sm, true);
85 }

```

To correctly receive data which is sent LSB-first, the ISR is configured to shift to the right. After shifting in 8 bits, this unfortunately leaves our 8 data bits in bits 31:24 of the ISR, with 24 zeroes in the LSBs. One option here is an `in null, 24` instruction to shuffle the ISR contents down to 7:0. Another is to read from the FIFO at an offset of 3 bytes, with an 8-bit read, so that the processor's bus hardware (or the DMA's) picks out the relevant byte for free:

理想情况下，我们应舍弃未被起始位和停止位正确帧定的数据（并设置粘性标志以指示此状况），且当线路长时间保持低电平时暂停接收。我们可以将这些指令添加到程序中，代价是增加几条指令。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.pio) 第44至63行

```

44 .program uart_rx
45
46 ;稍微完善的8n1 UART接收器，可更优雅地处理帧错误和
47 ;中断条件。
48 ;IN引脚0和JMP引脚均映射至作为UART接收的GPIO。
49
50 start:
51 等待引脚0为0 ;阻塞，直到开始位被置位
52 设定x为7 [10]； 预加载位计数器，然后延迟，直到
53 bitloop: ;第一个数据位的中途（包括等待和设定，共12个周期）。
54 从引脚读取1位数据 ;将数据位移入ISR寄存器
55 jmp x-- bitloop [6] ;循环8次，每次循环耗时8个周期
56 jmp 引脚 good_stop ;检查停止位（应为高电平）
57
58 irq 4 相关 ;可能是帧错误或中断信号。设置一个粘滞标志，
59 等待引脚0为低电平 ;并等待线路恢复至空闲状态。
60 jmp start ;如果未检测到正确的帧结构，切勿推送数据。
61
62 good_stop: ;返回 start 之前无延迟；保持一定余量
63 push ;在 TX 时钟稍微偏快的情况下，这一点非常重要。

```

第二个示例未使用自动推送（第11.5.4节），而是采用显式 `push` 指令，以便根据是否检测到正确停止位决定是否推送。该 `.pio` 文件包含一个辅助函数，用于配置状态机并连接带上拉功能的 GPIO 端口：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.pio) 第67至85行

```

67 static inline void uart_rx_program_init(PIO pio, uint sm, uint offset, uint pin, uint baud) {
68 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
69 pio_gpio_init(pio, pin);
70 gpio_pull_up(pin);
71
72 pio_sm_config c = uart_rx_program_get_default_config(offset);
73 sm_config_set_in_pins(&c, pin); // 用于 WAIT 和 IN
74 sm_config_set_jmp_pin(&c, pin); // 用于 JMP
75 //右移位，禁用自动推送
76 sm_config_set_in_shift(&c, true, false, 32);
77 //由于不进行任何 TX 操作，FIFO 设置更深
78 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
79 //状态机每 8 次执行周期传输 1 位
80 float div = (float)clock_get_hz(clk_sys) / (8 * baud);
81 sm_config_set_clkdiv(&c, div);
82
83 pio_sm_init(pio, sm, offset, &c);
84 pio_sm_set_enabled(pio, sm, true);
85 }

```

为正确接收按最低有效位优先方式发送的数据，中断服务程序配置为右移位。在左移8位后，遗憾的是，我们的8位数据位位于ISR的31:24位，而最低有效位（LSB）中有24个零。此处的一种选择是执行一条 `in null, 24` 指令，将ISR内容下移至7:0位。另一种方法是从FIFO偏移3字节处进行8位读取，从而使处理器总线硬件（或DMA硬件）自动挑选相关字节，且不额外费力：

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.pio) Lines 87 - 93

```

87 static inline char uart_rx_program_getc(PIO pio, uint sm) {
88 // 8-bit read from the uppermost byte of the FIFO, as data is left-justified
89 io_rw_8 *rxfifo_shift = (io_rw_8*)&pio->rf[sm] + 3;
90 while (pio_sm_is_rx_fifo_empty(pio, sm))
91 tight_loop_contents();
92 return (char)*rxfifo_shift;
93 }
```

An example program shows how this UART RX program can be used to receive characters sent by one of the hardware UARTs on RP2350. A wire must be connected from GPIO4 to GPIO3 for this program to function. To make the wrangling of 3 different serial ports a little easier, this program uses core 1 to print out a string on the test UART (UART 1), and the code running on core 0 will pull out characters from the PIO state machine, and pass them along to the UART used for the debug console (UART 0). Another approach here would be interrupt-based IO, using PIO's FIFO IRQs. If the **SM0\_RXNEMPTY** bit is set in the **IRQ0\_INTE** register, then PIO will raise its first interrupt request line whenever there is a character in state machine 0's RX FIFO.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.c)

```

29 // Check the pin is compatible with the platform
30 #error Attempting to use a pin>=32 on a platform that does not support it
31
32 // Ask core 1 to print a string, to make things easier on core 0
33 void core1_main() {
34 const char *s = (const char *) multicore_fifo_pop_blocking();
35 uart_puts(HARD_UART_INST, s);
36 }
37
38 int main() {
39 // Console output (also a UART, yes it's confusing)
40 setup_default_uart();
41 printf("Starting PIO UART RX example\n");
```

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.pio) 第87至93行

```

87 static inline char uart_rx_program_getc(PIO pio, uint sm) {
88 // 从FIFO最高字节进行8位读取，因数据为左对齐
89 io_rw_8 *rxfifo_shift = (io_rw_8*)&pio->rxf[sm] + 3;
90 while (pio_sm_is_rx_fifo_empty(pio, sm))
91 tight_loop_contents();
92 return (char)*rxfifo_shift;
93 }
```

示例程序展示了如何使用该UART RX程序接收由RP2350某硬件UART发送的字符。该程序需将GPIO4连接至GPIO3方能正常工作。为简化对三个不同串口的管理，该程序利用核心1在测试UART（UART 1）上打印字符串，核心0运行的代码则从PIO状态机提取字符，并传递至调试控制台所用的UART（UART 0）。另一种方法是基于中断的IO，采用PIO的FIFO中断请求（IRQ）。若IRQ0\_INTERRUPT寄存器中SM0\_RXNEMPTY位被置位，则每当状态机0的RX FIFO中有字符时，PIO将触发其第一个中断请求信号。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/uart\\_rx/uart\\_rx.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/uart_rx/uart_rx.c)

```

71 putchar(c);
72 }
73
74 // 此操作将释放资源并卸载程序
75 pio_remove_program_and_unclaim_sm(&uart_rx_program, pio, sm, offset);
76 }
```

## 11.6.5. 曼彻斯特码串行发送与接收

图59。曼彻斯特串行线路编码。每个数据位由高脉冲后跟低脉冲（表示“0”位）或低脉冲后跟高脉冲（表示“1”位）表示。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) 第8行至30行

```

8 .program manchester_tx
9 .side_set 1 opt
10
11 ; 每12个周期传输一位。‘0’ 编码为高—低序列
12 ; （每部分持续半个比特周期，即6个周期），‘1’ 编码为
13 ; 低—高序列。
14 ;
15 ; side-set位0必须映射至用于TX的GPIO。
16 ; 必须启用Autopull——本程序不关心阈值。
17 ; 程序从公共标签'start'开始。
18
19 .wrap_target
20 do_1:
21 nop side 0 [5] ; 低电平持续6个周期（5个延迟周期，加1个nop周期）
22 jmp get_bit side 1 [3] ; 高电平持续4个周期。'get_bit'需要额外2个周期。
```

```

23 do_0:
24 nop side 1 [5] ; Output high for 6 cycles
25 nop side 0 [3] ; Output low for 4 cycles
26 public start:
27 get_bit:
28 out x, 1 ; Always shift out one bit from OSR to X, so we can
29 jmp !x do_0 ; branch on it. Autopull refills the OSR when empty.
30 .wrap

```

Starting from the label called `start`, this program shifts one data bit at a time into the X register, so that it can branch on the value. Depending on the outcome, it uses side-set to drive either a 1-0 or 0-1 sequence onto the chosen GPIO. This program uses autopull (Section 11.5.4.2) to automatically replenish the OSR from the TX FIFO once a certain amount of data has been shifted out, without interrupting program control flow or timing. This feature is enabled by a helper function in the `.pio` file which configures and starts the state machine:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) Lines 33 - 46

```

33 static inline void manchester_tx_program_init(PIO pio, uint sm, uint offset, uint pin, float
 div) {
34 pio_sm_set_pins_with_mask(pio, sm, 0, 1u << pin);
35 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
36 pio_gpio_init(pio, pin);
37
38 pio_sm_config c = manchester_tx_program_get_default_config(offset);
39 sm_config_set_sideset_pins(&c, pin);
40 sm_config_set_out_shift(&c, true, true, 32);
41 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
42 sm_config_set_clkdiv(&c, div);
43 pio_sm_init(pio, sm, offset + manchester_tx_offset_start, &c);
44
45 pio_sm_set_enabled(pio, sm, true);
46 }

```

Another state machine can be programmed to recover the original data from the transmitted signal:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) Lines 49 - 71

```

49 .program manchester_rx
50
51 ; Assumes line is idle low, first bit is 0
52 ; One bit is 12 cycles
53 ; a '0' is encoded as 10
54 ; a '1' is encoded as 01
55 ;
56 ; Both the IN base and the JMP pin mapping must be pointed at the GPIO used for RX.
57 ; Autopush must be enabled.
58 ; Before enabling the SM, it should be placed in a 'wait 1, pin' state, so that
59 ; it will not start sampling until the initial line idle state ends.
60
61 start_of_0: ; We are 0.25 bits into a 0 - signal is high
62 wait 0 pin 0 ; Wait for the 1->0 transition - at this point we are 0.5 into the bit
63 in y, 1 [8] ; Emit a 0, sleep 3/4 of a bit
64 jmp pin start_of_0 ; If signal is 1 again, it's another 0 bit, otherwise it's a 1
65
66 .wrap_target
67 start_of_1: ; We are 0.25 bits into a 1 - signal is 1
68 wait 1 pin 0 ; Wait for the 0->1 transition - at this point we are 0.5 into the bit
69 in x, 1 [8] ; Emit a 1, sleep 3/4 of a bit
70 jmp pin start_of_0 ; If signal is 0 again, it's another 1 bit otherwise it's a 0

```

```

23 do_0:
24 nop side 1 [5] ; 输出高电平持续6个周期
25 nop side 0 [3]; 输出低电平，持续4个周期
26 public start:
27 get_bit:
28 out x, 1 ; 始终从OSR移出一位到X，这样我们可以
29 jmp !x do_0 ; 根据该位进行跳转。Autopull在OSR为空时会自动补充。
30 .wrap

```

从名为 `start` 的标签开始，该程序每次将一个数据位移入 X 寄存器，从而基于该值进行跳转。根据结果，它使用 side-set 驱动所选 GPIO 上的 1-0 或 0-1 序列。该程序使用 autopull（第 11.5.4.2 节）自动从 TX FIFO 补充 OSR，在移出一定数据量后，无需中断程序控制流程或时序。此功能由 `.pio` 文件中的辅助函数启用，该函数配置并启动状态机：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) 第 33 至 46 行

```

33 static inline void manchester_tx_program_init(PIO pio, uint sm, uint offset, uint pin, float
 div) {
34 pio_sm_set_pins_with_mask(pio, sm, 0, 1u << pin);
35 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
36 pio_gpio_init(pio, pin);
37
38 pio_sm_config c = manchester_tx_program_get_default_config(offset);
39 sm_config_set_sideset_pins(&c, pin);
40 sm_config_set_out_shift(&c, true, true, 32);
41 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
42 sm_config_set_clkdiv(&c, div);
43 pio_sm_init(pio, sm, offset + manchester_tx_offset_start, &c);
44
45 pio_sm_set_enabled(pio, sm, true);
46 }

```

另一状态机可以被编程以从传输信号中恢复原始数据：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) 第 49 至 71 行

```

49 .program manchester_rx
50
51 ; 假设线路空闲为低电平，且第一位为0
52 ; 一个比特为12个周期
53 ; '0' 编码为10
54 ; '1' 编码为01
55 ;
56 ; IN基准和JMP引脚映射必须指向用于接收 (RX) 的GPIO。
57 ; 必须启用自动推送 (Autopush)。
58 ; 在启用状态机 (SM) 之前，应将其置于“wait 1, pin”状态，
59 ; 以确保其在初始线路空闲状态结束前不会开始采样。
60
61 start_of_0: ; 当前处于0的0.25比特时——信号为高电平
62 wait 0 pin 0 ; 等待1到0的转换——此时已进入比特的0.5处
63 在 y, 1 [8] ; 发出0，休眠3/4比特时间
64 jmp pin start_of_0; 若信号再次为1，则表示另一个0比特，否则为1比特
65
66 .wrap_target
67 start_of_1: ; 我们处于1的第0.25比特处——信号为1
68 等待1引脚为0 ; 等待0到1的转换——此时处于比特的第0.5位置
69 在 x 中, 1 [8] ; 发送一个1，暂停3/4比特时间
70 jmp pin start_of_0; 如果信号再次为0，则表示另一个1比特，否则为0

```

```
71 .wrap
```

The main complication here is staying aligned to the input transitions, as the transmitter's and receiver's clocks may drift relative to one another. In Manchester code there is always a transition in the centre of the symbol, and based on the initial line state (high or low) we know the direction of this transition, so we can use a `wait` instruction to resynchronise to the line transitions on every data bit.

This program expects the X and Y registers to be initialised with the values 1 and 0 respectively, so that a constant 1 or 0 can be provided to the `in` instruction. The code that configures the state machine initialises these registers by executing some `set` instructions before setting the program running.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) Lines 74 - 94

```
74 static inline void manchester_rx_program_init(PIO pio, uint sm, uint offset, uint pin, float
 div) {
75 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
76 pio_gpio_init(pio, pin);
77
78 pio_sm_config c = manchester_rx_program_get_default_config(offset);
79 sm_config_set_in_pins(&c, pin); // for WAIT
80 sm_config_set_jmp_pin(&c, pin); // for JMP
81 sm_config_set_in_shift(&c, true, true, 32);
82 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
83 sm_config_set_clkdiv(&c, div);
84 pio_sm_init(pio, sm, offset, &c);
85
86 // X and Y are set to 0 and 1, to conveniently emit these to ISR/FIFO.
87 pio_sm_exec(pio, sm, pio_encode_set(pio_x, 1));
88 pio_sm_exec(pio, sm, pio_encode_set(pio_y, 0));
89 // Assume line is idle low, and first transmitted bit is 0. Put SM in a
90 // wait state before enabling. RX will begin once the first 0 symbol is
91 // detected.
92 pio_sm_exec(pio, sm, pio_encode_wait_pin(1, 0) | pio_encode_delay(2));
93 pio_sm_set_enabled(pio, sm, true);
94 }
```

The example C program in the SDK will transmit Manchester serial data from GPIO2 to GPIO3 at approximately 10 Mb/s (assuming a system clock of 125 MHz).

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.c) Lines 20 - 43

```
20 int main() {
21 stdio_init_all();
22
23 PIO pio = pio0;
24 uint sm_tx = 0;
25 uint sm_rx = 1;
26
27 uint offset_tx = pio_add_program(pio, &manchester_tx_program);
28 uint offset_rx = pio_add_program(pio, &manchester_rx_program);
29 printf("Transmit program loaded at %d\n", offset_tx);
30 printf("Receive program loaded at %d\n", offset_rx);
31
32 manchester_tx_program_init(pio, sm_tx, offset_tx, pin_tx, 1.f);
33 manchester_rx_program_init(pio, sm_rx, offset_rx, pin_rx, 1.f);
34
35 pio_sm_set_enabled(pio, sm_tx, false);
36 pio_sm_put_blocking(pio, sm_tx, 0);
37 pio_sm_put_blocking(pio, sm_tx, 0x0ff0a55a);
38 pio_sm_put_blocking(pio, sm_tx, 0x12345678);
```

```
71 .wrap
```

此处主要难点在于保持与输入转换的同步，因发射器与接收器的时钟可能彼此漂移。在曼彻斯特编码中，符号中心处总有一次转换，依据初始线路状态（高电平或低电平），即可判断转换方向，从而可使用 `wait` 指令在每个数据比特处重新同步线路转换。

本程序要求X寄存器和Y寄存器分别初始化为1和0，以便为 `in` 指令提供常量1或0。用于配置状态机的代码通过执行一些 `set` 指令初始化这些寄存器，然后启动程序运行。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.pio) 第74至94行

```
74 static inline void manchester_rx_program_init(PIO pio, uint sm, uint offset, uint pin, float
 div) {
75 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
76 pio_gpio_init(pio, pin);
77
78 pio_sm_config c = manchester_rx_program_get_default_config(offset);
79 sm_config_set_in_pins(&c, pin); // 用于WAIT
80 sm_config_set_jmp_pin(&c, pin); // 用于JMP
81 sm_config_set_in_shift(&c, true, true, 32);
82 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
83 sm_config_set_clkdiv(&c, div);
84 pio_sm_init(pio, sm, offset, &c);
85
86 // X 和 Y 被设置为0和1，以便于向ISR/FIFO发送这两个值。
87 pio_sm_exec(pio, sm, pio_encode_set(pio_x, 1));
88 pio_sm_exec(pio, sm, pio_encode_set(pio_y, 0));
89 // 假设线路空闲为低电平，且首个传输位为0。将状态机置于
90 // 启用前的等待状态。一旦检测到第一个0符号，RX将开始
91 // 接收。
92 pio_sm_exec(pio, sm, pio_encode_wait_pin(1, 0) | pio_encode_delay(2));
93 pio_sm_set_enabled(pio, sm, true);
94 }
```

SDK中的示例C程序将从GPIO2以约10 Mb/s的速率向GPIO3传输曼彻斯特编码的串行数据，前提是假设系统时钟为125 MHz。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester\\_encoding/manchester\\_encoding.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/manchester_encoding/manchester_encoding.c) 第20行至第43行

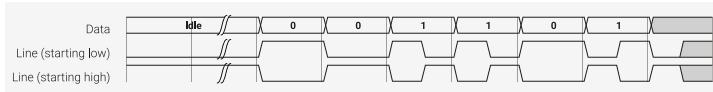

```
20 int main() {
21 stdio_init_all();
22
23 PIO pio = pio0;
24 uint sm_tx = 0;
25 uint sm_rx = 1;
26
27 uint offset_tx = pio_add_program(pio, &manchester_tx_program);
28 uint offset_rx = pio_add_program(pio, &manchester_rx_program);
29 printf("发送程序加载地址: %d\n", offset_tx);
30 printf("接收程序加载地址: %d\n", offset_rx);
31
32 manchester_tx_program_init(pio, sm_tx, offset_tx, pin_tx, 1.f);
33 manchester_rx_program_init(pio, sm_rx, offset_rx, pin_rx, 1.f);
34
35 pio_sm_set_enabled(pio, sm_tx, false);
36 pio_sm_put_blocking(pio, sm_tx, 0);
37 pio_sm_put_blocking(pio, sm_tx, 0x0ff0a55a);
38 pio_sm_put_blocking(pio, sm_tx, 0x12345678);
```

```

39 pio_sm_set_enabled(pio, sm_tx, true);
40
41 for (int i = 0; i < 3; ++i)
42 printf("%08x\n", pio_sm_get_blocking(pio, sm_rx));
43 }
```

## 11.6.6. Differential Manchester (BMC) TX and RX

*Figure 60. Differential Manchester serial line code, also known as biphase mark code (BMC). The line transitions at the start of every bit period. The presence of a transition in the centre of the bit period signifies a 1 data bit, and the absence, a 0 bit. These encoding rules are the same whether the line has an initial high or low state.*

The transmit program is similar to the Manchester example: it repeatedly shifts a bit from the OSR into X (relying on autopull to refill the OSR in the background), branches, and drives a GPIO up and down based on the value of this bit. The added complication is that the pattern we drive onto the pin depends not just on the value of the data bit, as with vanilla Manchester encoding, but also on the state the line was left in at the end of the last bit period. This is illustrated in [Figure 60](#), where the pattern is inverted if the line is initially high. To cope with this, there are two copies of the test-and-drive code, one for each initial line state, and these are linked together in the correct order by a sequence of jumps.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) Lines 8 - 35

```

8 .program differential_manchester_tx
9 .side_set 1 opt
10
11 ; Transmit one bit every 16 cycles. In each bit period:
12 ; - A '0' is encoded as a transition at the start of the bit period
13 ; - A '1' is encoded as a transition at the start *and* in the middle
14 ;
15 ; Side-set bit 0 must be mapped to the data output pin.
16 ; Autopull must be enabled.
17
18 public start:
19 initial_high:
20 out x, 1 ; Start of bit period: always assert transition
21 jmp !x high_0 side 1 [6] ; Test the data bit we just shifted out of OSR
22 high_1:
23 nop
24 jmp initial_high side 0 [6] ; For `1` bits, also transition in the middle
25 high_0:
26 jmp initial_low [7] ; Otherwise, the line is stable in the middle
27
28 initial_low:
29 out x, 1 ; Always shift 1 bit from OSR to X so we can
30 jmp !x low_0 side 0 [6] ; branch on it. Autopull refills OSR for us.
31 low_1:
32 nop
33 jmp initial_low side 1 [6] ; If there are two transitions, return to
34 low_0:
35 jmp initial_high [7] ; the initial line state is flipped!
```

The `.pio` file also includes a helper function to initialise a state machine for differential Manchester TX, and connect it to a chosen GPIO. We arbitrarily choose a 32-bit frame size and LSB-first serialisation (`shift_right` is true in `sm_config_set_out_shift`), but as the program operates on one bit at a time, we could change this by reconfiguring the state machine.

```

39 pio_sm_set_enabled(pio, sm_tx, true);
40
41 for (int i = 0; i < 3; ++i)
42 printf("%08x\n", pio_sm_get_blocking(pio, sm_rx));
43 }

```

### 11.6.6. 差分曼彻斯特编码（BMC）发送与接收

图60。差分曼彻斯特特串行线路编码，也称为双相标记编码（BMC）。

线路在每个

比特周期开始时发生跳变。

比特周期中间

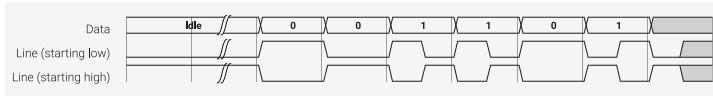

的跳变表示一个<sub>1</sub>数据位，

跳变的缺失表示

一个<sub>0</sub>位。无论

线路初始状态为高还是低，编码

规则均相同。

发送程序与曼彻斯特编码示例类似：它反复将位从OSR移入X寄存器（依赖自动拉取机制在后台填充OSR），执行分支，并根据该位的值驱动GPIO引脚电平上下跳变。

额外的复杂性在于，驱动引脚的信号模式不仅取决于数据位的值（如普通曼彻斯特编码），还取决于上一比特周期结束时线路的状态。这在图60中有所示，当线路初始为高电平时，模式被反转。为应对此情况，测试与驱动代码各有两份副本，分别对应每种初始线路状态，这些副本通过一系列跳转按正确顺序连接。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) 第8至35行

```

8 .program differential_manchester_tx
9 .side_set 1 opt
10
11 ; 每16个周期传输一位。在每个位周期内：
12 ; - ‘0’ 编码为位周期开始时发生跳变
13 ; - ‘1’ 编码为位周期开始及中间均发生跳变
14 ;
15 ; Side-set位0必须映射至数据输出引脚。
16 ; 必须启用Autopull功能。
17
18 public start:
19 initial_high:
20 out x, 1 ; 位周期开始：始终断言跳变
21 jmp !x high_0 side 1 [6] ; 测试我们刚刚从只读存储器（OSR）移出的数据位
22 high_1:
23 nop
24 jmp initial_high side 0 [6] ; 对于`1`位，也在中间发生跳变
25 high_0:
26 jmp initial_low [7] ; 否则，线路在中间保持稳定状态
27
28 initial_low:
29 out x, 1 ; 始终从只读存储器（OSR）向X寄存器移位1位，以便我们能
30 jmp !x low_0 side 0 [6] ; 依据该位进行分支。自动拉取功能会为我们重新填充OSR。
31 low_1:
32 nop
33 jmp initial_low side 1 [6] ; 如果有两次跳变，则返回
34 low_0:
35 jmp initial_high [7] ; 初始线路状态已翻转！

```

该.pio文件还包含一个辅助函数，用于初始化差分曼彻斯特TX的状态机，并将其连接到指定GPIO。我们任意选择了32位帧大小和LSB优先串行化（shift\_right 在 sm\_config\_set\_out\_shift 中设置为 true），但由于程序每次处理一位，我们可以通  
过重新配置状态机来更改此设置。

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) Lines 38 - 53

```

38 static inline void differential_manchester_tx_program_init(PIO pio, uint sm, uint offset,
39 uint pin, float div) {
40 pio_sm_set_pins_with_mask(pio, sm, 0, 1u << pin);
41 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
42 pio_gpio_init(pio, pin);
43
44 pio_sm_config c = differential_manchester_tx_program_get_default_config(offset);
45 sm_config_set_sideset_pins(&c, pin);
46 sm_config_set_out_shift(&c, true, true, 32);
47 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
48 sm_config_set_clkdiv(&c, div);
49 pio_sm_init(pio, sm, offset + differential_manchester_tx_offset_start, &c);
50
51 // Execute a blocking pull so that we maintain the initial line state until data is
52 // available
53 pio_sm_exec(pio, sm, pio_encode_pull(false, true));
54 pio_sm_set_enabled(pio, sm, true);
55 }
```

The RX program uses the following strategy:

1. Wait until the initial transition at the start of the bit period, so we stay aligned to the transmit clock
2. Then, wait 3/4 of the configured bit period, so that we are centred on the second half-bit-period (see [Figure 60](#))
3. Sample the line at this point to determine whether there are one or two transitions in this bit period
4. Repeat

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) Lines 55 - 85

```

55 .program differential_manchester_rx
56
57 ; Assumes line is idle low
58 ; One bit is 16 cycles. In each bit period:
59 ; - A '0' is encoded as a transition at time 0
60 ; - A '1' is encoded as a transition at time 0 and a transition at time T/2
61 ;
62 ; The IN mapping and the JMP pin select must both be mapped to the GPIO used for
63 ; RX data. Autopush must be enabled.
64
65 public start:
66 initial_high: ; Find rising edge at start of bit period
67 wait 1 pin, 0 [11] ; Delay to eye of second half-period (i.e 3/4 of way
68 jmp pin high_0 ; through bit) and branch on RX pin high/low.
69 high_1:
70 in x, 1 ; Second transition detected (a '1' data symbol)
71 jmp initial_high
72 high_0:
73 in y, 1 [1] ; Line still high, no centre transition (data is '0')
74 ; Fall-through
75
76 .wrap_target
77 initial_low: ; Find falling edge at start of bit period
78 wait 0 pin, 0 [11] ; Delay to eye of second half-period
79 jmp pin low_1
80 low_0:
81 in y, 1 ; Line still low, no centre transition (data is '0')
82 jmp initial_high
83 low_1: ; Second transition detected (data is '1')
84 in x, 1 [1]
```

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) 第38至53行

```

38 static inline void differential_manchester_tx_program_init(PIO pio, uint sm, uint offset,
 uint pin, float div) {
39 pio_sm_set_pins_with_mask(pio, sm, 0, 1u << pin);
40 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
41 pio_gpio_init(pio, pin);
42
43 pio_sm_config c = differential_manchester_tx_program_get_default_config(offset);
44 sm_config_set_sideset_pins(&c, pin);
45 sm_config_set_out_shift(&c, true, true, 32);
46 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_TX);
47 sm_config_set_clkdiv(&c, div);
48 pio_sm_init(pio, sm, offset + differential_manchester_tx_offset_start, &c);
49
50 // 执行阻塞式拉取，以保持初始线路状态直至数据可用
51
52 pio_sm_exec(pio, sm, pio_encode_pull(false, true));
53 pio_sm_set_enabled(pio, sm, true);
54 }
```

接收程序采用以下策略：

1. 等待位周期开始时的初始跳变，以维持与发送时钟的对齐
2. 随后，等待已配置位周期的3/4，以使采样位于第二个半位周期的中心（参见图60）
3. 此时采样线路，以判定该位周期内存在一处或两处跳变
4. 重复

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) 第55至85行

```

55 .program differential_manchester_rx
56
57 ; 假设线路空闲时为低电平
58 ; 一个比特周期为16个时钟周期。在每个比特周期内：
59 ; - '0' 通过在时间0处发生跳变进行编码
60 ; - '1' 通过在时间0和时间T/2处发生跳变进行编码
61 ;
62 ; IN映射和JMP引脚选择均必须映射至用于
63 ; 接收（RX）数据的GPIO引脚。必须启用自动推送（Autopush）。
64
65 public start:
66 initial_high: ; 在比特周期开始时检测上升沿
67 等待1号引脚, 0 [11]; 延时至半周期观察点（即3/4周期处）
68 跳转至 pin high_0 ; 比特周期）并根据RX引脚的高/低电平分支。
69 high_1:
70 输入x, 1 ; 检测到第二次跳变（数据符号`1`）
71 跳转至 initial_high
72 high_0:
73 输入y, 1 [1] ; 线路仍处于高电平，未发生中心跳变（数据为`0`）
74 ; 贯穿
75
76 .wrap_target
77 initial_low: ; 在位周期开始时检测下降沿
78 wait 0 pin, 0 [11]; 延时至半周期后半段的眼区
79 jmp pin low_1
80 low_0:
81 in y, 1 ; 线路仍处于低电平，未发生中心跳变（数据为`0`）
82 跳转至 initial_high
83 low_1: ; 检测到第二次跳变（数据为`1`）
84 in x, 1 [1]
```

```
85 .wrap
```

This code assumes that X and Y have the values 1 and 0, respectively. This is arranged for by the included C helper function:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) Lines 88 - 104

```
88 static inline void differential_manchester_rx_program_init(PIO pio, uint sm, uint offset,
 uint pin, float div) {
89 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
90 pio_gpio_init(pio, pin);
91
92 pio_sm_config c = differential_manchester_rx_program_get_default_config(offset);
93 sm_config_set_in_pins(&c, pin); // for WAIT
94 sm_config_set_jmp_pin(&c, pin); // for JMP
95 sm_config_set_in_shift(&c, true, true, 32);
96 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
97 sm_config_set_clkdiv(&c, div);
98 pio_sm_init(pio, sm, offset, &c);
99
100 // X and Y are set to 0 and 1, to conveniently emit these to ISR/FIFO.
101 pio_sm_exec(pio, sm, pio_encode_set(pio_x, 1));
102 pio_sm_exec(pio, sm, pio_encode_set(pio_y, 0));
103 pio_sm_set_enabled(pio, sm, true);
104 }
```

All the pieces now exist to loopback some serial data over a wire between two GPIOs.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.c)

```

29 printf("Receive program loaded at %d\n", offset_rx);
30 }
```

```
85 .wrap
```

此代码假设X和Y的值分别为1和0。该假设由所包含的C辅助函数进行设置：

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/pio/differential\\_manchester/differential\\_manchester.pio](https://github.com/raspberrypi/pico-examples/blob/master/pio/differential_manchester/differential_manchester.pio) 第88至104行

```
88 static inline void differential_manchester_rx_program_init(PIO pio, uint sm, uint offset,
89 uint pin, float div) {
90 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, false);
91 pio_gpio_init(pio, pin);
92
93 pio_sm_config c = differential_manchester_rx_program_get_default_config(offset);
94 sm_config_set_in_pins(&c, pin); // 用于WAIT
95 sm_config_set_jmp_pin(&c, pin); // 用于JMP
96 sm_config_set_in_shift(&c, true, true, 32);
97 sm_config_set_fifo_join(&c, PIO_FIFO_JOIN_RX);
98 sm_config_set_clkdiv(&c, div);
99 pio_sm_init(pio, sm, offset, &c);
100
101 // X 和 Y 分别设置为 0 和 1，便于将其发出至 ISR/FIFO。
102 pio_sm_exec(pio, sm, pio_encode_set(pio_x, 1));
103 pio_sm_exec(pio, sm, pio_encode_set(pio_y, 0));
104 pio_sm_set_enabled(pio, sm, true);
105 }
```

所有必要组件现已就绪，可在两根 GPIO 之间通过线路实现串行数据回环。

```

## 11.6.7. I2C

Figure 61. A 1-byte I2C read transfer. In the idle state, both lines float high. The initiator drives SDA low (a Start condition), followed by 7 address bits A6-A0, and a direction bit (Read/nWrite). The target drives SDA low to acknowledge the address (ACK). Data bytes follow. The target serialises data on SDA, clocked out by SCL. Every 9th clock, the initiator pulls SDA low to acknowledge the data, except on the last byte, where it leaves the line high (NAK). Releasing SDA whilst SCL is high is a Stop condition, returning the bus to idle.

I2C is an ubiquitous serial bus first described in the Dead Sea Scrolls, and later used by Philips Semiconductor. Two wires with pullup resistors form an open-drain bus, and multiple agents address and signal one another over this bus by driving the bus lines low, or releasing them to be pulled high. It has a number of unusual attributes:

- SCL can be held low at any time, for any duration, by any member of the bus (not necessarily the target or initiator of the transfer). This is known as clock stretching. The bus does not advance until all drivers release the clock.
- Members of the bus can be a target of one transfer and initiate other transfers (the master/slave roles are not fixed). However this is poorly supported by most I2C hardware.
- SCL is not an edge-sensitive clock, rather SDA must be valid the entire time SCL is high.
- In spite of the transparency of SDA against SCL, transitions of SDA whilst SCL is high are used to mark beginning and end of transfers (Start/Stop), or a new address phase within one (Restart).

The PIO program listed below handles serialisation, clock stretching, and checking of ACKs in the initiator role. It provides a mechanism for escaping PIO instructions in the FIFO datastream, to issue Start/Stop/Restart sequences at appropriate times. Provided no unexpected NAKs are received, this can perform long sequences of I2C transfers from a DMA buffer, without processor intervention.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/I2C/i2c.pio> Lines 8 - 73

```

8 .program i2c
9 .side_set 1 opt pindirs
10
11 ; TX Encoding:
12 ; | 15:10 | 9 | 8:1 | 0 |
13 ; | Instr | Final | Data | NAK |
14 ;
15 ; If Instr has a value n > 0, then this FIFO word has no
16 ; data payload, and the next n + 1 words will be executed as instructions.
17 ; Otherwise, shift out the 8 data bits, followed by the ACK bit.
18 ;
19 ; The Instr mechanism allows stop/start/restart sequences to be programmed
20 ; by the processor, and then carried out by the state machine at defined points
21 ; in the datastream.
22 ;
23 ; The "Final" field should be set for the final byte in a transfer.
24 ; This tells the state machine to ignore a NAK: if this field is not
25 ; set, then any NAK will cause the state machine to halt and interrupt.

```

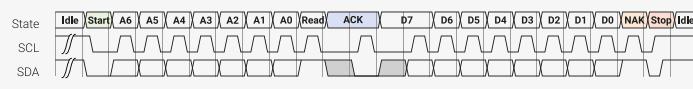

```

31 // 配置状态机, 设置比特率为 5 Mbps
32 differential_manchester_tx_program_init(pio, sm_tx, offset_tx, pin_tx, 125.f / (16 * 5));
33 differential_manchester_rx_program_init(pio, sm_rx, offset_rx, pin_rx, 125.f / (16 * 5));
34
35 pio_sm_set_enabled(pio, sm_tx, false);
36 pio_sm_put_blocking(pio, sm_tx, 0);
37 pio_sm_put_blocking(pio, sm_tx, 0x0ff0a55a);
38 pio_sm_put_blocking(pio, sm_tx, 0x12345678);
39 pio_sm_set_enabled(pio, sm_tx, true);
40
41 for (int i = 0; i < 3; ++i)
42 printf("%08x\n", pio_sm_get_blocking(pio, sm_rx));
43 }

```

## 11.6.7. I2C

图61。一次1字节的I2C读取传输。在空闲状态下，两个线路均处于上拉悬空状态。主控端将SDA拉低（起始条件），随后发送7位地址A6-A0及一个方向位（读/写）。从控端将SDA拉低以确认地址（ACK），随后传输数据字节。从控端在SDA线上串行发送数据，由SCL时钟驱动。每第9个时钟周期，主控端将SDA拉低以确认数据，除最后一个字节外，该字节主控端保持SDA高电平（NAK）。在SCL处于高电平时释放SDA即构成停止条件，使总线返回空闲状态。

I2C是一种广泛应用的串行总线，最早描述于死海古卷，后由飞利浦半导体采用。该总线由两根带上拉电阻的线组成开放漏极结构，多个设备通过拉低或释放线路实现寻址及信号传输。它具有多项非同寻常的属性：

- SCL可在任何时间、任何持续时间内，由总线上的任一成员保持为低电平（不一定是传输的目标或发起者）。此现象称为时钟延展（clock stretching）。总线在所有驱动器释放时钟之前不会前进。
- 总线成员既可作为一次传输的目标，又可发起其他传输（主/从角色并非固定不变）。然而，大多数I2C硬件对此支持较弱。
- SCL非边沿敏感时钟，SDA必须在SCL为高电平期间始终有效。
- 尽管SDA对SCL透明，但SDA在SCL高电平期间的跳变用于标示传输的开始与结束（即起始/停止），或同次传输中新地址阶段的开始（即重启）。

下述PIO程序在发起者角色中负责处理序列化、时钟延展及ACK检查。该程序提供一种机制，可在FIFO数据流中转义PIO指令，以便在适当时机发出起始/停止/重启序列。在未收到意外NAK的情况下，该功能可从DMA缓冲区执行长序列的I2C传输，无需处理器干预。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c.pio> 第8行至第73行

```

8 .program i2c
9 .side_set 1 opt pindirs
10
11 ; 发送编码：
12 ; | 15:10 | 9 | 8:1 | 0 |
13 ; | 指令 | 结束 | 数据 | NAK |
14 ;
15 ; 如果Instr的值n > 0，则该FIFO字无
16 ; 数据负载，接下来的n+1个字节将作为指令执行。
17 ; 否则，先移出8位数据，然后移出ACK位。
18 ;
19 ; Instr机制允许处理器编程停止/启动/重复启动序列，
20 ; 并由状态机在数据流中的指定点执行，
21 ;
22 ;
23 ; "Final"字段应设置于传输的最后一个字节。
24 ; 此字段指示状态机忽略NAK：若该字段未设置，
25 ; 任何NAK将导致状态机停止并产生中断。

```

```

26 ;
27 ; Autopull should be enabled, with a threshold of 16.
28 ; Autopush should be enabled, with a threshold of 8.
29 ; The TX FIFO should be accessed with halfword writes, to ensure
30 ; the data is immediately available in the OSR.
31 ;
32 ; Pin mapping:
33 ; - Input pin 0 is SDA, 1 is SCL (if clock stretching used)
34 ; - Jump pin is SDA
35 ; - Side-set pin 0 is SCL
36 ; - Set pin 0 is SDA
37 ; - OUT pin 0 is SDA
38 ; - SCL must be SDA + 1 (for wait mapping)
39 ;
40 ; The OE outputs should be inverted in the system IO controls!
41 ; (It's possible for the inversion to be done in this program,
42 ; but costs 2 instructions: 1 for inversion, and one to cope
43 ; with the side effect of the MOV on TX shift counter.)
44
45 do_nack:
46 jmp y-- entry_point ; Continue if NAK was expected
47 irq wait 0 rel ; Otherwise stop, ask for help
48
49 do_byte:
50 set x, 7 ; Loop 8 times
51 bitloop:
52 out pindirs, 1 [7] ; Serialise write data (all-ones if reading)
53 nop side 1 [2] ; SCL rising edge
54 wait 1 pin, 1 [4] ; Allow clock to be stretched
55 in pins, 1 [7] ; Sample read data in middle of SCL pulse
56 jmp x-- bitloop side 0 [7] ; SCL falling edge
57
58 ; Handle ACK pulse
59 out pindirs, 1 [7] ; On reads, we provide the ACK.
60 nop side 1 [7] ; SCL rising edge
61 wait 1 pin, 1 [7] ; Allow clock to be stretched
62 jmp pin do_nack side 0 [2] ; Test SDA for ACK/NAK, fall through if ACK
63
64 public entry_point:
65 .wrap_target
66 out x, 6 ; Unpack Instr count
67 out y, 1 ; Unpack the NAK ignore bit
68 jmp !x do_byte ; Instr == 0, this is a data record.
69 out null, 32 ; Instr > 0, remainder of this OSR is invalid
70 do_exec:
71 out exec, 16 ; Execute one instruction per FIFO word
72 jmp x-- do_exec ; Repeat n + 1 times
73 .wrap

```

The IO mapping required by the I2C program is quite complex, due to the different ways that the two serial lines must be driven and sampled. One interesting feature is that state machine must drive the output enable high when the output is low, since the bus is open-drain, so the sense of the data is inverted. This could be handled in the PIO program (e.g. `mov osr, ~osr`), but instead we can use the IO controls on RP2350 to perform this inversion in the GPIO muxes, saving an instruction.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c.pio> Lines 81 - 121

```

81 static inline void i2c_program_init(PIO pio, uint sm, uint offset, uint pin_sda, uint
82 pin_scl) {
83 assert(pin_scl == pin_sda + 1);
84 pio_sm_config c = i2c_program_get_default_config(offset);

```

```

26 ;
27 ; 应启用自动拉取功能，阈值设为 16。
28 ; 应启用自动推送功能，阈值设为 8。
29 ; 应使用半字写入访问 TX FIFO，以确保
30 ; 数据能立即在 OSR 中可用。
31 ;
32; 引脚映射:
33 ; - 输入引脚 0 为 SDA, 1 为 SCL (若使用时钟拉伸)
34; - 跳转引脚为 SDA
35; - 侧边设置引脚 0 为 SCL
36; - 设定引脚 0 为 SDA
37; - 输出引脚 0 为 SDA
38 ; - SCL 必须等于 SDA + 1 (用于等待映射)
39 ;
40 ; 系统 IO 控制中应对 OE 输出进行取反!
41 ; (在本程序中可执行取反,
42 ; 但将消耗 2 条指令：一条用于取反，另一条用于处理
43 ; 伴随 MOV 指令对 TX 移位计数器产生的副作用。
44
45 do_nack:
46 jmp y-- entry_point ; 如预期收到 NAK，则继续
47 irq wait 0 rel ; 否则停止，并寻求帮助
48
49 do_byte:
50 set x, 7 ; 循环8次
51 bitloop:
52 out pindirs, 1 [7] ; 序列化写入数据 (读取时全为 1)
53 nop side 1 [2] ; SCL 上升沿
54 wait 1 pin, 1 [4] ; 允许时钟拉伸
55 in pins, 1 [7] ; 在 SCL 脉冲中间采样读取的数据
56 jmp x-- bitloop side 0 [7] ; SCL 下降沿
57
58 ; 处理 ACK 脉冲
59 out pindirs, 1 [7] ; 读取时，我们提供ACK响应。
60 nop side 1 [7]; SCL 上升沿
61 wait 1 pin, 1 [7] ; 允许时钟拉伸
62 jmp 引脚 do_nack 侧 0 [2]; 测试 SDA 是否为 ACK／NAK，若为 ACK 则继续执行
63
64 公共入口点:
65 .wrap_target
66 out x, 6 ; 解包指令计数
67 out y, 1 ; 解包 NAK 忽略位
68 jmp !x do_byte ; 指令 == 0，此为数据记录。
69 out null, 32 ; 指令 > 0，此 OSR 余下部分无效
70 do_exec:
71 out exec, 16 ; 每个 FIFO 字执行一条指令
72 jmp x-- do_exec ; 重复 n+1 次
73 .wrap

```

I2C 程序所需的 IO 映射较为复杂，原因在于两条串行线路必须以不同方式进行驱动和采样。一个值得注意的特性是，状态机在输出为低电平时必须将输出使能置高，因总线采用开漏设计，数据的逻辑含义因此被反转。此项处理可在 PIO 程序中完成（例如 `mov osr, ~osr`），但我们也可利用 RP2350 的 IO 控制功能，在 GPIO 复用器中实现此反转，从而节省指令数。

Pico 示例地址：<https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c.pio>，范围为第 81 行至第 121 行

```

81 static inline void i2c_program_init(PIO pio, uint sm, uint offset, uint pin_sda, uint
82 pin_scl) {
83 assert(pin_scl == pin_sda + 1);
84 pio_sm_config c = i2c_program_get_default_config(offset);

```

```

84
85 // IO mapping
86 sm_config_set_out_pins(&c, pin_sda, 1);
87 sm_config_set_set_pins(&c, pin_sda, 1);
88 sm_config_set_in_pins(&c, pin_sda);
89 sm_config_set_sideset_pins(&c, pin_scl);
90 sm_config_set_jmp_pin(&c, pin_sda);
91
92 sm_config_set_out_shift(&c, false, true, 16);
93 sm_config_set_in_shift(&c, false, true, 8);
94
95 float div = (float)clock_get_hz(clk_sys) / (32 * 100000);
96 sm_config_set_clkdiv(&c, div);
97
98 // Try to avoid glitching the bus while connecting the IOs. Get things set
99 // up so that pin is driven down when PIO asserts OE low, and pulled up
100 // otherwise.
101 gpio_pull_up(pin_scl);
102 gpio_pull_up(pin_sda);
103 uint32_t both_pins = (1u << pin_sda) | (1u << pin_scl);
104 pio_sm_set_pins_with_mask(pio, sm, both_pins, both_pins);
105 pio_sm_set_pindirs_with_mask(pio, sm, both_pins, both_pins);
106 pio_gpio_init(pio, pin_sda);
107 pio_gpio_set_oeover(pin_sda, GPIO_OVERRIDE_INVERT);
108 pio_gpio_init(pio, pin_scl);
109 pio_gpio_set_oeover(pin_scl, GPIO_OVERRIDE_INVERT);
110 pio_sm_set_pins_with_mask(pio, sm, 0, both_pins);
111
112 // Clear IRQ flag before starting, and make sure flag doesn't actually
113 // assert a system-level interrupt (we're using it as a status flag)
114 pio_set_irq0_source_enabled(pio, (enum pio_interrupt_source) ((uint) pis_interrupt0 +
sm), false);
115 pio_set_irq1_source_enabled(pio, (enum pio_interrupt_source) ((uint) pis_interrupt0 +
sm), false);
116 pio_interrupt_clear(pio, sm);
117
118 // Configure and start SM
119 pio_sm_init(pio, sm, offset + i2c_offset_entry_point, &c);
120 pio_sm_set_enabled(pio, sm, true);
121 }

```

We can also use the PIO assembler to generate a table of instructions for passing through the FIFO, for Start/Stop/Restart conditions.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c.pio> Lines 126 - 136

```

126 .program set_scl_sda
127 .side_set 1 opt
128
129 ; Assemble a table of instructions which software can select from, and pass
130 ; into the FIFO, to issue START/STOP/RSTART. This isn't intended to be run as
131 ; a complete program.
132
133 set pindirs, 0 side 0 [7] ; SCL = 0, SDA = 0
134 set pindirs, 1 side 0 [7] ; SCL = 0, SDA = 1
135 set pindirs, 0 side 1 [7] ; SCL = 1, SDA = 0
136 set pindirs, 1 side 1 [7] ; SCL = 1, SDA = 1

```

The example code does blocking software IO on the state machine's FIFOs, to avoid the extra complexity of setting up the system DMA. For example, an I2C start condition is enqueued like so:

```

84
85 // IO 映射
86 sm_config_set_out_pins(&c, pin_sda, 1);
87 sm_config_set_set_pins(&c, pin_sda, 1);
88 sm_config_set_in_pins(&c, pin_sda);
89 sm_config_set_sideset_pins(&c, pin_scl);
90 sm_config_set_jmp_pin(&c, pin_sda);
91
92 sm_config_set_out_shift(&c, false, true, 16);
93 sm_config_set_in_shift(&c, false, true, 8);
94
95 float div = (float)clock_get_hz(clk_sys) / (32 * 100000);
96 sm_config_set_clkdiv(&c, div);
97
98 // 尽量避免在连接 IO 时引起总线毛刺。先将
99 // 设置为当 PIO 断言 OE 置低时引脚被拉低，并保持上拉
100 // 否则。
101 gpio_pull_up(pin_scl);
102 gpio_pull_up(pin_sda);
103 uint32_t both_pins = (1u << pin_sda) | (1u << pin_scl);
104 pio_sm_set_pins_with_mask(pio, sm, both_pins, both_pins);
105 pio_sm_set_pindirs_with_mask(pio, sm, both_pins, both_pins);
106 pio_gpio_init(pio, pin_sda);
107 gpio_set_oeover(pin_sda, GPIO_OVERRIDE_INVERT);
108 pio_gpio_init(pio, pin_scl);
109 gpio_set_oeover(pin_scl, GPIO_OVERRIDE_INVERT);
110 pio_sm_set_pins_with_mask(pio, sm, 0, both_pins);
111
112 // 启动前清除 IRQ 标志，并确保该标志不会实际
113 // 触发系统级中断（该标志仅作为状态标识）
114 pio_set_irq0_source_enabled(pio, (enum pio_interrupt_source) ((uint) pis_interrupt0 +
sm), false);
115 pio_set_irq1_source_enabled(pio, (enum pio_interrupt_source) ((uint) pis_interrupt0 +
sm), false);
116 pio_interrupt_clear(pio, sm);
117
118 // 配置并启动状态机
119 pio_sm_init(pio, sm, offset + i2c_offset_entry_point, &c);
120 pio_sm_set_enabled(pio, sm, true);
121 }

```

我们也可以使用PIO汇编器生成一张指令表，用于通过FIFO传递Start/Stop/Restart条件。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c.pio> 第126至136行

```

126 .program set_scl_sda
127 .side_set 1 opt
128
129 ; 组装一张指令表，软件可以从中选择，并将130；传入FIFO，以发出START/STOP/RSTART信号。此
程序并非设计为完整程序运行。131；
130
131
132
133 set pindirs, 0 side 0 [7] ; SCL = 0, SDA = 0
134 set pindirs, 1 side 0 [7] ; SCL = 0, SDA = 1
135 set pindirs, 0 side 1 [7] ; SCL = 1, SDA = 0
136 set pindirs, 1 side 1 [7] ; SCL = 1, SDA = 1

```

示例代码在状态机的 FIFO 上执行阻塞式软件 IO，以避免配置系统 DMA 的额外复杂性。例如，I2C 启动条件的入队如下：

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio\\_i2c.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio_i2c.c) Lines 69 - 74

```

69 void pio_i2c_start(PIO pio, uint sm) {
70 pio_i2c_put_or_err(pio, sm, 2u << PIO_I2C_ICOUNT_LSB); // Escape
 code for 3 instruction sequence
71 pio_i2c_put_or_err(pio, sm, set_scl_sda_program_instructions[I2C_SC1_SD0]); // We are
 already in idle state, just pull SDA low
72 pio_i2c_put_or_err(pio, sm, set_scl_sda_program_instructions[I2C_SC0_SD0]); // Also
 pull clock low so we can present data
73 pio_i2c_put_or_err(pio, sm, pio_encode_mov(pio_isr, pio_null)); // Ensure
 ISR counter is clear following a write
74 }
```

Because I2C can go wrong at so many points, we need to be able to check the error flag asserted by the state machine, clear the halt and restart it, before asserting a Stop condition and releasing the bus.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio\\_i2c.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio_i2c.c) Lines 15 - 17

```

15 bool pio_i2c_check_error(PIO pio, uint sm) {
16 return pio_interrupt_get(pio, sm);
17 }
```

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio\\_i2c.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio_i2c.c) Lines 19 - 23

```

19 void pio_i2c_resume_after_error(PIO pio, uint sm) {
20 pio_sm_drain_tx_fifo(pio, sm);
21 pio_sm_exec(pio, sm, (pio->sm[sm].execctrl & PIO_SM0_EXECCTRL_WRAP_BOTTOM_BITS) >>
 PIO_SM0_EXECCTRL_WRAP_BOTTOM_LSB);
22 pio_interrupt_clear(pio, sm);
23 }
```

We need some higher-level functions to pass correctly-formatted data though the FIFOs and insert Starts, Stops, NAKs and so on at the correct points. This is enough to present a similar interface to the other hardware I2Cs on RP2350.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c\\_bus\\_scan.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c_bus_scan.c) Lines 13 - 42

```

13 int main() {
14 stdio_init_all();
15
16 PIO pio = pio0;
17 uint sm = 0;
18 uint offset = pio_add_program(pio, &i2c_program);
19 i2c_program_init(pio, sm, offset, PIN_SDA, PIN_SCL);
20
21 printf("\nPIO I2C Bus Scan\n");
22 printf(" 0 1 2 3 4 5 6 7 8 9 A B C D E F\n");
23
24 for (int addr = 0; addr < (1 << 7); ++addr) {
25 if (addr % 16 == 0) {
26 printf("%02x ", addr);
27 }
28 // Perform a 0-byte read from the probe address. The read function
29 // returns a negative result NAK'd any time other than the last data
30 // byte. Skip over reserved addresses.
31 int result;
32 if (reserved_addr(addr))
33 result = -1;
34 else
```

Pico 示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio\\_i2c.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio_i2c.c) 第 69 至 74 行

```

69 void pio_i2c_start(PIO pio, uint sm) {
70 pio_i2c_put_or_err(pio, sm, 2u << PIO_I2C_ICOUNT_LSB); // 转义
 3条指令序列的代码
71 pio_i2c_put_or_err(pio, sm, set_scl_sda_program_instructions[I2C_SC1_SD0]); // 我们已处于空闲状态
 , 直接将SDA拉低
72 pio_i2c_put_or_err(pio, sm, set_scl_sda_program_instructions[I2C_SC0_SD0]); // 同时将时钟拉低以
 便传输数据
73 pio_i2c_put_or_err(pio, sm, pio_encode_mov(pio_isr, pio_null)); // 确保
 写入操作后_ISR计数器已清零
74 }
```

由于I2C在多个环节可能出错，必须能够检查状态机的错误标志，清除暂停状态并重新启动，随后才断言停止条件并释放总线。

Pico 示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio\\_i2c.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio_i2c.c) 第15至17行

```

15 bool pio_i2c_check_error(PIO pio, uint sm) {
16 return pio_interrupt_get(pio, sm);
17 }
```

Pico 示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio\\_i2c.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/pio_i2c.c) 第19至23行

```

19 void pio_i2c_resume_after_error(PIO pio, uint sm) {
20 pio_sm_drain_tx_fifo(pio, sm);
21 pio_sm_exec(pio, sm, (pio->sm[sm].execctrl & PIO_SM0_EXECCTRL_WRAP_BOTTOM_BITS) >>
 PIO_SM0_EXECCTRL_WRAP_BOTTOM_LSB);
22 pio_interrupt_clear(pio, sm);
23 }
```

我们需要一些更高级的函数，能够通过FIFO传递格式正确的数据，并在适当位置插入起始、停止、NAK等信号。这足以  
为RP2350上的其他硬件I2C提供类似的接口。

Pico示例: [https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c\\_bus\\_scan.c](https://github.com/raspberrypi/pico-examples/blob/master/pio/i2c/i2c_bus_scan.c) 第13至42行

```

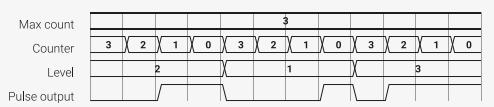

13 int main() {
14 stdio_init_all();
15
16 PIO pio = pio0;
17 uint sm = 0;
18 uint offset = pio_add_program(pio, &i2c_program);
19 i2c_program_init(pio, sm, offset, PIN_SDA, PIN_SCL);
20
21 printf("\nPIO I2C总线扫描\n");
22 printf(" 0 1 2 3 4 5 6 7 8 9 A B C D E F\n");
23
24 for (int addr = 0; addr < (1 << 7); ++addr) {
25 if (addr % 16 == 0) {
26 printf("%02x ", addr);
27 }
28 // 从探针地址执行 0 字节读取。读取函数
29 // 除最后一个数据字节外，任何时候都返回负结果 NAK。
30 // byte. 跳过保留地址。
31 int result;
32 if (reserved_addr(addr))
33 result = -1;
34 else
```

```

35 result = pio_i2c_read_blocking(pio, sm, addr, NULL, 0);
36
37 printf(result < 0 ? "." : "@");
38 printf(addr % 16 == 15 ? "\n" : " ");
39 }
40 printf("Done.\n");
41 return 0;
42 }
```

## 11.6.8. PWM

*Figure 62. Pulse width modulation (PWM). The state machine outputs positive voltage pulses at regular intervals. The width of these pulses is controlled, so that the line is high for some controlled fraction of the time (the duty cycle). One use of this is to smoothly vary the brightness of an LED, by pulsing it faster than human persistence of vision.*

This program repeatedly counts down to 0 with the Y register, whilst comparing the Y count to a pulse width held in the X register. The output is asserted low before counting begins, and asserted high when the value in Y reaches X. Once Y reaches 0, the process repeats, and the output is once more driven low. The fraction of time that the output is high is therefore proportional to the pulse width stored in X.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.pio> Lines 10 - 22

```

10 .program pwm
11 .side_set 1 opt
12
13 pull noblock side 0 ; Pull from FIFO to OSR if available, else copy X to OSR.
14 mov x, osr ; Copy most-recently-pulled value back to scratch X
15 mov y, isr ; ISR contains PWM period. Y used as counter.
16 countloop:
17 jmp x!=y noset ; Set pin high if X == Y, keep the two paths length matched
18 jmp skip side 1
19 noset:
20 nop ; Single dummy cycle to keep the two paths the same length
21 skip:
22 jmp y-- countloop ; Loop until Y hits 0, then pull a fresh PWM value from FIFO
```

Often, a PWM can be left at a particular pulse width for thousands of pulses, rather than supplying a new pulse width each time. This example highlights how a non-blocking **PULL** (Section 11.4.7) can achieve this: if the TX FIFO is empty, a non-blocking **PULL** will copy X to the OSR. After pulling, the program copies the OSR into X, so that it can be compared to the count value in Y. The net effect is that, if a new duty cycle value has not been supplied through the TX FIFO at the start of this period, the duty cycle from the previous period (which has been copied from X to OSR via the failed **PULL**, and then back to X via the **MOV**) is reused, for as many periods as necessary.

Another useful technique shown here is using the ISR as a configuration register, if **IN** instructions are not required. System software can load an arbitrary 32-bit value into the ISR (by executing instructions directly on the state machine), and the program will copy this value into Y each time it begins counting. The ISR can be used to configure the range of PWM counting, and the state machine's clock divider controls the rate of counting.

To start modulating some pulses, we first need to map the state machine's side-set pins to the GPIO we want to output PWM on, and tell the state machine where the program is loaded in the PIO instruction memory:

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.pio> Lines 25 - 31

```

25 static inline void pwm_program_init(PIO pio, uint sm, uint offset, uint pin) {
26 pio_gpio_init(pio, pin);
27 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);
```

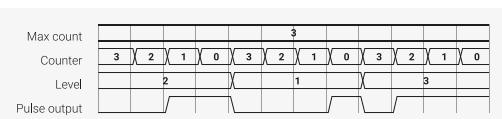

```

35 result = pio_i2c_read_blocking(pio, sm, addr, NULL, 0);
36
37 printf(result < 0 ? "." : "@");
38 printf(addr % 16 == 15 ? "\n" : " ");
39 }
40 printf("完成。\\n");
41 return 0;
42 }

```

### 11.6.8. PWM

图 62。脉宽调制（PWM）。状态机以固定时间间隔输出正电压脉冲。脉冲宽度受到控制，使线路在某一受控的时间比例内保持高电平（占空比）。此用法之一是通过以高于人类视觉暂留速度的频率脉冲控制LED，实现亮度的平滑调节。

该程序反复使用Y寄存器从指定数值倒计数至0，同时将Y寄存器中的计数值与存储于X寄存器的脉冲宽度进行比较。计数开始前，输出端保持低电平；当Y的值达到X时，输出端置为高电平。Y递减至0后，流程重复，输出端再次被拉低。因此，输出为高电平的时间比例与存储于X寄存器中的脉冲宽度成正比。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.pio> 第10至22行

```

10 .program pwm
11 .side_set 1 opt
12
13 pull noblock side 0 ; 若 FIFO 中有数据，则拉取至 OSR；否则复制 X 至 OSR。
14 mov x, osr ; 将最近拉取的数据复制回寄存器 X
15 mov y, isr ; ISR 包含 PWM 周期。Y 用作计数器。
16 countloop:
17 jmp x!=y noset ; 若 X == Y，则将引脚置高，保持两条路径长度匹配。
18 jmp skip 侧 1
19 noset:
20 nop ; 单个空指令周期以保持两条路径长度一致。
21 skip:
22 jmp y-- countloop ; 循环直到 Y 变为 0，然后从 FIFO 拉取新的 PWM 值。

```

通常，PWM 可在特定脉冲宽度保持数千个脉冲，无需每次都提供新的脉冲宽度。本示例展示了非阻塞 PULL（第 11.4.7 节）如何实现此功能：若 TX FIFO 为空，非阻塞 PULL 会将 X 复制到 OSR。拉取后，程序将 OSR 复制回 X，以供与 Y 中的计数值比较。最终效果是，若在该周期开始时 TX FIFO 未提供新的占空比值，则会重复使用（通过失败的 PULL 将 X 复制到 OSR，再通过 MOV 复制回 X 的）上一个周期的占空比值，重复使用所需的周期数。

这里展示的另一种有用技术是在不需要 IN 指令时，将 ISR 用作配置寄存器。

系统软件可以向 ISR 加载任意 32 位数值（通过直接在状态机上执行指令），程序将在每次开始计数时将该数值复制到 Y 寄存器。ISR 可用于配置 PWM 计数范围、状态机的时钟分频器控制计数速率。

要开始调制脉冲，首先需将状态机的 side-set 引脚映射至欲输出 PWM 的 GPIO，并告知状态机程序在 PIO 指令存储器中的加载位置：

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.pio> 第25至31行

```

25 static inline void pwm_program_init(PIO pio, uint sm, uint offset, uint pin) {
26 pio_gpio_init(pio, pin);
27 pio_sm_set_consecutive_pindirs(pio, sm, pin, 1, true);

```

```

28 pio_sm_config c = pwm_program_get_default_config(offset);
29 sm_config_set_sideset_pins(&c, pin);
30 pio_sm_init(pio, sm, offset, &c);
31 }
```

A little footwork is required to load the ISR with the desired counting range:

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.c> Lines 14 - 20

```

14 void pio_pwm_set_period(PIO pio, uint sm, uint32_t period) {
15 pio_sm_set_enabled(pio, sm, false);
16 pio_sm_put_blocking(pio, sm, period);
17 pio_sm_exec(pio, sm, pio_encode_pull(false, false));
18 pio_sm_exec(pio, sm, pio_encode_out(pio_isr, 32));
19 pio_sm_set_enabled(pio, sm, true);
20 }
```

Once this is done, the state machine can be enabled, and PWM values written directly to its TX FIFO.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.c> Lines 23 - 25

```

23 void pio_pwm_set_level(PIO pio, uint sm, uint32_t level) {
24 pio_sm_put_blocking(pio, sm, level);
25 }
```

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.c> Lines 27 - 51

```

27 int main() {
28 stdio_init_all();
29 #ifndef PICO_DEFAULT_LED_PIN
30 #warning pio/pwm example requires a board with a regular LED
31 puts("Default LED pin was not defined");
32 #else
33
34 // todo get free sm
35 PIO pio = pio0;
36 int sm = 0;
37 uint offset = pio_add_program(pio, &pwm_program);
38 printf("Loaded program at %d\n", offset);
39
40 pwm_program_init(pio, sm, offset, PICO_DEFAULT_LED_PIN);
41 pio_pwm_set_period(pio, sm, (1u << 16) - 1);
42
43 int level = 0;
44 while (true) {
45 printf("Level = %d\n", level);
46 pio_pwm_set_level(pio, sm, level * level);
47 level = (level + 1) % 256;
48 sleep_ms(10);
49 }
50 #endif
51 }
```

If the TX FIFO is kept topped up with fresh pulse width values, this program will consume a new pulse width for each pulse. Once the FIFO runs dry, the program will again start reusing the most recently supplied value.

```

28 pio_sm_config c = pwm_program_get_default_config(offset);
29 sm_config_set_sideset_pins(&c, pin);
30 pio_sm_init(pio, sm, offset, &c);
31 }
```

加载ISR以设置所需计数范围需要一定的准备工作：

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.c> 第14至20行

```

14 void pio_pwm_set_period(PIO pio, uint sm, uint32_t period) {
15 pio_sm_set_enabled(pio, sm, false);
16 pio_sm_put_blocking(pio, sm, period);
17 pio_sm_exec(pio, sm, pio_encode_pull(false, false));
18 pio_sm_exec(pio, sm, pio_encode_out(pio_isr, 32));
19 pio_sm_set_enabled(pio, sm, true);
20 }
```

一旦完成，状态机即可启用，并且 PWM 值可以直接写入其 TX FIFO。

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.c> 第23-25行

```

23 void pio_pwm_set_level(PIO pio, uint sm, uint32_t level) {
24 pio_sm_put_blocking(pio, sm, level);
25 }
```

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/pwm/pwm.c> 第27-51行

```

27 int main() {
28 stdio_init_all();
29 #ifndef PICO_DEFAULT_LED_PIN
30 #warning pio/pwm 示例需要带常规 LED 的开发板
31 puts("未定义默认 LED 引脚");
32 #else
33
34 // 待办 获取空闲的状态机
35 PIO pio = pio0;
36 int sm = 0;
37 uint offset = pio_add_program(pio, &pwm_program);
38 printf("Loaded program at %d\n", offset);
39
40 pwm_program_init(pio, sm, offset, PICO_DEFAULT_LED_PIN);
41 pio_pwm_set_period(pio, sm, (1u << 16) - 1);
42
43 int level = 0;
44 while (true) {
45 printf("Level = %d\n", level);
46 pio_pwm_set_level(pio, sm, level * level);
47 level = (level + 1) % 256;
48 sleep_ms(10);
49 }
50 #endif
51 }
```

若TX FIFO持续补充新脉冲宽度值，该程序将为每个脉冲消耗一个新的脉冲宽度。一旦FIFO耗尽，程序将重新使用最近提供的数值。

## 11.6.9. Addition

Although not designed for computation, PIO is quite likely Turing-complete, provided a long enough piece of tape can be found. It is conjectured that it could run DOOM, given a sufficiently high clock speed.

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/addition/addition.pio> Lines 7 - 25

```

7 .program addition
8
9 ; Pop two 32 bit integers from the TX FIFO, add them together, and push the
10 ; result to the TX FIFO. Autopush/pull should be disabled as we're using
11 ; explicit push and pull instructions.
12 ;
13 ; This program uses the two's complement identity x + y == ~(~x - y)
14
15 pull
16 mov x, ~osr
17 pull
18 mov y, osr
19 jmp test ; this loop is equivalent to the following C code:
20 incr: ; while (y--)
21 jmp x-- test ; x--;
22 test: ; This has the effect of subtracting y from x, eventually.
23 jmp y-- incr
24 mov isr, ~x
25 push

```

A full 32-bit addition takes only around one minute at 125 MHz. The program pulls two numbers from the TX FIFO and pushes their sum to the RX FIFO, which is perfect for use either with the system DMA, or directly by the processor:

Pico Examples: <https://github.com/raspberrypi/pico-examples/blob/master/pio/addition/addition.c>

```

1 /**

3 *
4 * SPDX-License-Identifier: BSD-3-Clause
5 */
6
7 #include <stdlib.h>
8 #include <stdio.h>
9
10 #include "pico/stl.h"
11 #include "hardware/pio.h"
12 #include "addition.pio.h"
13
14 // Pop quiz: how many additions does the processor do when calling this function
15 uint32_t do_addition(PIO pio, uint sm, uint32_t a, uint32_t b) {
16 pio_sm_put_blocking(pio, sm, a);
17 pio_sm_put_blocking(pio, sm, b);
18 return pio_sm_get_blocking(pio, sm);
19 }
20
21 int main() {
22 stdio_init_all();
23
24 PIO pio = pio0;
25 uint sm = 0;
26 uint offset = pio_add_program(pio, &addition_program);
27 addition_program_init(pio, sm, offset);
28
29 printf("Doing some random additions:\n");

```

### 11.6.9. 加法运算

尽管未设计用于计算，PIO极有可能是图灵完备的，前提是在纸带足够长的情况下。据推测，若时钟频率足够高，它可能能够运行DOOM。

Pico示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/addition/addition.pio> 第7至25行

```

7 .program addition
8
9 ;从TX FIFO中弹出两个32位整数，将它们相加，并将结果（10）推回TX FIFO。由于我们使用显式的
10 ;推送和弹出指令，故应禁用自动推送/弹出功能。
11 ;显式的推送和弹出指令。
12 ;
13 ;该程序使用二进制补码恒等式 $x + y == \sim(\sim x - y)$
14
15 pull
16 mov x, ~osr
17 pull
18 mov y, osr
19 jmp test ;该循环等同于以下C语言代码：
20 incr: ; while (y--)
21 jmp x-- test ; x--;
22 test: ;该循环最终实现了从x中减去y的效果。
23 jmp y-- incr
24 mov isr, ~x
25 push

```

一个完整的32位加法在125 MHz时钟下仅需约一分钟。程序从TX FIFO中读取两个数字，并将它们的和写入RX FIFO，这非常适合与系统DMA协作，或由处理器直接操作：

Pico 示例：<https://github.com/raspberrypi/pico-examples/blob/master/pio/addition/addition.c>

```

1 /**

6
7 #include <stdlib.h>
8 #include <stdio.h>
9
10 #include "pico/stl.h"
11 #include "hardware/pio.h"
12 #include "addition.pio.h"
13
14 // 快问快答：调用此函数时处理器执行了多少次加法？
15 uint32_t do_addition(PIO pio, uint sm, uint32_t a, uint32_t b) {
16 pio_sm_put_blocking(pio, sm, a);
17 pio_sm_put_blocking(pio, sm, b);
18 return pio_sm_get_blocking(pio, sm);
19 }
20
21 int main() {
22 stdio_init_all();
23
24 PIO pio = pio0;
25 uint sm = 0;
26 uint offset = pio_add_program(pio, &addition_program);
27 addition_program_init(pio, sm, offset);
28
29 printf("执行一些随机加法操作:\n");

```

```

30 for (int i = 0; i < 10; ++i) {
31 uint a = rand() % 100;
32 uint b = rand() % 100;
33 printf("%u + %u = %u\n", a, b, do_addition(pio, sm, a, b));
34 }
35 }
```

## 11.6.10. Further examples

[Raspberry Pi Pico-series C/C++ SDK](#) has a PIO chapter which goes into depth on some software-centric topics not presented here. It includes a PIO + DMA logic analyser example that can sample every GPIO on every cycle (a bandwidth of nearly 4Gbps at 125 MHz, although this does fill up RP2350's RAM somewhat quickly).

There are also further examples in the `pio/` directory in the [Pico Examples](#) repository.

Some of the more experimental example code, such as DPI and SD card support, is currently located in the [Pico Extras](#) and [Pico Playground](#) repositories. The PIO parts of these are functional, but the surrounding software stacks are still in an experimental state.

## 11.7. List of registers

The PIO0 and PIO1 registers start at base addresses of `0x50200000` and `0x50300000` respectively (defined as `PIO0_BASE` and `PIO1_BASE` in SDK).

Table 981. List of PIO registers

Offset	Name	Info
0x000	<a href="#">CTRL</a>	PIO control register
0x004	<a href="#">FSTAT</a>	FIFO status register
0x008	<a href="#">FDEBUG</a>	FIFO debug register
0x00c	<a href="#">FLEVEL</a>	FIFO levels
0x010	<a href="#">TXF0</a>	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO. Attempting to write to a full FIFO has no effect on the FIFO state or contents, and sets the sticky FDEBUG_TXOVER error flag for this FIFO.
0x014	<a href="#">TXF1</a>	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO. Attempting to write to a full FIFO has no effect on the FIFO state or contents, and sets the sticky FDEBUG_TXOVER error flag for this FIFO.
0x018	<a href="#">TXF2</a>	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO. Attempting to write to a full FIFO has no effect on the FIFO state or contents, and sets the sticky FDEBUG_TXOVER error flag for this FIFO.
0x01c	<a href="#">TXF3</a>	Direct write access to the TX FIFO for this state machine. Each write pushes one word to the FIFO. Attempting to write to a full FIFO has no effect on the FIFO state or contents, and sets the sticky FDEBUG_TXOVER error flag for this FIFO.

```

30 for (int i = 0; i < 10; ++i) {
31 uint a = rand() % 100;
32 uint b = rand() % 100;
33 printf("%u + %u = %u\n", a, b, do_addition(pio, sm, a, b));
34 }
35 }
```

### 11.6.10. 进一步示例

Raspberry Pi Pico系列C/C++ SDK包含一个PIO章节，详细介绍了此处未涉及的部分软件相关主题。其中包括一个PIO + DMA逻辑分析仪示例，能够在每个周期采样所有GPIO（在125 MHz时带宽接近4Gbps，但这会较快耗尽RP2350的RAM）。

在Pico示例库的 `pio/` 目录中还有更多示例。

部分更具实验性质的示例代码，如DPI和SD卡支持，当前存放于Pico Extras与Pico Playground代码库中。这些代码中的PIO部分功能完整，但相关软件栈仍处于实验状态。

## 11.7. 寄存器列表

PIO0和PIO1寄存器的基地址分别为 `0x50200000` 和 `0x50300000`（在SDK中定义为PIO0\_BASE和PIO1\_BASE）。

表981. PIO  
寄存器列表

偏移量	名称	说明
0x000	<code>CTRL</code>	PIO控制寄存器
0x004	<code>FSTAT</code>	FIFO状态寄存器
0x008	<code>FDEBUG</code>	FIFO调试寄存器
0x00c	<code>FLEVEL</code>	FIFO水位
0x010	<code>TXF0</code>	此状态机的TX FIFO的直接写访问端口。每次写入操作将向FIFO推送一个字。写入已满的FIFO不会改变FIFO状态或内容，并会为该FIFO设置粘性FDEBUG_TXOVER错误标志。
0x014	<code>TXF1</code>	此状态机的TX FIFO的直接写访问端口。每次写入操作将向FIFO推送一个字。写入已满的FIFO不会改变FIFO状态或内容，并会为该FIFO设置粘性FDEBUG_TXOVER错误标志。
0x018	<code>TXF2</code>	此状态机的TX FIFO的直接写访问端口。每次写入操作将向FIFO推送一个字。写入已满的FIFO不会改变FIFO状态或内容，并会为该FIFO设置粘性FDEBUG_TXOVER错误标志。
0x01c	<code>TXF3</code>	此状态机的TX FIFO的直接写访问端口。每次写入操作将向FIFO推送一个字。写入已满的FIFO不会改变FIFO状态或内容，并会为该FIFO设置粘性FDEBUG_TXOVER错误标志。

Offset	Name	Info
0x020	RXF0	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO. Attempting to read from an empty FIFO has no effect on the FIFO state, and sets the sticky FDEBUG_RXUNDER error flag for this FIFO. The data returned to the system on a read from an empty FIFO is undefined.
0x024	RXF1	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO. Attempting to read from an empty FIFO has no effect on the FIFO state, and sets the sticky FDEBUG_RXUNDER error flag for this FIFO. The data returned to the system on a read from an empty FIFO is undefined.
0x028	RXF2	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO. Attempting to read from an empty FIFO has no effect on the FIFO state, and sets the sticky FDEBUG_RXUNDER error flag for this FIFO. The data returned to the system on a read from an empty FIFO is undefined.
0x02c	RXF3	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO. Attempting to read from an empty FIFO has no effect on the FIFO state, and sets the sticky FDEBUG_RXUNDER error flag for this FIFO. The data returned to the system on a read from an empty FIFO is undefined.
0x030	IRQ	<p>State machine IRQ flags register. Write 1 to clear. There are eight state machine IRQ flags, which can be set, cleared, and waited on by the state machines. There's no fixed association between flags and state machines – any state machine can use any flag.</p> <p>Any of the eight flags can be used for timing synchronisation between state machines, using IRQ and WAIT instructions. Any combination of the eight flags can also be routed out to either of the two system-level interrupt requests, alongside FIFO status interrupts – see e.g. IRQ0_INTE.</p>
0x034	IRQ_FORCE	Writing a 1 to each of these bits will forcibly assert the corresponding IRQ. Note this is different to the INTF register: writing here affects PIO internal state. INTF just asserts the processor-facing IRQ signal for testing ISRs, and is not visible to the state machines.
0x038	INPUT_SYNC_BYPASS	<p>There is a 2-flipflop synchronizer on each GPIO input, which protects PIO logic from metastabilities. This increases input delay, and for fast synchronous IO (e.g. SPI) these synchronizers may need to be bypassed. Each bit in this register corresponds to one GPIO.</p> <p>0 → input is synchronized (default)      1 → synchronizer is bypassed      If in doubt, leave this register as all zeroes.</p>
0x03c	DBG_PADOUT	Read to sample the pad output values PIO is currently driving to the GPIOs. On RP2040 there are 30 GPIOs, so the two most significant bits are hardwired to 0.
0x040	DBG_PADOE	Read to sample the pad output enables (direction) PIO is currently driving to the GPIOs. On RP2040 there are 30 GPIOs, so the two most significant bits are hardwired to 0.

偏移量	名称	说明
0x020	RXF0	对该状态机的RX FIFO进行直接读取访问。每次读取会从FIFO弹出一个字。尝试从空FIFO读取不会影响FIFO状态，但会为该FIFO设置粘滞的FDEBUG_RXUNDER错误标志。从空FIFO读取返回的数据未定义。
0x024	RXF1	对该状态机的RX FIFO进行直接读取访问。每次读取会从FIFO弹出一个字。尝试从空FIFO读取不会影响FIFO状态，但会为该FIFO设置粘滞的FDEBUG_RXUNDER错误标志。从空FIFO读取返回的数据未定义。
0x028	RXF2	对该状态机的RX FIFO进行直接读取访问。每次读取会从FIFO弹出一个字。尝试从空FIFO读取不会影响FIFO状态，但会为该FIFO设置粘滞的FDEBUG_RXUNDER错误标志。从空FIFO读取返回的数据未定义。
0x02c	RXF3	对该状态机的RX FIFO进行直接读取访问。每次读取会从FIFO弹出一个字。尝试从空FIFO读取不会影响FIFO状态，但会为该FIFO设置粘滞的FDEBUG_RXUNDER错误标志。从空FIFO读取返回的数据未定义。
0x030	IRQ	状态机IRQ标志寄存器。写入1以清除。共有八个状态机IRQ标志，状态机可设置、清除并等待这些标志。标志与状态机之间无固定对应关系——任何状态机均可使用任一标志。  这八个标志中的任意一个均可用于状态机间的时序同步，结合IRQ和WAIT指令使用。这八个标志的任意组合也可与FIFO状态中断一起路由至两个系统级中断请求中的任意一个——详见如IRQ0_INTE。
0x034	IRQ_FORCE	向这些位写入1会强制激活对应IRQ。请注意，这与INTF寄存器不同： 此处写入会影响PIO内部状态。INTF仅用于断言面向处理器的IRQ信号以测试ISR，对状态机不可见。
0x038	INPUT_SYNC_BYPASS	每个GPIO输入端设有两级触发器同步器，以保护PIO逻辑免受亚稳态影响。这会增加输入延迟，对于高速同步IO（例如SPI），可能需要绕过这些同步器。该寄存器的每个位对应一个GPIO。  0 → 输入同步（默认） 1 → 同步器已绕过 若不确定，请将此寄存器保持全零。
0x03c	DBG_PADOUT	读取此寄存器以采样PIO当前驱动至GPIO的端口输出值。RP2040上共有30个GPIO，因此最高两位硬连线为0。
0x040	DBG_PADOE	读取此寄存器以采样PIO当前驱动至GPIO的端口输出使能（方向）。RP2040上共有30个GPIO，因此最高两位硬连线为0。

## PIO：CTRL 寄存器

偏移: 0x000

### 描述

PIO 控制寄存器

表 982. CTRL  
寄存器

位	描述	类型	复位
31:27	保留。	-	-
26	<b>NEXTPREV_CLKDIV_RESTART:</b> 写入 1 以重启相邻 PIO 块中状态机的时钟分频器，相邻关系由同一写入操作中的 NEXT_PIO_MASK 和 PREV_PIO_MASK 指定。  这相当于向这些 PIO 的 CTRL 寄存器中对应的 CLKDIV_RESTART 位写入 1。	SC	0x0
25	<b>NEXTPREV_SM_DISABLE:</b> 写入 1 以禁用相邻 PIO 块中的状态机，相邻关系由同一写入操作中的 NEXT_PIO_MASK 和 PREV_PIO_MASK 指定。  这相当于清除这些 PIO 的 CTRL 寄存器中对应的 SM_ENABLE 位。	SC	0x0
24	<b>NEXTPREV_SM_ENABLE:</b> 写入 1 以启用相邻 PIO 块中的状态机，相邻关系由同一写入操作中的 NEXT_PIO_MASK 和 PREV_PIO_MASK 指定。  这相当于在这些 PIO 的 CTRL 寄存器中设置相应的 SM_ENABLE 位。  如果同时设置了 OTHERS_SM_ENABLE 和 OTHERS_SM_DISABLE，则以禁用为优先。	SC	0x0

Bits	Description	Type	Reset
23:20	<p><b>NEXT_PIO_MASK:</b> A mask of state machines in the neighbouring higher-numbered PIO block in the system (or PIO block 0 if this is the highest-numbered PIO block) to which to apply the operations specified by NEXTPREV_CLKDIV_RESTART, NEXTPREV_SM_ENABLE, and NEXTPREV_SM_DISABLE in the same write.</p> <p>This allows state machines in a neighbouring PIO block to be started/stopped/clock-synced exactly simultaneously with a write to this PIO block's CTRL register.</p> <p>Note that in a system with two PIOs, NEXT_PIO_MASK and PREV_PIO_MASK actually indicate the same PIO block. In this case the effects are applied cumulatively (as though the masks were OR'd together).</p> <p>Neighbouring PIO blocks are disconnected (status signals tied to 0 and control signals ignored) if one block is accessible to NonSecure code, and one is not.</p>	SC	0x0
19:16	<p><b>PREV_PIO_MASK:</b> A mask of state machines in the neighbouring lower-numbered PIO block in the system (or the highest-numbered PIO block if this is PIO block 0) to which to apply the operations specified by OP_CLKDIV_RESTART, OP_ENABLE, OP_DISABLE in the same write.</p> <p>This allows state machines in a neighbouring PIO block to be started/stopped/clock-synced exactly simultaneously with a write to this PIO block's CTRL register.</p> <p>Neighbouring PIO blocks are disconnected (status signals tied to 0 and control signals ignored) if one block is accessible to NonSecure code, and one is not.</p>	SC	0x0
15:12	Reserved.	-	-
11:8	<p><b>CLKDIV_RESTART:</b> Restart a state machine's clock divider from an initial phase of 0. Clock dividers are free-running, so once started, their output (including fractional jitter) is completely determined by the integer/fractional divisor configured in SMx_CLKDIV. This means that, if multiple clock dividers with the same divisor are restarted simultaneously, by writing multiple 1 bits to this field, the execution clocks of those state machines will run in precise lockstep.</p> <p>Note that setting/clearing SM_ENABLE does not stop the clock divider from running, so once multiple state machines' clocks are synchronised, it is safe to disable/reenable a state machine, whilst keeping the clock dividers in sync.</p> <p>Note also that CLKDIV_RESTART can be written to whilst the state machine is running, and this is useful to resynchronise clock dividers after the divisors (SMx_CLKDIV) have been changed on-the-fly.</p>	SC	0x0

位	描述	类型	复位
23:20	<p><b>NEXT_PIO_MASK:</b> 系统中邻近、编号更高的PIO块（如果当前为最高编号PIO块，则为PIO块0）中状态机的掩码，用于在同一次写操作中应用NEXTPREV_CLKDIV_RESTART、NEXTPREV_SM_ENABLE和NEXTPREV_SM_DISABLE所指定的操作。</p> <p>该机制允许邻近PIO块中的状态机在写入此PIO块的CTRL寄存器时，实现启动、停止及时钟同步的完全同步。</p> <p>需注意，含有两个PIO的系统中，NEXT_PIO_MASK和PREV_PIO_MASK实际上指向同一PIO块。在此情况下，效果以累积方式施加（等同于对这些掩码进行按位或操作）。</p> <p>当一个PIO块允许非安全代码访问而另一个不允许时，邻近PIO块会被断开（状态信号被拉低至0，且控制信号被忽略）。</p>	SC	0x0
19:16	<p><b>PREV_PIO_MASK:</b> 系统中相邻编号较低的PIO块（若当前为PIO块0，则指编号最高的PIO块）中的状态机掩码，用以在同一次写入操作中对由OP_CLKDIV_RESTART、OP_ENABLE及OP_DISABLE指定的操作施加影响。</p> <p>该机制允许邻近PIO块中的状态机在写入此PIO块的CTRL寄存器时，实现启动、停止及时钟同步的完全同步。</p> <p>当一个PIO块允许非安全代码访问而另一个不允许时，邻近PIO块会被断开（状态信号被拉低至0，且控制信号被忽略）。</p>	SC	0x0
15:12	保留。	-	-
11:8	<p><b>CLKDIV_RESTART:</b> 从初始相位0重新启动状态机的时钟分频器。时钟分频器为自由运行状态，启动后其输出（包括分数抖动）完全由SMx_CLKDIV中配置的整数/分数除数决定。由此可知，若通过向该字段写入多个‘1’位同时重启多个除数相同的时钟分频器，则这些状态机的执行时钟将实现精确锁步。</p> <p>请注意，设置或清除SM_ENABLE不会停止时钟分频器的运行，因此一旦多个状态机的时钟同步，即便禁用或重新启用某一状态机，只要保持时钟分频器同步仍是安全的。</p> <p>另请注意，CLKDIV_RESTART 可在状态机运行时写入，这对于在分频器（SMx_CLKDIV）动态更改后重新同步时钟分频器非常有用。</p>	SC	0x0

Bits	Description	Type	Reset
7:4	<p><b>SM_RESTART:</b> Write 1 to instantly clear internal SM state which may be otherwise difficult to access and will affect future execution.</p> <p>Specifically, the following are cleared: input and output shift counters; the contents of the input shift register; the delay counter; the waiting-on-IRQ state; any stalled instruction written to SMx_INSTR or run by OUT/MOV EXEC; any pin write left asserted due to OUT_STICKY.</p> <p>The contents of the output shift register and the X/Y scratch registers are not affected.</p>	SC	0x0
3:0	<p><b>SM_ENABLE:</b> Enable/disable each of the four state machines by writing 1/0 to each of these four bits. When disabled, a state machine will cease executing instructions, except those written directly to SMx_INSTR by the system.</p> <p>Multiple bits can be set/cleared at once to run/halt multiple state machines simultaneously.</p>	RW	0x0

## PIO: FSTAT Register

Offset: 0x004

### Description

FIFO status register

Table 983. FSTAT Register

Bits	Description	Type	Reset
31:28	Reserved.	-	-

23:20	Reserved.	-	-
19:16	<b>TXFULL:</b> State machine TX FIFO is full	RO	0x0
15:12	Reserved.	-	-
11:8	<b>RXEMPTY:</b> State machine RX FIFO is empty	RO	0xf
7:4	Reserved.	-	-
3:0	<b>RXFULL:</b> State machine RX FIFO is full	RO	0x0

## PIO: FDEBUG Register

Offset: 0x008

### Description

FIFO debug register

Table 984. FDEBUG Register

Bits	Description	Type	Reset
31:28	Reserved.	-	-
27:24	<b>TXSTALL:</b> State machine has stalled on empty TX FIFO during a blocking PULL, or an OUT with autopull enabled. Write 1 to clear.	WC	0x0
23:20	Reserved.	-	-

位	描述	类型	复位
7:4	<p><b>SM_RESTART</b>: 写入1以立即清除内部状态机状态，该状态可能难以访问且将影响未来的执行。</p> <p>具体而言，将清除以下内容：输入和输出移位计数器；输入移位寄存器的内容；延迟计数器；等待IRQ的状态；写入SMx_INSTR或通过OUT/MOV EXEC执行的任何被阻塞指令；任何因OUT_STICKY而持续保持激活的引脚写操作。</p> <p>输出移位寄存器及X/Y暂存寄存器的内容不受影响。</p>	SC	0x0
3:0	<p><b>SM_ENABLE</b>: 通过对这四个位分别写入1或0来启用或禁用四个状态机中的每一个。禁用时，状态机将停止执行指令，除非该指令由系统直接写入SMx_INSTR。</p> <p>可以同时设置或清除多个位，以实现多个状态机的并行运行或停止。</p>	读写	0x0

## PIO: FSTAT 寄存器

偏移: 0x004

### 说明

FIFO 状态寄存器

表 983。FSTAT 寄存器

位	描述	类型	复位
31:28	保留。	-	-
27:24	<b>TXEMPTY</b> : 状态机 TX FIFO 为空	只读	0xf
23:20	保留。	-	-
19:16	<b>TXFULL</b> : 状态机 TX FIFO 已满	只读	0x0
15:12	保留。	-	-
11:8	<b>RXEMPTY</b> : 状态机 RX FIFO 为空	只读	0xf
7:4	保留。	-	-
3:0	<b>RXFULL</b> : 状态机 RX FIFO 已满	只读	0x0

## PIO: FDEBUG 寄存器

偏移: 0x008

### 说明

FIFO 调试寄存器

表 984。FDEBUG 寄存器

位	描述	类型	复位
31:28	保留。	-	-
27:24	<b>TXSTALL</b> : 状态机在阻塞 PULL 操作期间因 TX FIFO 为空，或在启用自动拉取的 OUT 操作中而停止。写入 1 以清除。	WC	0x0
23:20	保留。	-	-

Bits	Description	Type	Reset
19:16	<b>TXOVER:</b> TX FIFO overflow (i.e. write-on-full by the system) has occurred. Write 1 to clear. Note that write-on-full does not alter the state or contents of the FIFO in any way, but the data that the system attempted to write is dropped, so if this flag is set, your software has quite likely dropped some data on the floor.	WC	0x0
15:12	Reserved.	-	-
11:8	<b>RXUNDER:</b> RX FIFO underflow (i.e. read-on-empty by the system) has occurred. Write 1 to clear. Note that read-on-empty does not perturb the state of the FIFO in any way, but the data returned by reading from an empty FIFO is undefined, so this flag generally only becomes set due to some kind of software error.	WC	0x0
7:4	Reserved.	-	-
3:0	<b>RXSTALL:</b> State machine has stalled on full RX FIFO during a blocking PUSH, or an IN with autopush enabled. This flag is also set when a nonblocking PUSH to a full FIFO took place, in which case the state machine has dropped data. Write 1 to clear.	WC	0x0

## PIO: FLEVEL Register

Offset: 0x00c

### Description

FIFO levels

Table 985. FLEVEL Register

Bits	Description	Type	Reset

TXF1, TXF2, TXF3  
寄存器

位	描述	类型	复位
31:0	此状态机的 TX FIFO 的直接写访问端口。每次写入操作将向 FIFO 推送一个字。写入已满的 FIFO 不会改变 FIFO 状态或内容，并会为该 FIFO 设置粘性 FDEB UG_TXOVER 错误标志。	WF	0x00000000

## PIO: RXF0、RXF1、RXF2、RXF3 寄存器

偏移: 0x020, 0x024, 0x028, 0x02c

Table 987. RXF0,  
RXF1, RXF2, RXF3  
Registers

Bits	Description	Type	Reset
31:0	Direct read access to the RX FIFO for this state machine. Each read pops one word from the FIFO. Attempting to read from an empty FIFO has no effect on the FIFO state, and sets the sticky FDEBUG_RXUNDER error flag for this FIFO. The data returned to the system on a read from an empty FIFO is undefined.	RF	-

## PIO: IRQ Register

Offset: 0x030

Table 988. IRQ  
Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	<p>State machine IRQ flags register. Write 1 to clear. There are eight state machine IRQ flags, which can be set, cleared, and waited on by the state machines. There's no fixed association between flags and state machines – any state machine can use any flag.</p> <p>Any of the eight flags can be used for timing synchronisation between state machines, using IRQ and WAIT instructions. Any combination of the eight flags can also routed out to either of the two system-level interrupt requests, alongside FIFO status interrupts – see e.g. IRQ0_INTE.</p>	WC	0x00

## PIO: IRQ\_FORCE Register

Offset: 0x034

Table 989. IRQ\_FORCE  
Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	<p>Writing a 1 to each of these bits will forcibly assert the corresponding IRQ. Note this is different to the INTF register: writing here affects PIO internal state. INTF just asserts the processor-facing IRQ signal for testing ISRs, and is not visible to the state machines.</p>	WF	0x00

## PIO: INPUT\_SYNC\_BYPASS Register

Offset: 0x038

Table 990.  
INPUT\_SYNC\_BYPASS  
Register

Bits	Description	Type	Reset
31:0	<p>There is a 2-flipflop synchronizer on each GPIO input, which protects PIO logic from metastabilities. This increases input delay, and for fast synchronous IO (e.g. SPI) these synchronizers may need to be bypassed. Each bit in this register corresponds to one GPIO.</p> <p>0 → input is synchronized (default) 1 → synchronizer is bypassed If in doubt, leave this register as all zeroes.</p>	RW	0x00000000

## PIO: DBG\_PADOUT Register

Offset: 0x03C

表987。RXF0,  
RXF1, RXF2, RXF3  
寄存器

位	描述	类型	复位
31:0	对该状态机的RX FIFO进行直接读取访问。每次读取将从FIFO弹出一个字。尝试从空的FIFO读取不会改变FIFO的状态，但会为该FIFO设置粘滞的FDEBUG_RXUNDER错误标志。 从空的FIFO读取返回给系统的数据是未定义的。	RF	-

## PIO：IRQ寄存器

偏移量：0x030

表988。IRQ  
寄存器

位	描述	类型	复位
31:8	保留。	-	-
7:0	状态机IRQ标志寄存器。写入1以清除。共有八个状态机IRQ标志，状态机可设置、清除并等待这些标志。标志与状态机之间无固定对应关系——任何状态机均可使用任一标志。  这八个标志中的任意一个均可用于状态机间的时序同步，结合IRQ和WAIT指令使用。这八个标志的任意组合也可与FIFO状态中断一起路由至两个系统级中断请求中的任意一个——详见如IRQ0_INTE。	WC	0x00

## PIO：IRQ\_FORCE寄存器

偏移：0x034

表989。IRQ\_FORCE  
寄存器

位	描述	类型	复位
31:8	保留。	-	-
7:0	向这些位写入1将强制触发对应的IRQ。 注意，此处不同于INTF寄存器：在此写入会影响PIO的内部状态。INTF仅用于断言面向处理器的IRQ信号以测试ISR，对状态机不可见。	WF	0x00

## PIO：INPUT\_SYNC\_BYPASS寄存器

偏移量：0x038

表990。  
INPUT\_SYNC\_BYPASS  
寄存器

位	描述	类型	复位
31:0	每个GPIO输入端设有两级触发器同步器，以保护PIO逻辑免受亚稳态影响。这会增加输入延迟，对于高速同步IO（例如SPI），可能需要绕过这些同步器。 该寄存器的每个位对应一个GPIO。  0 → 输入同步（默认） 1 → 同步器已绕过 若不确定，请将此寄存器保持全零。	读写	0x00000000

## PIO：DBG\_PADOUT寄存器

偏移量：0x03c

Table 991.  
DBG\_PADOUT Register

Bits	Description	Type	Reset
31:0	Read to sample the pad output values PIO is currently driving to the GPIOs. On RP2040 there are 30 GPIOs, so the two most significant bits are hardwired to 0.	RO	0x00000000

## PIO: DBG\_PADOUT Register

Offset: 0x040

Offsets: 0x0c8, 0x0e0, 0x0f8, 0x110

### Description

Clock divisor register for state machine  $N$

Frequency = clock freq / (CLKDIV\_INT + CLKDIV\_FRAC / 256)

Table 995.  
*SM0\_CLKDIV,  
 SM1\_CLKDIV,  
 SM2\_CLKDIV,  
 SM3\_CLKDIV  
 Registers*

Bits	Description	Type	Reset
31:16	<b>INT:</b> Effective frequency is sysclk/(int + frac/256). Value of 0 is interpreted as 65536. If INT is 0, FRAC must also be 0.	RW	0x0001
15:8	<b>FRAC:</b> Fractional part of clock divisor	RW	0x00
7:0	Reserved.	-	-

## PIO: SM0\_EXECCTRL, SM1\_EXECCTRL, SM2\_EXECCTRL, SM3\_EXECCTRL Registers

Offsets: 0x0cc, 0x0e4, 0x0fc, 0x114

### Description

Execution/behavioural settings for state machine  $N$

Table 996.  
*SM0\_EXECCTRL,  
 SM1\_EXECCTRL,  
 SM2\_EXECCTRL,  
 SM3\_EXECCTRL  
 Registers*

Bits	Description	Type	Reset
31	<b>EXEC_STALLED:</b> If 1, an instruction written to SMx_INSTR is stalled, and latched by the state machine. Will clear to 0 once this instruction completes.	RO	0x0
30	<b>SIDE_EN:</b> If 1, the MSB of the Delay/Side-set instruction field is used as side-set enable, rather than a side-set data bit. This allows instructions to perform side-set optionally, rather than on every instruction, but the maximum possible side-set width is reduced from 5 to 4. Note that the value of PINCTRL_SIDESET_COUNT is inclusive of this enable bit.	RW	0x0
29	<b>SIDE_PINDIR:</b> If 1, side-set data is asserted to pin directions, instead of pin values	RW	0x0
28:24	<b>JMP_PIN:</b> The GPIO number to use as condition for JMP PIN. Unaffected by input mapping.	RW	0x00
23:19	<b>OUT_EN_SEL:</b> Which data bit to use for inline OUT enable	RW	0x00
18	<b>INLINE_OUT_EN:</b> If 1, use a bit of OUT data as an auxiliary write enable When used in conjunction with OUT_STICKY, writes with an enable of 0 will deassert the latest pin write. This can create useful masking/override behaviour due to the priority ordering of state machine pin writes (SM0 < SM1 < ...)	RW	0x0
17	<b>OUT_STICKY:</b> Continuously assert the most recent OUT/SET to the pins	RW	0x0
16:12	<b>WRAP_TOP:</b> After reaching this address, execution is wrapped to wrap_bottom. If the instruction is a jump, and the jump condition is true, the jump takes priority.	RW	0x1f

偏移量: 0x0c8、0x0e0、0x0f8、0x110

### 描述

状态机  $N$  的时钟分频寄存器

频率 = 时钟频率 / (CLKDIV\_INT + CLKDIV\_FRAC / 256)

表995。  
 $SM0\_CLKDIV$ ,  
 $SM1\_CLKDIV$ ,  
 $SM2\_CLKDIV$ ,  
 $SM3\_CLKDIV$  寄存器

位	描述	类型	复位
31:16	<b>INT:</b> 有效频率为 sysclk/(int + frac/256)。 值为0时，表示为65536。若 INT 为0，则 FRAC 也必须为0。	读写	0x0001
15:8	<b>FRAC:</b> 时钟分频器的分数部分	读写	0x00
7:0	保留。	-	-

## PIO: SM0\_EXECCTRL, SM1\_EXECCTRL, SM2\_EXECCTRL, SM3\_EXECCTRL 寄存器

偏移地址: 0x0cc, 0x0e4, 0x0fc, 0x114

### 描述

状态机的执行/行为设置  $N$

表996。  
 $SM0\_EXECCTRL$ ,  
 $SM1\_EXECCTRL$ ,  
 $SM2\_EXECCTRL$ ,  
 $SM3\_EXECCTRL$  寄存器

位	描述	类型	复位
31	<b>EXEC_STALLED:</b> 若为1，写入 $SMx\_INSTR$ 的指令将被阻塞，并由状态机锁存。指令完成后，将自动清零为0。	只读	0x0
30	<b>SIDE_EN:</b> 如果为1，延迟/侧边设置指令字段的最高有效位 (MSB) 将作为侧边设置启用位，而非侧边设置数据位。这允许指令可选择执行侧边设置，而非每条指令均执行，然而最大侧边设置宽度会由5位减少至4位。请注意，PINCTRL_SIDESET_COUNT 的数值包含此启用位。	读写	0x0
29	<b>SIDE_PINDIR:</b> 如果为1，侧边设置数据将用作引脚方向信号，而非引脚数值。	读写	0x0
28:24	<b>JMP_PIN:</b> 用作 JMP PIN 条件的 GPIO 编号，且不受输入映射影响。	读写	0x00
23:19	<b>OUT_EN_SEL:</b> 指定用于内联 OUT 使能的数据位。	读写	0x00
18	<b>INLINE_OUT_EN:</b> 如果为1，使用 OUT 数据位中的一位作为辅助写入使能。与 OUT_STICKY 结合使用时，使能为0的写入操作将撤销最近一次的引脚写入。此机制可实现有效的掩码及覆盖行为。  上述行为源于状态机引脚写入的优先级顺序 ( $SM0 < SM1 < \dots$ )。	读写	0x0
17	<b>OUT_STICKY:</b> 持续断言最近的 OUT/SET 信号至引脚	读写	0x0
16:12	<b>WRAP_TOP:</b> 达到该地址后，执行将回绕至 wrap_bottom。  若指令为跳转且跳转条件满足，则跳转操作优先执行。	读写	0x1f

Bits	Description	Type	Reset
11:7	<b>WRAP_BOTTOM</b> : After reaching wrap_top, execution is wrapped to this address.	RW	0x00
6:5	<b>STATUS_SEL</b> : Comparison used for the MOV x, STATUS instruction.	RW	0x0
	Enumerated values:		
	0x0 → TXLEVEL: All-ones if TX FIFO level < N, otherwise all-zeroes		
	0x1 → RXLEVEL: All-ones if RX FIFO level < N, otherwise all-zeroes		
	0x2 → IRQ: All-ones if the indexed IRQ flag is raised, otherwise all-zeroes		
4:0	<b>STATUS_N</b> : Comparison level or IRQ index for the MOV x, STATUS instruction.  If STATUS_SEL is TXLEVEL or RXLEVEL, then values of STATUS_N greater than the current FIFO depth are reserved, and have undefined behaviour.	RW	0x00
	Enumerated values:		
	0x00 → IRQ: Index 0-7 of an IRQ flag in this PIO block		
	0x08 → IRQ_PREVPIO: Index 0-7 of an IRQ flag in the next lower-numbered PIO block		
	0x10 → IRQ_NEXTPIO: Index 0-7 of an IRQ flag in the next higher-numbered PIO block		

## PIO: SM0\_SHIFTCTRL, SM1\_SHIFTCTRL, SM2\_SHIFTCTRL, SM3\_SHIFTCTRL Registers

Offsets: 0x0d0, 0x0e8, 0x100, 0x118

### Description

Control behaviour of the input/output shift registers for state machine N

Table 997.  
SM0\_SHIFTCTRL,  
SM1\_SHIFTCTRL,  
SM2\_SHIFTCTRL,  
SM3\_SHIFTCTRL  
Registers

Bits	Description	Type	Reset
31	<b>FJOIN_RX</b> : When 1, RX FIFO steals the TX FIFO's storage, and becomes twice as deep.  TX FIFO is disabled as a result (always reads as both full and empty). FIFOs are flushed when this bit is changed.	RW	0x0
30	<b>FJOIN_TX</b> : When 1, TX FIFO steals the RX FIFO's storage, and becomes twice as deep.  RX FIFO is disabled as a result (always reads as both full and empty). FIFOs are flushed when this bit is changed.	RW	0x0
29:25	<b>PULL_THRESH</b> : Number of bits shifted out of OSR before autopull, or conditional pull (PULL IFEMPTY), will take place.  Write 0 for value of 32.	RW	0x00
24:20	<b>PUSH_THRESH</b> : Number of bits shifted into ISR before autopush, or conditional push (PUSH IFFULL), will take place.  Write 0 for value of 32.	RW	0x00
19	<b>OUT_SHIFTDIR</b> : 1 = shift out of output shift register to right. 0 = to left.	RW	0x1
18	<b>IN_SHIFTDIR</b> : 1 = shift input shift register to right (data enters from left). 0 = to left.	RW	0x1

位	描述	类型	复位
11:7	<b>WRAP_BOTTOM</b> : 达到 wrap_top 后，执行将回绕至该地址。	读写	0x00
6:5	<b>STATUS_SEL</b> : 用于 MOV x, STATUS 指令的比较选择。	读写	0x0
	枚举值：		
	0x0 → TXLEVEL: 当 TX FIFO 水平低于 N 时全为1，否则全为0		
	0x1 → RXLEVEL: 当 RX FIFO 水平低于 N 时全为1，否则全为0		
	0x2 → IRQ: 当索引的 IRQ 标志被触发时全为1，否则全为0		
4:0	<b>STATUS_N</b> : 用于 MOV x, STATUS 指令的比较级别或 IRQ 索引。 若 STATUS_SEL 为 TXLEVEL 或 RXLEVEL，则 STATUS_N 大于当前 FIFO 深度的值视为保留，行为未定义。	读写	0x00
	枚举值：		
	0x00 → IRQ: 此PIO块中IRQ标志的索引0-7		
	0x08 → IRQ_PREVPIO: 编号较低的PIO块中IRQ标志的索引0-7		
	0x10 → IRQ_NEXTPIO: 编号较高的PIO块中IRQ标志的索引0-7		

## PIO: SM0\_SHIFTCTRL, SM1\_SHIFTCTRL, SM2\_SHIFTCTRL, SM3\_SHIFTCTRL 寄存器

偏移: 0x0d0, 0x0e8, 0x100, 0x118

### 描述

控制状态机N输入/输出移位寄存器的行为

表997。  
SM0\_SHIFTCTRL,  
SM1\_SHIFTCTRL,  
SM2\_SHIFTCTRL,  
SM3\_SHIFTCTRL  
寄存器

位	描述	类型	复位
31	<b>FJOIN_RX</b> : 当值为1时，RX FIFO将占用TX FIFO的存储空间，深度加倍。  因此TX FIFO被禁用（始终显示为既满又空）。 当此位发生改变时，FIFO将被刷新。	读写	0x0
30	<b>FJOIN_TX</b> : 当该位为1时，TX FIFO将占用RX FIFO的存储空间，其深度加倍。  RX FIFO因此被禁用（其状态始终同时被读为满和空）。 当此位发生改变时，FIFO将被刷新。	读写	0x0
29:25	<b>PULL_THRESH</b> : 在自动拉取或条件拉取（PULL IFEMPTY）发生之前，从OSR移出的位数。 写入值32时实际写入0。	读写	0x00
24:20	<b>PUSH_THRESH</b> : 在自动推送或条件推送（PUSH IFFULL）发生之前，推入ISR的位数。 写入值32时实际写入0。	读写	0x00
19	<b>OUT_SHIFTDIR</b> : 1表示输出移位寄存器向右移，0表示向左移。	读写	0x1
18	<b>IN_SHIFTDIR</b> : 1表示输入移位寄存器向右移（数据从左侧进入），0表示向左移。	读写	0x1

Bits	Description	Type	Reset
17	<b>AUTOPULL:</b> Pull automatically when the output shift register is emptied, i.e. on or following an OUT instruction which causes the output shift counter to reach or exceed PULL_THRESH.	RW	0x0
16	<b>AUTOPUSH:</b> Push automatically when the input shift register is filled, i.e. on an IN instruction which causes the input shift counter to reach or exceed PUSH_THRESH.	RW	0x0
15	<p><b>FJOIN_RX_PUT:</b> If 1, disable this state machine's RX FIFO, make its storage available for random write access by the state machine (using the <code>put</code> instruction) and, unless FJOIN_RX_GET is also set, random read access by the processor (through the RXFx_PUTGETy registers).</p> <p>If FJOIN_RX_PUT and FJOIN_RX_GET are both set, then the RX FIFO's registers can be randomly read/written by the state machine, but are completely inaccessible to the processor.</p> <p>Setting this bit will clear the FJOIN_TX and FJOIN_RX bits.</p>	RW	0x0
14	<p><b>FJOIN_RX_GET:</b> If 1, disable this state machine's RX FIFO, make its storage available for random read access by the state machine (using the <code>get</code> instruction) and, unless FJOIN_RX_PUT is also set, random write access by the processor (through the RXFx_PUTGETy registers).</p> <p>If FJOIN_RX_PUT and FJOIN_RX_GET are both set, then the RX FIFO's registers can be randomly read/written by the state machine, but are completely inaccessible to the processor.</p> <p>Setting this bit will clear the FJOIN_TX and FJOIN_RX bits.</p>	RW	0x0
13:5	Reserved.	-	-
4:0	<p><b>IN_COUNT:</b> Set the number of pins which are not masked to 0 when read by an IN PINS, WAIT PIN or MOV x, PINS instruction.</p> <p>For example, an IN_COUNT of 5 means that the 5 LSBs of the IN pin group are visible (bits 4:0), but the remaining 27 MSBs are masked to 0. A count of 32 is encoded with a field value of 0, so the default behaviour is to not perform any masking.</p> <p>Note this masking is applied in addition to the masking usually performed by the IN instruction. This is mainly useful for the MOV x, PINS instruction, which otherwise has no way of masking pins.</p>	RW	0x00

## PIO: SM0\_ADDR, SM1\_ADDR, SM2\_ADDR, SM3\_ADDR Registers

Offsets: 0x0dc, 0x0f4, 0x10c, 0x124

### Description

State machine pin control

Table 1000.  
**SM0\_PINCTRL,  
SM1\_PINCTRL,  
SM2\_PINCTRL,  
SM3\_PINCTRL Registers**

Bits	Description	Type	Reset
31:29	<b>SIDESET_COUNT:</b> The number of MSBs of the Delay/Side-set instruction field which are used for side-set. Inclusive of the enable bit, if present. Minimum of 0 (all delay bits, no side-set) and maximum of 5 (all side-set, no delay).	RW	0x0
28:26	<b>SET_COUNT:</b> The number of pins asserted by a SET. In the range 0 to 5 inclusive.	RW	0x5
25:20	<b>OUT_COUNT:</b> The number of pins asserted by an OUT PINS, OUT PINDIRS or MOV PINS instruction. In the range 0 to 32 inclusive.	RW	0x00
19:15	<b>IN_BASE:</b> The pin which is mapped to the least-significant bit of a state machine's IN data bus. Higher-numbered pins are mapped to consecutively more-significant data bits, with a modulo of 32 applied to pin number.	RW	0x00
14:10	<b>SIDESET_BASE:</b> The lowest-numbered pin that will be affected by a side-set operation. The MSBs of an instruction's side-set/delay field (up to 5, determined by SIDESET_COUNT) are used for side-set data, with the remaining LSBs used for delay. The least-significant bit of the side-set portion is the bit written to this pin, with more-significant bits written to higher-numbered pins.	RW	0x00
9:5	<b>SET_BASE:</b> The lowest-numbered pin that will be affected by a SET PINS or SET PINDIRS instruction. The data written to this pin is the least-significant bit of the SET data.	RW	0x00
4:0	<b>OUT_BASE:</b> The lowest-numbered pin that will be affected by an OUT PINS, OUT PINDIRS or MOV PINS instruction. The data written to this pin will always be the least-significant bit of the OUT or MOV data.	RW	0x00

**RXF0\_PUTGET0 Register**

Bits	Description	Type	Reset
31:0	Direct read/write access to entry 0 of SM0's RX FIFO, if SHIFTCTRL_FJOIN_RX_PUT xor SHIFTCTRL_FJOIN_RX_GET is set.	RW	0x00000000

## PIO: RXF0\_PUTGET1 Register

Offset: 0x12c

表 999。  
**SM0\_INSTR,**  
**SM1\_INSTR,**  
**SM2\_INSTR,**  
**SM3\_INSTR 寄存器**

位	描述	类型	复位
31:16	保留。	-	-
15:0	读取以查看状态机 N 程序计数器当前指向的指令。  写入以立即执行指令（包括跳转），随后恢复执行。	读写	-

## PIO: SM0\_PINCTRL、SM1\_PINCTRL、SM2\_PINCTRL、SM3\_PINCTRL 寄存器

偏移量: 0x0dc、0x0f4、0x10c、0x124

### 描述

状态机引脚控制

表 1000。  
**SM0\_PINCTRL,**  
**SM1\_PINCTRL,**  
**SM2\_PINCTRL,**  
**SM3\_PINCTRL 寄存器**

位	描述	类型	复位
31:29	<b>SIDESET_COUNT:</b> 延迟/附加设置指令字段中用于附加设置的最高有效位数。包含启用位（如存在）。最少为0（所有延迟位，无侧置），最多为5（所有侧置，无延迟）。	读写	0x0
28:26	<b>SET_COUNT:</b> 由SET断言的引脚数量。范围为0至5（含）。	读写	0x5
25:20	<b>OUT_COUNT:</b> 由OUT PINS、OUT PINDIRS或MOV PINS指令断言的引脚数量。范围为0至32（含）。	读写	0x00
19:15	<b>IN_BASE:</b> 映射到状态机IN数据总线最低有效位的引脚。编号较高的引脚依次映射到更高有效位，且对引脚编号应用模32运算。	读写	0x00
14:10	<b>SIDESET_BASE:</b> 受侧置操作影响的编号最低的引脚。指令侧置/延迟字段的最高有效位（最多5位，由SIDESET_COUNT决定）用于侧置数据，剩余最低有效位用于延迟。侧置部分的最低有效位写入此引脚，更高有效位写入编号更高的引脚。	读写	0x00
9:5	<b>SET_BASE:</b> 将受 SET PINS 或 SET PINDIRS 指令影响的编号最低的引脚。写入此引脚的数据是 SET 数据的最低有效位。	读写	0x00
4:0	<b>OUT_BASE:</b> 将受 OUT PINS、OUT PINDIRS 或 MOV PINS 指令影响的编号最低的引脚。写入此引脚的数据始终是 OUT 或 MOV 数据的最低有效位。	读写	0x00

# Chapter 12. Peripherals

## 12.1. UART

### Arm documentation

Excerpted from the [PrimeCell UART \(PL011\) Technical Reference Manual](#). Used with permission.

RP2350 has 2 identical instances of a UART peripheral, based on the Arm Primecell UART (PL011) (Revision r1p5).

Each instance supports the following features:

- Separate 32×8 TX and 32×12 RX FIFOs
- Programmable baud rate generator, clocked by `clk_peri` (see [Figure 33](#))
- Standard asynchronous communication bits (start, stop, parity) added on transmit and removed on receive
- Line break detection
- Programmable serial interface (5, 6, 7, or 8 bits)
- 1 or 2 stop bits
- Programmable hardware flow control

Each UART can be connected to a number of GPIO pins as defined in the GPIO muxing [table](#) in [Section 9.4](#). Connections to the GPIO muxing use a prefix including the UART instance name `uart0_` or `uart1_`, and include the following:

- Transmit data `tx` (referred to as `UARTTXD` in the following sections)
- Received data `rx` (referred to as `UARTRXD` in the following sections)
- Output flow control `rts` (referred to as `nUARTRTS` in the following sections)
- Input flow control `cts` (referred to as `nUARTCTS` in the following sections)

The modem mode and IrDA mode of the PL011 are not supported.

The `UARTCLK` is driven from `clk_peri`, and `PCLK` is driven from the system clock `clk_sys` (see [Figure 33](#)).

### 12.1.1. Overview

The UART performs:

- Serial-to-parallel conversion on data received from a peripheral device
- Parallel-to-serial conversion on data transmitted to the peripheral device

The CPU reads and writes data and control/status information through the AMBA APB interface. The transmit and receive paths are buffered with internal FIFO memories that store up to 32 bytes independently in both transmit and receive modes.

The UART:

- Includes a programmable baud rate generator that generates a common transmit and receive internal clock from the UART internal reference clock input, `UARTCLK`
- Offers similar functionality to the industry-standard 16C650 UART device
- Supports a maximum baud rate of `UARTCLK` / 16 in UART mode (7.8 Mbaud at 125MHz)

# 第12章 外设

## 12.1. UART

Arm 文档

摘自 PrimeCell UART (PL011) 技术参考手册，已获授权使用。

RP2350 配备两个基于 Arm PrimeCell UART (PL011) (版本 r1p5) 的相同 UART 外设实例。

每个实例支持以下功能：

- 独立的 32×8 发送 (TX) 和 32×12 接收 (RX) FIFO
- 可编程波特率发生器，时钟源为 `clk_peri` (见图33)
- 标准异步通信位（起始位、停止位、奇偶校验），发送时添加，接收时移除
- 线路中断检测
- 可编程串行接口（5、6、7 或 8 位）
- 1 或 2 个停止位
- 可编程硬件流控

每个 UART 均可连接至多个 GPIO 引脚，详见第9.4节的 GPIO 复用表。GPIO 复用连接使用 UART 实例名称为前缀 `uart0_` 或 `uart1_`，包含以下内容：

- 传输数据 `tx` (在以下章节中称为 `UARTTXD`)
- 接收数据 `rx` (在以下章节中称为 `UARTRXD`)
- 输出流控制 `rts` (在以下章节中称为 `nUARTRTS`)
- 输入流控制 `cts` (在以下章节中称为 `nUARTCTS`)。PL011的调制解调器

模式和IrDA模式不被支持。

`UARTCLK`由`clk_peri`驱动，`PCLK`由系统时钟 `clk_sys`驱动 (参见图33)。

### 12.1.1. 概述

UART执行以下功能：

- 对从外围设备接收的数据进行串行转并行转换。
- 对传输至外围设备的数据进行并行转串行转换。

CPU通过AMBA APB接口读写数据及控制/状态信息。收发路径均配备内部FIFO缓存器，在发送和接收模式中独立存储最多32字节。

UART具备以下功能：

- 包含一个可编程波特率发生器，从UART内部参考时钟输入 `UARTCLK`产生通用的发送和接收内部时钟
- 提供与行业标准16C650 UART设备类似的功能
- 支持UART模式下最大波特率为 `UARTCLK / 16` (在125MHz时为7.8 Mbaud)

The UART operation and baud rate values are controlled by the Line Control Register ([UARTLCR\\_H](#)) and the baud rate divisor registers: Integer Baud Rate Register ([UARTIBRD](#)), and Fractional Baud Rate Register ([UARTFBRD](#)).

The UART can generate:

- Individually maskable interrupts from the receive (including timeout), transmit, modem status and error conditions
- A single combined interrupt so that the output is asserted if any of the individual interrupts are asserted and unmasked
- DMA request signals for interfacing with a Direct Memory Access (DMA) controller

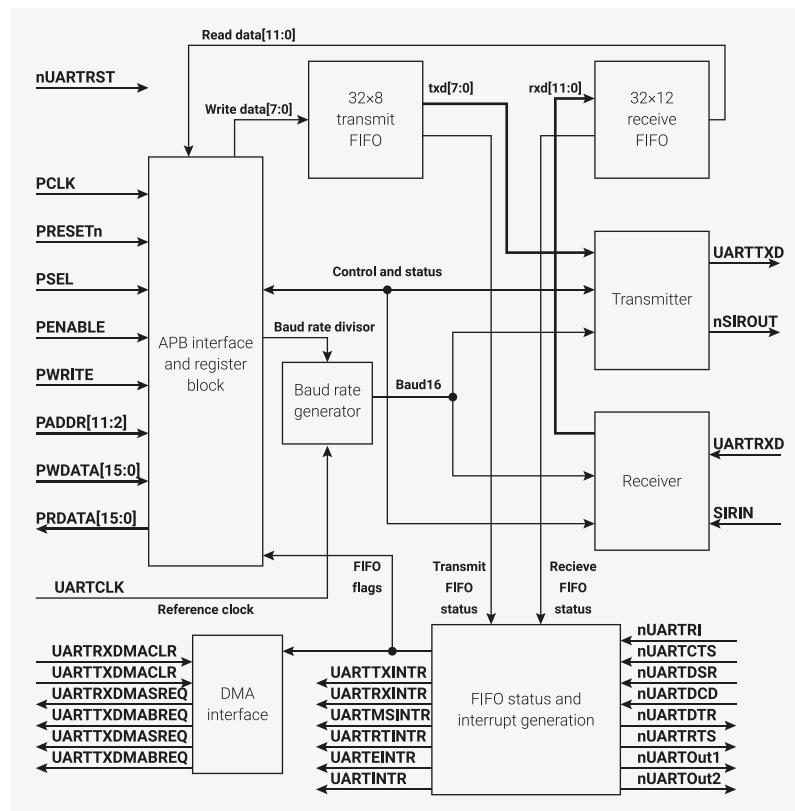

If a framing, parity, or break error occurs during reception, the appropriate error bit is set and stored in the FIFO. If an overrun condition occurs, the overrun register bit is set immediately and FIFO data is prevented from being overwritten.

You can program the FIFOs to be 1-byte deep providing a conventional double-buffered UART interface.

There is a programmable hardware flow control feature that uses the [nUARTCTS](#) input and the [nUARTRTS](#) output to automatically control the serial data flow.

## 12.1.2. Functional description

Figure 63. UART block diagram. Test logic is not shown for clarity.

### 12.1.2.1. AMBA APB interface

The AMBA APB interface generates read and write decodes for accesses to status/control registers, and the transmit and receive FIFOs.

### 12.1.2.2. Register block

The register block stores data written, or to be read across the AMBA APB interface.

UART的操作及波特率数值由行控制寄存器（**UARTLCR\_H**）和波特率除数寄存器：整数波特率寄存器（**UARTIBRD**）及分数波特率寄存器（**UARTFBRD**）控制。

UART可产生：

- 可单独屏蔽的来自接收（包括超时）、发送、调制解调器状态及错误条件的中断
- 单一组合中断，若任何单独中断被触发且未屏蔽，则该输出被断言
- 用于与直接存储器访问（DMA）控制器接口的DMA请求信号

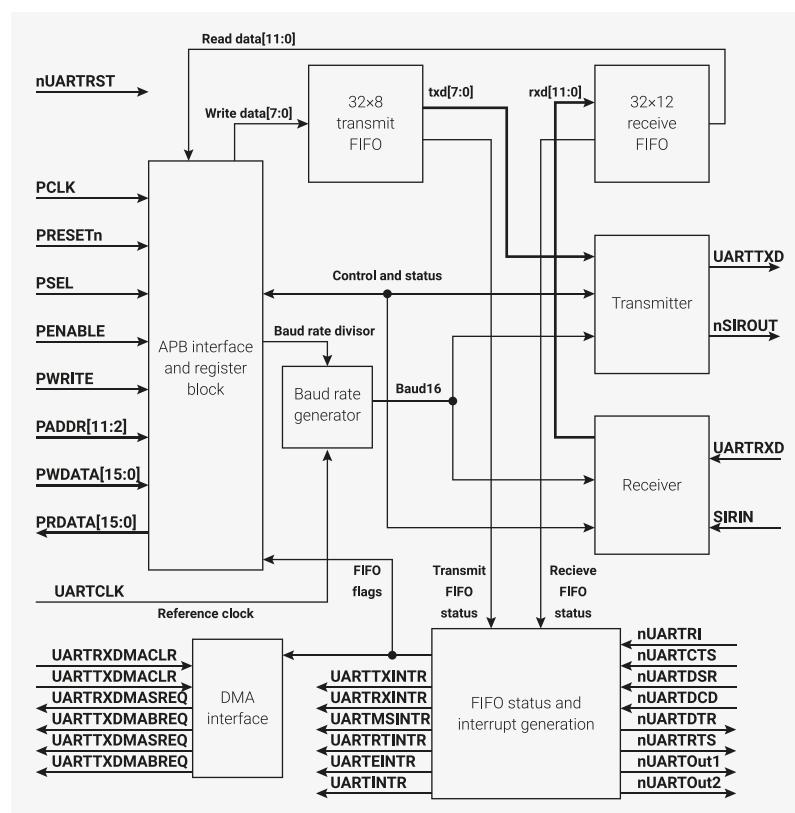

若接收过程中发生帧错误、奇偶校验错误或中断错误，相应错误位将被设置并存储于FIFO中。若发生溢出情况，溢出寄存器位会立即被设置，且会阻止FIFO数据被覆盖。

您可以将FIFO配置为1字节深度，以提供传统的双缓冲UART接口。

具备可编程硬件流控制功能，利用 **nUARTCTS** 输入和 **nUARTRTS** 输出自动控制串行数据流。

## 12.1.2. 功能描述

图 63. UART 方框图  
为清晰起见，未显示测试逻辑

### 12.1.2.1. AMBA APB接口

AMBA APB接口为访问状态/控制寄存器及发送和接收FIFO生成读写译码信号。

### 12.1.2.2. 寄存器块

寄存器块存储通过AMBA APB接口写入或将被读取的数据。

### 12.1.2.3. Baud rate generator

The baud rate generator contains free-running counters that generate the internal clocks: Baud16 and IrLPBaud16 signals. Baud16 provides timing information for UART transmit and receive control. Baud16 is a stream of pulses with a width of one [UARTCLK](#) clock period and a frequency of 16 times the baud rate.

### 12.1.2.4. Transmit FIFO

The transmit FIFO is an 8-bit wide, 32 location deep, FIFO memory buffer. CPU data written across the APB interface is stored in the FIFO until read out by the transmit logic. When disabled, the transmit FIFO acts like a one byte holding register.

### 12.1.2.5. Receive FIFO

The receive FIFO is a 12-bit wide, 32 location deep, FIFO memory buffer. Received data and corresponding error bits are stored in the receive FIFO by the receive logic until read out by the CPU across the APB interface. When disabled, the receive FIFO acts like a one byte holding register.

### 12.1.2.6. Transmit logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. Control logic outputs the serial bit stream in the following order:

1. Start bit
2. Data bits (Least Significant Bit (LSB) first)
3. Parity bit
4. Stop bits according to the programmed configuration in control registers

### 12.1.2.7. Receive logic

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Receive logic includes overrun, parity, frame error checking, and line break detection; you can find the output of these checks in the status that accompanies the data written to the receive FIFO.

### 12.1.2.8. Interrupt generation logic

The UART generates individual maskable active HIGH interrupts to the processor interrupt controllers. To generate combined interrupts, the UART outputs an OR function of the individual interrupt requests.

For more information, see [Section 12.1.6](#).

### 12.1.2.9. DMA interface

The UART provides an interface to connect to the DMA controller as a UART DMA; for more information, see [Section 12.1.5](#).

### 12.1.2.3. 波特率发生器

波特率发生器包含自由运行计数器，用以生成内部时钟信号：Baud16与IrLPBaud16。Baud16为UART的发送与接收控制提供时序信息。Baud16是一种脉冲流，脉冲宽度为一个UARTCLK时钟周期，频率为波特率的16倍。

### 12.1.2.4. 发送 FIFO

发送 FIFO 是一个8位宽、深度为32个位置的先进先出存储器缓冲区。通过 APB 接口写入的 CPU 数据存储于 FIFO 中，直至被发送逻辑读取。禁用时，发送 FIFO 表现为一个一字节暂存寄存器。

### 12.1.2.5. 接收 FIFO

接收 FIFO 是一个12位宽、深度为32个位置的先进先出存储器缓冲区。接收逻辑将接收到的数据及其相应错误位存储于接收 FIFO 中，直至 CPU 通过 APB 接口读取。禁用时，接收 FIFO 表现为一个一字节暂存寄存器。

### 12.1.2.6. 发送逻辑

发送逻辑对从发送 FIFO 读取的数据执行并行到串行的转换。控制逻辑按以下顺序输出串行比特流：

1. 起始位
2. 数据位（最低有效位（LSB）优先）
3. 校验位
4. 停止位根据控制寄存器中所编程的配置确定

### 12.1.2.7. 接收逻辑

接收逻辑在检测到有效起始脉冲后，对接收的比特流执行串行转并行转换。接收逻辑包括超限检测、校验检测、帧错误检测及线路中断检测；您可以在随数据写入接收FIFO时附带的状态中查阅这些检测结果。

### 12.1.2.8. 中断生成逻辑

UART向处理器中断控制器生成各个可屏蔽的高电平有效中断信号。为生成组合中断，UART输出各个中断请求的逻辑或（OR）函数。

更多信息详见第12.1.6节。

### 12.1.2.9. DMA接口

UART提供作为UART DMA的接口以连接DMA控制器；更多信息详见第12.1.5节。

### 12.1.2.10. Synchronizing registers and logic

The UART supports both asynchronous and synchronous operation of the clocks, **PCLK** and **UARTCLK**. The UART implements always-on synchronisation registers and handshaking logic. This has a minimal impact on performance and area. The UART performs control signal synchronisation on both directions of data flow (from the **PCLK** to the **UARTCLK** domain, and from the **UARTCLK** to the **PCLK** domain).

## 12.1.3. Operation

### 12.1.3.1. Clock signals

The frequency selected for **UARTCLK** must accommodate the required range of baud rates:

- **FUARTCLK** (min)  $\geq 16 \times \text{baud\_rate}$  (max)
- **FUARTCLK** (max)  $\leq 16 \times 65535 \times \text{baud\_rate}$  (min)

For example, for a range of baud rates from 110 baud to 460800 baud the **UARTCLK** frequency must be between 7.3728MHz to 115.34MHz.

To use all baud rates, the **UARTCLK** frequency must fall within the required error limits.

There is also a constraint on the ratio of clock frequencies for **PCLK** to **UARTCLK**. The frequency of **UARTCLK** must be no more than 5/3 times faster than the frequency of **PCLK**:

- $\text{FUARTCLK} \leq 5/3 \times \text{FPCLK}$

For example, in UART mode, to generate 921600 baud when **UARTCLK** is 14.7456MHz, **PCLK** must be greater than or equal to 8.85276MHz. This ensures that the UART has sufficient time to write the received data to the receive FIFO.

### 12.1.3.2. UART operation

Control data is written to the UART Line Control Register, **UARTLCR**. This register is 30 bits wide internally, but provides external access through the APB interface by writes to the following registers:

- **UARTLCR\_H**, which defines the following:
  - transmission parameters
  - word length
  - buffer mode
  - number of transmitted stop bits
  - parity mode
  - break generation
- **UARTIBRD**, which defines the integer baud rate divider
- **UARTFBRD**, which defines the fractional baud rate divider

#### 12.1.3.2.1. Fractional baud rate divider

The baud rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The baud rate generator uses the baud rate divisor to determine the bit period. The fractional baud rate divider enables the use of any clock with a frequency greater than 3.6864MHz to act as **UARTCLK**, while it is still possible to generate all the standard baud rates.

The 16-bit integer is written to the Integer Baud Rate Register, **UARTIBRD**. The 6-bit fractional part is written to the Fractional Baud Rate Register, **UARTFBRD**. The Baud Rate Divisor has the following relationship to **UARTCLK**:

### 12.1.2.10. 寄存器与逻辑的同步

UART支持时钟的异步和同步操作，分别为 **PCLK** 与 **UARTCLK**。UART实现了常时同步寄存器及握手逻辑。此设计对性能与面积的影响极小。UART对数据流双向的控制信号进行同步（从 **PCLK** 域至 **UARTCLK** 域，以及从 **UARTCLK** 域至 **PCLK** 域）。

## 12.1.3. 操作

### 12.1.3.1. 时钟信号

所选 **UARTCLK** 频率必须符合所需的波特率范围：

- **FUARTCLK** (最小值)  $\geq 16 \times \text{baud\_rate} (最大值)$
- **FUARTCLK** (最大值)  $\leq 16 \times 65535 \times \text{baud\_rate} (最小值)$

例如，波特率范围为 110 baud 至 460800 baud 时，**UARTCLK** 频率必须介于 7.3728MHz 至 115.34MHz 之间。

为使用所有波特率，**UARTCLK** 频率必须处于规定的误差限度内。

针对 **PCLK** 与 **UARTCLK** 的时钟频率比率亦有限制。**UARTCLK** 的频率不得超过 **PCLK** 频率的 5/3 倍，具体如下：

- $\text{FUARTCLK} \leq 5/3 \times \text{FPCLK}$

例如，在 UART 模式下，当 **UARTCLK** 为 14.7456MHz 时，为生成 921600 波特率，**PCLK** 必须大于或等于 8.85276MHz。此条件确保 UART 有足够时间将接收数据写入接收 FIFO 缓冲区。

### 12.1.3.2 UART 操作

控制数据写入 UART 线路控制寄存器 **UARTLCR**。该寄存器内部宽度为 30 位，但通过 APB 接口对以下寄存器的写访问提供外部接口：

- **UARTLCR\_H**，具体定义如下：
  - 传输参数
  - 字长
  - 缓冲模式
  - 发送停止位数
  - 奇偶校验模式
  - 断帧生成
- **UARTIBRD**，定义整数波特率分频器
- **UARTFBRD**，定义小数波特率分频器

#### 12.1.3.2.1. 小数波特率分频器

波特率分频器是一个由 16 位整数和 6 位小数组成的 22 位数。波特率发生器使用波特率分频器确定比特周期。小数波特率分频器允许使用频率高于 3.6864MHz 的任意时钟作为 **UARTCLK**，同时仍可生成所有标准波特率。

16 位整数写入整数波特率寄存器 **UARTIBRD**。6 位小数部分写入小数波特率寄存器 **UARTFBRD**。波特率分频器与 **UARTCLK** 之间的关系如下：

Baud Rate Divisor =  $\text{UARTCLK}/(16 \times \text{Baud Rate}) = BRD_I + BRD_F$  where  $BRD_I$  is the integer part and  $BRD_F$  is the fractional part separated by a decimal point as shown in [Figure 64](#).

*Figure 64. Baud rate divisor.*

To calculate the 6-bit number ( $m$ ), multiply the fractional part of the required baud rate divisor by 64 ( $2^n$ , where  $n$  is the width of the [UARTFBRD](#) register) and add 0.5 to account for rounding errors:

$$m = \text{integer}(BRD_F \times 2^n + 0.5)$$

The UART generates an internal clock enable signal, Baud16. This is a stream of [UARTCLK](#)-wide pulses with an average frequency of 16 times the required baud rate. Divide this signal by 16 to give the transmit clock. A low number in the baud rate divisor produces a short bit period, and a high number in the baud rate divisor produces a long bit period.

#### 12.1.3.2.2. Data transmission or reception

The UART uses two 32-byte FIFOs to store data received and transmitted. The receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the Line Control Register, [UARTLCR\\_H](#). Data continues to be transmitted until there is no data left in the transmit FIFO. The BUSY signal goes HIGH immediately after data writes to the transmit FIFO (that is, the FIFO is non-empty) and remains asserted HIGH while data transmits. BUSY is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. BUSY can be asserted HIGH even though the UART might no longer be enabled.

For each sample of data, three readings are taken and the majority value is kept. In the following paragraphs, the middle sampling point is defined, and one sample is taken either side of it.

When the receiver is idle ([UARTRXD](#) continuously 1, in the marking state) and a LOW is detected on the data input (a start bit has been received), the receive counter, with the clock enabled by Baud16, begins running and data is sampled on the eighth cycle of that counter in UART mode, or the fourth cycle of the counter in SIR mode to allow for the shorter logic 0 pulses (half way through a bit period).

The start bit is valid if [UARTRXD](#) is still LOW on the eighth cycle of Baud16, otherwise a false start bit is detected and it is ignored.

If the start bit was valid, successive data bits are sampled on every 16th cycle of Baud16 (that is, one bit period later) according to the programmed length of the data characters. The parity bit is then checked if parity mode was enabled.

Lastly, a valid stop bit is confirmed if [UARTRXD](#) is HIGH, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that word

#### 12.1.3.2.3. Error bits

The receive FIFO stores three error bits in bits 8 (framing), 9 (parity), and 10 (break), each associated with a particular character. An additional error bit, stored in bit 11 of the receive FIFO, indicates an overrun error.

#### 12.1.3.2.4. Overrun bit

The overrun bit is not associated with the character in the receive FIFO. The overrun error is set when the FIFO is full and the next character is completely received in the shift register. The data in the shift register is overwritten, but it is not written into the FIFO. When an empty location becomes available in the FIFO, another character is received and the state of the overrun bit is copied into the receive FIFO along with the received character. The overrun state is then cleared. [Table 1025](#) lists the bit functions of the receive FIFO.

波特率除数 =  $\text{UARTCLK}/(16 \times \text{波特率}) = BRD_I + BRD_F$  其中  $BRD_I$  为整数部分， $BRD_F$  为如图64所示，用小数点分隔的分数部分。

图 64. 波特率分频器

要计算6位数（），将所需波特率除数的小数部分乘以64（，其中为 **UARTFBRD** 寄存器的位宽），并加0.5<sup>24</sup>考虑舍入误差：

$$m = \text{integer}(BRD_F \times 2^n + 0.5)$$

UART生成一个内部时钟使能信号Baud16。该信号是一串宽度为 **UARTCLK** 的脉冲，平均频率为所需波特率的16倍。将该信号除以16以生成发送时钟。波特率除数较低时比特周期较短，波特率除数较高时比特周期较长。

#### 12.1.3.2.2. 数据传输或接收

UART 使用两个32字节的 FIFO 分别存储接收和发送的数据。接收FIFO的每个字符额外包含四位状态信息。对于发送，数据写入发送FIFO。若UART已启用，将按照线路控制寄存器 **UARTLCR\_H** 中指示的参数启动数据帧传输。数据将持续传输，直至发送FIFO无数据。数据写入发送FIFO后BUSY信号立即置高（即FIFO非空），且在数据传输期间保持高电平。仅当发送FIFO为空且最后一个字符（包括停止位）已从移位寄存器传输完毕时，BUSY信号被清除。尽管UART可能已不再启用，BUSY信号仍可保持高电平。

对于每次数据采样，执行三次读数，并保留多数值。以下段落中定义了中间采样点，并在其两侧各采集一个样本。

当接收器空闲（**UARTRXD** 持续为1，处于标记状态）且在数据输入端检测到低电平（接收到起始位）时，在Baud16时钟使能下，接收计数器开始计数。UART模式下于该计数器第八个周期采样数据，SIR模式下于第四个周期采样，以适应更短的逻辑0脉冲（位周期中点）。

若 **UARTRXD** 在Baud16的第八个周期仍为LOW，则起始位有效；否则视为假起始位并予以忽略。

若起始位有效，后续数据位依据数据字符的编程长度，于Baud16的每第16个周期（即一个比特周期之后）采样。若启用奇偶校验模式，则随后校验奇偶校验位。

最后，若 **UARTRXD** 为HIGH，则确认有效停止位；否则发生帧错误。接收到完整字后，数据存入接收FIFO，同时关联该字的任何错误位。

#### 12.1.3.2.3. 错误位

接收FIFO在第8位（帧错误）、第9位（奇偶校验错误）及第10位（中断错误）存储三个错误位，每位对应特定字符。接收FIFO第11位存储附加错误位，表示溢出错误。

#### 12.1.3.2.4. 超限位

超限位与接收FIFO中的字符无关。当FIFO已满且下一个字符完全接收进移位寄存器时，超限错误被设置。移位寄存器中的数据将被覆盖，但不会写入FIFO。当FIFO中出现空闲位置时，另一个字符被接收，超限位的状态与该接收字符一起复制到接收FIFO中。随后超限状态被清除。

表1025列出了接收FIFO的各个位功能。

Table 1025. Receive FIFO bit functions

FIFO bit	Function
11	Overrun indicator
10	Break error
9	Parity error
8	Framing error
7:0	Received data

#### 12.1.3.2.5. Disabling the FIFOs

The bottom entry of the transmit and receive sides of the UART both have the equivalent of a 1-byte holding register. You can manipulate flags to disable the FIFOs, allowing you to use the bottom entry of the FIFOs as a 1-byte register. However, this doesn't physically disable the FIFOs. When using the FIFOs as a 1-byte register, a write to the data register bypasses the holding register unless the transmit shift register is already in use.

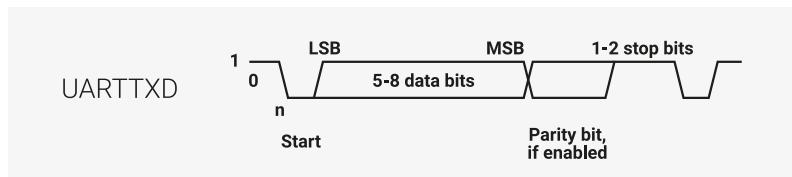

#### 12.1.3.2.6. System and diagnostic loopback testing

To perform loopback testing for UART data, set the Loop Back Enable (LBE) bit to 1 in the Control Register, [UARTCR](#).

Data transmitted on [UARTTXD](#) is received on the [UARTRXD](#) input.

#### 12.1.3.3. UART character frame

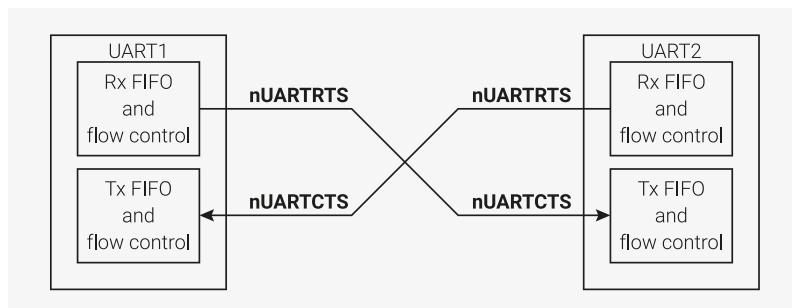

Figure 65. UART character frame.

#### 12.1.4. UART hardware flow control

The fully-selectable hardware flow control feature enables you to control the serial data flow with the [nUARTRTS](#) output and [nUARTCTS](#) input signals. Figure 66 shows how to communicate between two devices using hardware flow control:

Figure 66. Hardware flow control between two similar devices.

When the RTS flow control is enabled, [nUARTRTS](#) is asserted until the receive FIFO is filled up to the programmed watermark level. When the CTS flow control is enabled, the transmitter can only transmit data when [nUARTCTS](#) is asserted.

The hardware flow control is selectable using the [RTSEn](#) and [CTSEn](#) bits in the Control Register, [UARTCR](#). Table 1026 shows how to configure [UARTCR](#) register bits to enable RTS and/or CTS.

表1025。接收  
FIFO位功能

FIFO位	功能
11	超限指示
10	断帧错误
9	奇偶校验错误
8	帧错误
7:0	接收数据

#### 12.1.3.2.5. 禁用FIFO

UART收发两端的底层条目均等同于一个1字节的保持寄存器。

您可以操作标志以禁用FIFO，从而将FIFO底层条目作为一个1字节寄存器使用。

然而，这并未物理禁用FIFO。当将FIFO用作1字节寄存器时，写入数据寄存器会绕过保持寄存器，除非发送移位寄存器已被使用。

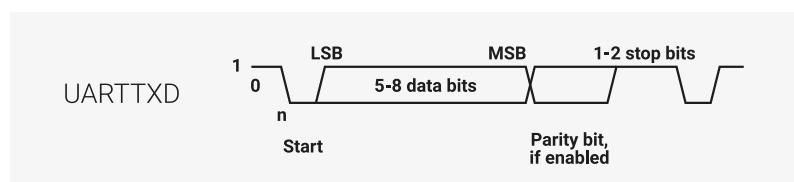

#### 12.1.3.2.6. 系统及诊断环回测试

要执行UART数据的环回测试，请在控制寄存器 [UARTCR](#) 中将环回使能（Loop Back Enable, LBE）位设为1。

通过 [UARTTXD](#) 输出的数据将在 [UARTRXD](#) 输入端接收。

#### 12.1.3.3. UART字符帧

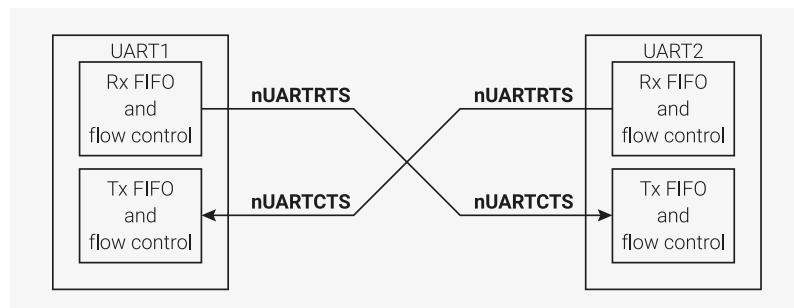

图65. UART  
字符帧。

#### 12.1.4. UART 硬件流控

全选硬件流控功能使您能够通过 [nUARTRTS](#) 输出信号和 [nUARTCTS](#) 输入信号控制串行数据流。图66展示了使用硬件流控在两个设备间进行通信的方式：

图66。两个相似  
设备之间的硬件流  
控示意。

启用RTS流控时，[nUARTRTS](#)将在接收FIFO填充至设定水位线之前被置为激活状态。当启用CTS流控时，发送器仅在[UARTCTS](#)断言时方可发送数据。

硬件流控可通过控制寄存器 [UARTCR](#) 中的 [RTSEn](#) 和 [CTSEn](#) 位进行选择。表 1026 显示了如何配置 [UARTCR](#) 寄存器位以启用 RTS 和/或 CTS。

Table 1026. Control bits to enable and disable hardware flow control.

UARTCR register bits		
CTSEn	RTSEn	Description
1	1	Both RTS and CTS flow control enabled
1	0	Only CTS flow control enabled
0	1	Only RTS flow control enabled
0	0	Both RTS and CTS flow control disabled

#### **NOTE**

When RTS flow control is enabled, the software cannot use the RTSEn bit in the Control Register ([UARTCR](#)) to control the status of [nUARTRTS](#).

#### 12.1.4.1. RTS flow control

The RTS flow control logic is linked to the programmable receive FIFO watermark levels.

When RTS flow control is disabled, the receive FIFO receives data until full, or no more data is transmitted to it.

When RTS flow control is enabled, the [nUARTRTS](#) is asserted until the receive FIFO fills up to the watermark level. When the receive FIFO reaches the watermark level, the [nUARTRTS](#) signal is de-asserted. This indicates that the FIFO has no more room to receive data. The transmission of data is expected to cease after the current character has been transmitted. When the receive FIFO drains below the watermark level, the [nUARTRTS](#) signal is reasserted.

#### 12.1.4.2. CTS flow control

The CTS flow control logic is linked to the [nUARTCTS](#) signal.

When CTS flow control is disabled, the transmitter transmits data until the transmit FIFO is empty.

When CTS flow control is enabled, the transmitter checks the [nUARTCTS](#) signal before transmitting each byte. It only transmits the byte if the [nUARTCTS](#) signal is asserted. As long as the transmit FIFO is not empty and [nUARTCTS](#) is asserted, data continues to transmit. If the transmit FIFO is empty and the [nUARTCTS](#) signal is asserted, no data is transmitted. If the [nUARTCTS](#) signal is de-asserted during transmission, the transmitter finishes transmitting the current character before stopping.

### 12.1.5. UART DMA interface

The UART provides an interface to connect to a DMA controller. The DMA operation of the UART is controlled using the DMA Control Register, [UARTDMACR](#). The DMA interface includes the following signals:

For receive:

[UARTRXDMASREQ](#)

Single character DMA transfer request, asserted by the UART. For receive, one character consists of up to 12 bits. This signal is asserted when the receive FIFO contains at least one character.

[UARTRXDMABREQ](#)

Burst DMA transfer request, asserted by the UART. This signal is asserted when the receive FIFO contains more characters than the programmed watermark level. You can program the watermark level for each FIFO using the Interrupt FIFO Level Select Register ([UARTIFLS](#)).

表 1026。用于启用和禁用硬件流控的控制位。

UARTCR 寄存器位		
CTSEn	RTSEn	描述
1	1	同时启用 RTS 和 CTS 流控
1	0	仅启用 CTS 流控
0	1	仅启用 RTS 流控
0	0	同时禁用 RTS 和 CTS 流控

#### ① 注意

启用 RTS 流控时，软件不可使用控制寄存器（UARTCR）中的 RTSEn 位来控制 UARTRTS 的状态。

#### 12.1.4.1. RTS 流控

RTS 流控逻辑与可编程接收 FIFO 水位线级别相关联。

当 RTS 流控被禁用时，接收 FIFO 将接收数据直至满，或无更多数据传输。

当 RTS 流控启用时，nUARTRTS 信号将在接收 FIFO 填充至水位线前被断言。当接收 FIFO 达到水位线时，nUARTRTS 信号将取消断言。这表示 FIFO 已无更多空间用于接收数据。预计数据传输将在当前字符发送完成后停止。

当接收 FIFO 低于水位线时，nUARTRTS 信号将重新断言。

#### 12.1.4.2. CTS 流控

CTS 流控逻辑与 nUARTCTS 信号相关联。

当 CTS 流控被禁用时，发射器将传输数据直到发送 FIFO 为空。

当 CTS 流控启用时，发射器在发送每个字节前会检查 nUARTCTS 信号。只有在 nUARTCTS 信号被断言时，才传输该字节。只要发送 FIFO 非空且 nUARTCTS 被断言，数据将持续传输。如果发送 FIFO 为空且 nUARTCTS 信号被断言，则不传输数据。如果在传输过程中 nUARTCTS 信号被取消断言，发送器将在完成当前字符传输后停止。

#### 12.1.5. UART DMA 接口

UART 提供与 DMA 控制器连接的接口。UART 的 DMA 操作通过 DMA 控制寄存器 UARTDMACR 进行控制。DMA 接口包括以下信号：

接收：

**UARTRXDMASREQ**

单字符 DMA 传输请求，由 UART 断言。对于接收，一字符最多包含 12 位。

当接收 FIFO 至少包含一个字符时，该信号被断言。

**UARTRXDMABREQ**

突发 DMA 传输请求，由 UART 断言。当接收 FIFO 中的字符数超过设定水位线时，该信号被断言。可以通过中断 FIFO 水平选择寄存器 UARTIFLS 为每个 FIFO 设置水位线。

**UARTRXDMACLR**

DMA request clear, asserted by a DMA controller to clear the receive request signals. If DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

For transmit:

**UARTTXDMASREQ**

Single character DMA transfer request, asserted by the UART. For transmit, one character consists of up to eight bits. This signal is asserted when there is at least one empty location in the transmit FIFO.

**UARTTXDMABREQ**

Burst DMA transfer request, asserted by the UART. This signal is asserted when the transmit FIFO contains less characters than the watermark level. You can program the watermark level for each FIFO using the Interrupt FIFO Level Select Register ([UARTIFLS](#)).

**UARTRXDMACLR**

DMA request clear, asserted by a DMA controller to clear the transmit request signals. If DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

The burst transfer and single transfer request signals are not mutually exclusive: they can both be asserted at the same time. When the receive FIFO exceeds the watermark level, the burst transfer request and the single transfer request signals are both asserted. When the receive FIFO is below than the watermark level, only the single transfer request signal is asserted. This is useful in situations where the number of characters left to be received in the stream is less than a burst.

Consider a scenario where the watermark level is set to four, but 19 characters are left to be received. The DMA controller then transfers four bursts of four characters and three single transfers to complete the stream.

**i NOTE**

For the remaining three characters, the UART cannot assert the burst request.

Each request signal remains asserted until the relevant DMACLR signal is asserted. After the request clear signal is de-asserted, a request signal can become active again, depending on the conditions described previously. All request signals are de-asserted if the UART is disabled or the relevant DMA enable bit, **TXDMAE** or **RXDMAE**, in the DMA Control Register, [UARTDMACR](#), is cleared.

If you disable the FIFOs in the UART, it operates in character mode. Character mode limits FIFO transfers to a single character at a time, so only the DMA single transfer mode can operate. In character mode, only the [UARTRXDMASREQ](#) and [UARTTXDMASREQ](#) request signals can be asserted. For information about disabling the FIFOs, see the Line Control Register, [UARTLCR\\_H](#).

When the UART is in the FIFO enabled mode, data transfers can use either single or burst transfers depending on the programmed watermark level and the amount of data in the FIFO. [Table 1027](#) lists the trigger points for [UARTRXDMABREQ](#) and [UARTTXDMABREQ](#), depending on the watermark level, for the transmit and receive FIFOs.

*Table 1027. DMA trigger points for the transmit and receive FIFOs.*

Watermark level	Burst length	
	Transmit (number of empty locations)	Receive (number of filled locations)
1/8	28	4
1/4	24	8
1/2	16	16
3/4	8	24
7/8	4	28

In addition, the **DMAONERR** bit in the DMA Control Register, [UARTDMACR](#), supports the use of the receive error interrupt,

**UARTRXDMACLR**

DMA请求清除信号，由DMA控制器发送以清除接收请求信号。若请求DMA突发传输，则在突发传输最后一条数据传送时，清除信号被发送。

关于发送：

**UARTTXDMASREQ**

单字符DMA传输请求，由UART发送。对于发送操作，一个字符最多包含八位。当发送FIFO至少有一个空闲位置时，该信号被发送。

**UARTTXDMABREQ**

突发DMA传输请求，由UART发送。当发送FIFO中的字符数量低于水位线时，该信号被发送。可以通过中断FIFO水平选择寄存器**UARTIFLS**为每个FIFO设置水位线。

**UARTTXDMACLR**

DMA请求清除信号，由DMA控制器发送以清除发送请求信号。若请求DMA突发传输，则在突发传输最后一条数据传送时，清除信号被发送。

突发传输请求和单次传输请求信号并不互斥：两者可以同时被发送。当接收FIFO超过水位线时，突发传输请求信号与单次传输请求信号均被发送。当接收FIFO低于水位线水平时，仅断言单次传输请求信号。此功能适用于流中剩余待接收字符数少于一次突发传输的情况。

假设水位线设置为四，但剩余待接收字符数为十九。DMA控制器随后进行四次四字符突发传输和三次单字符传输以完成数据流。

**i 注意**

对于剩余的三个字符，UART无法断言突发请求信号。

每个请求信号持续保持断言状态，直至相关DMACLR信号被断言。请求清除信号解除断言后，依据前述条件，请求信号可重新激活。如果UART被禁用或DMA控制寄存器UARTDMACR中的相关DMA使能位 **TXDMAE** 或 **RXDMAE** 被清除，所有请求信号将被解除断言。

若在UART中禁用FIFO，则其以字符模式运行。字符模式限制FIFO一次只能传输一个字符，因此仅支持DMA单次传输模式。在字符模式下，仅可断言**UARTRXDMASREQ** 和 **UARTTXDMASREQ** 请求信号。有关禁用FIFO的详细信息，请参见行控制寄存器UARTLCR\_H。

当UART处于FIFO启用模式时，数据传输可根据配置的水位线水平和FIFO中的数据量，采用单次或突发传输。表1027列出了传输和接收FIFO中，基于水位线水平的**UARTRXDMAREQ** 和 **UARTTXDMAREQ** 触发点。

表1027。传输  
和接收FIFO的DMA  
触发点

水位线水平	突发长度	
	传输（空位置数量 ）	接收（填充位置数量）
1/8	28	4
1/4	24	8
1/2	16	16
3/4	8	24
7/8	4	28

此外，DMA控制寄存器 **UARTDMACR** 中的 **DMAONERR** 位支持接收错误中断功能，

**UARTEINTR**. It enables the DMA receive request outputs, **UARTRXDMASREQ** or **UARTRXDMABREQ**, to be masked out when the UART error interrupt, **UARTEINTR**, is asserted. The DMA receive request outputs remain inactive until the **UARTEINTR** is cleared. The DMA transmit request outputs are unaffected.

Figure 67. DMA transfer waveforms.

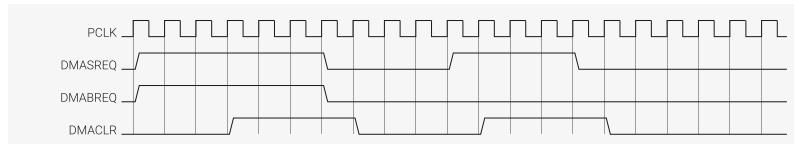

Figure 67 shows the timing diagram for both a single transfer request and a burst transfer request with the appropriate **DMACLR** signal. The signals are all synchronous to PCLK. For the sake of clarity it is assumed that there is no synchronization of the request signals in the DMA controller.

## 12.1.6. Interrupts

There are eleven maskable interrupts generated in the UART. On RP2350, only the combined interrupt output, **UARTINTR**, is connected.

To enable or disable individual interrupts, change the mask bits in the Interrupt Mask Set/Clear Register, **UARTIMSC**. Set the appropriate mask bit HIGH to enable the interrupt.

The transmit and receive dataflow interrupts **UARTRXINTR** and **UARTTXINTR** have been separated from the status interrupts. This enables you to use **UARTRXINTR** and **UARTTXINTR** to read or write data in response to FIFO trigger levels.

The error interrupt, **UARTEINTR**, can be triggered when there is an error in the reception of data. A number of error conditions are possible.

The modem status interrupt, **UARTMSINTR**, is a combined interrupt of all the individual modem status signals.

The status of the individual interrupt sources can be read either from the Raw Interrupt Status Register, **UARTRIS**, or from the Masked Interrupt Status Register, **UARTMIS**.

### 12.1.6.1. **UARTMSINTR**

The modem status interrupt is asserted if any of the modem status signals (**nUARTCTS**, **nUARTDCD**, **nUARTDSR**, and **nUARTRI**) change. To clear the modem status interrupt, write a 1 to the bits corresponding to the modem status signals that generated the interrupt in the Interrupt Clear Register (**UARTICR**).

### 12.1.6.2. **UARTRXINTR**

The receive interrupt changes state when one of the following events occurs:

- The FIFOs are enabled and the receive FIFO reaches the programmed trigger level. This asserts the receive interrupt HIGH. To clear the receive interrupt, read data from the receive FIFO until it drops below the trigger level.
- The FIFOs are disabled (have a depth of one location) and data is received, thereby filling the receive FIFO. This asserts the receive interrupt HIGH. To clear the receive interrupt, perform a single read from the receive FIFO.

In both cases, you can also clear the interrupt manually.

### 12.1.6.3. **UARTTXINTR**

The transmit interrupt changes state when one of the following events occurs:

- The FIFOs are enabled and the transmit FIFO is equal to or lower than the programmed trigger level. This asserts the transmit interrupt HIGH. To clear the transmit interrupt, write data to the transmit FIFO until it exceeds the

**UARTEINTR。** 当UART错误中断UARTEINTR被触发时，允许屏蔽DMA接收请求输出，**UARTRXDMASREQ**或**UARTRXDMABREQ**。DMA接收请求输出将保持非激活状态，直到**UARTEINTR**被清除。DMA发送请求输出不受影响。

图67。DMA  
传输波形。

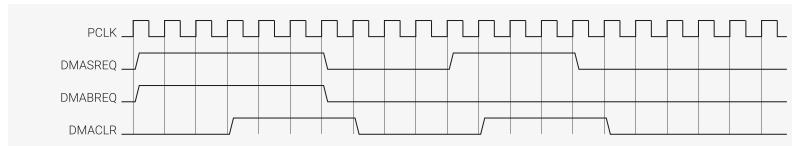

图67显示了单次传输请求和带有相应**DMACLR**信号的突发传输请求的时序图。所有信号均与PCLK同步。为明确起见，假定DMA控制器中请求信号无同步处理。

## 12.1.6. 中断

UART产生十一种可屏蔽中断。在RP2350中，仅连接了合并中断输出，**UARTINTR**。

要启用或禁用单个中断，请修改中断屏蔽设置/清除寄存器 **UARTIMSC**中的掩码位。将相应的掩码位设置为高电平以使能中断。

发送和接收数据流中断 **UARTRXINTR**和 **UARTTXINTR**已从状态中断中分离。

这使您能够使用 **UARTRXINTR**和 **UARTTXINTR**根据FIFO触发级别读取或写入数据。

错误中断 **UARTEINTR**可在接收数据发生错误时触发。可能存在多种错误状态。

调制解调器状态中断 **UARTMSINTR**是所有单个调制解调器状态信号的组合中断。

单个中断源的状态可以从原始中断状态寄存器 **UARTRIS**或屏蔽中断状态寄存器 **UARTMIS**读取。

### 12.1.6.1. **UARTMSINTR**

当任何调制解调器状态信号（**nUARTCTS**、**nUARTDCD**、**nUARTDSR**和 **nUARTRI**）发生变化时，调制解调器状态中断将被断言。要清除调制解调器状态中断，请向中断清除寄存器（**UARTICR**）中对应于产生中断的调制解调器状态信号的位写入1。

### 12.1.6.2. **UARTRXINTR**

当发生以下任一情况时，接收中断状态将发生变化：

- FIFO已启用且接收FIFO达到设定的触发级别。这将使接收中断变为高电平。要清除接收中断，请从接收FIFO读取数据，直到其低于触发级别。
- FIFO已禁用（深度仅为一个位置）且接收到数据，从而填满接收FIFO，这将使接收中断变为高电平。要清除接收中断，请执行一次从接收FIFO的读取操作。

以上两种情况均可通过手动操作清除中断。

### 12.1.6.3. **UARTTXINTR**

当发生以下任一情况时，发送中断状态将发生变化：

- FIFO已启用且发送FIFO的内容等于或低于设定的触发级别。此操作将使发送中断置为高电平。要清除发送中断，请向发送FIFO写入数据，直到其超过

trigger level.

- The FIFOs are disabled (have a depth of one location) and there is no data present in the transmit FIFO. This asserts the transmit interrupt HIGH. To clear the transmit interrupt, perform a single write to the transmit FIFO.

In both cases, you can also clear the interrupt manually.

To update the transmit FIFO, write data to the transmit FIFO before or after enabling the UART and the interrupts.

#### NOTE

The transmit interrupt is based on a transition through a level, rather than on the level itself. When the interrupt and the UART is enabled before any data is written to the transmit FIFO, the interrupt is not set. The interrupt is only set after written data leaves the single location of the transmit FIFO and it becomes empty.

#### 12.1.6.4. [UARTRTINTR](#)

The receive timeout interrupt is asserted when the receive FIFO is not empty and no more data is received during a 32-bit period.

The receive timeout interrupt is cleared in the following scenarios:

- the FIFO becomes empty through reading all the data or by reading the holding register
- a 1 is written to the corresponding bit of the Interrupt Clear Register, [UARTICR](#)

#### 12.1.6.5. [UARTEINTR](#)

The error interrupt is asserted when an error occurs in the reception of data by the UART. The interrupt can be caused by a number of different error conditions:

- framing
- parity
- break
- overrun

To determine the cause of the interrupt, read the Raw Interrupt Status Register ([UARTRIS](#)) or the Masked Interrupt Status Register ([UARTMIS](#)). To clear the interrupt, write to the relevant bits of the Interrupt Clear Register, [UARTICR](#) (bits 7 to 10 are the error clear bits).

#### 12.1.6.6. [UARTINTR](#)

The interrupts are also combined into a single output, that is an OR function of the individual masked sources. You can connect this output to a system interrupt controller to provide another level of masking on a individual peripheral basis.

The combined UART interrupt is asserted if any of the individual interrupts are asserted and enabled.

### 12.1.7. Programmer's model

The SDK provides a `uart_init` function to configure the UART with a particular baud rate. Once the UART is initialised, the user must configure a GPIO pin as `UART_TX` and `UART_RX`. See [Section 9.10.1](#) for more information on selecting a GPIO function.

To initialise the UART, the `uart_init` function takes the following steps:

1. De-asserts the reset

触发电平。

- FIFO被禁用（深度为单个位置），且发送FIFO中无数据。此操作将发送中断置为高电平。要清除发送中断，请对发送FIFO执行一次写入操作。

以上两种情况均可通过手动操作清除中断。

更新发送FIFO时，可在启用UART和中断之前或之后写入数据。

#### 注意

发送中断基于电平的变化触发，而非电平本身。当中断及UART在未向发送FIFO写入任何数据前即被启用时，中断不会触发。只有在写入数据离开发送FIFO的单一位置且FIFO变为空时，中断才会触发。

#### 12.1.6.4. **UARTRTINTR**

当接收FIFO非空且在32位周期内无新数据接收时，接收超时中断被触发。

接收超时中断在以下情况下被清除：

- 通过读取所有数据或读取保持寄存器，使 FIFO 变为空
- 在中断清除寄存器 **UARTICR** 的相应位写入 1

#### 12.1.6.5. **UARTEINTR**

当 UART 接收数据发生错误时，错误中断将被触发。该中断可能由多种不同的错误条件引起：

- 帧错误
- 奇偶校验错误
- 中断符错误
- 溢出错误

要确定中断原因，请读取原始中断状态寄存器（**UARTRIS**）或屏蔽中断状态寄存器（**UARTMIS**）。要清除中断，请向中断清除寄存器 **UARTICR** 的相关位写入数据（第7至10位为错误清除位）。

#### 12.1.6.6. **UARTINTR**

这些中断还被合并为单一输出，即各个屏蔽中断源的逻辑或功能结果。您可以将此输出连接到系统中断控制器，以便基于单个外设提供另一层屏蔽。

只要任一单独中断被断言且已启用，组合 UART 中断即被断言。

#### 12.1.7. 程序员模型

SDK 提供了 **uart\_init** 函数，用于配置特定波特率的 UART。UART 初始化后，用户必须将某个 GPIO 引脚配置为 **UART\_TX** 和 **UART\_RX**。有关 GPIO 功能选择的详细信息，请参见第 9.10.1 节。

初始化 UART 时，**uart\_init** 函数执行以下步骤：

1. 取消复位断言

2. Enables `clk_peri`
3. Sets enable bits in the control register
4. Enables the FIFOs
5. Sets the baud rate divisors
6. Sets the format

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/p2\\_common/hardware\\_uart/uart.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/p2_common/hardware_uart/uart.c) Lines 42 - 92

```

42 uint uart_init(uart_inst_t *uart, uint baudrate) {
43 invalid_params_if(HARDWARE_UART, uart != uart0 && uart != uart1);
44
45 if (uart_clock_get_hz(uart) == 0) {
46 return 0;
47 }

```

### 12.1.7.1. Baud rate calculation

The UART baud rate is derived from dividing `clk_peri`.

If the required baud rate is 115200 and  $\text{UARTCLK} = 125\text{MHz}$  then:

$$\text{Baud Rate Divisor} = (125 \times 10^6) / (16 \times 115200) \approx 67.817$$

Therefore,  $\text{BRDI} = 67$  and  $\text{BRDF} = 0.817$ ,

Therefore, fractional part,  $m = \text{integer}(0.817 \times 64) + 0.5 = 52$

Generated baud rate divider =  $67 + 52/64 = 67.8125$

$$\text{Generated baud rate} = (125 \times 10^6) / (16 \times 67.8125) \approx 115207$$

$$\text{Error} = (\text{abs}(115200 - 115207) / 115200) \times 100 \approx 0.006\%$$

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_uart/uart.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_uart/uart.c) Lines 155 - 180

```

155 uint uart_set_baudrate(uart_inst_t *uart, uint baudrate) {
156 invalid_params_if(HARDWARE_UART, baudrate == 0);
157 uint32_t baud_rate_div = (8 * uart_clock_get_hz(uart) / baudrate) + 1;
158 uint32_t baud_ibrd = baud_rate_div >> 7;
159 uint32_t baud_fbrd;
160
161 if (baud_ibrd == 0) {
162 baud_ibrd = 1;
163 baud_fbrd = 0;
164 } else if (baud_ibrd >= 65535) {
165 baud_ibrd = 65535;
166 baud_fbrd = 0;
167 } else {
168 baud_fbrd = (baud_rate_div & 0x7f) >> 1;
169 }
170
171 uart_get_hw(uart)->ibrd = baud_ibrd;
172 uart_get_hw(uart)->fbrd = baud_fbrd;
173
174 // PL011 needs a (dummy) LCR_H write to latch in the divisors.
175 // We don't want to actually change LCR_H contents here.
176 uart_write_lcr_bits_masked(uart, 0, 0);
177
178 // See datasheet
179 return (4 * uart_clock_get_hz(uart)) / (64 * baud_ibrd + baud_fbrd);
180 }
```

### 12.1.8. List of registers

The UART0 and UART1 registers start at base addresses of `0x40070000` and `0x40078000` respectively (defined as `UART0_BASE` and `UART1_BASE` in SDK).

Table 1028. List of  
UART registers

Offset	Name	Info
0x000	UARTDR	Data Register, UARTDR
0x004	UARTRSR	Receive Status Register/Error Clear Register, UARTRSR/UARTECR
0x018	UARTFR	Flag Register, UARTFR
0x020	UARTILPR	IrDA Low-Power Counter Register, UARTILPR

### 12.1.7.1. 波特率计算

UART 波特率通过除以 `clk_peri` 计算得出。

如果所需波特率为 115200，且  $\text{UARTCLK} = 125\text{MHz}$ ，则：

$$\text{波特率除数} = (125 \times 10^6) / (16 \times 115200) \approx 67.817$$

因此， $\text{BRDI} = 67$ ， $\text{BRDF} = 0.817$ ，

因此，分数部分  $m = \text{integer}(0.817 \times 64) + 0.5 = 52$

生成的波特率除频器 =  $67 + 52/64 = 67.8125$

$$\text{生成的波特率} = (125 \times 10^6) / (16 \times 67.8125) \approx 115207$$

误差 =  $(\text{abs}(115200 - 115207) / 115200) \times 100 \approx 0.006\%$

SDK：[https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_uart/uart.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_uart/uart.c) 第155至180行

```

155 uint uart_set_baudrate(uart_inst_t *uart, uint baudrate) {
156 invalid_params_if(HARDWARE_UART, baudrate == 0);
157 uint32_t baud_rate_div = (8 * uart_clock_get_hz(uart) / baudrate) + 1;
158 uint32_t baud_ibrd = baud_rate_div >> 7;
159 uint32_t baud_fbrd;
160
161 if (baud_ibrd == 0) {
162 baud_ibrd = 1;
163 baud_fbrd = 0;
164 } else if (baud_ibrd >= 65535) {
165 baud_ibrd = 65535;
166 baud_fbrd = 0;
167 } else {
168 baud_fbrd = (baud_rate_div & 0x7f) >> 1;
169 }
170
171 uart_get_hw(uart)->ibrd = baud_ibrd;
172 uart_get_hw(uart)->fbrd = baud_fbrd;
173
174 // PL011 需要进行（伪）LCR_H 写操作以锁存除数。
175 // 此处不应实际更改 LCR_H 内容。
176 uart_write_lcr_bits_masked(uart, 0, 0);
177
178 // 详见数据手册
179 返回 (4 * uart_clock_get_hz(uart)) / (64 * baud_ibrd + baud_fbrd);
180 }
```

### 12.1.8. 寄存器列表

UART0 和 UART1 寄存器的基地址分别为 `0x40070000` 和 `0x40078000`（在 SDK 中定义为 `UART0_BASE` 和 `UART1_BASE`）。

## UART: UARTDR Register

Offset: 0x000

### Description

Data Register, UARTDR

Table 1029. UARTDR Register

Bits	Description	Type	Reset
31:12	Reserved.	-	-
11	<b>OE</b> : Overrun error. This bit is set to 1 if data is received and the receive FIFO is already full. This is cleared to 0 once there is an empty space in the FIFO and a new character can be written to it.	RO	-
10	<b>BE</b> : Break error. This bit is set to 1 if a break condition was detected, indicating that the received data input was held LOW for longer than a full-word transmission time (defined as start, data, parity and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state), and the next valid start bit is received.	RO	-
9	<b>PE</b> : Parity error. When set to 1, it indicates that the parity of the received data character does not match the parity that the EPS and SPS bits in the Line Control Register, UARTLCR_H. In FIFO mode, this error is associated with the character at the top of the FIFO.	RO	-

偏移：0x000

### 描述

数据寄存器 UARTDR

表 1029. UARTDR 寄存器

位	描述	类型	复位
31:12	保留。	-	-
11	<b>OE</b> : 溢出错误。当接收到数据且接收 FIFO 已满时，此位被置为 1。一旦 FIFO 中出现空位并可写入新字符，该位即被清零为 0。	只读	-
10	<b>BE</b> : 断路错误。当检测到断路条件时，此位被置为 1，表示接收数据输入保持低电平的时间超过完整字传输时间（包括起始位、数据位、奇偶校验位和停止位）。在 FIFO 模式下，此错误关联于 FIFO 顶部的字符。发生断路时，仅有一个 0 字符加载入 FIFO。只有接收数据输入恢复为 1（标记状态）且接收到下一个有效起始位后，下一字符才被允许进入 FIFO。	只读	-
9	<b>PE</b> : 奇偶校验错误。当该位置为1时，表示接收的数据字符的奇偶校验与线路控制寄存器UARTLCR_H中的EPS和SPS位指定的奇偶校验不符。在FIFO模式下，该错误关联于FIFO顶部的字符。	只读	-

Bits	Description	Type	Reset
8	<b>FE</b> : Framing error. When set to 1, it indicates that the received character did not have a valid stop bit (a valid stop bit is 1). In FIFO mode, this error is associated with the character at the top of the FIFO.	RO	-
7:0	<b>DATA</b> : Receive (read) data character. Transmit (write) data character.	RWF	-

## UART: UARTRSR Register

Offset: 0x004

### Description

Receive Status Register/Error Clear Register, UARTRSR/UARTECR

Table 1030. UARTRSR Register

Bits	Description	Type	Reset
31:4	Reserved.	-	-
3	<b>OE</b> : Overrun error. This bit is set to 1 if data is received and the FIFO is already full. This bit is cleared to 0 by a write to UARTECR. The FIFO contents remain valid because no more data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must now read the data, to empty the FIFO.	WC	0x0
2	<b>BE</b> : Break error. This bit is set to 1 if a break condition was detected, indicating that the received data input was held LOW for longer than a full-word transmission time (defined as start, data, parity, and stop bits). This bit is cleared to 0 after a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.	WC	0x0
1	<b>PE</b> : Parity error. When set to 1, it indicates that the parity of the received data character does not match the parity that the EPS and SPS bits in the Line Control Register, UARTLCR_H. This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO.	WC	0x0
0	<b>FE</b> : Framing error. When set to 1, it indicates that the received character did not have a valid stop bit (a valid stop bit is 1). This bit is cleared to 0 by a write to UARTECR. In FIFO mode, this error is associated with the character at the top of the FIFO.	WC	0x0

## UART: UARTFR Register

Offset: 0x018

### Description

Flag Register, UARTFR

Table 1031. UARTFR Register

Bits	Description	Type	Reset
31:9	Reserved.	-	-
8	<b>RI</b> : Ring indicator. This bit is the complement of the UART ring indicator, nUARTRI, modem status input. That is, the bit is 1 when nUARTRI is LOW.	RO	-

位	描述	类型	复位
8	<b>FE</b> : 帧错误。当该位置为1时，表示接收的字符没有有效的停止位（有效停止位为1）。在FIFO模式下，该错误关联于FIFO顶部的字符。	只读	-
7:0	<b>DATA</b> : 接收（读取）数据字符。发送（写入）数据字符。	RWF	-

位	描述	类型	复位
31:8	保留。	-	-
7	<b>SPS</b> : 固定奇偶校验选择。0 = 禁用固定奇偶校验；1 = 如下之一：* 若 EPS 位为 0，则校验位作为 1 发送并校验；* 若 EPS 位为 1，则校验位作为 0 发送并校验。当 PEN 位禁用奇偶校验生成和校验时，该位无效。	读写	0x0
6:5	<b>WLEN</b> : 字长。这些位指示帧中传输或接收的数据位数，具体如下：b11 = 8 位；b10 = 7 位；b01 = 6 位；b00 = 5 位。	读写	0x0
4	<b>FEN</b> : 启用FIFO: 0 = 禁用FIFO（字符模式），即FIFO变为1字节深的保持寄存器；1 = 启用发送和接收FIFO缓冲区（FIFO模式）。	读写	0x0
3	<b>STP2</b> : 选择两个停止位。如果该位设置为1，则在帧结束时发送两个停止位。接收逻辑不会检查是否接收到两个停止位。	读写	0x0
2	<b>EPS</b> : 奇偶校验选择。控制UART在传输和接收期间使用的校验类型：0 = 奇校验。UART生成或检查数据及校验位中‘1’的奇数个数。1 = 偶校验。UART生成或检查数据及校验位中‘1’的偶数个数。当 PEN 位禁用奇偶校验生成和校验时，该位无效。	读写	0x0
1	<b>PEN</b> : 校验使能：0 = 禁用校验且不向数据帧添加校验位；1 = 启用校验生成和检测。	读写	0x0
0	<b>BRK</b> : 发送中断信号。如果该位被置为1，则在完成当前字符传输后，UARTT XD输出端将持续输出低电平。为确保中断命令正确执行，软件必须至少将该位设置两个完整帧周期。正常使用时，该位必须清零（设置为0）。	读写	0x0

## UART: UARTCR 寄存器

Offset: 0x030

**Description**

Control Register, UARTCR

Table 1036. UARTCR Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15	<b>CTSEN:</b> CTS hardware flow control enable. If this bit is set to 1, CTS hardware flow control is enabled. Data is only transmitted when the nUARTCTS signal is asserted.	RW	0x0
14	<b>RTSEN:</b> RTS hardware flow control enable. If this bit is set to 1, RTS hardware flow control is enabled. Data is only requested when there is space in the receive FIFO for it to be received.	RW	0x0
13	<b>OUT2:</b> This bit is the complement of the UART Out2 (nUARTOut2) modem status output. That is, when the bit is programmed to a 1, the output is 0. For DTE this can be used as Ring Indicator (RI).	RW	0x0
12	<b>OUT1:</b> This bit is the complement of the UART Out1 (nUARTOut1) modem status output. That is, when the bit is programmed to a 1 the output is 0. For DTE this can be used as Data Carrier Detect (DCD).	RW	0x0
11	<b>RTS:</b> Request to send. This bit is the complement of the UART request to send, nUARTRTS, modem status output. That is, when the bit is programmed to a 1 then nUARTRTS is LOW.	RW	0x0
10	<b>DTR:</b> Data transmit ready. This bit is the complement of the UART data transmit ready, nUARTDTR, modem status output. That is, when the bit is programmed to a 1 then nUARTDTR is LOW.	RW	0x0
9	<b>RXE:</b> Receive enable. If this bit is set to 1, the receive section of the UART is enabled. Data reception occurs for either UART signals or SIR signals depending on the setting of the SIREN bit. When the UART is disabled in the middle of reception, it completes the current character before stopping.	RW	0x1
8	<b>TXE:</b> Transmit enable. If this bit is set to 1, the transmit section of the UART is enabled. Data transmission occurs for either UART signals, or SIR signals depending on the setting of the SIREN bit. When the UART is disabled in the middle of transmission, it completes the current character before stopping.	RW	0x1
7	<b>LBE:</b> Loopback enable. If this bit is set to 1 and the SIREN bit is set to 1 and the SIRTEST bit in the Test Control Register, UARTTCR is set to 1, then the nSIROUT path is inverted, and fed through to the SIRIN path. The SIRTEST bit in the test register must be set to 1 to override the normal half-duplex SIR operation. This must be the requirement for accessing the test registers during normal operation, and SIRTEST must be cleared to 0 when loopback testing is finished. This feature reduces the amount of external coupling required during system test. If this bit is set to 1, and the SIRTEST bit is set to 0, the UARTRXD path is fed through to the UARTRXD path. In either SIR mode or UART mode, when this bit is set, the modem outputs are also fed through to the modem inputs. This bit is cleared to 0 on reset, to disable loopback.	RW	0x0
6:3	Reserved.	-	-

偏移量: 0x030

**描述**

控制寄存器, UARTCR

表 1036. UARTCR  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15	<b>CTSEN</b> : 使能CTS硬件流控。若该位被置为1，则启用CTS硬件流控。仅当nUARTCTS信号被断言时，数据才会被传输。	读写	0x0
14	<b>RTSEN</b> : 使能RTS硬件流控。若该位被置为1，则启用RTS硬件流控。仅当接收FIFO有可用空间时，才请求数据。	读写	0x0
13	<b>OUT2</b> : 此位为UART Out2 (nUARTOut2) 调制解调器状态信号的反码。即当该位被编程为1时，输出为0。对于DTE，此位可用作振铃指示 (RI)。	读写	0x0
12	<b>OUT1</b> : 该位为UART Out1 (nUARTOut1) 调制解调器状态输出的反码。即当该位被编程为1时，输出为0。对于DTE，此位可用作载波检测 (DCD)。	读写	0x0
11	<b>RTS</b> : 请求发送。该位为UART请求发送信号nUARTRTS调制解调器状态输出的反码。即当该位被编程为1时，nUARTRTS为低电平。	读写	0x0
10	<b>DTR</b> : 数据传输准备就绪。该位为UART数据传输准备信号nUARTDTR调制解调器状态输出的反码。即当该位被编程为1时，nUARTDTR为低电平。	读写	0x0
9	<b>RXE</b> : 接收使能。若此位被置为1，则启用UART的接收部分。数据接收针对UART信号或SIR信号，取决于SIREN位的设置。UART在接收过程中若被禁用，将完成当前字符后再停止。	读写	0x1
8	<b>TXE</b> : 发送使能。若此位被置为1，则启用UART的发送部分。数据传输针对UART信号或SIR信号，取决于SIREN位的设置。UART在传输过程中若被禁用，将完成当前字符后再停止。	读写	0x1
7	<b>LBE</b> : 回环使能。若此位、SIREN位及测试控制寄存器UARTTCR中的SIRTEST位均置为1，则nSIROUT路径将反转后传递至SIRIN路径。须将测试寄存器中的SIRTEST位置为1，方能覆盖标准的半双工SIR操作。此项为正常操作期间访问测试寄存器的必要条件，且在回环测试完成后，SIRTEST必须清零。该功能减少了系统测试过程中所需的外部耦合数量。若该位设为1且SIRTEST位为0，则UARTTxD路径将直接传输至UARTRxD路径。无论处于SIR模式还是UART模式，当该位被设置时，调制解调器的输出也将传输至其输入端。该位在复位时自动清零，以禁用回环功能。	读写	0x0
6:3	保留。	-	-

Bits	Description	Type	Reset
2	<b>SIRLP:</b> SIR low-power IrDA mode. This bit selects the IrDA encoding mode. If this bit is cleared to 0, low-level bits are transmitted as an active high pulse with a width of 3 / 16th of the bit period. If this bit is set to 1, low-level bits are transmitted with a pulse width that is 3 times the period of the IrLPBaud16 input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances.	RW	0x0
1	<b>SIREN:</b> SIR enable: 0 = IrDA SIR ENDEC is disabled. nSIROUT remains LOW (no light pulse generated), and signal transitions on SIRIN have no effect. 1 = IrDA SIR ENDEC is enabled. Data is transmitted and received on nSIROUT and SIRIN. UARTRXD remains HIGH, in the marking state. Signal transitions on UARTRXD or modem status inputs have no effect. This bit has no effect if the UARTEN bit disables the UART.	RW	0x0
0	<b>UARTEN:</b> UART enable: 0 = UART is disabled. If the UART is disabled in the middle of transmission or reception, it completes the current character before stopping. 1 = the UART is enabled. Data transmission and reception occurs for either UART signals or SIR signals depending on the setting of the SIREN bit.	RW	0x0

## UART: UARTIFLS Register

Offset: 0x034

### Description

Interrupt FIFO Level Select Register, UARTIFLS

Table 1037. UARTIFLS Register

Bits	Description	Type	Reset
31:6	Reserved.	-	-
5:3	<b>RXIFLSEL:</b> Receive interrupt FIFO level select. The trigger points for the receive interrupt are as follows: b000 = Receive FIFO becomes $\geq$ 1 / 8 full b001 = Receive FIFO becomes $\geq$ 1 / 4 full b010 = Receive FIFO becomes $\geq$ 1 / 2 full b011 = Receive FIFO becomes $\geq$ 3 / 4 full b100 = Receive FIFO becomes $\geq$ 7 / 8 full b101-b111 = reserved.	RW	0x2
2:0	<b>TXIFLSEL:</b> Transmit interrupt FIFO level select. The trigger points for the transmit interrupt are as follows: b000 = Transmit FIFO becomes $\leq$ 1 / 8 full b001 = Transmit FIFO becomes $\leq$ 1 / 4 full b010 = Transmit FIFO becomes $\leq$ 1 / 2 full b011 = Transmit FIFO becomes $\leq$ 3 / 4 full b100 = Transmit FIFO becomes $\leq$ 7 / 8 full b101-b111 = reserved.	RW	0x2

## UART: UARTIMSC Register

Offset: 0x038

### Description

Interrupt Mask Set/Clear Register, UARTIMSC

Table 1038. UARTIMSC Register

Bits	Description	Type	Reset
31:11	Reserved.	-	-
10	<b>OEIM:</b> Overrun error interrupt mask. A read returns the current mask for the UARTOEINTR interrupt. On a write of 1, the mask of the UARTOEINTR interrupt is set. A write of 0 clears the mask.	RW	0x0

位	描述	类型	复位
2	<b>SIRLP</b> : SIR低功耗IrDA模式。该位用于选择IrDA编码模式。若该位清零，低电平比特将作为宽度为比特周期3/16的高电平脉冲进行传输。若该位置1，低电平比特将以IrLPBaud16输入信号周期三倍的脉冲宽度传输，无论所选比特率为何。设置该位可降低功耗，但可能会减少传输距离。	读写	0x0
1	<b>SIREN</b> : SIR使能：0 = 禁用IrDA SIR ENDEC。nSIROUT保持低电平（不产生光脉冲），且SIRIN上的信号跳变无效。1 = 启用IrDA SIR ENDEC。数据通过nSIROUT和SIRIN传输和接收。UARTTXD保持高电平，处于标记状态。UARTRXD或调制解调器状态输入上的信号跳变无效。若UARTEN位禁用UART，则该位无效。	读写	0x0
0	<b>UARTEN</b> : UART使能：0 = 禁用UART。如果在传输或接收过程中禁用UART，将完成当前字符后停止。1 = 启用UART。数据传输与接收根据SIREN位的设置，通过UART信号或SIR信号进行。	读写	0x0

## 12.2. I2C

### Synopsys Documentation

Synopsys Proprietary. Used with permission.

I2C is a commonly used 2-wire interface that can be used to connect devices for low speed data transfer using clock **SCL** and data **SDA** wires.

RP2350 has two identical instances of an I2C controller. The external pins of each controller are connected to GPIO pins as defined in the GPIO muxing [table](#) in [Section 9.4](#). The muxing options give some IO flexibility.

## 12.2. I2C

### Synopsys 文档

Synopsys 专有。经许可使用。

I2C 是一种常用的双线接口，可用于通过时钟线 SCL 和数据线 SDA 连接设备，实现低速数据传输。

RP2350 具有两个相同的 I2C 控制器实例。每个控制器的外部引脚连接至第 9.4 节 GPIO 复用表中定义的 GPIO 引脚。复用选项提供一定的 IO 灵活性。

## 12.2.1. Features

Each I2C controller is based on a configuration of the Synopsys [DW\\_apb\\_i2c \(v2.03a\)](#) IP. The following features are supported:

- Master or Slave (Default to Master mode)
- Standard mode, Fast mode or Fast mode plus
- Default slave address [0x055](#)
- Supports 10-bit addressing in Master mode
- 16-element transmit buffer
- 16-element receive buffer
- Can be driven from DMA
- Can generate interrupts

### 12.2.1.1. Standard

The I2C controller was designed for I2C Bus specification, version 6.0, dated April 2014.

### 12.2.1.2. Clocking

All clocks in the I2C controller are connected to [clk\\_sys](#), including [ic\\_clk](#), which is mentioned in later sections. The I2C clock is generated by dividing down this clock, controlled by registers inside the block.

### 12.2.1.3. IOs

Each controller must connect its clock [SCL](#) and data [SDA](#) to one pair of GPIOs. The I2C standard requires that drivers drive a signal low, or when not driven the signal will be pulled high. This applies to SCL and SDA. The GPIO pads should be configured for:

- pull-up enabled
- slew rate limited
- schmitt trigger enabled

#### **i** NOTE

There should also be external pull-ups on the board as the internal pad pull-ups may not be strong enough to pull up external circuits.

## 12.2.2. IP configuration

I2C configuration details (each instance is fully independent):

- 32-bit APB access
- Supports Standard mode, Fast mode or Fast mode plus (not High speed)
- Default slave address of [0x055](#)
- Master or Slave mode
- Master by default (Slave mode disabled at reset)

## 12.2.1. 功能特性

每个 I2C 控制器基于 Synopsys DW\_apb\_i2c(v2.03a) IP 配置，支持以下特性：

- 主设备或从设备（默认主模式）
- 标准模式、快速模式或快速模式增强
- 默认从设备地址为 0x055
- 主模式支持 10 位地址
- 16 单元发送缓冲区
- 16 单元接收缓冲区
- 支持 DMA 驱动
- 可产生中断

### 12.2.1.1. 标准

I2C 控制器设计遵循 2014 年 4 月发布的 I2C 总线规范，第 6.0 版。

### 12.2.1.2. 时钟

I2C 控制器中的所有时钟均连接至 clk\_sys，包括后文提及的 ic\_clk。I2C 时钟通过分频生成，由模块内部寄存器控制。

### 12.2.1.3. 输入输出端口

每个控制器必须将时钟信号 SCL 和数据信号 SDA 连接到一对 GPIO。I2C 标准要求驱动器将信号拉低，非驱动状态下信号由上拉电阻拉高。该要求适用于 SCL 和 SDA。GPIO 引脚应配置为：

- 启用上拉
- 限制转换速率
- 启用施密特触发器

#### **i 注意**

电路板上还应配置外部上拉，因为内部引脚上的上拉可能不足以将外部电路拉高。  
外部电路。

## 12.2.2. IP 配置

I2C 配置详情（每个实例完全独立）：

- 32 位 APB 访问
- 支持标准模式、快速模式及快速模式加（不支持高速模式）
- 默认从机地址为 0x055
- 主机模式或从机模式
- 默认主机模式（复位时从机模式禁用）

- 10-bit addressing supported in master mode (7-bit by default)
- 16 entry transmit buffer
- 16 entry receive buffer
- Allows restart conditions when a master (can be disabled for legacy device support)
- Configurable timing to adjust `TsuDAT/ThDAT`
- General calls responded to on reset
- Interface to DMA
- Single interrupt output
- Configurable timing to adjust clock frequency
- Spike suppression (default 7 `clk_sys` cycles)
- Can NACK after data received by Slave
- Hold transfer when TX FIFO empty
- Hold bus until space available in RX FIFO
- Restart detect interrupt in Slave mode
- Optional blocking Master commands (not enabled by default)

### 12.2.3. I2C overview

The I2C bus is a 2-wire serial interface, consisting of a serial data line `SDA` and a serial clock `SCL`. These wires carry information between the devices connected to the bus. Each device is recognized by a unique address and can operate as either a "transmitter" or "receiver", depending on the function of the device. Devices can also be considered as masters or slaves when performing data transfers. A master is a device that initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

**NOTE**

The I2C block must only be programmed to operate in either master OR slave mode only. Operating as a master and slave simultaneously is not supported.

The I2C block can operate in these modes:

- standard mode (with data rates from 0 to 100 kb/s),
- fast mode (with data rates up to 400 kb/s),
- fast mode plus (with data rates up to 1000 kb/s).

These modes are not supported:

- High-speed mode (with data rates up to 3.4Mb/s),
- Ultra-Fast Speed Mode (with data rates up to 5Mb/s).

**NOTE**

References to fast mode also apply to fast mode plus, unless specifically stated otherwise.

The I2C block can communicate with devices in one of these modes as long as they are attached to the bus. Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices at up to 100 kb/s over the I2C bus system. However, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I2C bus system as they cannot follow the higher transfer rate; unpredictable states would occur.

- 主机模式支持 10 位寻址（默认 7 位寻址）
- 16 条传输缓冲区条目
- 16 条接收缓冲区条目
- 允许主机执行重启条件（可为兼容旧设备而禁用）
- 可配置定时以调整 `TsuDAT`/`ThDAT`
- 复位后响应通用调用
- 具备 DMA 接口
- 单一中断输出
- 可配置定时以调整时钟频率
- 脉冲抑制（默认 7 个 `clk_sys` 周期）
- 从机接收数据后可响应 NACK
- 当 TX FIFO 为空时保持传输
- 保持总线，直到 RX FIFO 中有可用空间
- 从模式下重新启动检测中断
- 可选阻塞式主设备命令（默认未启用）

### 12.2.3. I2C 概述

I2C总线是一种两线串行接口，包括串行数据线 `SDA`和串行时钟线 `SCL`。这些线缆在连接至总线的设备之间传递信息。每个设备通过唯一地址识别，并可根据设备功能作为“发送器”或“接收器”运行。执行数据传输时，设备亦可被视为主设备或从设备。主设备为启动总线数据传输并生成时钟信号以允许传输的设备。此时，任何被寻址的设备均视为从设备。

#### 注意

I2C模块必须仅配置为主模式或从模式之一。不支持同时作为主设备和从设备运行。

I2C模块可运行于以下模式：

- 标准模式（数据速率为0至100 kb/s），
- 快速模式（数据速率最高可达400 kb/s），
- 快速增强模式（数据速率最高可达1000 kb/s）。

以下模式不被支持：

- 高速模式（数据速率最高可达3.4 Mb/s），
- 超高速模式（数据速率最高可达5 Mb/s）。

#### 注意

除非另有特别说明，快速模式的相关描述同样适用于快速增强模式。

只要设备连接至总线，I2C模块便能以任一模式与之通信。

此外，快速模式设备具有向下兼容性。例如，快速模式设备可以通过I2C总线系统以最高100 kb/s的速率与标准模式设备通信。然而，标准模式设备不具备向上兼容性，因其无法适应更高的传输速率，不应纳入快速模式的I2C总线系统；否则可能导致不可预测的状态。

The following devices commonly use high-speed mode:

- LCD displays
- high-bit count ADCs
- high capacity EEPROMs

These devices typically need to transfer large amounts of data.

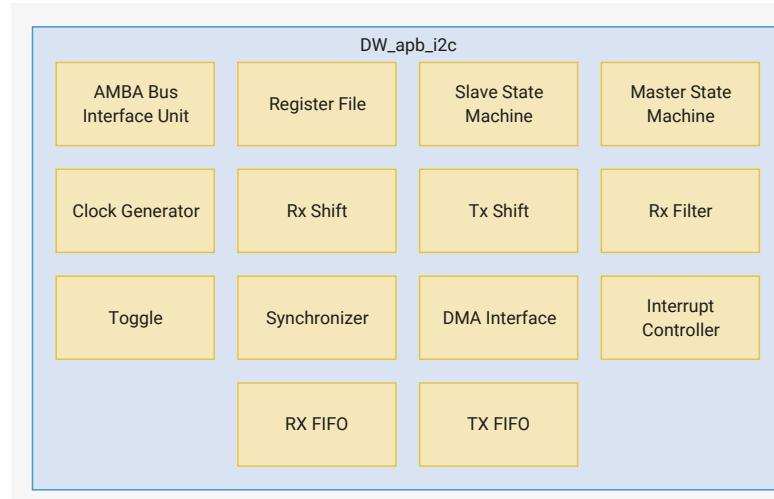

Most maintenance and control applications, the common use for the I<sup>2</sup>C bus, typically operate at 100 kHz in standard and fast modes. Any [DW\\_apb\\_i2c](#) device can be attached to an I<sup>2</sup>C bus. Every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus, but there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. The I<sup>2</sup>C block does not support SMBus and PMBus protocols (for System management and Power management).

The [DW\\_apb\\_i2c](#) is made up of:

- an AMBA APB slave interface
- an I<sup>2</sup>C interface
- FIFO logic to maintain coherency between the two interfaces

The blocks of the component are illustrated in [Figure 68](#).

Figure 68. I<sup>2</sup>C Block diagram

The following define the functions of the blocks in [Figure 68](#):

- **AMBA Bus Interface Unit:** Takes the APB interface signals and translates them into a common generic interface that allows the register file to be bus protocol-agnostic.
- **Register File:** Contains configuration registers and is the interface with software.
- **Slave State Machine:** Follows the protocol for a slave and monitors bus for address match.
- **Master State Machine:** Generates the I<sup>2</sup>C protocol for the master transfers.
- **Clock Generator:** Calculates the required timing to do the following:
  - Generate the [SCL](#) clock when configured as a master
  - Check for bus idle
  - Generate a START and a STOP
  - Setup the data and hold the data
- **RX Shift:** Takes data into the design and extracts it in byte format.

以下设备通常使用高速模式：

- 液晶显示屏
- 高位数模数转换器
- 高容量EEPROM

这些设备通常需要传输大量数据。

大多数维护和控制应用，即I2C总线的常见用途，通常以100 kHz的标准模式和快速模式运行。任何 DW\_apb\_i2c 设备均可连接至I2C总线。每个设备都能与任何主机通信，实现双向信息传递。总线上必须至少有一个主机（例如微控制器或数字信号处理器），但也可存在多个主机，且需要它们进行所有权仲裁。本章后续将介绍多个主机和仲裁机制。该I2C模块不支持SMBus及PMBus协议（系统管理和电源管理协议）。

DW\_apb\_i2c由以下部分组成：

- 一个AMBA APB从属接口
- 一个I2C接口
- 用于维护两个接口一致性的FIFO逻辑

该组件的结构如图68所示。

图68。I2C块图

以下定义了图68中各模块的功能：

- **AMBA总线接口单元：**接收APB接口信号并将其转换为通用接口，从而使寄存器文件与总线协议无关。
- **寄存器文件：**包含配置寄存器，是与软件的接口。
- **从属状态机：**遵循从属协议并监控总线以匹配地址。
- **主控状态机：**生成主控传输所需的I2C协议。
- **时钟发生器：**计算执行以下操作所需的时序：
  - 在配置为主控时生成 SCL 时钟
  - 检查总线是否空闲
  - 生成启动（START）和停止（STOP）信号
  - 设置并保持数据
- **接收移位寄存器：**将数据接入设计并以字节格式提取。

- **TX Shift:** Presents data supplied by CPU for transfer on the I2C bus.
- **RX Filter:** Detects the events in the bus; for example, start, stop and arbitration lost.
- **Toggle:** Generates pulses on both sides and toggles to transfer signals across clock domains.
- **Synchronizer:** Transfers signals from one clock domain to another.
- **DMA Interface:** Generates the handshaking signals to the central DMA controller in order to automate the data transfer without CPU intervention.
- **Interrupt Controller:** Generates the raw interrupt and interrupt flags, allowing them to be set and cleared.
- **RX FIFO/TX FIFO:** Holds the RX FIFO and TX FIFO register banks and controllers, along with their status levels.

## 12.2.4. I2C terminology

This section defines key terms used in various parts of the I2C.

### 12.2.4.1. I2C bus terms

The following terms relate to how the role of the I2C device and how it interacts with other I2C devices on the bus.

#### Transmitter

the device that sends data to the bus. A transmitter can either be a device that initiates the data transmission to the bus (a master-transmitter) or the device that responds to a request from the master to send data to the bus (a slave-transmitter).

#### Receiver

the device that receives data from the bus. A receiver can either be a device that receives data on its own request (a master-receiver) or a device that receives data in response to a request from the master (a slave-receiver).

#### Master

the component that initializes a transfer (START command), generates the clock **SCL** signal and terminates the transfer (STOP command). A master can be either a transmitter or a receiver.

#### Slave

the device addressed by the master. A slave can be either receiver or transmitter.

#### Multi-master

the ability for more than one master to co-exist on the bus at the same time without collision or data loss.

#### Arbitration

the predefined procedure that authorizes only one master at a time to take control of the bus. For more information about this behaviour, refer to [Section 12.2.8](#).

#### Synchronization

the predefined procedure that synchronizes the clock signals provided by two or more masters. For more information about this feature, refer to [Section 12.2.9](#).

#### SDA

the data signal line (Serial Data).

#### SCL

the clock signal line (Serial Clock).

- **发送移位寄存器**: 输出CPU提供的数据以进行I2C总线传输。
- **接收滤波器**: 检测总线上的各类事件；例如启动、停止及仲裁丢失。
- **切换器**: 在两端产生脉冲并切换，用于跨时钟域传输信号。
- **同步器**: 实现信号从一个时钟域向另一个时钟域的传输。
- **DMA接口**: 生成与中央DMA控制器的握手信号，实现无CPU干预的自动数据传输。
  
- **中断控制器**: 生成原始中断信号和中断标志，支持其设置与清除。
- **RX FIFO/TX FIFO**: 包含RX FIFO和TX FIFO寄存器组及控制器及其状态级别。

## 12.2.4. I2C 术语

本节定义I2C各部分使用的关键术语。

### 12.2.4.1. I2C总线术语

以下术语涉及I2C设备的角色及其与总线上其他I2C设备的交互。

#### 发送器

向总线发送数据的设备。发送器可以是发起数据传输的设备（主发送器），也可以是响应主机请求向总线发送数据的设备（从发送器）。

#### 接收器

从总线接收数据的设备。接收器可以是自行请求接收数据的设备（主接收器），也可以是响应主机请求接收数据的设备（从接收器）。

#### 主设备

初始化传输（START命令）、产生时钟信号SCL并终止传输（STOP命令）的组件。主设备可以是发送器或接收器。

#### 从设备

由主设备寻址的设备。从设备可以是接收器或发送器。

#### 多主设备

多个主设备能够在总线上同时共存且无冲突或数据丢失的能力。

#### 仲裁

授权同一时间仅允许一个主设备控制总线的预定义程序。有关此行为的更多信息，请参见第12.2.8节。

#### 同步

用于同步两个或多个主设备所提供时钟信号的预定义程序。有关此功能的更多信息，请参见第12.2.9节。

#### SDA

数据信号线（串行数据线）。

#### SCL

时钟信号线（串行时钟线）。

### 12.2.4.2. Bus transfer terms

The following terms are specific to data transfers that occur to and from the I<sup>2</sup>C bus.

#### START (RESTART)

A data transfer begins with a START or RESTART condition. The level of the **SDA** data line changes from high to low, while the **SCL** clock line remains high. When this occurs, the bus becomes busy.

#### NOTE

START and RESTART conditions are functionally identical.

#### STOP

A data transfer is terminated by a STOP condition. This occurs when the level on the **SDA** data line passes from the low state to the high state, while the **SCL** clock line remains high. When the data transfer has been terminated, the bus is free or idle once again. The bus stays busy if a RESTART is generated instead of a STOP condition.

### 12.2.5. I<sup>2</sup>C behaviour

The **DW\_apb\_i2c** can be controlled with software to be one of the following:

- An I<sup>2</sup>C master only, communicating with other I<sup>2</sup>C slaves
- An I<sup>2</sup>C slave only, communicating with one or more I<sup>2</sup>C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to and from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I<sup>2</sup>C protocol also allows multiple masters to reside on the I<sup>2</sup>C bus and uses an arbitration procedure to determine bus ownership.

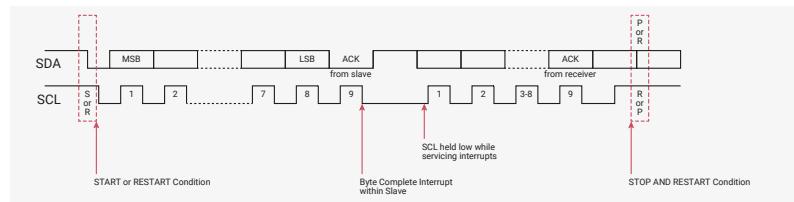

Each slave has a unique address determined by the system designer. When a master wants to communicate with a slave:

1. The master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave.
2. The slave then sends an acknowledge (ACK) pulse after the address.

When the master (master-transmitter) writes to the slave (slave-receiver), the receiver gets one byte of data. This transaction continues until the master terminates the transmission with a STOP condition.

When the master reads from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master. The master then acknowledges the transaction with the ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. This behaviour is illustrated in Figure 69.

Figure 69. Data transfer on the I<sup>2</sup>C Bus

The **DW\_apb\_i2c** is a synchronous serial interface. The **SDA** line is a bidirectional signal that changes only while the **SCL** line is low except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages.

The I<sup>2</sup>C protocols implemented in **DW\_apb\_i2c** are described in more details in [Section 12.2.6](#).

### 12.2.4.2 总线传输术语

以下术语专指发生在I2C总线上的数据传输。

#### 起始（重新起始）

数据传输从 START 或 RESTART 条件开始。当 SCL 时钟线保持高电平时，SDA 数据线的电平由高变低。此时，总线变为忙碌状态。

#### 注意

START 和 RESTART 条件在功能上完全相同。

#### STOP

数据传输由 STOP 条件终止。当 SCL 时钟线保持高电平时，SDA 数据线的电平由低变高，即发生此情况。数据传输终止后，总线再次处于空闲状态。如果产生 RESTART 条件而非 STOP 条件，总线将保持忙碌状态。

### 12.2.5. I2C 行为

DW\_apb\_i2c 可通过软件控制设置为以下模式之一：

- 仅作为 I2C 主设备，与其他 I2C 从设备通信。
- 仅作为 I2C 从设备，与一个或多个 I2C 主设备通信。

主设备负责生成时钟信号并控制数据传输。从设备负责向主设备传输或接收数据。数据确认由接收数据的设备发送，该设备可以是主设备或从设备。如前所述，I2C 协议允许多个主设备存在于 I2C 总线上，并采用仲裁程序确定总线所有权。

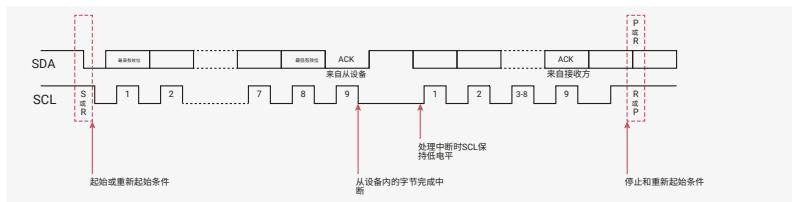

每个从设备具有由系统设计者确定的唯一地址。当主设备欲与从设备通信时：

1. 主设备发送 START/RESTART 条件，随后发送从设备地址及一个控制位 (R/W)，以确定主设备是发送数据还是接收数据。
2. 从设备随后在地址后发送确认 (ACK) 信号。

当主设备（主发送器）向从设备（从接收器）写入时，接收器获取一个字节数据。该事务持续进行，直至主设备以 STOP 条件终止传输。

当主设备从从设备读取时（主接收器），从设备（从发送器）向主设备传送一个数据字节。主设备随后通过 ACK 脉冲确认该事务。该事务持续进行，直到主设备在接收最后一个字节后未确认（发送 NACK），随后发出 STOP 条件，或在发出 RESTART 条件后寻址另一从设备，从而终止传输。该行为如图69所示。

图69。I2C总线上的数据传输

DW\_apb\_i2c 是一种同步串行接口。SDA 线为双向信号，仅在 SCL 线为低电平时发生变化，停止 (STOP)、启动 (START) 及重新启动 (RESTART) 条件除外。输出驱动器采用开漏 (open-drain) 或开集电极 (open-collector) 结构，以实现总线上的线与 (wire-AND) 功能。总线上设备数量的最大限制仅取决于最大电容规格 400 pF。数据以字节包形式传输。

实现于 DW\_apb\_i2c 中的 I2C 协议详见第 12.2.6 节。

### 12.2.5.1. START and STOP generation

When operating as an I2C master, putting data into the TX FIFO causes the `DW_apb_i2c` to generate a START condition on the I2C bus. Writing a 1 to `IC_DATA_CMD.STOP` causes the `DW_apb_i2c` to generate a STOP condition on the I2C bus; a STOP condition is not issued if this bit is not set, even if the TX FIFO is empty.

When operating as a slave, the `DW_apb_i2c` does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the `DW_apb_i2c`, it holds the `SCL` line low until read data has been supplied to it. This stalls the I2C bus until read data is provided to the slave `DW_apb_i2c`, or the `DW_apb_i2c` slave is disabled by writing a 0 to `IC_ENABLE.ENABLE`.

### 12.2.5.2. Combined formats

The `DW_apb_i2c` supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. The `DW_apb_i2c` does not support mixed address and mixed address format - that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa-combined format transactions. To initiate combined format transfers, `IC_CON.IC_RESTART_EN` should be set to 1. With this value set and operating as a master, when the `DW_apb_i2c` completes an I2C transfer, it checks the TX FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the TX FIFO is empty when the current I2C transfer completes:

- `IC_DATA_CMD.STOP` is checked and:
  - If set to 1, a STOP bit is issued.
  - If set to 0, the `SCL` is held low until the next command is written to the TX FIFO.

For more details, refer to [Section 12.2.7](#).

## 12.2.6. I2C protocols

This section defines protocols used in the `DW_apb_i2c`.

### 12.2.6.1. START and STOP conditions

When the bus is idle, both the `SCL` and `SDA` signals are pulled high through external pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a **START condition**: a high-to-low transition of the `SDA` signal while `SCL` is 1. When the master wants to terminate the transmission, the master issues a **STOP condition**: a low-to-high transition of the `SDA` signal while `SCL` is 1. [Figure 70](#) shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the `SDA` signal must be stable when `SCL` is set to 1.

*Figure 70. I2C START and STOP Condition*

### 12.2.5.1. 启动 (START) 和停止 (STOP) 条件的产生

作为I2C主控时，将数据写入TX FIFO会使 DW\_apb\_i2c在I2C总线上产生启动 (START) 条件。向IC\_DATA\_CMD.STOP写入1会使 DW\_apb\_i2c在I2C总线上产生停止 (STOP) 条件；若未设置该位，即使TX FIFO为空，也不会发出停止 (STOP) 条件。

当以从机模式运行时， DW\_apb\_i2c不会按照协议产生 START 和 STOP 条件。然而，如果向 DW\_apb\_i2c发出读请求，该设备将保持 SCL线为低电平，直至读取数据提供完成。这会阻塞 I2C 总线，直到将读取数据传送至从属设备 DW\_apb\_i2c，或通过向 IC\_ENABLE.ENABLE 寄存器写入 0 以禁用 DW\_apb\_i2c从机功能。

### 12.2.5.2 组合格式

DW\_apb\_i2c支持在 7 位和 10 位寻址模式下的混合读写组合格式事务。

DW\_apb\_i2c不支持混合地址格式的组合格式事务，即不支持先进行 7 位地址事务后接 10 位地址事务，或反之亦然。要启动组合格式传输，需将 IC\_CON.IC\_RESTART\_EN 设置为 1。在该值设置且作为主设备运行时，当 DW\_apb\_i2c完成 I2C 传输后，会检查 TX FIFO 并执行下一次传输。若此次传输方向与前一次传输不同，则采用组合格式发起传输。当前 I2C 传输完成且 TX FIFO 为空时：

- 检查 IC\_DATA\_CMD.STOP，且：
  - 若设置为 1，则发送 STOP 位。
  - 若设置为 0，则在下一命令写入 TX FIFO 前， SCL 保持低电平。

详情请参阅第 12.2.7 节。

## 12.2.6. I2C 协议

本节定义了 DW\_apb\_i2c所使用的协议。

### 12.2.6.1. START 和 STOP 条件

总线空闲时，总线上 SCL和 SDA信号通过外部上拉电阻被拉高。主设备欲开始总线传输时，发出**START** 条件：即在SCL为 1 时，SDA由高电平跳变至低电平。当主设备欲终止传输时，主设备会发出**STOP**条件：在SCL信号为1时，SDA信号由低电平跳变至高电平。图70展示了**START**和**STOP**条件的时序。

当数据在总线上传输时， SDA信号在 SCL 为高电平时必须保持稳定。

图70。 I2C启动  
与停止条件

### NOTE

The signal transitions for the START/STOP conditions, as depicted in [Figure 70](#), reflect those observed at the output signals of the master driving the I<sup>2</sup>C bus. Care should be taken when observing the SDA/SCL signals at the input signals of slaves, because unequal line delays may result in an incorrect SDA/SCL timing relationship.

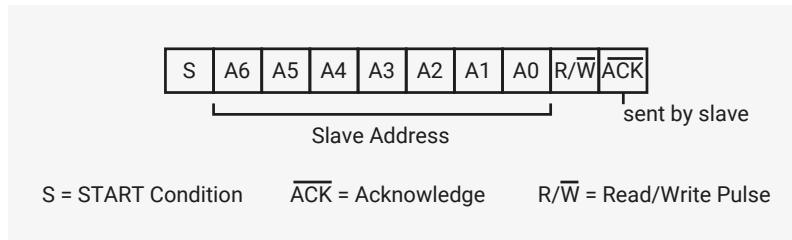

## 12.2.6.2. Addressing slave protocol

There are two address formats: 7-bit and 10-bit.

### 12.2.6.2.1. 7-bit address format

In the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) defines the R/W status, as shown in [Figure 71](#). When bit 0 is set to 0, the master writes to the slave. When bit 0 is set to 1, the master reads from the slave.

Figure 71. I<sup>2</sup>C 7-bit Address Format

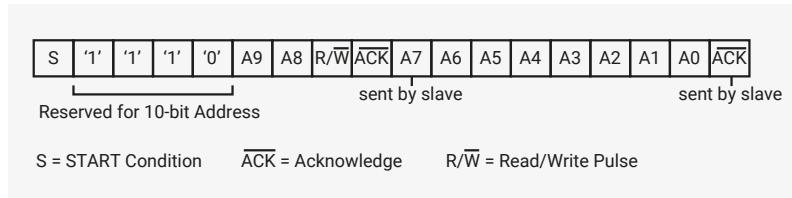

### 12.2.6.2.2. 10-bit address format

The 10-bit address format transfers two bytes for each 10-bit address.

- In the first byte, the first five bits (bits 7:3) indicate a 10-bit transfer. The next two bits (bits 2:1) contain bits 9:8 of the slave address. The LSB bit (bit 0) defines the R/W status.
- The second byte contains bits 7:0 of the slave address.

[Figure 72](#) shows the 10-bit address format:

Figure 72. 10-bit Address Format

[This table](#) defines the special purpose and reserved first byte addresses.

Table 1051.  
I<sup>2</sup>C/SMBus Definition  
of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General Call Address. <a href="#">DW_apb_i2c</a> places the data in the receive buffer and issues a General Call interrupt.
0000 000	1	START byte. For more details, refer to <a href="#">Section 12.2.6.4</a> .
0000 001	X	CBUS address. <a href="#">DW_apb_i2c</a> ignores these accesses.
0000 010	X	Reserved.

### 注意

图70所示的START/STOP条件信号跳变，反映了驱动I2C总线的主设备输出信号情况。观察从设备输入端的 SDA/SCL信号时，应注意线路时延不一致可能导致 SDA/SCL时序关系出现误差。

## 12.2.6.2. 从设备寻址协议

地址格式有两种：7位和10位。

### 12.2.6.2.1. 7位地址格式

在7位地址格式中，第一个字节的高七位（位7至位1）设定从机地址，最低位（位0）定义读/写状态，如图71所示。当位0设为0时，主机向从机写入数据。当位0设为1时，主机从从机读取数据。

图71. I2C 7位地址格式

### 12.2.6.2.2. 10位地址格式

10位地址格式每个10位地址传输两个字节。

- 第一个字节中的前五位（位7至位3）表示10位地址传输。后两个位（位2:1）包含从属设备地址的位9:8。最低有效位（位0）定义读/写状态。
- 第二个字节包含从属设备地址的位7:0。

图 72 显示了 10 位地址格式：

图 72. 10 位地址格式

本表定义了特殊用途及保留的首字节地址。

表 1051.  
I2C/SMBus 首字节  
位定义

从机地址	读/写位	描述
0000 000	0	通用呼叫地址。 <a href="#">DW_apb_i2c</a> 将数据放入接收缓冲区， 并触发通用呼叫中断。
0000 000	1	起始字节。详细信息请参见第 <a href="#">12.2.6.4</a> 节。
0000 001	X	CBUS地址。 <a href="#">DW_apb_i2c</a> 忽略 这些访问。
0000 010	X	保留。

Slave Address	R/W Bit	Description
0000 011	X	Reserved.
0000 1XX	X	High-speed master code (for more information, refer to <a href="#">Section 12.2.8</a> ).
1111 1XX	X	Reserved.
1111 0XX	X	10-bit slave addressing.
0001 000	X	SMBus Host. (not supported)
0001 100	X	SMBus Alert Response Address. (not supported)
1100 001	X	SMBus Device Default Address. (not supported)

[DW\\_apb\\_i2c](#) does not restrict you from using reserved addresses. However, if you use these reserved addresses, you may experience incompatibilities with I2C components.

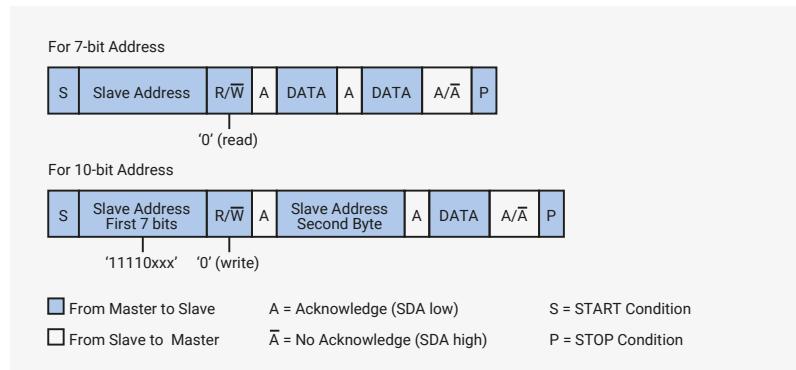

### 12.2.6.3. Transmitting and receiving protocol

The master can initiate data transmission and reception to and from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to/from the bus, acting as either a slave-transmitter or slave-receiver, respectively.

#### 12.2.6.3.1. Master-transmitter and slave-receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When no slave-receiver responds with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the [SDA](#) line high so that the master can abort the transfer. If the master-transmitter is transmitting data as shown in [Figure 73](#), the slave-receiver responds to the master-transmitter with an acknowledge pulse after every byte of data is received.

Figure 73. I2C Master-Transmitter Protocol

#### 12.2.6.3.2. Master-receiver and slave-transmitter

If the master is receiving data as shown in [Figure 74](#) the master responds to the slave-transmitter with an acknowledge pulse after receiving each byte of data, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the [SDA](#) line after detecting No Acknowledge (NACK) so that the master can issue a STOP condition.

从机地址	读/写位	描述
0000 011	X	保留。
0000 1XX	X	高速主控制码（详情请参见第12.2.8节）。
1111 1XX	X	保留。
1111 0XX	X	10位从地址。
0001 000	X	SMBus主机。（不支持）
0001 100	X	SMBus警报响应地址。（不支持）
1100 001	X	SMBus设备默认地址。（不支持）

DW\_apb\_i2c不限制您使用保留地址。但若使用这些保留地址，可能会导致与I2C组件不兼容。

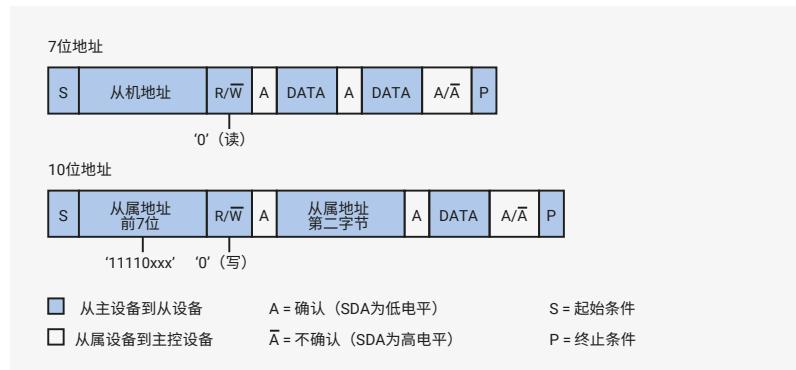

### 12.2.6.3 发送和接收协议

主控制器可在总线上发起数据发送与接收，充当主发送器或主接收器。从机响应主控制器请求，执行向总线数据发送或接收，分别充当从发送器或从接收器。

#### 12.2.6.3.1. 主发射器与从接收器

所有数据均以字节格式传输，且每次数据传输的字节数无限制。主设备发送地址和读写位或向从设备传输一字节数据后，从接收器必须响应确认信号（ACK）。若无从接收器以ACK脉冲响应，则主设备通过发出停止条件中止传输。从设备必须保持 SDA线为高电平，以便主设备能够中止传输。如果主发射器正在传输数据（如图73所示），从接收器在接收每字节数据后向主发射器发送确认脉冲。

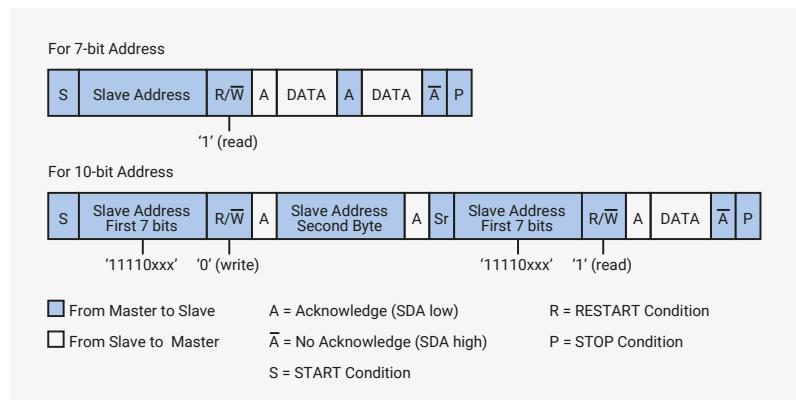

图73。I2C 主控设备-发送协议

#### 12.2.6.3.2. 主接收从发送

如图74所示，若主控设备处于接收状态，除最后一字节外，主控设备在接收每个数据字节后都会向从发送器发送确认脉冲。主接收器通过此方式告知从发送器这是最后一个字节。从发送器检测到无确认（NACK）后释放 SDA线，以便主控设备发出停止条件。

Figure 74. I<sup>2</sup>C Master-Receiver Protocol

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the DW\_apb\_i2c can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the DW\_apb\_i2c supports, see [Section 12.2.5.2](#).

#### NOTE

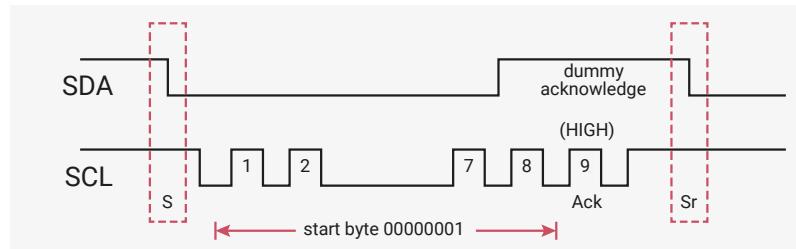

The DW\_apb\_i2c must be completely disabled before the target slave address register (IC\_TAR) can be reprogrammed.

#### 12.2.6.4. START BYTE Transfer Protocol

The START BYTE transfer protocol is designed for systems that do not have an on-board dedicated I<sup>2</sup>C hardware module. When the DW\_apb\_i2c is addressed as a slave, it always samples the I<sup>2</sup>C bus at the highest speed supported so that it never requires a START BYTE transfer. However, when DW\_apb\_i2c is a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it.

This protocol consists of the transmission of seven zeros, followed by a one, as illustrated in [Figure 75](#). This allows the processor polling the bus to under-sample the address phase until zero is detected. Once the microcontroller detects a zero, it switches from the under sampling rate to the correct rate of the master.

Figure 75. I<sup>2</sup>C Start Byte Transfer

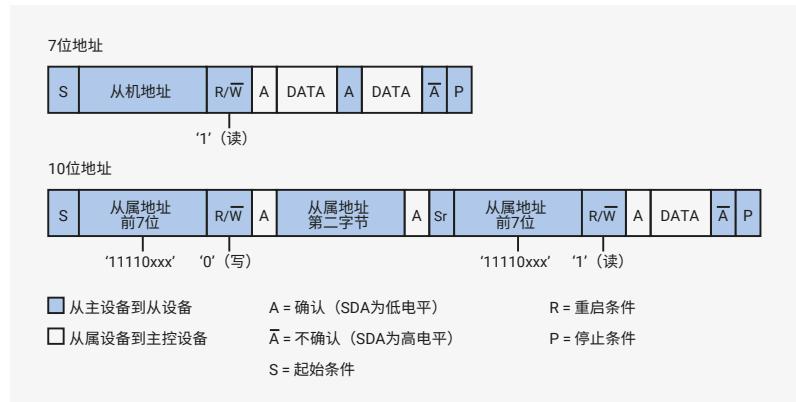

The START BYTE procedure is as follows:

1. Master generates a START condition.
2. Master transmits the START byte (**0000 0001**).
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus)
4. No slave sets the ACK signal to zero.
5. Master generates a RESTART (R) condition.

Hardware receivers do not respond to the START BYTE procedure because it uses a reserved address and resets after the RESTART condition generates.

图74。I2C 主控设备-接收协议

当主设备不希望通过STOP条件释放总线时，主设备可以发送RESTART条件。

这与START条件相同，只不过发生在ACK脉冲之后。在主模式下，DW\_apb\_i2c能够通过方向不同的传输与同一从设备通信。有关DW\_apb\_i2c支持的组合格式事务的详细描述，请参见第12.2.5.2节。

### 注意

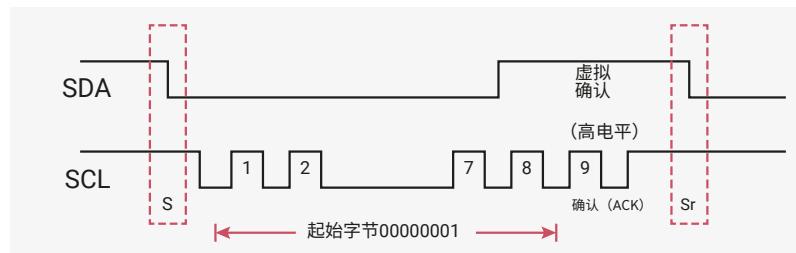

必须先完全禁用DW\_apb\_i2c，才能重新编程目标从设备地址寄存器（IC\_TAR）。

#### 12.2.6.4. START BYTE传输协议

START BYTE传输协议专为无板载专用I2C硬件模块的系统设计。当DW\_apb\_i2c作为从设备被寻址时，它总是以其支持的最高速率采样I2C总线，因此无需START BYTE传输。然而，当DW\_apb\_i2c作为主设备时，支持在每次传输开始时生成START BYTE传输，以满足从设备的需求。

该协议包括发送七个零，随后是一个一，如图75所示。这使得轮询总线的处理器能够在检测到零之前对地址阶段进行欠采样。一旦微控制器检测到零，便会从欠采样速率切换至主设备的正确速率。

图75. I2C起始字节传输

START BYTE过程如下：

1. 主设备生成START条件。
2. 主设备发送START字节（0000 0001）。
3. 主设备发送ACK时钟脉冲。（仅为符合总线上字节处理格式而设）
4. 无从设备将ACK信号拉低。
5. 主设备生成RESTART（重启）条件。

硬件接收器不响应START BYTE过程，因其使用保留地址，且在RESTART条件产生后复位。

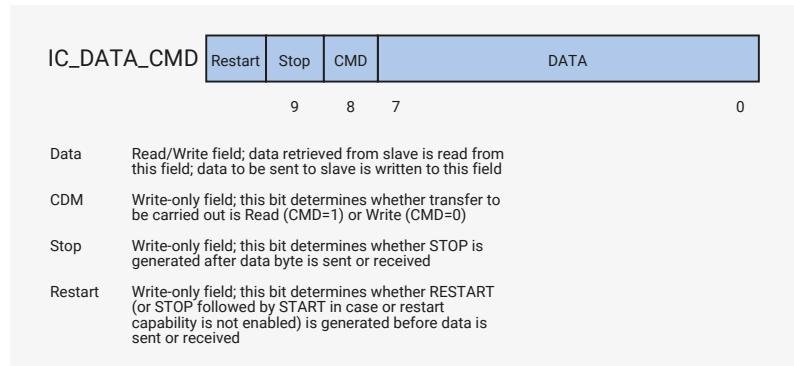

## 12.2.7. TX FIFO Management and START, STOP and RESTART Generation

When operating as a master, the `DW_apb_i2c` component supports the mode of TX (transmit) FIFO management illustrated in [Figure 76](#).

### 12.2.7.1. TX FIFO management

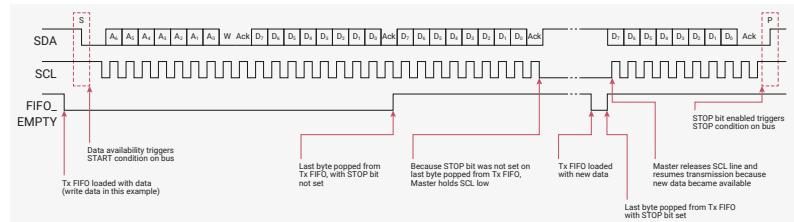

The component does not generate a STOP if the TX FIFO becomes empty; in this situation the component holds the `SCL` line low, stalling the bus until a new entry is available in the TX FIFO. A STOP condition is generated only when the user specifically requests it by setting bit nine (Stop bit) of the command written to `IC_DATA_CMD` register. [Figure 76](#) shows the bits in the `IC_DATA_CMD` register.

[Figure 76.](#)  
`IC_DATA_CMD`  
Register

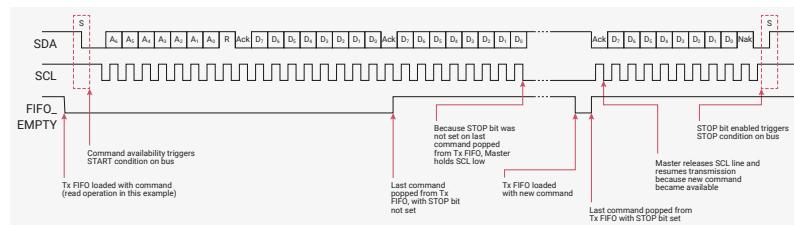

[Figure 77](#) illustrates the behaviour of the `DW_apb_i2c` when the TX FIFO becomes empty while operating as a master transmitter, as well as the generation of a STOP condition.

[Figure 77.](#) Master Transmitter - TX FIFO Empties/STOP Generation

[Figure 78](#) illustrates the behaviour of the `DW_apb_i2c` when the TX FIFO becomes empty while operating as a master receiver, as well as the generation of a STOP condition.

[Figure 78.](#) Master Receiver - TX FIFO Empties/STOP Generation

[Figure 79](#) and [Figure 80](#) illustrate configurations where the user can control the generation of RESTART conditions on the I<sup>2</sup>C bus. If bit 10 (Restart) of the `IC_DATA_CMD` register is set and the restart capability is enabled (`IC_RESTART_EN=1`), a RESTART is generated before the data byte is written to or read from the slave. If the restart capability is not enabled, a STOP followed by a START is generated in place of the RESTART. [Figure 79](#) illustrates this situation during operation as a master transmitter.

## 12.2.7. 发送 FIFO 管理及 START、STOP 和 RESTART 生成

作为主设备操作时，DW\_apb\_i2c组件支持图76所示的TX（发送）FIFO管理模式。

### 12.2.7.1 TX FIFO管理

当TX FIFO变为空时，组件不会生成STOP信号；此时，组件保持SCL线为低电平，暂停总线，直到TX FIFO中有新条目可用。只有用户在写入IC\_DATA\_CMD寄存器的命令中明确设置第九位（停止位）时，才会生成STOP条件。图76显示了IC\_DATA\_CMD寄存器的各个位。

图76。

IC\_DATA\_CMD  
寄存器

图77说明了DW\_apb\_i2c作为主机发送器工作时，TX FIFO变为空时的行为，以及STOP条件的生成。

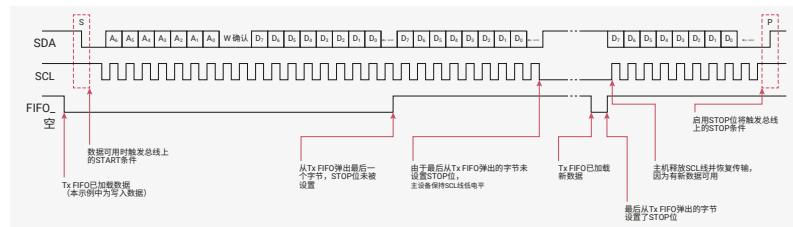

图77。主设备  
发送器 - TX FIFO  
清空/STOP  
生成

图78说明了DW\_apb\_i2c作为主接收器运行时，当TX FIFO变为空时的行为，以及STOP条件的生成。

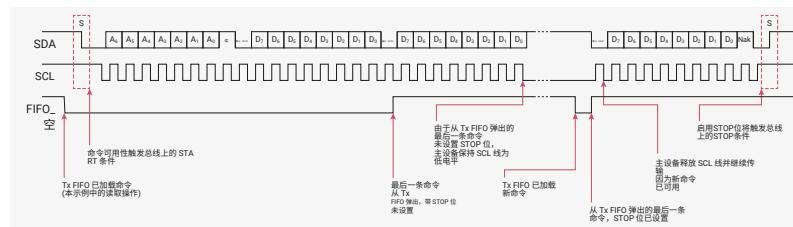

图 78。主接收器 - TX FIFO清空/  
停止信号生  
成

图 79 和图 80 展示了用户可控制 I2C 总线上 RESTART 条件生成的配置。如果 IC\_DATA\_CMD 寄存器的第 10 位（Restart）被设置且重启功能启用（IC\_RESTART\_EN=1），则在数据字节写入或读取从设备之前会生成 RESTART。如未启用重启功能，则以 STOP 后跟 START 替代 RESTART。图 79 展示作为主设备发送器时的此操作情形。

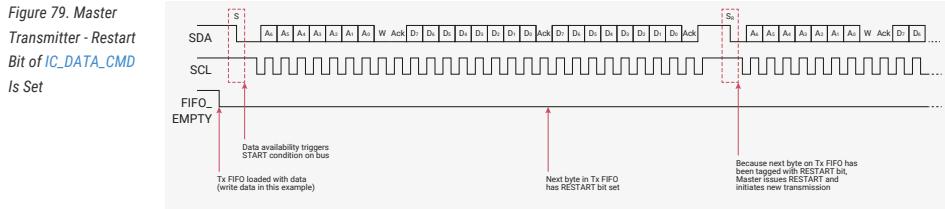

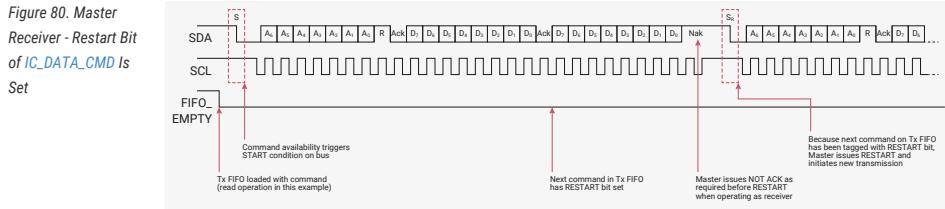

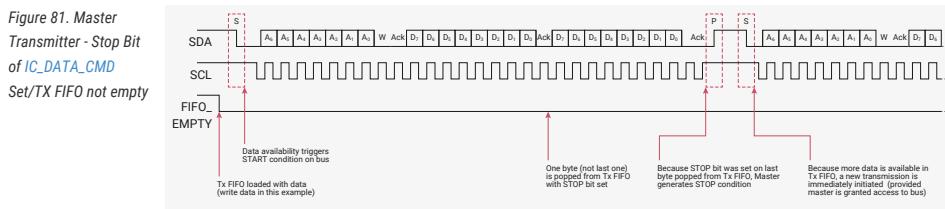

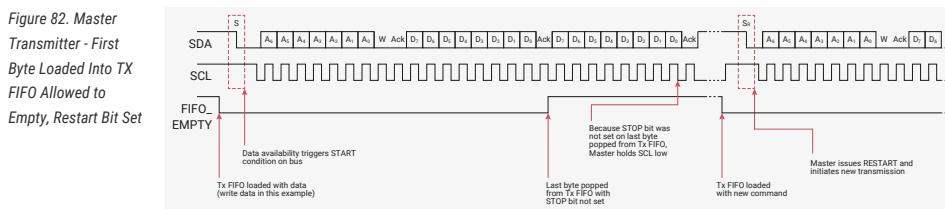

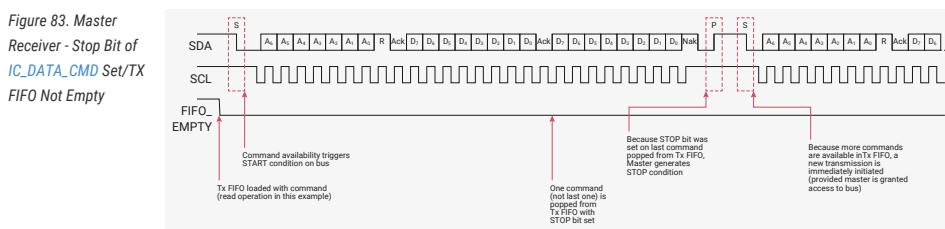

**Figure 80** illustrates the same situation, but during operation as a master receiver.**Figure 81** illustrates operation as a master transmitter where the Stop bit of the IC\_DATA\_CMD register is set and the TX FIFO is not empty.**Figure 82** illustrates operation as a master transmitter where the first byte loaded into the TX FIFO is allowed to go empty with the Restart bit set.**Figure 83** illustrates operation as a master receiver where the Stop bit of the IC\_DATA\_CMD register is set and the TX FIFO is not empty.**Figure 84** illustrates operation as a master receiver where the first command loaded after the TX FIFO is allowed to empty and the Restart bit is set.

图79。主发送器 - IC\_DATA\_CMD 寄存器的重启位已置位

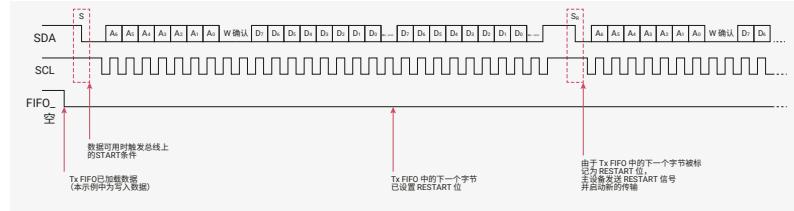

图80展示了相同情况，但操作为主设备接收器时的情形。

图80。主设备接收器 - IC\_DATA\_CMD 寄存器的重启位被设置

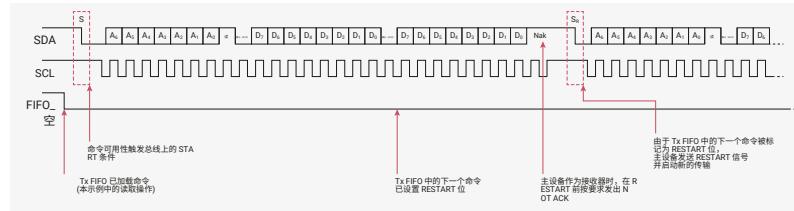

图81展示了作为主设备发送器操作时, IC\_DATA\_CMD 寄存器的停止位被设置且 TX FIFO 非空的情况。

图81。主发送器 - IC\_DATA\_CMD 停止位已置位, TX FIFO非空

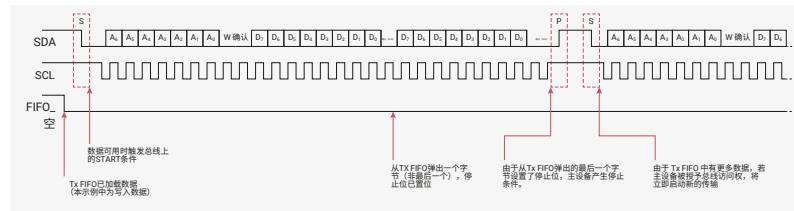

图82说明了主设备发送器的操作, 其中加载到TX FIFO的第一个字节允许清空, 并设置了重启位。

图82。主设备发送器—允许第一个字节清空, 重启位已设置

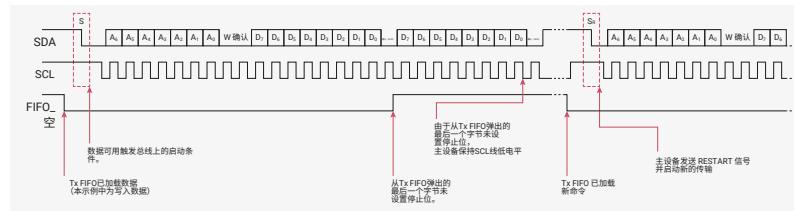

图83展示了作为主设备接收器的操作, 其中IC\_DATA\_CMD寄存器的停止位被设置且TX FIFO非空。

图83。主设备接收器 - IC\_DATA\_CMD 停止位已设置/发送 FIFO非空

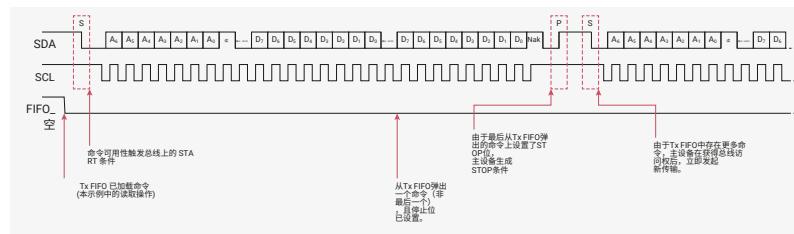

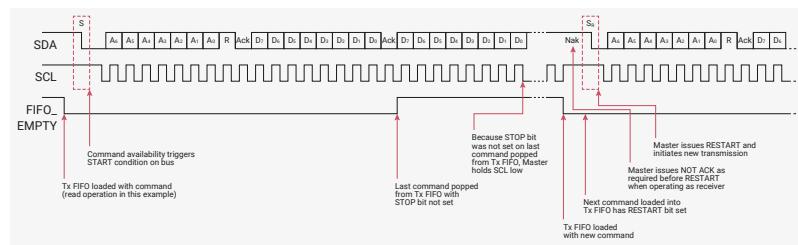

图84展示了作为主设备接收器的操作, 其中在TX FIFO被允许清空后加载了首个命令, 并且Restart位被设置。

Figure 84. Master Receiver - First Command Loaded After TX FIFO Allowed to Empty/Restart Bit Set

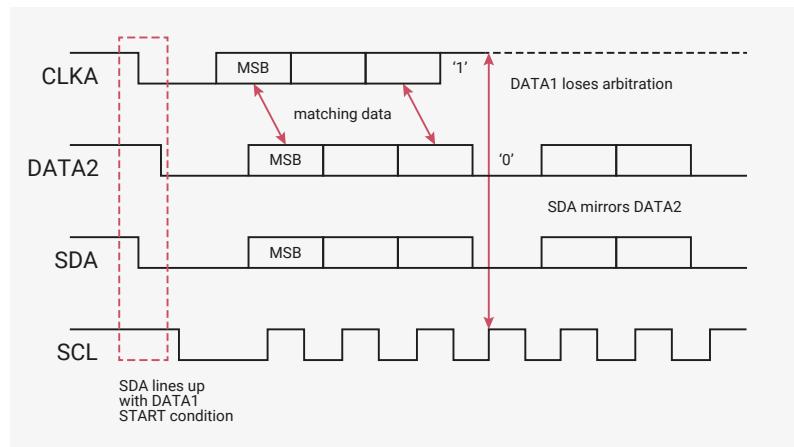

### 12.2.8. Multiple master arbitration

The [DW\\_apb\\_i2c](#) bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I2C bus, there is an arbitration procedure if both try to take control of the bus at the same time by generating a START condition at the same time. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state.

Arbitration takes place on the [SDA](#) line, while the [SCL](#) line is set to 1. The master, which transmits a one while the other master transmits zero, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters address the same slave device, the arbitration could go into the data phase.

Upon detecting that it has lost arbitration to another master, the [DW\\_apb\\_i2c](#) stops generating [SCL](#) by disabling the output driver. [Figure 85](#) illustrates the timing of two masters arbitrating on the bus.

Figure 85. Multiple Master Arbitration

Control of the bus is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus.

Arbitration is not allowed between the following conditions:

- A RESTART condition and a data bit
- A STOP condition and a data bit
- A RESTART condition and a STOP condition

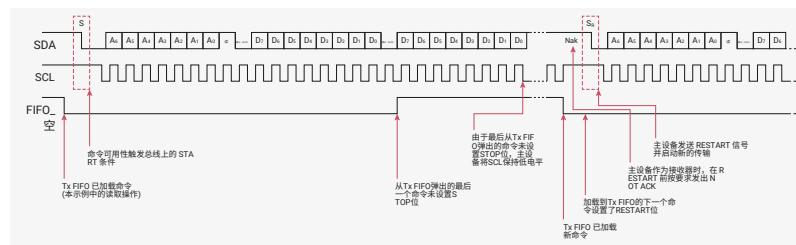

**i NOTE**

Slaves do not participate in the arbitration process.

### 12.2.9. Clock synchronisation

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the [SCL](#) clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of [SCL](#).

图84。主设备  
接收器 - TX FIFO  
允许清空后  
加载的首个  
命令/Restart位  
已设置

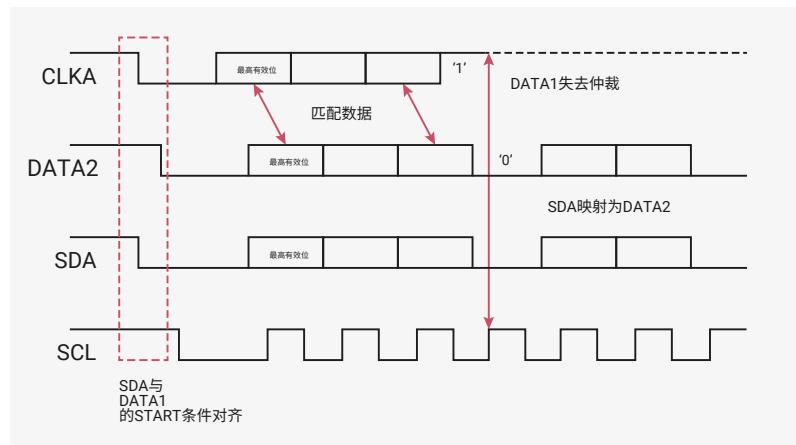

### 12.2.8. 多主仲裁

**DW\_apb\_i2c**总线协议允许多个主设备共存于同一总线。当总线上有两个主设备且两者同时通过同时生成START条件争夺总线控制权时，将执行仲裁程序。一旦主设备（例如微控制器）掌控总线，除非该主设备发送STOP条件并使总线进入空闲状态，否则其他主设备不得取得控制权。

仲裁过程发生在 **SDA**线上，同时 **SCL**线保持为1。发送1的主设备在另一主设备发送0时，失去仲裁并关闭其数据输出级。失去仲裁的主设备可继续生成时钟，直至字节传输结束。若两个主设备同时寻址同一从设备，仲裁可能延续至数据传输阶段。

检测到被另一主设备仲裁失败后，**DW\_apb\_i2c**通过禁用输出驱动停止生成 **SCL**信号。图85展示了两个主设备在总线上进行仲裁的时序。

图85。多主设  
备仲裁

总线控制由地址或主控码及竞争主控器发送的数据决定，因此总线上无中央主控器，也不存在任何优先级顺序。

下列情况之间不允许进行仲裁：

- 重启（RESTART）条件与数据位
- 停止（STOP）条件与数据位
- 重启（RESTART）条件与停止（STOP）条件

**i 注意**

从设备不参与仲裁过程。

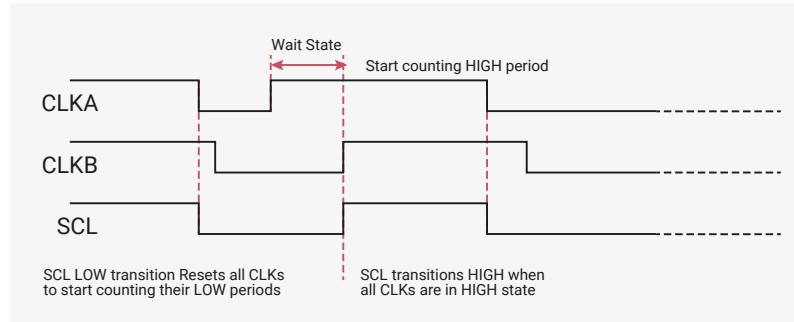

### 12.2.9. 时钟同步

当两个或多个主控器同时试图在总线上传输信息时，必须进行仲裁并同步 **SCL**时钟。所有主控器均生成各自时钟以传输消息。数据仅在 **SCL**的高电平期间有效

clock. Clock synchronisation is performed using the wired-AND connection to the **SCL** signal. When the master transitions the **SCL** clock to zero, the master starts counting the low time of the **SCL** clock and transitions the **SCL** clock signal to one at the beginning of the next clock period. However, if another master is holding the **SCL** line to 0, then the master goes into a HIGH wait state until the **SCL** clock line transitions to one.

All masters then count off their high time, and the master with the shortest high time transitions the **SCL** line to zero. The masters then count out their low time and the one with the longest low time forces the other masters into a HIGH wait state. Therefore, a synchronized **SCL** clock is generated, which is illustrated in Figure 86. Optionally, slaves may hold the **SCL** line low to slow down the timing on the I<sup>2</sup>C bus.

Figure 86. Multi-Master Clock Synchronisation

## 12.2.10. Operation modes

This section provides information about operation modes.

### **i** NOTE

Only set the **DW\_apb\_i2c** to operate as an I<sup>2</sup>C Master or an I<sup>2</sup>C Slave. Never set the **DW\_apb\_i2c** to operate as both simultaneously. To avoid this, never simultaneously set **IC\_CON.IC\_SLAVE\_DISABLE** and **IC\_CON.MASTER\_MODE** to zero and one, respectively.

### 12.2.10.1. Slave mode operation

This section discusses slave mode procedures.

#### 12.2.10.1.1. Initial configuration

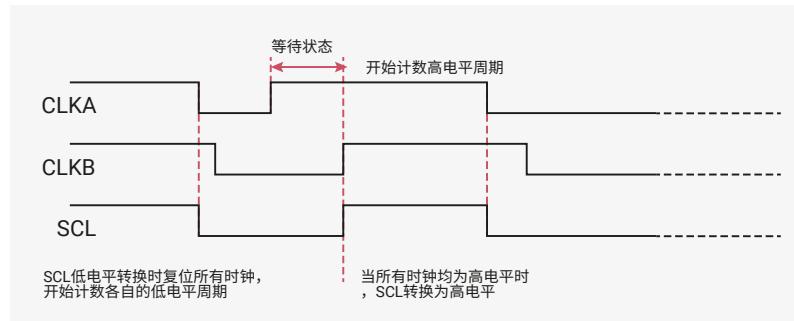

To use the **DW\_apb\_i2c** as a slave, perform the following steps:

1. Disable the **DW\_apb\_i2c** by writing a 0 to **IC\_ENABLE.ENABLE**.
2. Write to the **IC\_SAR** register (bits 9:0) to set the slave address. This is the address to which the **DW\_apb\_i2c** responds.
3. Write to the **IC\_CON** register to specify which type of addressing is supported (7-bit or 10-bit by setting bit 3). Enable the **DW\_apb\_i2c** in slave-only mode by writing a 0 into bit six (**IC\_CON.IC\_SLAVE\_DISABLE**) and a 0 to bit zero (**IC\_CON.MASTER\_MODE**).

时钟。时钟同步通过对 **SCL** 信号的有线与（wired-AND）连接实现。当主控器将 **SCL** 时钟拉低至零时，主控器开始计数 **SCL** 时钟的低电平时间，并在下一时钟周期开始时将 **SCL** 时钟信号拉高至高电平。然而，若另一主控设备将 **SCL** 线保持为 0，则主控设备进入高等待状态，直至 **SCL** 时钟线转换为 1。

所有主控设备随后计数其高电平时间，拥有最短高电平时间的主控设备将 **SCL** 线拉低。主控设备继续计数其低电平时间，具有最长低电平时间的主控设备强制其他主控设备进入高等待状态。由此产生一个同步的 **SCL** 时钟信号，如图86所示。从设备可选择将 **SCL** 线拉低，以减缓I2C总线的时序。

图86。多主设备  
时钟  
同步

## 12.2.10. 操作模式

本节提供有关操作模式的详细信息。

### ① 注意

仅将 **DW\_apb\_i2c** 配置为 I2C 主设备或从设备，切勿同时配置为两者。为避免此情况，切勿同时将 **IC\_CON.IC\_SLAVE\_DISABLE** 设为 0 和 **IC\_CON.MASTER\_MODE** 设为 1。

### 12.2.10.1. 从属模式操作

本节讨论从属模式的操作流程。

#### 12.2.10.1.1. 初始配置

要使用 **DW\_apb\_i2c** 作为从属设备，请执行以下步骤：

1. 通过向 **IC\_ENABLE.ENABLE** 写入 0 来禁用 **DW\_apb\_i2c**。
2. 向 **IC\_SAR** 寄存器（位 9:0）写入数据以设置从属地址。该地址即为 **DW\_apb\_i2c** 响应的地址。
3. 通过向 **IC\_CON** 寄存器写入数据以指定支持的寻址类型（设置第 3 位以选择 7 位或 10 位寻址）。  
通过向第六位（**IC\_CON.IC\_SLAVE\_DISABLE**）写入 0，且向第零位（**IC\_CON.MASTER\_MODE**）写入 0，以仅从属模式启用 **DW\_apb\_i2c**。

**NOTE**

Slaves and masters can use different addressing settings. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa.

4. Enable the `DW_apb_i2c` by writing a 1 to `IC_ENABLE.ENABLE`.

**NOTE**

Depending on the reset values chosen, steps two and three may not be necessary because the reset values can be configured. For instance, if the device is only going to be a master, there would be no need to set the slave address because you can configure `DW_apb_i2c` to have the slave disabled after reset and to enable the master after reset. The values stored are static and do not need to be reprogrammed if the `DW_apb_i2c` is disabled.

**WARNING**

Only bring the `DW_apb_i2c` Slave out of reset when the I2C bus is IDLE. De-asserting the reset when a transfer is ongoing on the bus causes internal synchronization flip-flops used to synchronize `SDA` and `SCL` to toggle from a reset value of one to the actual value on the bus. This can result in `SDA` toggling from one to zero while `SCL` is one, thereby causing a false START condition to be detected by the `DW_apb_i2c` Slave. This scenario can also be avoided by configuring the `DW_apb_i2c` with `IC_SLAVE_DISABLE = 1` and `MASTER_MODE = 1` so that the Slave interface is disabled after reset. It can then be enabled by programming `IC_CON[0] = 0` and `IC_CON[6] = 0` after the internal `SDA` and `SCL` have synchronized to the value on the bus; this takes approximately six `ic_clk` cycles after reset de-assertion.

#### 12.2.10.1.2. Slave-transmitter operation for a single byte

When another I2C master device on the bus addresses the `DW_apb_i2c` and requests data, the `DW_apb_i2c` acts as a slave-transmitter. The following steps occur:

1. The other I2C master device initiates an I2C transfer with an address that matches the slave address in the `IC_SAR` register of the `DW_apb_i2c`.
2. The `DW_apb_i2c` acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter.
3. The `DW_apb_i2c` asserts the `RD_REQ` interrupt (bit five of the `IC_RAW_INTR_STAT` register) and holds the `SCL` line low. It remains in a wait state until software responds. If the `RD_REQ` interrupt has been masked, due to `IC_INTR_MASK.M_RD_REQ` being set to zero, use a hardware and/or software timing routine to instruct the CPU to perform periodic reads of the `IC_RAW_INTR_STAT` register.
  - o Reads that indicate `IC_RAW_INTR_STAT.RD_REQ` being set to one must be treated as the equivalent of the `RD_REQ` interrupt being asserted.
  - o Software must then act to satisfy the I2C transfer.
  - o The timing interval used should be in the order of 10 times the fastest `SCL` clock period the `DW_apb_i2c` can handle. For example, for 400 kb/s, the timing interval is 25µs.

**NOTE**

The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I2C bus.

4. If there is any data remaining in the TX FIFO before receiving the read request, the `DW_apb_i2c` asserts a `TX_ABRT` interrupt (bit six of the `IC_RAW_INTR_STAT` register) to flush the old data from the TX FIFO. If the `TX_ABRT` interrupt has been masked, due to `IC_INTR_MASK.M_TX_ABRT` being set to zero, re-use the timing routine described in the previous step to read the `IC_RAW_INTR_STAT` register.

**i 注意**

从机与主机可以采用不同的寻址设置。例如，从机可被编程为7位寻址，主机可为10位寻址，反之亦然。

4. 通过向IC\_ENABLE.ENABLE寄存器写入1来启用 DW\_apb\_i2c。

**i 注意**

根据配置的复位值，步骤二和步骤三可能无需执行，因为复位值可直接配置。例如，若设备仅作为主机使用，无需设置从机地址，因可配置 DW\_apb\_i2c在复位后禁用从机并启用主机功能。存储的值为静态值，若 DW\_apb\_i2c被禁用，则无需重新编程。

**— 警告**

仅在I2C总线空闲时解除 DW\_apb\_i2c从机的复位。若总线正进行数据传输时解除复位，会导致用于同步 SDA和 SCL的内部同步触发器由复位状态1切换至总线上的实际值，从而可能使 SDA在 SCL为1时从1跳变至0，导致 DW\_apb\_i2c从机误判为启动条件。为避免此情况，可将 DW\_apb\_i2c配置为IC\_SLAVE\_DISABLE=1及MASTER\_MODE=1，从而在复位后禁用从机接口。然后，可以通过在内部 SDA和 SCL与总线上的值同步后，将IC\_CON[0] = 0和IC\_CON[6] = 0编程启用；这大约需要重置信号取消置位后六个 ic\_clk周期。

**12.2.10.1.2. 单字节从机发送器操作**

当总线上另一个I2C主设备寻址 DW\_apb\_i2c并请求数据时， DW\_apb\_i2c作为从机发送器响应。以下步骤随之发生：

1. 其他I2C主设备启动I2C传输，地址与 DW\_apb\_i2c的IC\_SAR寄存器中的从机地址匹配。
2. DW\_apb\_i2c应答该地址，并识别传输方向，表明其作为从机发送器身份。
3. DW\_apb\_i2c断言RD\_REQ中断（IC\_RAW\_INTR\_STAT寄存器第5位），并将SCL线保持低电平，处于等待软件响应的状态。如果RD\_REQ中断已被屏蔽，原因是  
由于IC\_INTR\_MASK.M\_RD\_REQ被设置为零，应使用硬件和/或软件定时程序指示CPU周期性读取IC\_RAW\_INTR\_STAT寄存器。
  - o 当读取显示IC\_RAW\_INTR\_STAT.RD\_REQ被设置为1时，必须视同RD\_REQ中断被触发。
  - o 软件随后必须采取措施以完成I2C传输。
  - o 所用定时间隔应约为DW\_apb\_i2c可处理的最快SCL时钟周期的10倍。例如，对于400 kb/s，定时间隔为25μs。

**i 注意**

推荐使用数值10，因为这大致是I2C总线上传输单字节数据所需的时间。

4. 如果在接收读请求之前TX FIFO中仍有数据， DW\_apb\_i2c将断言 TX\_ABRT中断（IC\_RAW\_INTR\_STAT寄存器的第六位）以清空TX FIFO中的旧数据。若由于IC\_INTR\_MASK.M\_TX\_ABRT被设置为零导致TX\_ABRT中断被屏蔽，则应重复使用前述定时程序读取IC\_RAW\_INTR\_STAT寄存器。

**NOTE**

Because the **DW\_apb\_i2c**'s TX FIFO is forced into a flushed/reset state whenever a **TX\_ABRT** event occurs, software must release the **DW\_apb\_i2c** from this state by reading the **IC\_CLR\_TX\_ABRT** register before attempting to write into the TX FIFO. See register **IC\_RAW\_INTR\_STAT** for more details.

- Reads that indicate bit six (**R\_TX\_ABRT**) being set to one must be treated as the equivalent of the **TX\_ABRT** interrupt being asserted.
  - There is no further action required from software.
  - The timing interval used should be similar to that described in the previous step for the **IC\_RAW\_INTR\_STAT.RD\_REQ** register.
5. Software writes to the **IC\_DATA\_CMD** register with the data to be written (by writing a 0 in bit 8).
  6. Software must clear the **RD\_REQ** and **TX\_ABRT** interrupts (bits five and six, respectively) of the **IC\_RAW\_INTR\_STAT** register before proceeding. If the **RD\_REQ** or **TX\_ABRT** interrupts have been masked, then clearing of the **IC\_RAW\_INTR\_STAT** register will have already been performed when either the **R\_RD\_REQ** or **R\_TX\_ABRT** bit has been read as one.
  7. The **DW\_apb\_i2c** releases the **SCL** and transmits the byte.
  8. The master may hold the I2C bus by issuing a RESTART condition or release the bus by issuing a STOP condition.

**NOTE**

Slave-Transmitter Operation for a single byte is not applicable in Ultra-Fast mode, since this mode does not support read transfers.

**12.2.10.1.3. Slave-receiver operation for a single byte**

When another I2C master device on the bus addresses the **DW\_apb\_i2c** and is sending data, the **DW\_apb\_i2c** acts as a slave-receiver and the following steps occur:

1. The other I2C master device initiates an I2C transfer with an address that matches the **DW\_apb\_i2c**'s slave address in the **IC\_SAR** register.
2. The **DW\_apb\_i2c** acknowledges the sent address and recognizes the direction of the transfer to indicate that the **DW\_apb\_i2c** is acting as a slave-receiver.
3. **DW\_apb\_i2c** receives the transmitted byte and places it in the receive buffer.

**NOTE**

If the Rx (receive) FIFO is completely filled with data when a byte is pushed, then the **DW\_apb\_i2c** slave holds the I2C **SCL** line low until the Rx FIFO has some space, and then continues with the next read request.

4. **DW\_apb\_i2c** asserts the **RX\_FULL** interrupt **IC\_RAW\_INTR\_STAT.RX\_FULL**. If the **RX\_FULL** interrupt has been masked, due to setting **IC\_INTR\_MASK.M\_RX\_FULL** to zero or setting **IC\_TX\_TL** to a value larger than zero, you should implement a timing routine (described in [Section 12.2.10.1.2](#)) for periodic reads of the **IC\_STATUS** register. This timing routine should treat reads of the **IC\_STATUS** register, with bit 3 (**RFNE**) set at one as the equivalent of an **RX\_FULL** interrupt.
5. Software may read the byte from the **IC\_DATA\_CMD** register (bits 7:0).
6. The other master device may hold the I2C bus by issuing a RESTART condition, or release the bus by issuing a STOP condition.

### ● 注意

由于 DW\_apb\_i2c 的 TX FIFO 在发生 TX\_ABRT 事件时被强制置于刷新/复位状态，软件必须通过读取 IC\_CLR\_TX\_ABRT 寄存器解除该状态，然后才能尝试写入 TX FIFO。详见寄存器 IC\_RAW\_INTR\_STAT。

- 读取值中若第六位（R\_TX\_ABRT）被置为1，须视同 TX\_ABRT 中断被触发。
  - 软件无需再采取其他操作。
  - 所用的时间间隔应与前述步骤中对应 IC\_RAW\_INTR\_STAT.RD\_REQ 寄存器的时间间隔相似。
5. 软件通过将第8位写为0，向 IC\_DATA\_CMD 寄存器写入需发送的数据。
  6. 软件必须在继续操作前，清除 IC\_RAW\_INTR\_STAT 寄存器中第5位和第6位的 RD\_REQ 及 TX\_ABRT 中断。若 RD\_REQ 或 TX\_ABRT 中断已被屏蔽，则在读取到 R\_RD\_REQ 或 R\_TX\_ABRT 位为1时，IC\_RAW\_INTR\_STAT 寄存器已被清除。
  7. DW\_apb\_i2c 释放了 SCL 线并传输该字节。
  8. 主设备可通过发出重启（RESTART）条件保持 I2C 总线，或通过发出停止（STOP）条件释放总线。

### ● 注意

超高速（Ultra-Fast）模式下不适用单字节从设备发送操作，因为该模式不支持读传输。

#### 12.2.10.1.3. 单字节从设备接收操作

当总线上另一个 I2C 主设备对 DW\_apb\_i2c 寻址并发送数据时，DW\_apb\_i2c 作为从设备接收器，执行以下步骤：

1. 另一 I2C 主设备使用与 IC\_SAR 寄存器中 DW\_apb\_i2c 从设备地址匹配的地址启动 I2C 传输。
2. DW\_apb\_i2c 确认所发送的地址并识别传输方向，表明 DW\_apb\_i2c 正在作为从设备接收器工作。
3. DW\_apb\_i2c 接收传输的字节，并将其存入接收缓冲区。

### ● 注意

若在推送字节时 Rx（接收） FIFO 已满，则 DW\_apb\_i2c 从机会将 I2CSCL 线拉低，直至 Rx FIFO 具备空间，随后继续处理下一读请求。

4. DW\_apb\_i2c 会触发 RX\_FULL 中断 IC\_RAW\_INTR\_STAT.RX\_FULL。若因设置 IC\_INTR\_MASK.M\_RX\_FULL 为零或把 IC\_TX\_TL 设为大于零值而屏蔽 RX\_FULL 中断，应实施一个定时程序（参见第 12.2.10.1.2 节），以对 IC\_STATUS 寄存器进行周期性读取。该定时程序应将 IC\_STATUS 寄存器中第3位（RFNE）为1的读取视同 RX\_FULL 中断。
5. 软件可从 IC\_DATA\_CMD 寄存器（位7:0）读取该字节。
6. 另一个主设备可通过发出重启（RESTART）条件持有 I2C 总线，或通过发出停止（STOP）条件释放总线。

#### 12.2.10.1.4. Slave-transfer operation for bulk transfers

In the standard I<sup>2</sup>C protocol, all transactions are single byte transactions; the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) receives a read request (`RD_REQ`) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO.

`DW_apb_i2c` handles more data in the TX FIFO. This enables subsequent read requests to take data without raising an interrupt. This eliminates latencies incurred between interrupts. This mode only occurs when `DW_apb_i2c` acts as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the `DW_apb_i2c` holds the I<sup>2</sup>C `SCL` line low while it raises the read request interrupt (`RD_REQ`) and waits for a data write into the TX FIFO.

If the `RD_REQ` interrupt is masked by setting `IC_INTR_STAT.R_RD_REQ` to zero, use a timing routine to activate periodic reads of the `IC_RAW_INTR_STAT` register. Reads of `IC_RAW_INTR_STAT` that return bit five (`RD_REQ`) set to one must be treated as the equivalent of `RD_REQ`. This timing routine is similar to that described in [Section 12.2.10.1.2](#).

The `RD_REQ` interrupt is raised upon a read request. Always clear this interrupt when exiting the interrupt service handling routine (ISR). The ISR allows you to either write one byte or more than one byte into the TX FIFO. The master can request additional data at the end of a transmission by acknowledging the last byte. In this scenario, the slave must raise `RD_REQ` again.

If you know in advance that the remote master requests a packet of `n` bytes, you can write `n` byte to the TX FIFO. Then, when another master addresses `DW_apb_i2c` and requests data, the remote master will receive a continuous stream of data. This happens because the `DW_apb_i2c` slave continues to send data to the remote master as long as the remote master acknowledges the data sent and there is data available in the TX FIFO. There is no need to hold the `SCL` line low or to issue `RD_REQ` again.

If the remote master doesn't read all of the bytes from the TX FIFO, the `DW_apb_i2c` ignores the excess bytes with the following procedure:

- The `DW_apb_i2c` clears the TX FIFO.
- The `DW_apb_i2c` generates a transmit abort (`TX_ABRT`) event.

At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the TX FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the TX FIFO is cleared at that time.

#### 12.2.10.2. Master mode operation

This section discusses master mode procedures.

##### 12.2.10.2.1. Initial configuration

To use the `DW_apb_i2c` as a master, perform the following steps:

1. Disable the `DW_apb_i2c` by writing zero to `IC_ENABLE.ENABLE`.
2. Write to the `IC_CON` register to set the maximum speed mode supported (bits 2:1) and the desired speed of the `DW_apb_i2c` master-initiated transfers, either 7-bit or 10-bit addressing (bit 4). Ensure that bit six (`IC_SLAVE_DISABLE`) is written with a 1 and bit zero (`MASTER_MODE`) is written with a 1.

#### 12.2.10.1.4. 用于批量传输的从设备传输操作

在标准I2C协议中，所有事务均为单字节传输；程序员通过向从设备的TX FIFO写入一个字节来响应远程主设备的读请求。当从设备（作为发送方）接收到读请求（RD\_REQ）来自远程主设备（作为接收方）时，至少应在从设备发送方的TX FIFO中放入一条数据。

DW\_apb\_i2c处理TX FIFO中的更多数据，使随后的读请求可在不触发中断的情况下获取数据。此举消除了中断之间产生的延迟。此模式仅在 DW\_apb\_i2c作为从设备发送方时发生。若远程主设备确认了从设备发送方发送的数据且TX FIFO中无数据，DW\_apb\_i2c将在触发读请求中断（RD\_REQ）时将I2CSCL线保持为低电平，等待数据写入TX FIFO。

如果通过将 IC\_INTR\_STAT.R\_RD\_REQ 设置为零屏蔽了 RD\_REQ中断，则应使用定时例程周期性地读取 IC\_RAW\_INTR\_STAT 寄存器。读取 IC\_RAW\_INTR\_STAT 时若返回第5位（RD\_REQ）为1，必须将其视为 RD\_REQ中断。该定时例程类似于第12.2.10.1.2节所述。

RD\_REQ中断在发生读请求时触发。退出中断服务例程（ISR）时，务必清除此中断。ISR 允许向 TX FIFO 写入一个或多个字节。主设备可在传输结束时通过确认最后一个字节来请求更多数据。在此情况下，从设备必须再次触发RD\_REQ中断。

如果已知远端主设备请求的数据包长度为 n字节，可向 TX FIFO 写入 n字节。随后，当其他主设备访问 DW\_apb\_i2c并请求数据时，远端主设备将接收到连续的数据流。这是因为 DW\_apb\_i2c从属设备只要远程主设备确认所发送的数据且TX FIFO 中有数据，就会继续发送数据。无需将 SCL线保持低电平，也无需再次发出 RD\_REQ命令。

如果远程主设备未从TX FIFO中读取所有字节， DW\_apb\_i2c将按以下程序忽略多余字节：

- DW\_apb\_i2c会清空TX FIFO。
- DW\_apb\_i2c将产生传输中止（TX\_ABRT）事件。

当预期应答（ACK/NACK）时，如果收到NACK，表明远程主设备已获取所有所需数据。此时，奴隶状态机内部会触发标志以清除TX FIFO中的剩余数据。该标志会传递至FIFO所在的处理器总线时钟域，届时TX FIFO内容将被清空。

#### 12.2.10.2 主控模式操作

本节讨论主控模式的操作流程。

##### 12.2.10.2.1 初始配置

要将 DW\_apb\_i2c作为主控使用，请执行以下步骤：

1. 通过向 IC\_ENABLE.ENABLE 寄存器写入 0，禁用DW\_apb\_i2c。
2. 写入 IC\_CON 寄存器以设置支持的最大速率模式（位 2:1）及 DW\_apb\_i2c 主控发起传输所需的速率，支持 7 位或 10 位寻址（位 4）。确保第 6 位（IC\_SLAVE\_DISABLE）写入 1，第 0 位（MASTER\_MODE）写入 1。

**NOTE**

Slaves and masters can use different addressing settings. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa.

3. Write the address of the I2C device to be addressed to bits 9:0 of the [IC\\_TAR](#) register. This register also determines whether the I2C will perform a General Call or a START BYTE command.
4. Enable the [DW\\_apb\\_i2c](#) by writing a one to [IC\\_ENABLE](#).ENABLE.
5. Write the transfer direction and the data to be sent to the [IC\\_DATA\\_CMD](#) register. This step generates the START condition and the address byte on the [DW\\_apb\\_i2c](#). Once [DW\\_apb\\_i2c](#) is enabled and there is data in the TX FIFO, [DW\\_apb\\_i2c](#) starts reading the data.

**NOTE**

If you write to the [IC\\_DATA\\_CMD](#) register before enabling the [DW\\_apb\\_i2c](#), the data and commands are lost: the buffers are kept cleared when [DW\\_apb\\_i2c](#) is disabled.

The values stored are static and do not need to be reprogrammed when the [DW\\_apb\\_i2c](#) is disabled except for transfer direction and data. As a result, you may not need to perform steps two, three, four, and five if you already configured the reset values.

#### 12.2.10.2.2. Master transmit and master receive

The [DW\\_apb\\_i2c](#) supports switching back and forth between reading and writing dynamically. To transmit data, write data to the lower byte of the I2C RX/TX Data Buffer and Command Register ([IC\\_DATA\\_CMD](#)). For I2C write operations, write zero to the CMD bit [8]. Subsequently, to issue a read command, write a one to the CMD bit and write [don't care](#) to the lower byte of the [IC\\_DATA\\_CMD](#) register. The [DW\\_apb\\_i2c](#) master continues to initiate transfers as long as there are commands present in the TX FIFO. If the TX FIFO becomes empty, the master performs one of the following actions based on the value of [IC\\_DATA\\_CMD](#):

- If set to one, it issues a STOP condition after completing the current transfer.
- If set to zero, it holds [SCL](#) low until next command is written to the TX FIFO.

For more details, refer to [Section 12.2.7](#).

#### 12.2.10.3. Disabling [DW\\_apb\\_i2c](#)

The [IC\\_ENABLE\\_STATUS](#) register allows software to unambiguously determine when the I2C hardware has completely shut down.

**NOTE**

Earlier versions of [DW\\_apb\\_i2c](#) required the programmer to monitor two registers: ([IC\\_STATUS](#) and [IC\\_RAW\\_INTR\\_STAT](#)). RP2350 only requires the programmer to monitor [IC\\_ENABLE\\_STATUS](#).

To shut down I2C hardware, write a zero to [IC\\_ENABLE](#).ENABLE. The [DW\\_apb\\_i2c](#) master can be disabled only if the command currently processing when the de-assertion occurs has the STOP bit set to one. If you attempt to disable the [DW\\_apb\\_i2c](#) master while processing a command without the STOP bit set, the [DW\\_apb\\_i2c](#) master continues to remain active, holding the [SCL](#) line low until a new command is received in the TX FIFO.

To relinquish the I2C bus and disable [DW\\_apb\\_i2c](#) while the [DW\\_apb\\_i2c](#) master is processing a command without the STOP bit set, issue an [ABORT request](#).

**i 注意**

从机与主机可以采用不同的寻址设置。例如，从机可被编程为7位寻址，主机可为10位寻址，反之亦然。

3. 将目标 I2C 设备地址写入 IC\_TAR 寄存器的位 9:0。该寄存器还决定 I2C 是否执行通用调用（General Call）或启动字节命令（START BYTE）。
4. 通过向 IC\_ENABLE.ENABLE 写入 1，启用 DW\_apb\_i2c。
5. 将传输方向和要发送的数据写入 IC\_DATA\_CMD 寄存器。此步骤在 DW\_apb\_i2c 上产生 START 条件和地址字节。一旦启用 DW\_apb\_i2c 且 TX FIFO 中有数据，DW\_apb\_i2c 即开始读取数据。

**i 注意**

若在启用 DW\_apb\_i2c 之前写入 IC\_DATA\_CMD 寄存器，数据和命令将丢失：DW\_apb\_i2c 被禁用时缓冲区保持清空。

存储的值为静态值，除传输方向和数据外，DW\_apb\_i2c 禁用时无需重新编程。因此，若已配置复位值，可能无需执行第二、第三、第四及第五步。

#### 12.2.10.2.2. 主控发送与主控接收

DW\_apb\_i2c 支持读写操作的动态切换。为了传输数据，请将数据写入 I2C RX/TX 数据缓冲区及命令寄存器（IC\_DATA\_CMD）的低字节。针对 I2C 写操作，请将 CMD 位[8]写入零。随后，为发出读取命令，请将 CMD 位写入一，并将无关数据写入 IC\_DATA\_CMD 寄存器的低字节。只要 TX FIFO 中存在命令，DW\_apb\_i2c 主控器将持续发起传输。若 TX FIFO 变为空，主控器将根据 IC\_DATA\_CMD 的值执行以下任一操作：

- 若设置为一，当前传输完成后将发出 STOP 条件。
- 若设置为零，则保持 SCL 线为低电平，直至下一命令写入 TX FIFO。

详情请参阅第 12.2.7 节。

#### 12.2.10.3. 禁用 DW\_apb\_i2c

IC\_ENABLE\_STATUS 寄存器能够使软件明确判断 I2C 硬件何时已完全关闭。

**i 注意**

早期版本的 DW\_apb\_i2c 要求程序员监控两个寄存器（IC\_STATUS 和 IC\_RAW\_INTR\_STAT）。RP2350 仅要求程序员监控 IC\_ENABLE\_STATUS。

要关闭 I2C 硬件，请向 IC\_ENABLE.ENABLE 写入零。DW\_apb\_i2c 主控仅在去使能时，当前处理的命令 STOP 位被置为一时才允许禁用。若在处理未设置 STOP 位的命令时尝试禁用 DW\_apb\_i2c 主控，DW\_apb\_i2c 将继续保持激活状态，并保持 SCL 线低电平，直到 TX FIFO 收到新命令。

若在 DW\_apb\_i2c 主控处理未设置 STOP 位的命令时需要释放 I2C 总线并禁用 DW\_apb\_i2c，必须发出 ABORT 请求。

### 12.2.10.3.1. Procedure

1. Define a timer interval ( $t_{i2c\_poll}$ ) equal to the 10 times the signalling period for the highest I2C transfer speed used in the system and supported by [DW\\_apb\\_i2c](#). For example, if the highest I2C transfer mode is 400 kb/s,  $t_{i2c\_poll}$  is 25 $\mu$ s.
2. Define a maximum time-out parameter, [MAX\\_T\\_POLL\\_COUNT](#), such that if any repeated polling operation exceeds this maximum value, an error is reported.
3. Execute a blocking thread, process, or function that prevents any further I2C master transactions from starting from software, but allows any pending transfers to be completed.

**NOTE**

This step can be ignored if [DW\\_apb\\_i2c](#) is programmed to operate as an I2C slave only.

1. The variable [POLL\\_COUNT](#) is initialized to zero.
2. Set bit zero of the [IC\\_ENABLE](#) register to zero.
3. Read the [IC\\_ENABLE\\_STATUS](#) register and test the IC\_EN bit (bit 0). Increment POLL\_COUNT by one. If [POLL\\_COUNT >= MAX\\_T\\_POLL\\_COUNT](#), exit with the relevant error code.
4. If [IC\\_ENABLE\\_STATUS\[0\]](#) is one, sleep for  $t_{i2c\_poll}$  and proceed to the previous step. Otherwise, exit with a relevant success code.

### 12.2.10.4. Aborting I2C transfers

The [ABORT](#) control bit of the [IC\\_ENABLE](#) register allows the software to relinquish the I2C bus before completing the issued transfer commands from the TX FIFO. In response to an [ABORT](#) request, the controller issues the STOP condition over the I2C bus, followed by a TX FIFO flush. Aborting the transfer is allowed only in master mode of operation.

### 12.2.10.4.1. Procedure

1. Stop filling the TX FIFO ([IC\\_DATA\\_CMD](#)) with new commands.
2. When operating in DMA mode, disable the transmit DMA by setting [TDMAE](#) to zero.
3. Set [IC\\_ENABLE.ABORT](#) to one.
4. Wait for the [M\\_TX\\_ABRT](#) interrupt.
5. Read the [IC\\_TX\\_ABRT\\_SOURCE](#) register to identify the source as [ABRT\\_USER\\_ABRT](#).

## 12.2.11. Spike suppression

The [DW\\_apb\\_i2c](#) contains programmable spike suppression logic that matches requirements imposed by the I2C Bus Specification for SS/FS modes. This logic is based on counters that monitor the input signals ([SCL](#) and [SDA](#)), checking if they remain stable for a predetermined amount of [ic\\_clk](#) cycles before they are sampled internally. There is one separate counter for each signal ([SCL](#) and [SDA](#)). The number of [ic\\_clk](#) cycles can be programmed by the user. The value should account for the frequency of [ic\\_clk](#) and the relevant spike length specification. Each counter starts whenever its input signal changes value. Depending on the behaviour of the input signal, one of the following scenarios occurs:

- The input signal remains unchanged until the counter reaches its count limit value. When this happens, the counter resets and stops, and the internal version of the signal updates to the input value.
- The input signal changes again before the counter reaches its count limit value. When this happens, the counter resets and stops, but the internal version of the signal does not update.

The timing diagram in [Figure 87](#) illustrates the behaviour described above.

### 12.2.10.3.1. 操作流程

1. 定义定时器间隔 ( $t_{i2c,poll}$ )，其值等于系统中使用且由 `DW_apb_i2c` 支持的最高I2C传输速率对应信号周期的10倍。例如，若最高I2C传输模式为400 kb/s，则  $t_{i2c,poll}$  为25μs。
2. 定义最大超时参数 `MAX_T_POLL_COUNT`，若任何重复轮询操作超过该最大值，则报告错误。
3. 执行阻塞线程、进程或函数，在软件中阻止任何新的I2C主机事务启动，但允许所有挂起传输完成。

**注意**

若 `DW_apb_i2c` 被配置为仅作为I2C从机运行，则此步骤可省略。

1. 将变量 `POLL_COUNT` 初始化为零。
2. 将 `IC_ENABLE` 寄存器的第0位清零。
3. 读取 `IC_ENABLE_STATUS` 寄存器并检测 `IC_EN` 位（第0位）。将 `POLL_COUNT` 增加一。如果 `POLL_COUNT >= MAX_T_POLL_COUNT`，则退出并返回相应的错误代码。
4. 如果 `IC_ENABLE_STATUS[0]` 为 1，则睡眠  $t_{i2c,poll}$  并返回上一步。否则，退出并返回相应的成功代码。

### 12.2.10.4. 中止 I2C 传输

`IC_ENABLE` 寄存器的 `ABORT` 控制位允许软件在完成 TX FIFO 中发出的传输命令之前释放 I2C 总线。响应 `ABORT` 请求时，控制器将在 I2C 总线上发出 STOP 条件，随后清空 TX FIFO。仅允许在主控模式下中止传输。

### 12.2.10.4.1. 操作流程

1. 停止向 TX FIFO (`IC_DATA_CMD`) 添加新命令。
2. 在 DMA 模式下，将 `TDMAE` 设为零以禁用发送 DMA。
3. 将 `IC_ENABLE.ABORT` 设为 1。
4. 等待 `M_TX_ABRT` 中断。
5. 读取 `IC_TX_ABRT_SOURCE` 寄存器以识别源为 `ABRT_USER_ABRT`。

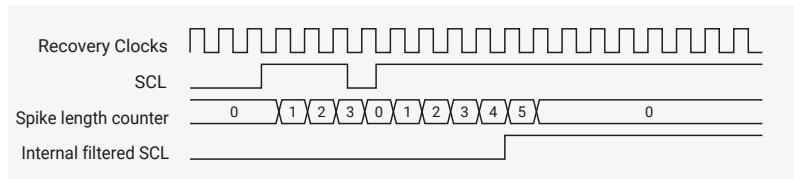

## 12.2.11. 突波抑制

`DW_apb_i2c` 包含可编程尖峰抑制逻辑，符合 I2C 总线规范对于 SS/FS 模式的要求。该逻辑基于计数器监测输入信号（SCL 和 SDA），验证其在预定的 `ic_clk` 周期内是否保持稳定，随后进行内部采样。每个信号（SCL 和 SDA）配备独立的计数器。用户可编程设置 `ic_clk` 周期数。该数值应结合 `ic_clk` 频率及相关尖峰长度规范进行设置。每当输入信号值发生变化时，相应计数器即开始计数。根据输入信号的行为，将发生以下一种情况：

- 输入信号保持不变，直至计数器达到设定的计数上限。当此情况发生时，计数器复位并停止，信号的内部版本更新为输入值。
- 输入信号在计数器达到计数限制值之前再次变化。当此情况发生时，计数器复位并停止，但信号的内部版本不会更新。

图87的时序图展示了上述行为。

Figure 87. Spike Suppression Example

#### **NOTE**

There is a 2-stage synchronizer on the `SCL` input. For the sake of simplicity, this synchronization delay was not included in the timing diagram in [Figure 87](#).

The I2C Bus Specification calls for different maximum spike lengths according to the operating mode (50 ns for SS and FS). Register `IC_FS_SPKLEN` holds the maximum spike length for SS and FS modes.

This register is 8 bits wide and accessible through the APB interface for reads and writes. However, you can only write to this register when the `DW_apb_i2c` is disabled. The minimum value that can be programmed into these registers is one; attempting to program a value smaller than one results in the value one being written.

The default value for these registers is based on the value of 100 ns for `ic_clk` period, so should be updated for the `clk_sys` period in use on RP2350.

#### **NOTE**

- Because the minimum value that can be programmed into the `IC_FS_SPKLEN` register is one, the spike length specification can be exceeded for low frequencies of `ic_clk`. Consider the simple example of a 10 MHz (100 ns period) `ic_clk`; in this case, the minimum spike length that can be programmed is 100 ns, which means that spikes up to this length are suppressed.
- Standard synchronization logic (two flip-flops in series) is implemented upstream of the spike suppression logic and is not affected in any way by the contents of the spike length registers or the operation of the spike suppression logic; the two operations (synchronization and spike suppression) are completely independent. Because the `SCL` and `SDA` inputs are asynchronous to `ic_clk`, there is one `ic_clk` cycle uncertainty in the sampling of these signals. Depending on when they occur relative to the rising edge of `ic_clk`, spikes of the same original length might show a difference of one `ic_clk` cycle after being sampled.
- Spike suppression is symmetrical; the behaviour is exactly the same for transitions from zero to one and from one to zero.

### 12.2.12. Fast mode plus operation

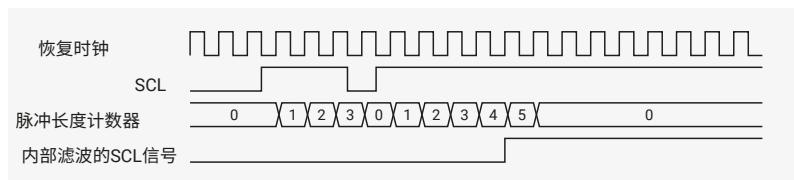

In fast mode plus, the `DW_apb_i2c` extends fast mode operation to support speeds up to 1000 kb/s. To enable the `DW_apb_i2c` for fast mode plus operation, perform the following steps before initiating any data transfer:

- Set `ic_clk` frequency greater than or equal to 32 MHz (refer to [Section 12.2.14.2.1](#)).
- Program the `IC_CON` register `[2:1] = 2'b10` for fast mode or fast mode plus.
- Program `IC_FS_SCL_LCNT` and `IC_FS_SCL_HCNT` registers to meet the fast mode plus `SCL` (refer to [Section 12.2.14](#)).
- Program the `IC_FS_SPKLEN` register to suppress the maximum spike of 50 ns.
- Program the `IC_SDA_SETUP` register to meet the minimum data setup time (`tSU; DAT`).

### 12.2.13. Bus clear feature

`DW_apb_i2c` supports the bus clear feature that provides graceful recovery of data `SDA` and clock `SCL` lines during unlikely events in which either the clock or data line is stuck at LOW.

图87。脉冲抑制示例

### 注意

在 `SCL` 输入端设有两级同步器。为简化起见，图87的时序图未包含此同步延迟。

I2C总线规范根据工作模式对最大脉冲长度有不同要求（SS和FS模式为50 ns）。寄存器IC\_FS\_SPKLEN存储SS和FS模式下的最大脉冲长度。

该寄存器宽8位，可通过APB接口进行读写。但仅当 `DW_apb_i2c` 被禁用时，才可写入此寄存器。这些寄存器可编程的最小值为一；

尝试写入小于一的值时，实际写入值将为一。

这些寄存器的默认值基于 `ic_clk` 周期为100纳秒，因此应根据RP2350上实际使用的`clk_sys`周期进行更新。

### 注意

- 由于IC\_FS\_SPKLEN寄存器可编程的最小值为一，针对低频率的 `ic_clk`，峰值长度可能会超过规格限制。考虑一个简单示例，10 MHz（周期100纳秒）的 `ic_clk`；在此情况下，可编程的最小峰值长度为100纳秒，意味着峰值长度不超过此值的峰将被抑制。
  - 标准同步逻辑（由两个串联触发器组成）位于峰值抑制逻辑之前，且其运行不受峰值长度寄存器内容或峰值抑制逻辑操作的影响；同步与峰值抑制两种操作完全独立。
- 由于 `SCL` 和 `SDA` 输入与 `ic_clk` 异步，因此采样这些信号时存在一个 `ic_clk` 周期的不确定性。根据它们相对于 `ic_clk` 上升沿的发生时间，相同长度的尖峰在采样后可能表现出一个 `ic_clk` 周期的差异。
- 尖峰抑制是对称的；从零到一以及从一到零的转换行为完全一致。

## 12.2.12. 快速模式加速操作

在快速模式加（fast mode plus）中，`DW_apb_i2c` 支持高达1000 kb/s的快速模式操作。在启动任何数据传输前，须执行以下步骤以启用`DW_apb_i2c`的快速模式加操作：

- 设置 `ic_clk` 频率不低于32 MHz（参见第12.2.14.2.1节）。
- 将IC\_CON寄存器的[2:1]位设置为2`b10`，以启用快速模式或快速模式加。
- 配置 IC\_FS\_SCL\_LCNT 和 IC\_FS\_SCL\_HCNT 寄存器以满足快速模式加速 `SCL` 的要求（参见第12.2.14节）。
- 配置 IC\_FS\_SPKLEN 寄存器以抑制最长50纳秒的脉冲尖峰。
- 配置 IC\_SDA\_SETUP 寄存器以满足最小数据建立时间（tSU; DAT）。

## 12.2.13. 总线清除功能

`DW_apb_i2c` 支持总线清除功能，该功能能在时钟线或数据线异常保持低电平时，优雅地恢复数据线SDA和时钟线SCL。

### 12.2.13.1. SDA line is stuck at LOW

In case of SDA line stuck at LOW, the master performs the following actions to recover as shown in Figure 88 and Figure 89:

1. Master sends a maximum of nine clock pulses to recover the bus LOW within those nine clocks.
  - o The number of clock pulses will vary with the number of bits that remain to be sent by the slave. As the maximum number of bits is nine, master sends up to nine clock pulses and allows the slave to recover.
  - o The master attempts to assert a Logic 1 on the SDA line and check whether SDA is recovered. If the SDA is not recovered, it will continue to send a maximum of nine SCL clocks.
2. If SDA line is recovered within nine clock pulses, the master will send STOP to release the bus.
3. If SDA line is not recovered even after the ninth clock pulse, you must hardware reset the system.

Figure 88. SDA Recovery with 9 SCL Clocks

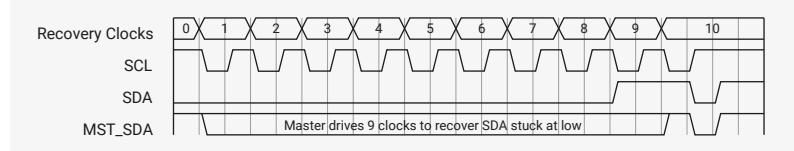

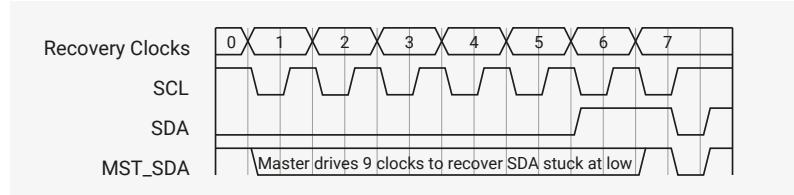

Figure 89. SDA Recovery with 6 SCL Clocks

### 12.2.13.2. SCL line is stuck at LOW

In the unlikely event (due to an electric failure of a circuit) where the clock (SCL) is stuck to LOW, there is no effective method to overcome this problem. Instead, reset the bus using the hardware reset signal.

### 12.2.14. IC\_CLK frequency configuration

When the DW\_apb\_i2c is configured as a Standard (SS), Fast (FS), or Fast-Mode Plus (FM+), the \*CNT registers must be set before any I2C bus transaction can take place in order to ensure proper I/O timing. The \*CNT registers are:

- [IC\\_SS\\_SCL\\_HCNT](#)
- [IC\\_SS\\_SCL\\_LCNT](#)
- [IC\\_FS\\_SCL\\_HCNT](#)
- [IC\\_FS\\_SCL\\_LCNT](#)

#### NOTE

The tBUF timing and setup/hold time of START, STOP and RESTART registers uses \*HCNT/\*LCNT register settings for the corresponding speed mode.

### 12.2.13.1. SDA 线保持低电平

如 SDA线保持低电平，主设备将执行图88和图89所示操作以实现恢复：

1. 主设备发送最多九个时钟脉冲，在这九个脉冲内恢复总线的低电平状态。
  - 时钟脉冲数量将根据从设备剩余待发送位数而定。由于最大位数为九，主设备发送最多九个时钟脉冲，并允许从设备进行恢复。
  - 主设备尝试在 SDA线上断言逻辑1，并检查 SDA线是否已恢复。若 SDA线未恢复，主设备将继续发送最多九个 SCL时钟信号。
2. 若 SDA线在九个时钟脉冲内恢复，主设备将发送停止信号以释放总线。
3. 若第九个时钟脉冲后 SDA线仍未恢复，必须对系统进行硬件复位。

图88. SDA  
通过9个 SCL时钟恢复  
时钟

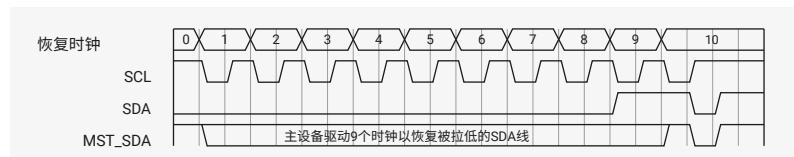

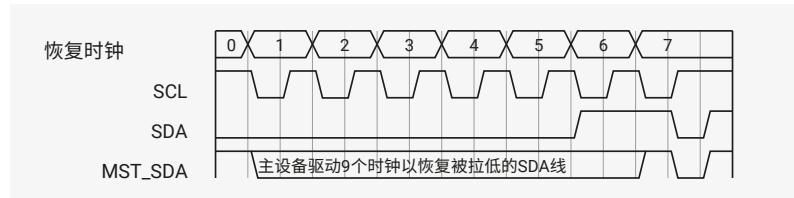

图89. SDA  
通过6个 SCL时钟恢复  
时钟

### 12.2.13.2. SCL 线被拉低

在极少数情况下（由电路电气故障导致），若时钟线（SCL）被拉低，暂无有效方法解决该问题。应使用硬件复位信号重置总线。

### 12.2.14. IC\_CLK 频率配置

当 DW\_apb\_i2c被配置为标准模式（SS）、快速模式（FS）或快速模式增强（FM+）时，必须在任何I2C总线传输开始之前设置 \*CNT寄存器，以确保正确的I/O时序。相关的 \*CNT寄存器如下：

- [IC\\_SS\\_SCL\\_HCNT](#)
- [IC\\_SS\\_SCL\\_LCNT](#)
- [IC\\_FS\\_SCL\\_HCNT](#)
- [IC\\_FS\\_SCL\\_LCNT](#)

#### i 注意

tBUF时序以及START、STOP和RESTART寄存器的建立/保持时间采用对应速度模式下的 \*HCNT/\*LCNT寄存器设置。

**NOTE**

It is not necessary to program any of the \*CNT registers if the `DW_apb_i2c` is enabled to operate only as an I2C slave, since these registers are used only to determine the `SCL` timing requirements for operation as an I2C master.

**Table 1052** lists the derivation of I2C timing parameters from the \*CNT programming registers.

*Table 1052. Derivation of I2C Timing Parameters from \*CNT Registers*

Timing Parameter	Symbol	Standard Speed	Fast Speed / Fast Speed Plus
LOW period of the <code>SCL</code> clock	<code>tLOW</code>	<code>IC_SS_SCL_LCNT</code>	<code>IC_FS_SCL_LCNT</code>
HIGH period of the <code>SCL</code> clock	<code>tHIGH</code>	<code>IC_SS_SCL_HCNT</code>	<code>IC_FS_SCL_HCNT</code>
Setup time for a repeated START condition	<code>tSU;STA</code>	<code>IC_SS_SCL_LCNT</code>	<code>IC_FS_SCL_HCNT</code>
Hold time (repeated) START condition	<code>tHD;STA</code>	<code>IC_SS_SCL_HCNT</code>	<code>IC_FS_SCL_HCNT</code>
Setup time for STOP condition	<code>tSU;STO</code>	<code>IC_SS_SCL_HCNT</code>	<code>IC_FS_SCL_HCNT</code>
Bus free time between a STOP and a START condition	<code>tBUF</code>	<code>IC_SS_SCL_LCNT</code>	<code>IC_FS_SCL_LCNT</code>
Spike length	<code>tSP</code>	<code>IC_FS_SPKLEN</code>	<code>IC_FS_SPKLEN</code>
Data hold time	<code>tHD;DAT</code>	<code>IC_SDA_HOLD</code>	<code>IC_SDA_HOLD</code>
Data setup time	<code>tSU;DAT</code>	<code>IC_SDA_SETUP</code>	<code>IC_SDA_SETUP</code>

#### 12.2.14.1. Minimum high and low counts in SS, FS, and FM+ modes.

When the `DW_apb_i2c` operates as an I2C master, in both transmit and receive transfers:

- `IC_SS_SCL_LCNT` and `IC_FS_SCL_LCNT` register values must be larger than `IC_FS_SPKLEN + 7`.
- `IC_SS_SCL_HCNT` and `IC_FS_SCL_HCNT` register values must be larger than `IC_FS_SPKLEN + 5`.

Details regarding the `DW_apb_i2c` high and low counts are as follows:

- The minimum value of `IC_*_SPKLEN + 7` for the \*`_LCNT` registers is due to the time required for the `DW_apb_i2c` to drive `SDA` after a negative edge of `SCL`.
- The minimum value of `IC_*_SPKLEN + 5` for the \*`_HCNT` registers is due to the time required for the `DW_apb_i2c` to sample `SDA` during the high period of `SCL`.
- The `DW_apb_i2c` adds one cycle to the programmed \*`_LCNT` value in order to generate the low period of the `SCL` clock; this is due to the counting logic for `SCL` low counting to (`*_LCNT + 1`).
- The `DW_apb_i2c` adds `IC_*_SPKLEN + 7` cycles to the programmed \*`_HCNT` value in order to generate the high period of the `SCL` clock, due to the following factors:
  - The counting logic for `SCL` high counts to (`*_HCNT + 1`).
  - The digital filtering applied to the `SCL` line incurs a delay of `SPKLEN + 2 ic_clk` cycles, where `SPKLEN` is `IC_FS_SPKLEN` if the component is operating in SS or FS.
  - Whenever `SCL` is driven one to zero by the `DW_apb_i2c` (completing the `SCL` high time) an internal logic latency of three `ic_clk` cycles is incurred. Consequently, the minimum `SCL` low time of which the `DW_apb_i2c` is capable is nine `ic_clk` periods ( $7 + 1 + 1$ ), while the minimum `SCL` high time is thirteen `ic_clk` periods ( $6 + 1 + 3 + 3$ ).

### 注意

若 DW\_apb\_i2c 仅被使能为 I2C 从设备，则无需配置任何 \*CNT 寄存器，因为这些寄存器仅用于确定作为 I2C 主设备时的 SCL 时序要求。

表1052列示了I2C时序参数基于 \*CNT编程寄存器的推导。

表1052。从 \*CNT 寄存器推导 I2C 定时参数

时序参数	符号	标准速率	高速 / 高速增强
SCL 时钟的低电平周期	tLOW	IC_SS_SCL_LCNT	IC_FS_SCL_LCNT
SCL 时钟的高电平周期	tHIGH	IC_SS_SCL_HCNT	IC_FS_SCL_HCNT
重复 START 条件的建立时间	tSU;STA	IC_SS_SCL_LCNT	IC_FS_SCL_HCNT
保持时间（重复）START 条件	tHD;STA	IC_SS_SCL_HCNT	IC_FS_SCL_HCNT
STOP 条件的建立时间	tSU;STO	IC_SS_SCL_HCNT	IC_FS_SCL_HCNT
STOP 和 START 条件之间的总线空闲时间	tBUF	IC_SS_SCL_LCNT	IC_FS_SCL_LCNT
尖峰时长	tSP	IC_FS_SPKLEN	IC_FS_SPKLEN
数据保持时间	tHD;DAT	IC_SDA_HOLD	IC_SDA_HOLD
数据建立时间	tSU;DAT	IC_SDA_SETUP	IC_SDA_SETUP

#### 12.2.14.1. SS、FS 和 FM+ 模式下的最小高低计数

当 DW\_apb\_i2c 作为 I2C 主设备进行发送和接收传输时：

- IC\_SS\_SCL\_LCNT 和 IC\_FS\_SCL\_LCNT 寄存器值必须大于 IC\_FS\_SPKLEN + 7。
- IC\_SS\_SCL\_HCNT 和 IC\_FS\_SCL\_HCNT 寄存器值必须大于 IC\_FS\_SPKLEN + 5。

关于 DW\_apb\_i2c 高低计数的详细说明如下：

- IC\_\*\_SPKLEN + 7 作为 \*\_LCNT 寄存器的最小值，是因为 DW\_apb\_i2c 在 SCL 负沿后驱动 SDA 所需的时间。
- IC\_\*\_SPKLEN + 5 作为 \*\_HCNT 寄存器的最小值，是由于 DW\_apb\_i2c 在 SCL 高电平期间采样 SDA 所需的时间。
  - DW\_apb\_i2c 在所编程的 \*\_LCNT 值上增加一个周期，以生成 SCL 时钟的低电平周期；这是由于 SCL 低电平的计数逻辑计数至 (\*\_LCNT + 1)。
  - DW\_apb\_i2c 在所编程的 \*\_HCNT 值上增加 IC\_\*\_SPKLEN + 7 个周期，以生成 SCL 时钟的高电平周期，原因如下：
    - SCL 高电平的计数逻辑计数至 (\*\_HCNT + 1)。
    - 施加于 SCL 线的数字滤波引入了 SPKLEN + 2 个 ic\_clk 周期的延迟，其中 SPKLEN 为 当组件处于 SS 或 FS 工作模式时，该值为 IC\_FS\_SPKLEN。
    - 每当 DW\_apb\_i2c 将 SCL 驱动由高电平拉至低电平（即完成 SCL 高电平时间）时，内部逻辑会产生三个 ic\_clk 周期的延迟。因此，DW\_apb\_i2c 所能实现的最小 SCL 低电平时间为九个 ic\_clk 周期 (7 + 1 + 1)，而最小 SCL 高电平时间为十三个 ic\_clk 周期 (6 + 1 + 3 + 3)。

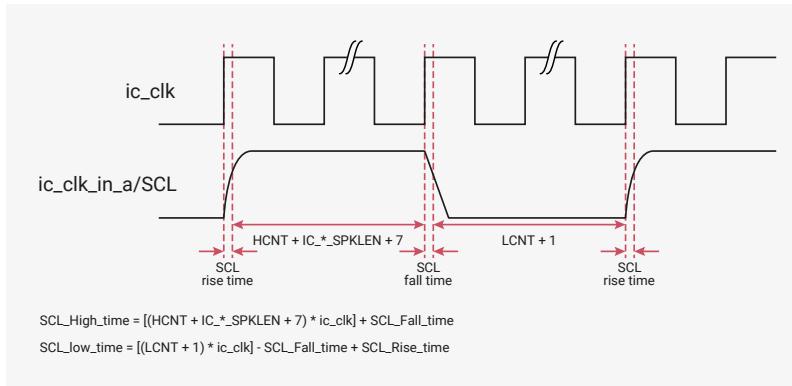

**NOTE**

The total high time and low time of **SCL** generated by the **DW\_apb\_i2c** master is also influenced by the rise time and fall time of the **SCL** line, as shown in the illustration and equations in [Figure 90](#). **SCL** rise and fall time parameters vary depending on external factors such as:

- Characteristics of the IO driver
- Pull-up resistor value
- Total capacitance on **SCL** line

These characteristics are beyond the control of the **DW\_apb\_i2c**.

Figure 90. Impact of **SCL** Rise Time and Fall Time on Generated **SCL**

#### 12.2.14.2. Minimum **IC\_CLK** frequency

This section describes the minimum **ic\_clk** frequencies that the **DW\_apb\_i2c** supports for each speed mode, and the associated high and low count values. In slave mode, **IC\_SDA\_HOLD** (Thd:dat) and **IC\_SDA\_SETUP** (Tsu:dat) need to be programmed to satisfy the I2C protocol timing requirements. The following examples are for the case where **IC\_FS\_SPKLEN** is programmed to two.

##### 12.2.14.2.1. Standard Mode (SM), Fast Mode (FM), and Fast Mode Plus (FM+)

This section details how to derive a minimum **ic\_clk** value for standard and fast modes of the **DW\_apb\_i2c**. Although the following method shows how to do fast mode calculations, you can also use the same method in order to do calculations for standard mode and fast mode plus.

**NOTE**

The following computations do not consider the **SCL\_Rise\_time** and **SCL\_Fall\_time**.

Given conditions and calculations for the minimum **DW\_apb\_i2c ic\_clk** value in fast mode:

- Fast mode has data rate of 400 kb/s; implies **SCL** period of  $1/400 \text{ kHz} = 2.5\mu\text{s}$
- Minimum hcnt value of 14 as a seed value; **IC\_HCNT\_FS = 14**
- Protocol minimum **SCL** high and low times:
  - **MIN\_SCL\_LOWtime\_FS = 1300 ns**
  - **MIN\_SCL\_HIGHTime\_FS = 600 ns**

Derived equations:

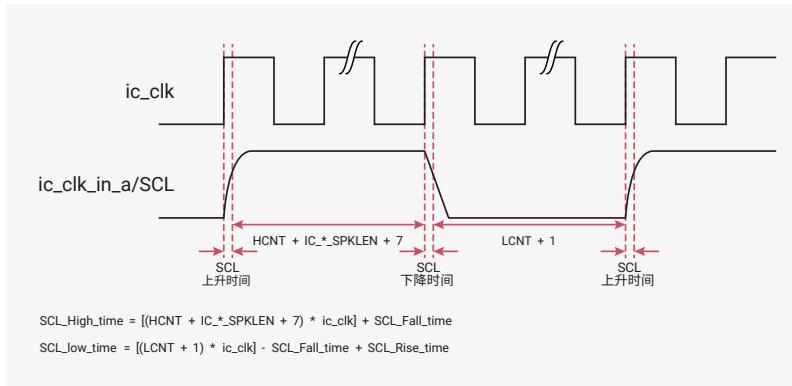

### 注意

DW\_apb\_i2c主设备生成的SCL总高电平时间和低电平时间还受到SCL信号线上升和下降时间的影响，如图90的示意图和公式所示。SCL上升时间和下降时间参数因外部因素而异，包括：

- IO驱动器的特性
- 上拉电阻的阻值
- SCL信号线上的总电容

以上特性均超出 DW\_apb\_i2c 的控制范围。

图90。SCL上升时间和下降时间对输出信号的影响  
SCL

### 12.2.14.2. 最小 IC\_CLK 频率

本节说明了 DW\_apb\_i2c 在各速率模式下支持的最小 ic\_clk 频率及对应的高计数和低计数值。在从属模式下，必须编程设置 IC\_SDA\_HOLD (Thd;dat) 和 IC\_SDA\_SETUP (Tsu:dat) 以满足 I2C 协议的时序要求。以下示例适用于将 IC\_FS\_SPKLEN 编程为二的情况。

#### 12.2.14.2.1. 标准模式 (SM)、快速模式 (FM) 及快速模式增强版 (FM+)

本节详细说明如何推导标准模式和快速模式下 DW\_apb\_i2c 的最小 ic\_clk 值。虽然以下方法展示了如何进行快速模式的计算，但您也可以使用相同方法计算标准模式和快速模式加。

### 注意

以下计算未考虑 SCL\_Rise\_time 和 SCL\_Fall\_time。

快速模式下最小 DW\_apb\_i2c ic\_clk 值的给定条件和计算：

- 快速模式的数据速率为 400 kb/s；意味着 SCL 周期为  $1/400 \text{ kHz} = 2.5 \mu\text{s}$
- 将最小 hcnt 值设为 14，作为初始值；  $\text{IC\_HCNT\_FS} = 14$
- 协议规定的最小 SCL 高电平和低电平时间：
  - $\text{MIN\_SCL\_LOWtime\_FS} = 1300 \text{ ns}$
  - $\text{MIN\_SCL\_HIGHtime\_FS} = 600 \text{ ns}$

推导方程：

$$\text{SCL\_PERIOD\_FS} / (\text{IC\_HCNT\_FS} + \text{IC\_LCNT\_FS}) = \text{IC\_CLK\_PERIOD}$$

$$\text{IC\_LCNT\_FS} \times \text{IC\_CLK\_PERIOD} = \text{MIN\_SCL\_LOWtime\_FS}$$

Combined, the previous equations produce the following:

$$\text{IC\_LCNT\_FS} \times (\text{SCL\_PERIOD\_FS} / (\text{IC\_LCNT\_FS} + \text{IC\_HCNT\_FS})) = \text{MIN\_SCL\_LOWtime\_FS}$$

Solving for `IC_LCNT_FS`:

$$\text{IC\_LCNT\_FS} \times (2.5\mu\text{s} / (\text{IC\_LCNT\_FS} + 14)) = 1.3\mu\text{s}$$

The previous equation gives:

$$\text{IC\_LCNT\_FS} = \text{roundup}(15.166) = 16$$

These calculations produce `IC_LCNT_FS = 16` and `IC_HCNT_FS = 14`, giving an `ic_clk` value of:

$$2.5\mu\text{s} / (16 + 14) = 83.3\text{ns} = 12 \text{ MHz}$$

Testing these results shows that protocol requirements are satisfied.

[Table 1053](#) lists the minimum `ic_clk` values for all modes with high and low count values.

Table 1053. `ic_clk` in Relation to High and Low Counts

Speed Mode	ic_clkfreq (MHz)	Minimum Value of IC_*_SPKLEN	SCL Low Time in 'ic_clk's	SCL Low Program Value	SCL Low Time	SCL High Time in 'ic_clk's	SCL High Program Value	SCL High Time
SS	2.7	1	13	12	4.7μs	14	6	5.2μs
FS	12.0	1	16	15	1.33μs	14	6	1.16μs
FM+	32	2	16	15	500 ns	16	7	500 ns

- The `IC_*_SCL_LCNT` and `IC_*_SCL_HCNT` registers are programmed using the `SCL` low and high program values in [Table 1053](#), which are calculated using `SCL` low count minus one, and `SCL` high counts minus eight, respectively. The values in [Table 1053](#) are based on `IC_SDA_RX_HOLD = 0`. The maximum `IC_SDA_RX_HOLD` value depends on the `IC_*_CNT` registers in Master mode.

- In order to compute the HCNT and LCNT considering RC timings, use the following equations:

$$\text{IC_HCNT\_*} = [(\text{HCNT} + \text{IC\_*_SPKLEN} + 7) * \text{ic\_clk}] + \text{SCL\_Fall\_time}$$

$$\text{IC_LCNT\_*} = [(\text{LCNT} + 1) * \text{ic\_clk}] - \text{SCL\_Fall\_time} + \text{SCL\_Rise\_time}$$

### 12.2.14.3. Calculating high and low counts

The calculations below show how to calculate `SCL` high and low counts for each speed mode in the `DW_apb_i2c`. For the calculations to work, the `ic_clk` frequencies used must not be less than the minimum `ic_clk` frequencies specified in [Table 1053](#).

The default `ic_clk` period value is set to 100 ns, so default `SCL` high and low count values are calculated for each speed

$$\text{SCL\_PERIOD\_FS} / (\text{IC\_HCNT\_FS} + \text{IC\_LCNT\_FS}) = \text{IC\_CLK\_PERIOD}$$

$$\text{IC\_LCNT\_FS} \times \text{IC\_CLK\_PERIOD} = \text{MIN\_SCL\_LOWtime\_FS}$$

综上所述，前述方程得出以下结果：

$$\text{IC\_LCNT\_FS} \times (\text{SCL\_PERIOD\_FS} / (\text{IC\_LCNT\_FS} + \text{IC\_HCNT\_FS})) = \text{MIN\_SCL\_LOWtime\_FS}$$

求解  $\text{IC\_LCNT\_FS}$ ：

$$\text{IC\_LCNT\_FS} \times (2.5\mu\text{s} / (\text{IC\_LCNT\_FS} + 14)) = 1.3 \mu\text{s}$$

上述方程得出：

$$\text{IC\_LCNT\_FS} = \text{roundup}(15.166) = 16$$

计算结果为  $\text{IC\_LCNT\_FS} = 16$  和  $\text{IC\_HCNT\_FS} = 14$ ，得到的  $\text{ic\_clk}$  值为：

$$2.5\mu\text{s} / (16 + 14) = 83.3\text{ns} = 12 \text{ MHz}$$

测试验证表明已满足协议要求。

表 1053 列出了所有模式下高低计数值对应的最小  $\text{ic\_clk}$  值。

表 1053。  $\text{ic\_clk}$  与高计数和低计数的关系

速度模式	$\text{ic\_clkfreq}$ (MHz)	$\text{IC\_*_SPKLEN}$ 的最小值	SCL 低电平时间以‘ $\text{ic\_clk}$ ’计数	SCL 低电平程序值	SCL 低电平时间	SCL 在 ‘ $\text{ic\_clk}$ ’时钟周期中的高电平时间	SCL 高电平程序值	SCL 高电平时间
SS	2.7	1	13	12	4.7μs	14	6	5.2μs
FS	12.0	1	16	15	1.33μs	14	6	1.16μs
FM+	32	2	16	15	500 ns	16	7	500 ns

- $\text{IC\_*_SCL\_LCNT}$  和  $\text{IC\_*_SCL\_HCNT}$  寄存器依据表 1053 中的 SCL 低电平及高电平编程值进行编程，该值分别通过 SCL 低计数减一及 SCL 高计数减八计算得出。表 1053 中的数值基于  $\text{IC\_SDA\_RX\_HOLD} = 0$ 。最大  $\text{IC\_SDA\_RX\_HOLD}$  值取决于主模式下的  $\text{IC\_*_CNT}$  寄存器。

- 为考虑 RC 时序计算 HCNT 和 LCNT，请使用以下公式：

$$\text{IC\_HCNT\_*} = [(HCNT + IC\_*_SPKLEN + 7) * ic\_clk] + SCL\_Fall\_time$$

$$\text{IC\_LCNT\_*} = [(LCNT + 1) * ic\_clk] - SCL\_Fall\_time + SCL\_Rise\_time$$

### 12.2.14.3. 高电平计数与低电平计数的计算

以下计算展示了如何计算 DW\_apb\_i2c 各速率模式下的 SCL 高电平和低电平计数。为了确保计算正确，所使用的  $\text{ic\_clk}$  频率不得低于表 1053 中规定的最低  $\text{ic\_clk}$  频率。

默认的  $\text{ic\_clk}$  周期值设为 100 ns，因此基于该时钟，为每种速度模式计算了默认的 SCL 高电平和低电平计数值。

mode based on this clock. These values need updating according to the guidelines below.

The equation to calculate the proper number of `ic_clk` signals required for setting the proper `SCL` clocks high and low times is as follows:

```
IC_xCNT = (ROUNDUP(MIN_SCL_xxxtime*OSCFREQ,0))

MIN_SCL_HIGHTime = Minimum High Period
MIN_SCL_HIGHTime = 4000ns for 100kb/s,
 600ns for 400kb/s,
 260ns for 1000kb/s,

MIN_SCL_LOWtime = Minimum Low Period
MIN_SCL_LOWtime = 4700ns for 100kb/s,
 1300ns for 400kb/s,
 500ns for 1000kb/s,

OSCFREQ = ic_clk Clock Frequency (Hz).
```

For example:

```
OSCFREQ = 100MHz
I2Cmode = fast, 400kb/s
MIN_SCL_HIGHTime = 600ns.
MIN_SCL_LOWtime = 1300ns.

IC_xCNT = (ROUNDUP(MIN_SCL_HIGH_LOWtime*OSCFREQ,0))

IC_HCNT = (ROUNDUP(600ns * 100MHz,0))
IC_HCNTSCL_PERIOD = 60
IC_LCNT = (ROUNDUP(1300ns * 100MHz,0))
IC_LCNTSCL_PERIOD = 130
Actual MIN_SCL_HIGHTime = 60*(1/100MHz) = 600ns
Actual MIN_SCL_LOWtime = 130*(1/100MHz) = 1300ns
```

## 12.2.15. DMA controller interface

The `DW_apb_i2c` has built-in DMA capability; it has a handshaking interface to the DMA Controller to request and control transfers. The APB bus is used to perform data transfers to and from the DMA. DMA transfers use single accesses, since the data rate is relatively low.

### 12.2.15.1. Enabling the DMA controller interface

To enable the DMA Controller interface on the `DW_apb_i2c`, you must write the DMA Control Register (`IC_DMA_CR`). Writing a one into the `TDMAE` bit field of `IC_DMA_CR` register enables the `DW_apb_i2c` transmit handshaking interface. Writing a one into the `RDMAE` bit field of the `IC_DMA_CR` register enables the `DW_apb_i2c` receive handshaking interface.

### 12.2.15.2. Overview of operation

The DMA Controller is programmed with the number of data items (transfer count) that are to be transmitted or received by `DW_apb_i2c`.

The transfer is broken into single transfers on the bus, each initiated by a request from the `DW_apb_i2c`.

上述数值均基于该时钟模式。这些数值需依据以下指导原则进行更新。

计算设定正确SCL时钟高低电平时间所需适当ic\_clk信号数量的公式如下：

```
IC_xCNT = (ROUNDUP(MIN_SCL_xxxtime*OSCFREQ, 0))

MIN_SCL_HIGHTime = 最小高电平周期
MIN_SCL_HIGHTime = 100 kb/s时为4000 ns, 40
 0 kb/s时为600 ns, 10
 00 kb/s时为260 ns,

MIN_SCL_LOWtime = 最小低电平周期
MIN_SCL_LOWtime = 100 kb/s时为4700 ns, 400
 kb/s时为1300 ns, 100
 0 kb/s时为500 ns,

OSCFREQ = ic_clk 时钟频率 (Hz) 。
```

例如：

```
OSCFREQ = 100MHz
I2Cmode = 快速, 400kb/s
MIN_SCL_HIGHTime = 600ns。
MIN_SCL_LOWtime = 1300ns.

IC_xCNT = (ROUNDUP(MIN_SCL_HIGH_LOWtime*OSCFREQ, 0))

IC_HCNT = (ROUNDUP(600ns * 100MHz, 0))
IC_HCNTSCL 周期 = 60
IC_LCNT = (ROUNDUP(1300ns * 100MHz, 0))
IC_LCNTSCL 周期 = 130
实际 MIN_SCL_HIGHTime = 60 * (1/100MHz) = 600ns
实际 MIN_SCL_LOWtime = 130 * (1/100MHz) = 1300ns
```

## 12.2.15. DMA 控制器接口

该 DW\_apb\_i2c 具备内置 DMA 功能；其具有与 DMA 控制器的握手接口，用以请求和控制传输。APB 总线用于执行与 DMA 之间的数据传输。由于数据速率相对较低，DMA 传输采用单次访问。

### 12.2.15.1. 启用DMA控制器接口

要在 DW\_apb\_i2c 上启用 DMA 控制器接口，必须写入 DMA 控制寄存器 (IC\_DMA\_CR)。

将 1 写入 IC\_DMA\_CR 寄存器的 TDMAE 位字段时，即启用 DW\_apb\_i2c 的发送握手接口。

将 1 写入 IC\_DMA\_CR 寄存器的 RDMAE 位字段时，即启用 DW\_apb\_i2c 的接收握手接口。

### 12.2.15.2. 操作概述

DMA 控制器被编程为处理由 DW\_apb\_i2c 传输或接收的数据项数量（传输计数）。

传输被分解为总线上的单次传输，每次传输由 DW\_apb\_i2c 发起请求。

For example, where the transfer count programmed into the DMA Controller is four. The DMA transfer consists of a series of four single transactions. If the [DW\\_apb\\_i2c](#) makes a transmit request to this channel, a single data item is written to the [DW\\_apb\\_i2c](#) TX FIFO. Similarly, if the [DW\\_apb\\_i2c](#) makes a receive request to this channel, a single data item is read from the [DW\\_apb\\_i2c](#) RX FIFO. Four separate requests must be made to this DMA channel before all four data items are written or read.

### 12.2.15.3. Watermark levels

In [DW\\_apb\\_i2c](#) the registers for setting watermarks to allow DMA bursts do not need to be set to anything other than their reset value. Specifically, [IC\\_DMA\\_TDLR](#) and [IC\\_DMA\\_RDLR](#) can be left at reset values of zero. This is because only single transfers are needed due to the low bandwidth of I2C relative to system bandwidth. Because the DMA controller normally has the highest priority on the system bus, transfers complete quickly.

### 12.2.16. Operation of interrupt registers

[Table 1054](#) lists the operation of the [DW\\_apb\\_i2c](#) interrupt registers and how they are set and cleared. Some bits are set by hardware and cleared by software, whereas other bits are set and cleared by hardware.

*Table 1054. Clearing and Setting of Interrupt Registers*

Interrupt Bit Fields	Set by Hardware/Cleared by Software	Set and Cleared by Hardware
RESTART_DET	Y	N
GEN_CALL	Y	N
START_DET	Y	N
STOP_DET	Y	N
ACTIVITY	Y	N
RX_DONE	Y	N
TX_ABRT	Y	N
RD_REQ	Y	N
TX_EMPTY	N	Y
TX_OVER	Y	N
RX_FULL	N	Y
RX_OVER	Y	N
RX_UNDER	Y	N

### 12.2.17. List of registers

The I2C0 and I2C1 registers start at base addresses of [0x40090000](#) and [0x40098000](#) respectively (defined as [I2C0\\_BASE](#) and [I2C1\\_BASE](#) in SDK).

例如，传输计数被编程为四。DMA传输由四次单独事务组成的一系列动作构成。如果 `DW_apb_i2c` 向该通道发出传输请求，则单个数据项会写入 `DW_apb_i2c` 的 TX FIFO。同样地，如果 `DW_apb_i2c` 向该通道发出接收请求，则单个数据项会从 `DW_apb_i2c` 的 RX FIFO 读取。在全部四个数据项完成写入或读取之前，必须向该 DMA 通道发出四次独立请求。

### 12.2.15.3. 水位线级别

在 `DW_apb_i2c` 中，用以设置 DMA 突发允许的水位线寄存器无需做任何非复位值设置。具体而言，`IC_DMA_TDLR` 和 `IC_DMA_RDLR` 可保持为复位值零。这是因为 I2C 相较于系统带宽传输速率较低，因此只需单次传输。由于 DMA 控制器通常在系统总线上拥有最高优先级，传输得以快速完成。

### 12.2.16. 中断寄存器操作

表1054列出了 `DW_apb_i2c` 中断寄存器的操作方式及其设置与清除方法。部分位由硬件设置并由软件清除，另一些位则由硬件设置和清除。

表1054。中断寄存器的设置与清除

中断位域	硬件设置／软件清除	硬件设置与清除
RESTART_DET	是	否
GEN_CALL	是	否
START_DET	是	否
STOP_DET	是	否
活动	是	否
RX_DONE	是	否
TX_ABRT	是	否
RD_REQ	是	否
TX_EMPTY	否	是
TX_OVER	是	否
RX_FULL	否	是
RX_OVER	是	否
RX_UNDER	是	否

### 12.2.17. 寄存器列表

I2C0 和 I2C1 寄存器的基地址分别为 `0x40090000` 和 `0x40098000`（在 SDK 中定义为 `I2C0_BASE` 和 `I2C1_BASE`）。

**NOTE**

You may see references to configuration constants in the I2C register descriptions; these are **fixed** values, set at hardware design time. A full list of their values can be found in `i2c.h` in the [pico-sdk GitHub repository](#).

## I2C: IC\_CON Register

Offset: 0x00

### Description

I2C Control Register. This register can be written only when the DW\_apb\_i2c is disabled, which corresponds to the IC\_ENABLE[0] register being set to 0. Writes at other times have no effect.

Read/Write Access: - bit 10 is read only. - bit 11 is read only - bit 16 is read only - bit 17 is read only - bits 18 and 19 are read only.

Table 1056. IC\_CON Register

Bits	Description	Type	Reset
31:11	Reserved.	-	-
10	<b>STOP_DET_IF_MASTER_ACTIVE:</b> Master issues the STOP_DET interrupt irrespective of whether master is active or not	RO	0x0
9	<b>RX_FIFO_FULL_HLD_CTRL:</b> This bit controls whether DW_apb_i2c should hold the bus when the Rx FIFO is physically full to its RX_BUFFER_DEPTH, as described in the IC_RX_FULL_HLD_BUS_EN parameter.  Reset value: 0x0.  Enumerated values:  0x0 → DISABLED: Overflow when RX_FIFO is full  0x1 → ENABLED: Hold bus when RX_FIFO is full	RW	0x0
8	<b>TX_EMPTY_CTRL:</b> This bit controls the generation of the TX_EMPTY interrupt, as described in the IC_RAW_INTR_STAT register.  Reset value: 0x0.  Enumerated values:  0x0 → DISABLED: Default behaviour of TX_EMPTY interrupt  0x1 → ENABLED: Controlled generation of TX_EMPTY interrupt	RW	0x0

0xfc	IC_COMP_TYPE	I2C 组件类型寄存器

## I2C: IC\_CON 寄存器

偏移: 0x00

### 说明

I2C 控制寄存器。仅当 DW\_apb\_i2c 被禁用时（对应 IC\_ENABLE[0] 寄存器设置为 0）才能写入该寄存器。其他时间的写入操作无效。

读写权限：- 位 10 只读。- 位 11 只读，- 位 16 只读，- 位 17 只读，- 位 18 和 19 只读。

表 1056. IC\_CON 寄存器

位	描述	类型	复位
31:11	保留。	-	-
10	<b>STOP_DET_IF_MASTER_ACTIVE:</b> 无论主设备是否处于活动状态，主设备均会触发 STOP_DET 中断	只读	0x0
9	<b>RX_FIFO_FULL_HLD_CTRL:</b> 该位控制 DW_apb_i2c 是否在 Rx FIFO 物理满至其 RX_BUFFER_DEPTH 时保持总线，详见 IC_RX_FULL_HLD_BUS_EN 参数。  复位值：0x0。	读写	0x0
	枚举值：		
	0x0 → 禁用：当 RX_FIFO 满时发生溢出		
	0x1 → 启用：当 RX_FIFO 满时保持总线		
8	<b>TX_EMPTY_CTRL:</b> 该位控制 TX_EMPTY 中断的生成，详见 IC_RAW_INTR_STATUS 寄存器说明。  复位值：0x0。	读写	0x0
	枚举值：		
	0x0 → 禁用：TX_EMPTY 中断的默认行为		
	0x1 → 启用：受控生成 TX_EMPTY 中断		

Bits	Description	Type	Reset
7	<p><b>STOP_DET_IFADDRESSED:</b> In slave mode: - 1'b1: issues the STOP_DET interrupt only when it is addressed. - 1'b0: issues the STOP_DET irrespective of whether it's addressed or not. Reset value: 0x0</p> <p>NOTE: During a general call address, this slave does not issue the STOP_DET interrupt if STOP_DET_IF_ADDRESSED = 1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR).</p>	RW	0x0
	Enumerated values:		
	0x0 → DISABLED: slave issues STOP_DET intr always		
	0x1 → ENABLED: slave issues STOP_DET intr only if addressed		
6	<p><b>IC_SLAVE_DISABLE:</b> This bit controls whether I2C has its slave disabled, which means once the presetn signal is applied, then this bit is set and the slave is disabled.</p> <p>If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.</p> <p>NOTE: Software should ensure that if this bit is written with 0, then bit 0 should also be written with a 0.</p>	RW	0x1
	Enumerated values:		
	0x0 → SLAVE_ENABLED: Slave mode is enabled		
	0x1 → SLAVE_DISABLED: Slave mode is disabled		
5	<p><b>IC_RESTART_EN:</b> Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several DW_apb_i2c operations. When RESTART is disabled, the master is prohibited from performing the following functions: - Sending a START BYTE - Performing any high-speed mode operation - High-speed mode operation - Performing direction changes in combined format mode - Performing a read operation with a 10-bit address By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple DW_apb_i2c transfers. If the above operations are performed, it will result in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register.</p> <p>Reset value: ENABLED</p>	RW	0x1
	Enumerated values:		
	0x0 → DISABLED: Master restart disabled		
	0x1 → ENABLED: Master restart enabled		
4	<b>IC_10BITADDR_MASTER:</b> Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. - 0: 7-bit addressing - 1: 10-bit addressing	RW	0x0
	Enumerated values:

	0x1 → ADDR_10BITS: 主控10位地址模式		

Bits	Description	Type	Reset
3	<b>IC_10BITADDR_SLAVE:</b> When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses. - 0: 7-bit addressing. The DW_apb_i2c ignores transactions that involve 10-bit addressing; for 7-bit addressing, only the lower 7 bits of the IC_SAR register are compared. - 1: 10-bit addressing. The DW_apb_i2c responds to only 10-bit addressing transfers that match the full 10 bits of the IC_SAR register.	RW	0x0
	Enumerated values:		
	0x0 → ADDR_7BITS: Slave 7Bit addressing		
	0x1 → ADDR_10BITS: Slave 10Bit addressing		
2:1	<b>SPEED:</b> These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. These bits must be programmed appropriately for slave mode also, as it is used to capture correct value of spike filter as per the speed mode.  This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.  1: standard mode (100 kbit/s)  2: fast mode (<=400 kbit/s) or fast mode plus (<=1000Kbit/s)  3: high speed mode (3.4 Mbit/s)  Note: This field is not applicable when IC_ULTRA_FAST_MODE=1	RW	0x2
	Enumerated values:		
	0x1 → STANDARD: Standard Speed mode of operation		
	0x2 → FAST: Fast or Fast Plus mode of operation		
	0x3 → HIGH: High Speed mode of operation		
0	<b>MASTER_MODE:</b> This bit controls whether the DW_apb_i2c master is enabled.  NOTE: Software should ensure that if this bit is written with '1' then bit 6 should also be written with a '1'.	RW	0x1
	Enumerated values:		
	0x0 → DISABLED: Master mode is disabled		
	0x1 → ENABLED: Master mode is enabled		

## I2C: IC\_TAR Register

**Offset:** 0x04

### Description

I2C Target Address Register

This register is 12 bits wide, and bits 31:12 are reserved. This register can be written to only when IC\_ENABLE[0] is set to 0.

Note: If the software or application is aware that the DW\_apb\_i2c is not using the TAR address for the pending

位	描述	类型	复位
3	<b>IC_10BITADDR_SLAVE:</b> 作为从机时，该位控制DW_apb_i2c响应7位或10位地址。- 0：7位寻址。DW_apb_i2c会忽略涉及10位寻址的事务；对于7位寻址，仅比较IC_SAR寄存器的低7位。- 1：10位寻址。DW_apb_i2c仅响应与IC_SAR寄存器完整10位匹配的10位寻址传输。	读写	0x0
	枚举值：		
	0x0 → ADDR_7BITS：从机7位寻址		
	0x1 → ADDR_10BITS：从机10位寻址		
2:1	<b>SPEED:</b> 这些位控制DW_apb_i2c的运行速率；仅当DW_apb_i2c工作于主控模式时，该设置才生效。 硬件防止软件编程非法值。 这些位在从模式下也必须进行适当编程，以便根据速度模式正确捕获尖峰滤波器的值。  该寄存器应仅编程为介于 1 至 IC_MAX_SPEED_MODE 范围内的值；否则，硬件将使用 IC_MAX_SPEED_MODE 的值更新该寄存器。  1：标准模式（100 kbit/s） 2：快速模式（<=400 kbit/s）或快速增强模式（<=1000 kbit/s） 3：高速模式（3.4 Mbit/s）  注意：当 IC_ULTRA_FAST_MODE=1 时，该字段不适用。	读写	0x2
	枚举值：		
	0x1 → STANDARD：标准速度操作模式		
	0x2 → FAST：快速或快速增强操作模式		
	0x3 → HIGH：高速操作模式		
0	<b>MASTER_MODE:</b> 此位用于控制是否启用 DW_apb_i2c 主控。  注意：软件应确保若该位写入“1”，则位6也应写入“1”。	读写	0x1
	枚举值：		
	0x0 → 禁用：主模式已禁用		
	0x1 → 启用：主模式已启用		

## I2C: IC\_TAR寄存器

偏移: 0x04

### 描述

I2C 目标地址寄存器

该寄存器宽度为12位，位31至12保留。仅当IC\_ENABLE[0]设置为0时，才允许写入该寄存器。

注意：若软件或应用程序知晓DW\_apb\_i2c未使用TAR地址来管理

commands in the Tx FIFO, then it is possible to update the TAR address even while the Tx FIFO has entries (IC\_STATUS[2]= 0). - It is not necessary to perform any write to this register if DW\_apb\_i2c is enabled as an I2C slave only.

Table 1057. IC\_TAR Register

Bits	Description	Type	Reset
31:12	Reserved.	-	-
11	<b>SPECIAL:</b> This bit indicates whether software performs a Device-ID or General Call or START BYTE command. - 0: ignore bit 10 GC_OR_START and use IC_TAR normally - 1: perform special I2C command as specified in Device_ID or GC_OR_START bit Reset value: 0x0	RW	0x0
	Enumerated values:		
	0x0 → DISABLED: Disables programming of GENERAL_CALL or START_BYTETransmission		
	0x1 → ENABLED: Enables programming of GENERAL_CALL or START_BYTETransmission		
10	<b>GC_OR_START:</b> If bit 11 (SPECIAL) is set to 1 and bit 13(Device-ID) is set to 0, then this bit indicates whether a General Call or START byte command is to be performed by the DW_apb_i2c. - 0: General Call Address - after issuing a General Call, only writes may be performed. Attempting to issue a read command results in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. The DW_apb_i2c remains in General Call mode until the SPECIAL bit value (bit 11) is cleared. - 1: START BYTE Reset value: 0x0	RW	0x0
	Enumerated values:		
	0x0 → GENERAL_CALL: GENERAL_CALL byte transmission		
	0x1 → START_BYTET: START byte transmission		
9:0	<b>IC_TAR:</b> This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTET, the CPU needs to write only once into these bits.  If the IC_TAR and IC_SAR are the same, loopback exists but the FIFOs are shared between master and slave, so full loopback is not feasible. Only one direction loopback mode is supported (simplex), not duplex. A master cannot transmit to itself; it can transmit to only a slave.	RW	0x055

## I2C: IC\_SAR Register

Offset: 0x08

### Description

I2C Slave Address Register

Table 1058. IC\_SAR Register

Bits	Description	Type	Reset
31:10	Reserved.	-	-

Tx FIFO中的待处理命令，则即使Tx FIFO中有条目（IC\_STATUS[2]=0），仍可更新TAR地址。- 若DW\_apb\_i2c仅作为I2C从机启用，则无需对该寄存器进行任何写操作。

表1057. IC\_TAR 寄存器

位	描述	类型	复位
31:12	保留。	-	-
11	<b>SPECIAL:</b> 该位指示软件是否执行设备 ID 命令、通用调用命令或起始字节命令。- 0：忽略第10位 GC_OR_START，并正常使用 IC_TAR - 1：按设备ID 或 GC_OR_START 位指定执行特殊 I2C 命令 复位值：0x0	读写	0x0
	枚举值：		
	0x0 → 禁用：禁用 GENERAL_CALL 或 START_BYTE 传输的编程		
	0x1 → 启用：启用 GENERAL_CALL 或 START_BYTE 传输的编程		
10	<b>GC_OR_START:</b> 若第11位（SPECIAL）设为1且第13位（设备 ID）设为0，则该位指示 DW_apb_i2c 是否执行通用调用或起始字节命令。- 0：通用调用地址 - 发出通用调用后，仅允许写操作。尝试发出读取命令将导致设置 IC_RA_W_INTR_STAT 寄存器的第6位（TX_ABRT）。DW_apb_i2c 将保持在General Call模式，直到SPECIAL位（第11位）被清除。- 1：START BYTE 重置值：0x0	读写	0x0
	枚举值：		
	0x0 → GENERAL_CALL：GENERAL_CALL字节传输		
	0x1 → START_BYTE：START字节传输		
9:0	<b>IC_TAR:</b> 用于任何主设备事务的目标地址。传输General Call时，这些位将被忽略。生成START BYTE时，CPU仅需写入这些位一次。  若IC_TAR与IC_SAR相同，则存在环回，但主从使用共享FIFO，无法实现完全环回。仅支持单向环回模式（单工），不支持双工模式。主设备不能向自身发送数据；只能向从设备发送数据。	读写	0x055

## I2C: IC\_SAR寄存器

偏移: 0x08

### 描述

I2C 从地址寄存器

表1058. IC\_SAR 寄存器

位	描述	类型	复位
31:10	保留。	-	-

Bits	Description	Type	Reset
9:0	<p><b>IC_SAR:</b> The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used.</p> <p>This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>Note: The default values cannot be any of the reserved address locations: that is, 0x00 to 0x07, or 0x78 to 0x7f. The correct operation of the device is not guaranteed if you program the IC_SAR or IC_TAR to a reserved value. Refer to <a href="#">Table 1051</a> for a complete list of these reserved values.</p>	RW	0x055

## I2C: IC\_DATA\_CMD Register

**Offset:** 0x10

### Description

I2C Rx/Tx Data Buffer and Command Register; this is the register the CPU writes to when filling the TX FIFO and the CPU reads from when retrieving bytes from RX FIFO.

The size of the register changes as follows:

Write: - 11 bits when IC\_EMPTYFIFO\_HOLD\_MASTER\_EN=1 - 9 bits when IC\_EMPTYFIFO\_HOLD\_MASTER\_EN=0 Read: - 12 bits when IC\_FIRST\_DATA\_BYTE\_STATUS = 1 - 8 bits when IC\_FIRST\_DATA\_BYTE\_STATUS = 0 Note: In order for the DW\_apb\_i2c to continue acknowledging reads, a read command should be written for every byte that is to be received; otherwise the DW\_apb\_i2c will stop acknowledging.

Table 1059.  
IC\_DATA\_CMD  
Register

Bits	Description	Type	Reset
31:12	Reserved.	-	-
11	<p><b>FIRST_DATA_BYTE:</b> Indicates the first data byte received after the address phase for receive transfer in Master receiver or Slave receiver mode.</p> <p>Reset value : 0x0</p> <p>NOTE: In case of APB_DATA_WIDTH=8,</p> <ol style="list-style-type: none"> <li>1. The user has to perform two APB Reads to IC_DATA_CMD in order to get status on 11 bit.</li> <li>2. In order to read the 11 bit, the user has to perform the first data byte read [7:0] (offset 0x10) and then perform the second read [15:8] (offset 0x11) in order to know the status of 11 bit (whether the data received in previous read is a first data byte or not).</li> <li>3. The 11th bit is an optional read field, user can ignore 2nd byte read [15:8] (offset 0x11) if not interested in FIRST_DATA_BYTE status.</li> </ol>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: Sequential data byte received		
	0x1 → ACTIVE: Non sequential data byte received		

位	描述	类型	复位
9:0	<p><b>IC_SAR:</b> 当I2C作为从设备运行时，IC_SAR保存从设备地址。对于7位寻址，仅使用IC_SAR[6:0]。</p> <p>仅当I2C接口被禁用时，即IC_ENABLE[0]寄存器设置为0，该寄存器方可写入。其他时间的写入操作无效。</p> <p>注意：默认值不得为任何保留地址，即0x00至0x07或0x78至0x7f。若将IC_SA_R或IC_TAR设置为保留值，则设备无法保证正常工作。完整保留值列表请参阅表1051。</p>	读写	0x055

## I2C: IC\_DATA\_CMD寄存器

偏移: 0x10

### 描述

I2C接收/发送数据缓冲区及命令寄存器；CPU填充TX FIFO时写入该寄存器，检索RX FIFO中字节时从该寄存器读取。

寄存器大小变化如下：

写入： - 当 IC\_EMPTYFIFO\_HOLD\_MASTER\_EN=1 时为 11 位 - 当 IC\_EMPTYFIFO\_HOLD\_MASTER\_EN=0 时为 9 位 读取：  
 - 当 IC\_FIRST\_DATA\_BYTE\_STATUS=1 时为 12 位 - 当 IC\_FIRST\_DATA\_BYTE\_STATUS=0 时为 8 位 注意：为确保 DW\_apb\_i2c 继续确认读取操作，必须为每个要接收的字节写入读取命令；  
 否则 DW\_apb\_i2c 将停止确认。

表 1059。  
IC\_DATA\_CMD  
寄存器

位	描述	类型	复位
31:12	保留。	-	-
11	<p><b>FIRST_DATA_BYTE:</b> 指示在主机接收或从机接收模式下，地址阶段后接收到的第一个数据字节。</p> <p>复位值：0x0</p> <p>注意：在 APB_DATA_WIDTH=8 的情况下，</p> <ol style="list-style-type: none"> <li>用户必须对 IC_DATA_CMD 执行两次 APB 读取操作以获取 11 位状态。</li> <li>为读取该 11 位，用户须先执行第一个数据字节的读取操作。 [7:0]（偏移量 0x10），然后执行第二次读取 [15:8]（偏移量 0x11），以确定第 11 位的状态（即先前读取的数据是否为第一个数据字节）。</li> <li>第 11 位为可选读取字段，用户可忽略第二字节的读取 [15:8] (偏移量 0x11)，若不关心 FIRST_DATA_BYTE 状态。</li> </ol>	只读	0x0
	枚举值：		
	0x0 → 非活动：接收连续数据字节		
	0x1 → 活动：接收非连续数据字节		

Bits	Description	Type	Reset
10	<p><b>RESTART:</b> This bit controls whether a RESTART is issued before the byte is sent or received.</p> <p>1 - If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.</p> <p>0 - If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.</p> <p>Reset value: 0x0</p>	SC	0x0
	Enumerated values:		
	0x0 → DISABLE: Don't Issue RESTART before this command		
	0x1 → ENABLE: Issue RESTART before this command		
9	<p><b>STOP:</b> This bit controls whether a STOP is issued after the byte is sent or received.</p> <p>- 1 - STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus. - 0 - STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO. Reset value: 0x0</p>	SC	0x0
	Enumerated values:		
	0x0 → DISABLE: Don't Issue STOP after this command		
	0x1 → ENABLE: Issue STOP after this command		
8	<p><b>CMD:</b> This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2con acts as a slave. It controls only the direction when it acts as a master.</p> <p>When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that the data in IC_DATA_CMD is to be transmitted.</p> <p>When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register), unless bit 11 (SPECIAL) in the IC_TAR register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a TX_ABRT interrupt occurs.</p> <p>Reset value: 0x0</p>	SC	0x0
	Enumerated values:		
	0x0 → WRITE: Master Write Command		

位	描述	类型	复位
10	<p><b>RESTART</b>: 该位控制在字节发送或接收之前是否发出重启信号。</p> <p>1 - 若 IC_RESTART_EN 为 1，则根据 CMD 的值，在数据发送/接收之前无论传输方向是否改变均发出 RESTART；若 IC_RESTART_EN 为 0，则改为先发出 STOP 信号，随后发出 START 信号。</p> <p>0 - 如果 IC_RESTART_EN 为 1，只有当传输方向相较于前一命令发生变化时才发出 RESTART；若 IC_RESTART_EN 为 0，则改为先发出 STOP 信号，随后发出 START 信号。</p> <p>复位值: 0x0</p>	SC	0x0
	枚举值:		
	0x0 → 禁用：在此命令之前不发出 RESTART		
	0x1 → 启用：在此命令之前发出 RESTART		
9	<p><b>STOP</b>: 该位控制在字节发送或接收后是否发出 STOP。</p> <p>- 1 - 发送此字节后，无论 Tx FIFO 是否为空均发出 STOP。若 Tx FIFO 非空，主设备将立即尝试通过发出 START 并争用总线开始新传输。- 0 - 发送此字节后，无论 Tx FIFO 是否为空均不发出 STOP。若 Tx FIFO 非空，主设备根据 CMD 位的值继续当前传输，发送/接收数据字节。若 Tx FIFO 为空，主设备保持 SCL 线低电平，阻塞总线，直至 Tx FIFO 有新命令。复位值：0x0</p>	SC	0x0
	枚举值:		
	0x0 → 禁用：此命令后不发送STOP信号		
	0x1 → 启用：此命令后发送STOP信号		
8	<p><b>CMD</b>: 此位控制执行读操作还是写操作。该位不控制 DW_apb_i2con 作为从设备时的传输方向。它仅控制该设备作为主设备时的传输方向。</p> <p>当命令进入 TX FIFO 时，此位用于区分写命令和读命令。在从设备接收模式下，该位为“无关”状态，因为不需要写入此寄存器。在从设备发送模式下，值为“0”表示将发送 IC_DATA_CMD 中的数据。</p> <p>编程此位时应注意：发送一般呼叫命令后尝试执行读操作会触发 TX_ABRT 中断 (IC_RAW_INTR_STAT 寄存器第 6 位)，除非 IC_TAR 寄存器第 11 位 (SPECIAL) 已被清除。如果在接收到 RD_REQ 中断后将该位写为“1”，则会引发 TX_A_BRT 中断。</p> <p>复位值: 0x0</p>	SC	0x0
	枚举值:		
	0x0 → 写入：主设备写命令		

Bits	Description	Type	Reset
	0x1 → READ: Master Read Command		
7:0	<b>DAT:</b> This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.  Reset value: 0x0	RW	0x00

## I2C: IC\_SS\_SCL\_HCNT Register

Offset: 0x14

### Description

Standard Speed I2C Clock SCL High Count Register

Table 1060.  
IC\_SS\_SCL\_HCNT  
Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	<b>IC_SS_SCL_HCNT:</b> This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock high-period count for standard speed. For more information, refer to 'IC_CLK Frequency Configuration'.  This register can be written only when the I2C interface is disabled which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.  The minimum valid value is 6; hardware prevents values less than this being written, and if attempted results in 6 being set. For designs with APB_DATA_WIDTH = 8, the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte is programmed.  NOTE: This register must not be programmed to a value higher than 65525, because DW_apb_i2c uses a 16-bit counter to flag an I2C bus idle condition when this counter reaches a value of IC_SS_SCL_HCNT + 10.	RW	0x0028

## I2C: IC\_SS\_SCL\_LCNT Register

Offset: 0x18

### Description

Standard Speed I2C Clock SCL Low Count Register

Table 1061.  
IC\_SS\_SCL\_LCNT  
Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-

位	描述	类型	复位
	0x1 → 读取：主设备读命令		
7:0	<b>DAT</b> ：此寄存器包含将在 I2C 总线上发送或接收的数据。若写入该寄存器且想执行读取操作，DW_apb_i2c 会忽略位 7:0（DAT）。但当读取此寄存器时，这些位返回 DW_apb_i2c 接口接收的数据值。  复位值：0x0	读写	0x00

## I2C: IC\_SS\_SCL\_HCNT 寄存器

偏移：0x14

### 说明

标准速率 I2C 时钟 SCL 高电平计数寄存器

表 1060。  
IC\_SS\_SCL\_HCNT  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	<b>IC_SS_SCL_HCNT</b> ：必须在进行任何 I2C 总线事务之前设置此寄存器，以确保正确的输入/输出时序。此寄存器设置标准速率下 SCL 时钟高电平周期计数。详情请参阅“IC_CLK 频率配置”。  仅当 I2C 接口被禁用，即 IC_ENABLE[0] 寄存器被设为 0 时，此寄存器方可写入。其他时间的写入操作无效。  最小有效值为 6；硬件防止写入小于该值的数值，若尝试写入则将自动设为 6。对于 APB_DATA_WIDTH = 8 的设计，编程顺序对于保证 DW_apb_i2c 的正确运行至关重要，必须先编程低字节。随后编程高字节。  注意：该寄存器不得被设置为大于 65525 的值，因为 DW_apb_i2c 使用 16 位计数器，当计数器达到 IC_SS_SCL_HCNT + 10 时，将标记 I2C 总线处于空闲状态。	读写	0x0028

位	描述	类型	复位
15:0	<p><b>IC_FS_SCL_LCNT</b>: 必须在任何 I2C 总线事务开始之前设置此寄存器，以保证正确的 I/O 时序。该寄存器设置快速模式下 SCL 时钟低电平的计数周期。该寄存器用于高速模式下发送主机代码和启动字节或通用呼叫。详细信息，请参阅“IC_CLK 频率配置”。</p> <p>当 IC_MAX_SPEED_MODE = standard 时，该寄存器将失效并变为只读，返回值为 0。</p> <p>仅当 I2C 接口被禁用时，即 IC_ENABLE[0] 寄存器设置为 0，该寄存器方可写入。其他时间的写入操作无效。</p> <p>最小有效值为 8；硬件禁止写入小于此值的数据，若尝试写入则寄存器将被设为 8。对于 APB_DATA_WIDTH = 8 的设计，编程顺序极为重要，以确保 DW_apb_i2c 的正常运行。必须先编程低字节。然后编程高字节。如果值小于 8，则计数值被更改为 8。</p>	读写	0x000d

## I2C: IC\_INTR\_STAT 寄存器

偏移: 0x2c

### 描述

I2C 中断状态寄存器

该寄存器中的每个位均对应 IC\_INTR\_MASK 寄存器中的一个掩码位。这些位通过读取相应的中断清除寄存器来清除。这些位的未屏蔽原始状态可在 IC\_RAW\_INTR\_STAT 寄存器中获得。

表 1064

	0x1 → ACTIVE: RX_UNDER interrupt is active		

## I2C: IC\_INTR\_MASK Register

Offset: 0x30

### Description

I2C Interrupt Mask Register.

These bits mask their corresponding interrupt status bits. This register is active low; a value of 0 masks the interrupt, whereas a value of 1 unmasks the interrupt.

位	描述	类型	复位
4	<b>R_TX_EMPTY:</b> 详见 IC_RAW_INTR_STAT 以获取 R_TX_EMPTY 位的详细描述。  复位值: 0x0	只读	0x0

1	<b>R_RX_OVER:</b> 详见 IC_RAW_INTR_STAT 寄存器中 R_RX_OVER 位的详细描述。  复位值: 0x0	只读	0x0
	枚举值:		
	0x0 → 未激活: R_RX_OVER 中断处于未激活状态		
	0x1 → 激活: R_RX_OVER 中断处于激活状态		
0	<b>R_RX_UNDER:</b> 详见 IC_RAW_INTR_STAT 寄存器中 R_RX_UNDER 位的详细描述。  复位值: 0x0	只读	0x0
	枚举值:		
	0x0 → 未激活: RX_UNDER 中断处于未激活状态		
	0x1 → 激活: RX_UNDER 中断处于激活状态		

## I2C: IC\_INTR\_MASK 寄存器

偏移: 0x30

### 描述

I2C 中断屏蔽寄存器。

这些位用于屏蔽对应的中断状态位。该寄存器为低电平有效；值为 0 表示中断被屏蔽，值为 1 表示中断未被屏蔽。

Table 1065.  
IC\_INTR\_MASK  
Register

Bits	Description	Type	Reset

	0x0 → ENABLED: RX_UNDER interrupt is masked		
	0x1 → DISABLED: RX_UNDER interrupt is unmasked		

## I2C: IC\_RAW\_INTR\_STAT Register

Offset: 0x34

### Description

I2C Raw Interrupt Status Register

Unlike the IC\_INTR\_STAT register, these bits are not masked so they always show the true status of the DW\_apb\_i2c.

Table 1066.  
IC\_RAW\_INTR\_STAT  
Register

Bits	Description	Type	Reset
31:13	Reserved.	-	-
12	<b>RESTART_DET</b> : Indicates whether a RESTART condition has occurred on the I2C interface when DW_apb_i2c is operating in Slave mode and the slave is being addressed. Enabled only when IC_SLV_RESTART_DET_EN=1.  Note: However, in high-speed mode or during a START BYTE transfer, the RESTART comes before the address field as per the I2C protocol. In this case, the slave is not the addressed slave when the RESTART is issued, therefore DW_apb_i2c does not generate the RESTART_DET interrupt.  Reset value: 0x0	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RESTART_DET interrupt is inactive		
	0x1 → ACTIVE: RESTART_DET interrupt is active		
11	<b>GEN_CALL</b> : Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling DW_apb_i2c or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. DW_apb_i2c stores the received data in the Rx buffer.  Reset value: 0x0	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: GEN_CALL interrupt is inactive		
	0x1 → ACTIVE: GEN_CALL interrupt is active		
10	<b>START_DET</b> : Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode.  Reset value: 0x0	RO	0x0
	Enumerated values:		

位	描述	类型	复位
0	<b>M_RX_UNDER</b> : 此位用于屏蔽IC_INTR_STAT寄存器中的R_RX_UNDER中断 ◦ 复位值: 0x1	读写	0x1
	枚举值:		
	0x0 → 启用: RX_UNDER中断被屏蔽		
	0x1 → 禁用: RX_UNDER中断未屏蔽		

## I2C: IC\_RAW\_INTR\_STAT 寄存器

偏移: 0x34

### 描述

I2C 原始中断状态寄存器

与 IC\_INTR\_STAT 寄存器不同，这些位未被屏蔽，因此始终显示 DW\_apb\_i2c 的真实状态。

表 1066。  
IC\_RAW\_INTR\_STAT  
寄存器

位	描述	类型	复位
31:13	保留。	-	-
12	<b>RESTART_DET</b> : 当 DW_apb_i2c 以从模式运行且从设备被寻址时，指示 I2C 接口是否发生了 RESTART 条件。仅在 IC_SLV_RESTART_DET_EN=1 时启用。  注意：根据 I2C 协议，在高速模式或 START BYTE 传输期间，RESTART 位于地址字段之前。在该情况下，RESTART 发出时从设备并非被寻址的对象，因此 DW_apb_i2c 不生成 RESTART_DET 中断。  复位值: 0x0	只读	0x0
	枚举值:		
	0x0 → 非活动: RESTART_DET 中断处于非活动状态		
	0x1 → 活动: RESTART_DET 中断处于活动状态		
11	<b>GEN_CALL</b> : 仅在收到并确认通用呼叫地址时置位。该状态将保持设置，直到通过禁用 DW_apb_i2c 或 CPU 读取 IC_CLR_GEN_CALL 寄存器的第 0 位时被清除。DW_apb_i2c 将接收的数据存储于 Rx 缓冲区。  复位值: 0x0	只读	0x0
	枚举值:		
	0x0 → 非活动: GEN_CALL 中断处于非激活状态		
	0x1 → 激活: GEN_CALL 中断处于激活状态		
10	<b>START_DET</b> : 指示 I2C 接口上是否发生了 START 或 RESTART 条件，无论 DW_apb_i2c 是处于主模式还是从模式。  复位值: 0x0	只读	0x0
	枚举值:		

Bits	Description	Type	Reset
	0x0 → INACTIVE: START_DET interrupt is inactive		
	0x1 → ACTIVE: START_DET interrupt is active		
9	<p><b>STOP_DET:</b> Indicates whether a STOP condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode.</p> <p>In Slave Mode: - If IC_CON[7]=1'b1 (STOP_DET_IFADDRESSED), the STOP_DET interrupt will be issued only if slave is addressed. Note: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IF_ADDRESSED=1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). - If IC_CON[7]=1'b0 (STOP_DET_IFADDRESSED), the STOP_DET interrupt is issued irrespective of whether it is being addressed. In Master Mode: - If IC_CON[10]=1'b1 (STOP_DET_IF_MASTER_ACTIVE), the STOP_DET interrupt will be issued only if Master is active. - If IC_CON[10]=1'b0 (STOP_DET_IFADDRESSED), the STOP_DET interrupt will be issued irrespective of whether master is active or not. Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: STOP_DET interrupt is inactive		
	0x1 → ACTIVE: STOP_DET interrupt is active		
8	<p><b>ACTIVITY:</b> This bit captures DW_apb_i2c activity and stays set until it is cleared. There are four ways to clear it: - Disabling the DW_apb_i2c - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the DW_apb_i2c module is idle, this bit remains set until cleared, indicating that there was activity on the bus.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RAW_INTR_ACTIVITY interrupt is inactive		
	0x1 → ACTIVE: RAW_INTR_ACTIVITY interrupt is active		
7	<p><b>RX_DONE:</b> When the DW_apb_i2c is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RX_DONE interrupt is inactive		
	0x1 → ACTIVE: RX_DONE interrupt is active		

位	描述	类型	复位
	0x0 → 非活动：START_DET 中断处于非激活状态		
	0x1 → 激活：START_DET 中断处于激活状态		
9	<p><b>STOP_DET：</b>指示 I2C 接口上是否发生了 STOP 条件，无论 DW_apb_i2c 是处于主模式还是从模式。</p> <p>在从模式下： - 若 IC_CON[7]=1'b1 (STOP_DET_IFADDRESSED) ，仅当从机被寻址时才会触发 STOP_DET 中断。注意：在一般调用地址期间，如果 STOP_DET_IF_ADDRESSED=1'b1，即使从设备通过生成ACK响应一般调用地址，也不会发出STOP_DET中断。仅当传输的地址与从设备地址 (SAR) 匹配时，才会生成STOP_DET中断。 - 如果IC_CON[7]=1'b0 (STOP_DET_IFADDRESSED) ，则无论是否被寻址，都会发出STOP_DET中断。主模式下： - 如果IC_CO N[10]=1'b1 (STOP_DET_IF_MASTER_ACTIVE) ，则仅当主设备处于活动状态时才发出STOP_DET中断。 - 如果IC_CON[10]=1'b0 (STOP_DET_IFADDRESSED) ，则无论主设备是否活动，都会发出STOP_DET中断。</p> <p>复位值：0x0</p>	只读	0x0
	枚举值：		
	0x0 → 非活动：STOP_DET 中断处于非活动状态		
	0x1 → 活动：STOP_DET 中断处于活动状态		
8	<p><b>ACTIVITY：</b>该位捕捉DW_apb_i2c的活动状态，并保持置位，直至被清除。清除该位有四种方法： - 禁用DW_apb_i2c模块 - 读取IC_CLR_ACTIVITY 寄存器 - 读取IC_CLR_INTR寄存器 - 系统复位一旦此位被置位，除非采用上述任一方法清除，否则其将持续保持置位状态。即便DW_apb_i2c模块处于空闲，此位仍保持置位，表明总线上曾有活动。</p> <p>复位值：0x0</p>	只读	0x0
	枚举值：		
	0x0 → 非活动状态：RAW_INTR_ACTIVITY 中断处于非活动状态		
	0x1 → 活动状态：RAW_INTR_ACTIVITY 中断处于活动状态		
7	<p><b>RX_DONE：</b>当DW_apb_i2c作为从机发送器时，若主机未确认已发送字节，此位将被置为1。该情况发生在传输的最后一个字节，表明传输已完成。</p> <p>复位值：0x0</p>	只读	0x0
	枚举值：		
	0x0 → 非活动状态：RX_DONE 中断处于非活动状态		
	0x1 → 活动：RX_DONE 中断处于激活状态		

Bits	Description	Type	Reset
6	<p><b>TX_ABRT:</b> This bit indicates if DW_apb_i2c, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places.</p> <p>Note: The DW_apb_i2c flushes/resets/empties the TX_FIFO and RX_FIFO whenever there is a transmit abort caused by any of the events tracked by the IC_TX_ABRT_SOURCE register. The FIFOs remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the Tx FIFO is then ready to accept more data bytes from the APB interface.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: TX_ABRT interrupt is inactive		
	0x1 → ACTIVE: TX_ABRT interrupt is active		
5	<p><b>RD_REQ:</b> This bit is set to 1 when DW_apb_i2c is acting as a slave and another I2C master is attempting to read data from DW_apb_i2c. The DW_apb_i2c holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RD_REQ interrupt is inactive		
	0x1 → ACTIVE: RD_REQ interrupt is active		
4	<p><b>TX_EMPTY:</b> The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. - When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. - When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0.</p> <p>Reset value: 0x0.</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: TX_EMPTY interrupt is inactive		
	0x1 → ACTIVE: TX_EMPTY interrupt is active		

位	描述	类型	复位
6	<p><b>TX_ABRT:</b> 该位指示 DW_apb_i2c 作为 I2C 发送方时，无法完成对发送 FIFO 内容的预期操作。此情况可在 I2C 主设备或从设备模式下发生，称为“发送中止”。当此位被置为 1 时，IC_TX_ABRT_SOURCE 寄存器将指示发送中止的具体原因。</p> <p>注意：每当因 IC_TX_ABRT_SOURCE 寄存器所跟踪的任一事件导致发送中止时，DW_apb_i2c 会刷新/重置/清空 TX_FIFO 和 RX_FIFO。FIFO 将保持在此刷新状态，直到读取 IC_CLR_TX_ABRT 寄存器。读取该寄存器后，Tx FIFO 即可准备好接收来自 APB 接口的更多数据字节。</p> <p>复位值：0x0</p>	只读	0x0
	枚举值：		
	0x0 → 非活动：TX_ABRT 中断处于非激活状态		
	0x1 → 活动：TX_ABRT 中断处于活动状态		
5	<p><b>RD_REQ:</b> 当 DW_apb_i2c 作为从设备，且另一 I2C 主设备试图从 DW_apb_i2c 读取数据时，该位被置为 1。DW_apb_i2c 将 I2C 总线保持在等待状态 (S CL=0)，直到该中断被处理，即从设备已被远程主设备寻址并请求传输数据。处理器必须响应此中断，随后将请求的数据写入 IC_DATA_CMD 寄存器。在处理器读取 IC_CLR_RD_REQ 寄存器后，该位被清零，置为 0。</p> <p>复位值：0x0</p>	只读	0x0
	枚举值：		
	0x0 → 非活动：RD_REQ 中断处于非活动状态		
	0x1 → 活动：RD_REQ 中断处于活动状态		
4	<p><b>TX_EMPTY:</b> TX_EMPTY 中断状态的行为取决于 IC_CON 寄存器中 TX_EMPT Y_CTRL 的设置。- 当 TX_EMPTY_CTRL = 0：发送缓冲区达到或低于 IC_TX_TL 寄存器中设置的阈值时，该位置为 1。- 当 TX_EMPTY_ CTRL = 1：发送缓冲区达到或低于 IC_TX_TL 寄存器中设置的阈值，且最近弹出命令的内部移位寄存器的地址/数据传输完成时，该位置为 1。当缓冲区级别超过阈值时，该位由硬件自动清除。当 IC_ENABLE[0] 设置为 0 时，TX FIFO 会被刷新并保持复位状态。因此，TX FIFO 显示无数据，只要主机或从机状态机处于活动状态，该位即被置为 1。当无任何活动且 ic_en=0 时，该位置为 0。</p> <p>复位值：0x0。</p>	只读	0x0
	枚举值：		
	0x0 → 非激活：TX_EMPTY 中断处于非激活状态		
	0x1 → ACTIVE：TX_EMPTY 中断处于激活状态。		

Bits	Description	Type	Reset
3	<p><b>TX_OVER:</b> Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: TX_OVER interrupt is inactive		
	0x1 → ACTIVE: TX_OVER interrupt is active		
2	<p><b>RX_FULL:</b> Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RX_FULL interrupt is inactive		
	0x1 → ACTIVE: RX_FULL interrupt is active		
1	<p><b>RX_OVER:</b> Set if the receive buffer is completely filled to IC_RX_BUFFER_DEPTH and an additional byte is received from an external I2C device. The DW_apb_i2c acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared.</p> <p>Note: If bit 9 of the IC_CON register (RX_FIFO_FULL_HLD_CTRL) is programmed to HIGH, then the RX_OVER interrupt never occurs, because the Rx FIFO never overflows.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RX_OVER interrupt is inactive		
	0x1 → ACTIVE: RX_OVER interrupt is active		
0	<p><b>RX_UNDER:</b> Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:		
	0x0 → INACTIVE: RX_UNDER interrupt is inactive		
	0x1 → ACTIVE: RX_UNDER interrupt is active		

位	描述	类型	复位
3	<b>TX_OVER:</b> 在发送过程中，若发送缓冲区已填满至IC_TX_BUF_FER_DEPTH且处理器试图通过写入IC_DATA_CMD寄存器发出另一条I2C命令时，该位被置位。当模块被禁用时，此位保持电平，直到主设备或从设备状态机进入空闲状态；且当ic_en为0时，该中断被清除。  复位值：0x0	只读	0x0
	枚举值：		
	0x0 → INACTIVE: TX_OVER中断处于非激活状态。		
	0x1 → ACTIVE: TX_OVER中断处于激活状态。		
2	<b>RX_FULL:</b> 当接收缓冲区达到或超过IC_RX_TL寄存器中的RX_TL阈值时置位。当缓冲区级别低于阈值时，该位由硬件自动清除。若模块被禁用（IC_ENABLE[0]=0），则RX FIFO将被清空并保持复位状态；因此，RX FIFO不会处于满状态。因此，无论后续活动如何，只要IC_ENABLE的第0位被设置为0，该位即被清除。  复位值：0x0	只读	0x0
	枚举值：		
	0x0 → 非活动：RX_FULL 中断处于非活动状态		
	0x1 → 活动：RX_FULL 中断处于活动状态		
1	<b>RX_OVER:</b> 当接收缓冲区完全填满时设置达到 IC_RX_BUFFER_DEPTH 并且从外部 I2C 设备接收了额外的一个字节。DW_apb_i2c 会对此进行确认，但在 FIFO 满载后接收的任何数据字节将丢失。如果模块被禁用（IC_ENABLE[0]=0），该位保持其电平，直到主机或从机状态机进入空闲状态，且当 ic_en 变为 0 时，该中断被清除。  注意：如果 IC_CON 寄存器的第 9 位（RX_FIFO_FULL_HLD_CTRL）被设置为高电平，则 RX_OVER 中断永远不会发生，因为 Rx FIFO 永远不会溢出。  复位值：0x0	只读	0x0
	枚举值：		
	0x0 → 非活动：RX_OVER 中断处于非活动状态		
	0x1 → 活动：RX_OVER 中断处于活动状态		
0	<b>RX_UNDER:</b> 当处理器尝试从 IC_DATA_CMD 寄存器读取空接收缓冲区时设置。如果模块被禁用（IC_ENABLE[0]=0），该位保持其电平，直到主机或从机状态机进入空闲状态，且当 ic_en 变为 0 时，该中断被清除。  复位值：0x0	只读	0x0
	枚举值：		
	0x0 → 未激活：RX_UNDER 中断处于未激活状态		
	0x1 → 激活：RX_UNDER 中断处于激活状态		

## I2C: IC\_RX\_TL Register

**Offset:** 0x38

### Description

I2C Receive FIFO Threshold Register

Table 1067. IC\_RX\_TL Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	<b>RX_TL:</b> Receive FIFO Threshold Level.  Controls the level of entries (or above) that triggers the RX_FULL interrupt (bit 2 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that hardware does not allow this value to be set to a value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 1 entry, and a value of 255 sets the threshold for 256 entries.	RW	0x00

## I2C: IC\_TX\_TL Register

**Offset:** 0x3C

### Description

I2C Transmit FIFO Threshold Register

Table 1068. IC\_TX\_TL Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	<b>TX_TL:</b> Transmit FIFO Threshold Level.  Controls the level of entries (or below) that trigger the TX_EMPTY interrupt (bit 4 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that it may not be set to value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 0 entries, and a value of 255 sets the threshold for 255 entries.	RW	0x00

## I2C: IC\_CLR\_INTR Register

**Offset:** 0x40

### Description

Clear Combined and Individual Interrupt Register

## I2C: IC\_RX\_TL 寄存器

偏移: 0x38

### 描述

I2C 接收 FIFO 阈值寄存器

表 1067. IC\_RX\_TL 寄存器

位	描述	类型	复位
31:8	保留。	-	-
7:0	<b>RX_TL</b> : 接收 FIFO 门限级别。  控制触发 RX_FULL 中断 (IC_RAW_INTR_STAT 寄存器第 2 位) 的条目数或以上的门限。有效范围为 0 至 255，且硬件不允许将该值设置超过缓冲区深度。如果尝试设置更大值，实际设置值将为缓冲区的最大深度。值为 0 表示门限为 1 条目，值为 255 表示门限为 256 条目。	读写	0x00

## I2C: IC\_TX\_TL 寄存器

偏移: 0x3c

位	描述	类型	复位
31:3	保留。	-	-
2	<b>TX_CMD_BLOCK</b> : 主模式下：- 1'b1: 即使 Tx FIFO 中有数据，也阻止在 I2C 总线上发送数据。- 1'b0: 一旦 Tx FIFO 中有首个数据，数据即自动开始在 I2C 总线上传输。注意：仅当 Tx FIFO 为空 (IC_STATUS[2] == 1) 且主机处于空闲状态 (IC_STATUS[5] == 0) 时，才能设置 TX_CMD_BLOCK 位以阻止主命令执行。Tx FIFO 中的任何后续命令均不会被执行，直到 TX_CMD_BLOCK 位被清除。复位值：  IC_TX_CMD_BLOCK_DEFAULT	读写	0x0
	枚举值：		
	0x0 → NOT_BLOCKED: Tx 命令执行未被阻止		
	0x1 → BLOCKED: Tx 命令执行被阻止		

Bits	Description	Type	Reset
1	<p><b>ABORT:</b> When set, the controller initiates the transfer abort. - 0: ABORT not initiated or ABORT done - 1: ABORT operation in progress The software can abort the I2C transfer in master mode by setting this bit. The software can set this bit only when ENABLE is already set; otherwise, the controller ignores any write to ABORT bit. The software cannot clear the ABORT bit once set. In response to an ABORT, the controller issues a STOP and flushes the Tx FIFO after completing the current transfer, then sets the TX_ABORT interrupt after the abort operation. The ABORT bit is cleared automatically after the abort operation.</p> <p>For a detailed description on how to abort I2C transfers, refer to 'Aborting I2C Transfers'.</p> <p>Reset value: 0x0</p>	RW	0x0
	Enumerated values:		
	0x0 → DISABLE: ABORT operation not in progress		
	0x1 → ENABLED: ABORT operation in progress		
0	<p><b>ENABLE:</b> Controls whether the DW_apb_i2c is enabled. - 0: Disables DW_apb_i2c (TX and RX FIFOs are held in an erased state) - 1: Enables DW_apb_i2c Software can disable DW_apb_i2c while it is active. However, it is important that care be taken to ensure that DW_apb_i2c is disabled properly. A recommended procedure is described in 'Disabling DW_apb_i2c'.</p> <p>When DW_apb_i2c is disabled, the following occurs: - The TX FIFO and RX FIFO get flushed. - Status bits in the IC_INTR_STAT register are still active until DW_apb_i2c goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the DW_apb_i2c stops the current transfer at the end of the current byte and does not acknowledge the transfer.</p> <p>In systems with asynchronous pclk and ic_clk when IC_CLK_TYPE parameter set to asynchronous (1), there is a two ic_clk delay when enabling or disabling the DW_apb_i2c. For a detailed description on how to disable DW_apb_i2c, refer to 'Disabling DW_apb_i2c'</p> <p>Reset value: 0x0</p>	RW	0x0
	Enumerated values:		
	0x0 → DISABLED: I2C is disabled		
	0x1 → ENABLED: I2C is enabled		

## I2C: IC\_STATUS Register

Offset: 0x70

### Description

I2C Status Register

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt.

When the I2C is disabled by writing 0 in bit 0 of the IC\_ENABLE register: - Bits 1 and 2 are set to 1 - Bits 3 and 10 are set to 0 When the master or slave state machines goes to idle and ic\_en=0: - Bits 5 and 6 are set to 0

位	描述	类型	复位
1	<p><b>ABORT</b>: 设置该位时，控制器将启动传输中止操作。- 0: 未启动中止或中止已完成 - 1: 中止操作正在进行中。软件可通过设置此位在主模式下中止 I2C 传输。仅当 ENABLE 已设置时，软件方可设置此位；否则，控制器将忽略对 ABORT 位的任何写入。一旦设置，软件无法清除 ABORT 位。响应中止请求时，控制器在完成当前传输后发出 STOP 信号并刷新 Tx FIFO，随后在中止操作完成后置位 TX_ABORT 中断。ABORT 位在中止操作完成后会自动清除。</p> <p>有关中止 I2C 传输的详细说明，请参阅“中止 I2C 传输”。</p> <p>复位值: 0x0</p>	读写	0x0
	枚举值:		
	0x0 → 禁用: ABORT 操作未进行		
	0x1 → 启用: ABORT 操作正在进行中		
0	<p><b>ENABLE</b>: 用于控制是否启用 DW_apb_i2c。- 0: 禁用 DW_apb_i2c (TX 和 RX FIFO 保持清空状态) - 1: 启用 DW_apb_i2c。软件可在 DW_apb_i2c 处于活动状态时禁用该功能。但是，必须确保 DW_apb_i2c 得到正确禁用，方可保证操作安全。推荐的操作流程详见“禁用 DW_apb_i2c”。</p> <p>当 DW_apb_i2c 被禁用时，发生以下情况：发送FIFO和接收FIFO将被清空。- IC_INTR_STAT 寄存器中的状态位仍会保持有效，直至 DW_apb_i2c 进入空闲状态。如果模块正在传输，则在当前传输完成后停止传输并清除传输缓冲区的内容。如果模块正在接收，DW_apb_i2c 会在当前字节结束时停止当前传输且不予以确认。</p> <p>在异步 pclk 和 ic_clk 的系统中，当 IC_CLK_TYPE 参数设置为异步 (1) 时，启用或禁用 DW_apb_i2c 会存在两个 ic_clk 时钟的延迟。关于如何禁用 DW_apb_i2c 的详细说明，请参阅“禁用 DW_apb_i2c”。</p> <p>复位值: 0x0</p>	读写	0x0
	枚举值:		
	0x0 → 禁用: I2C 被禁用		
	0x1 → 启用: I2C 被启用		

## I2C: IC\_STATUS 寄存器

偏移量: 0x70

### 描述

I2C 状态寄存器

本寄存器为只读，指示当前传输状态及 FIFO 状态。状态寄存器可在任何时间读取。该寄存器中的各位均不触发中断请求。

当通过在 IC\_ENABLE 寄存器的第0位写入0以禁用 I2C 时：- 第1位和第2位被置为1 - 第3位和第10位被置为0 当主机或从机状态机进入空闲状态且 ic\_en=0 时：- 第5位和第6位被置为0

Table 1081.  
IC\_STATUS Register

Bits	Description	Type	Reset
31:7	Reserved.	-	-
6	<b>SLV_ACTIVITY:</b> Slave FSM Activity Status. When the Slave Finite State Machine (FSM) is not in the IDLE state, this bit is set. - 0: Slave FSM is in IDLE state so the Slave part of DW_apb_i2c is not Active - 1: Slave FSM is not in IDLE state so the Slave part of DW_apb_i2c is Active Reset value: 0x0  Enumerated values: 0x0 → IDLE: Slave is idle 0x1 → ACTIVE: Slave not idle	RO	0x0
5	<b>MST_ACTIVITY:</b> Master FSM Activity Status. When the Master Finite State Machine (FSM) is not in the IDLE state, this bit is set. - 0: Master FSM is in IDLE state so the Master part of DW_apb_i2c is not Active - 1: Master FSM is not in IDLE state so the Master part of DW_apb_i2c is Active Note: IC_STATUS[0]-that is, ACTIVITY bit-is the OR of SLV_ACTIVITY and MST_ACTIVITY bits.  Reset value: 0x0  Enumerated values: 0x0 → IDLE: Master is idle 0x1 → ACTIVE: Master not idle	RO	0x0
4	<b>RFF:</b> Receive FIFO Completely Full. When the receive FIFO is completely full, this bit is set. When the receive FIFO contains one or more empty location, this bit is cleared. - 0: Receive FIFO is not full - 1: Receive FIFO is full Reset value: 0x0  Enumerated values: 0x0 → NOT_FULL: Rx FIFO not full 0x1 → FULL: Rx FIFO is full	RO	0x0
3	<b>RFNE:</b> Receive FIFO Not Empty. This bit is set when the receive FIFO contains one or more entries; it is cleared when the receive FIFO is empty. - 0: Receive FIFO is empty - 1: Receive FIFO is not empty Reset value: 0x0  Enumerated values: 0x0 → EMPTY: Rx FIFO is empty 0x1 → NOT_EMPTY: Rx FIFO not empty	RO	0x0
2	<b>TFE:</b> Transmit FIFO Completely Empty. When the transmit FIFO is completely empty, this bit is set. When it contains one or more valid entries, this bit is cleared. This bit field does not request an interrupt. - 0: Transmit FIFO is not empty - 1: Transmit FIFO is empty Reset value: 0x1  Enumerated values: 0x0 → NON_EMPTY: Tx FIFO not empty 0x1 → EMPTY: Tx FIFO is empty	RO	0x1
1	<b>TFNF:</b> Transmit FIFO Not Full. Set when the transmit FIFO contains one or more empty locations, and is cleared when the FIFO is full. - 0: Transmit FIFO is full - 1: Transmit FIFO is not full Reset value: 0x1  Enumerated values:	RO	0x1

## I2C: IC\_TXFLR Register

Offset: 0x74

### Description

I2C Transmit FIFO Level Register This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever: - The I2C is disabled - There is a transmit abort - that is, TX\_ABRT bit is set in the IC\_RAW\_INTR\_STAT register - The slave bulk transmit mode is aborted The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Table 1082. IC\_TXFLR Register

Bits	Description	Type	Reset

## I2C：IC\_SDA\_HOLD寄存器

偏移：0x7c

### 说明

I2C SDA 保持时间寄存器

此寄存器的位[15:0]用于控制从机和主机模式下传输期间SDA的保持时间  
(在SCL从高电平变为低电平之后)。

此寄存器的位[23:16]用于在接收端主机或从机模式下，当SCL为高电平时，延长SDA的转换(如有)。

either master or slave mode.

Writes to this register succeed only when IC\_ENABLE[0]=0.

The values in this register are in units of ic\_clk period. The value programmed in IC\_SDA\_TX\_HOLD must be greater than the minimum hold time in each mode (one cycle in master mode, seven cycles in slave mode) for the value to be implemented.

The programmed SDA hold time during transmit (IC\_SDA\_TX\_HOLD) cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N\_SCL\_LOW-2, where N\_SCL\_LOW is the duration of the low part of the scl period measured in ic\_clk cycles.

Table 1084.  
IC\_SDA\_HOLD  
Register

Bits	Description	Type	Reset
31:24	Reserved.	-	-
23:16	<b>IC_SDA_RX_HOLD:</b> Sets the required SDA hold time in units of ic_clk period, when DW_apb_i2c acts as a receiver.  Reset value: IC_DEFAULT_SDA_HOLD[23:16].	RW	0x00
15:0	<b>IC_SDA_TX_HOLD:</b> Sets the required SDA hold time in units of ic_clk period, when DW_apb_i2c acts as a transmitter.  Reset value: IC_DEFAULT_SDA_HOLD[15:0].	RW	0x0001

## I2C: IC\_TX\_ABRT\_SOURCE Register

Offset: 0x80

### Description

I2C Transmit Abort Source Register

This register has 32 bits that indicate the source of the TX\_ABRT bit. Except for Bit 9, this register is cleared whenever the IC\_CLR\_TX\_ABRT register or the IC\_CLR\_INTR register is read. To clear Bit 9, the source of the ABRT\_SBYTE\_NORSTR must be fixed first; RESTART must be enabled (IC\_CON[5]=1), the SPECIAL bit must be cleared (IC\_TAR[11]), or the GC\_OR\_START bit must be cleared (IC\_TAR[10]).

Once the source of the ABRT\_SBYTE\_NORSTR is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT\_SBYTE\_NORSTR is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Table 1085.  
IC\_TX\_ABRT\_SOURCE  
Register

Bits	Description	Type	Reset
31:23	<b>TX_FLUSH_CNT:</b> This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABRT interrupt. It is cleared whenever I2C is disabled.  Reset value: 0x0  Role of DW_apb_i2c: Master-Transmitter or Slave-Transmitter	RO	0x000
22:17	Reserved.	-	-
16	<b>ABRT_USER_ABRT:</b> This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1])  Reset value: 0x0  Role of DW_apb_i2c: Master-Transmitter	RO	0x0
	Enumerated values:		

无论是在主机还是从机模式。

仅当IC\_ENABLE[0]=0时，写入此寄存器才会成功。

该寄存器中的数值以ic\_clk周期为单位。写入IC\_SDA\_TX\_HOLD的值必须大于各模式的最小时长（主机模式为一个周期，从机模式为七个周期），方能生效。

传输过程中编程的SDA保持时间(IC\_SDA\_TX\_HOLD)在任何时刻均不得超过SCL低电平的持续时间。因此，编程值不得大于N\_SCL\_LOW-2，其中N\_SCL\_LOW是以ic\_clk周期为单位的SCL低电平持续时间。

## I2C: IC\_TX\_ABRT\_SOURCE寄存器

偏移: 0x80

### 描述

I2C 发送中止源寄存器

该寄存器包含32位，用于指示TX\_ABRT位的来源。除第9位外，每当读取IC\_CLR\_TX\_ABRT寄存器或IC\_CLR\_INTR寄存器时，均清除此寄存器。要清除第9位，必须先修正ABRT\_SBYTE\_NORSTRT的源；必须启用RESTART (IC\_CON[5]=1)，清除SPECIAL位 (IC\_TAR[11])，或清除GC\_OR\_START位 (IC\_TAR[10])。

一旦ABRT\_SBYTE\_NORSTRT的源头被修复，便可采用与清除此寄存器中其他位相同的方式清除此位。若在尝试清除此位前，ABRT\_SBYTE\_NORSTRT的源头未被修复，则第9位将清零一个时钟周期后重新置位。

表1085。  
IC\_TX\_ABRT\_SOURCE  
寄存器

位	描述	类型	复位
31:23	<b>TX_FLUSH_CNT:</b> 该字段指示因TX_ABRT中断而被清除的Tx FIFO数据命令数量。每当I2C被禁用时，该字段即被清零。  复位值：0x0  DW_apb_i2c的角色：主机发送器或从机发送器	只读	0x000
22:17	保留。	-	-
16	<b>ABRT_USER_ABRT:</b> 此位仅适用于主机模式。主机已检测到传输中止 (IC_ENABLE[1])。  复位值：0x0  DW_apb_i2c的角色：主机发送器	只读	0x0
	枚举值：		

Bits	Description	Type	Reset
	0x0 → ABRT_USER_ABRT_VOID: Transfer abort detected by master- scenario not present		
	0x1 → ABRT_USER_ABRT_GENERATED: Transfer abort detected by master		
15	<b>ABRT_SLVRD_INTX:</b> 1: When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register.  Reset value: 0x0  Role of DW_apb_i2c: Slave-Transmitter	RO	0x0
	Enumerated values:		
	0x0 → ABRT_SLVRD_INTX_VOID: Slave trying to transmit to remote master in read mode- scenario not present		
	0x1 → ABRT_SLVRD_INTX_GENERATED: Slave trying to transmit to remote master in read mode		
14	<b>ABRT_SLV_ARBLOST:</b> This field indicates that a Slave has lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then DW_apb_i2c no longer own the bus.  Reset value: 0x0  Role of DW_apb_i2c: Slave-Transmitter	RO	0x0
	Enumerated values:		
	0x0 → ABRT_SLV_ARBLOST_VOID: Slave lost arbitration to remote master- scenario not present		
	0x1 → ABRT_SLV_ARBLOST_GENERATED: Slave lost arbitration to remote master		
13	<b>ABRT_SLVFLUSH_TXFIFO:</b> This field specifies that the Slave has received a read command and some data exists in the TX FIFO, so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO.  Reset value: 0x0  Role of DW_apb_i2c: Slave-Transmitter	RO	0x0
	Enumerated values:		
	0x0 → ABRT_SLVFLUSH_TXFIFO_VOID: Slave flushes existing data in TX-FIFO upon getting read command- scenario not present		
	0x1 → ABRT_SLVFLUSH_TXFIFO_GENERATED: Slave flushes existing data in TX-FIFO upon getting read command		

位	描述	类型	复位
	0x0 → ABRT_USER_ABRT_VOID：主机未检测到传输中止情况		
	0x1 → ABRT_USER_ABRT_GENERATED：主控检测到传输中止		
15	<b>ABRT_SLVRD_INTX:</b> 1: 当处理器响应远程主控的从机模式数据传输请求，且用户在IC_DATA_CMD寄存器的CMD（第8位）写入1时。  复位值: 0x0  DW_apb_i2c的角色: 从设备-发送者	只读	0x0
	枚举值:

## I2C: IC\_SLV\_DATA\_NACK\_ONLY Register

Offset: 0x84

### Description

Generate Slave Data NACK Register

The register is used to generate a NACK for the data part of a transfer when DW\_apb\_i2c is acting as a slave-receiver. This register only exists when the IC\_SLV\_DATA\_NACK\_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the register's address has no effect.

A write can occur on this register if both of the following conditions are met: - DW\_apb\_i2c is disabled (IC\_ENABLE[0] = 0) - Slave part is inactive (IC\_STATUS[6] = 0) Note: The IC\_STATUS[6] is a register read-back location for the internal slv\_activity signal; the user should poll this before writing the ic\_slv\_data\_nack\_only bit.

Table 1086.  
IC\_SLV\_DATA\_NACK\_ONLY Register

Bits	Description	Type	Reset
31:1	Reserved.	-	-
0	<b>NACK:</b> Generate NACK. This NACK generation only occurs when DW_apb_i2c is a slave-receiver. If this register is set to a value of 1, it can only generate a NACK after a data byte is received; hence, the data transfer is aborted and the data received is not pushed to the receive buffer.  When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. - 1: generate NACK after data byte received - 0: generate NACK/ACK normally Reset value: 0x0	RW	0x0
	Enumerated values:		
	0x0 → DISABLED: Slave receiver generates NACK normally		
	0x1 → ENABLED: Slave receiver generates NACK upon data reception only		

## I2C: IC\_DMA\_CR Register

Offset: 0x88

### Description

DMA Control Register

The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC\_ENABLE.

Table 1087.  
IC\_DMA\_CR Register

Bits	Description	Type	Reset
31:2	Reserved.	-	-

	枚举值：		
	0x0 → INACTIVE：未生成该中止信号		
	0x1 → ACTIVE：因7位地址未被确认而生成该中止信号。		

## I2C: IC\_SLV\_DATA\_NACK\_ONLY 寄存器

偏移量：0x84

### 描述

生成从设备数据 NACK 寄存器

当 DW\_apb\_i2c 作为从机接收时，该寄存器用于生成传输数据部分的 NACK。

仅当 IC\_SLV\_DATA\_NACK\_ONLY 参数设置为 1 时，才存在该寄存器。当该参数被禁用时，该寄存器不存在，对该寄存器地址的写操作无任何效果。

仅当满足以下两个条件时，才允许对该寄存器进行写操作：- DW\_apb\_i2c 被禁用 (IC\_ENABLE[0] = 0) - 从机部分处于非活动状态 (IC\_STATUS[6] = 0) 注：IC\_STATUS[6] 是内部 slv\_activity 信号的寄存器读回位；用户应在写入 ic\_slv\_data\_nack\_only 位之前对该位进行轮询检查。

表 1086。  
IC\_SLV\_DATA\_NACK\_ONLY 寄存器

位	描述	类型	复位
31:1	保留。	-	-
0	<b>NACK：</b> 生成NACK。此NACK生成仅在DW_apb_i2c作为从机接收器时发生。 如果此寄存器设置为1，则仅能在接收数据字节后生成NACK；因此，数据传输将中止，接收到的数据不会写入接收缓冲区。  当寄存器设置为0时，将根据正常标准生成NACK或ACK。- 1：数据字节接收后生成NACK - 0：按正常方式生成NACK/ACK 重置值：0x0	读写	0x0
	枚举值：		
	0x0 → 禁用：从机接收器按正常方式生成NACK		
	0x1 → 启用：从机接收器仅在接收数据时生成NACK		

## I2C: IC\_DMA\_CR 寄存器

偏移量：0x88

### 描述

DMA控制寄存器

该寄存器用于启用DMA控制器接口的操作功能。传输和接收各有独立控制位。

无论 IC\_ENABLE 状态如何，均可进行编程。

表1087。  
IC\_DMA\_CR 寄存器

位	描述	类型	复位

DMA 发送数据水平寄存器

表1088。  
IC\_DMA\_TDLR  
寄存器

位	描述	类型	复位
31:4	保留。	-	-
3:0	<b>DMATDL:</b> 发送数据水位值。该字段控制发送逻辑发起 DMA 请求的阈值。其数值等同于水位线水平；即当发送 FIFO 中的有效数据条目数小于或等于此字段值且 TDMAE=1 时，dma_tx_req 信号将被生成。  复位值: 0x0	读写	0x0

## I2C: IC\_DMA\_RDLR 寄存器

偏移: 0x90

### 描述

I2C 接收数据级别寄存器

表 1089。  
IC\_DMA\_RDLR  
寄存器

位	描述	类型	复位
31:4	保留。	-	-
3:0	<b>DMARDL:</b> 接收数据级别。该位字段控制接收逻辑发出 DMA 请求的阈值。水位线等级 = DMARDL + 1；即，当接收 FIFO 中有效数据条目数大于或等于该字段值加 1 且 RDMAE = 1 时，产生 dma_rx_req。例如，当 DMARDL 为 0 时，只要接收 FIFO 中存在 1 个或以上的数据条目，即断言 dma_rx_req。  复位值: 0x0	读写	0x0

## I2C: IC\_SDA\_SETUP 寄存器

偏移: 0x94

**Description****I2C SDA Setup Register**

This register controls the amount of time delay (in terms of number of ic\_clk clock periods) introduced in the rising edge of SCL - relative to SDA changing - when DW\_apb\_i2c services a read request in a slave-transmitter operation. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

Writes to this register succeed only when IC\_ENABLE[0] = 0.

Note: The length of setup time is calculated using [(IC\_SDA\_SETUP - 1) \* (ic\_clk\_period)], so if the user requires 10 ic\_clk periods of setup time, they should program a value of 11. The IC\_SDA\_SETUP register is only used by the DW\_apb\_i2c when operating as a slave transmitter.

*Table 1090.  
IC\_SDA\_SETUP  
Register*

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	<b>SDA_SETUP:</b> SDA Setup. It is recommended that if the required delay is 1000ns, then for an ic_clk frequency of 10 MHz, IC_SDA_SETUP should be programmed to a value of 11. IC_SDA_SETUP must be programmed with a minimum value of 2.	RW	0x64

**I2C: IC\_ACK\_GENERAL\_CALL Register**

**Offset:** 0x98

**Description****I2C ACK General Call Register**

The register controls whether DW\_apb\_i2c responds with a ACK or NACK when it receives an I2C General Call address.

This register is applicable only when the DW\_apb\_i2c is in slave mode.

*Table 1091.  
IC\_ACK\_GENERAL\_CA  
LL Register*

Bits	Description	Type	Reset
31:1	Reserved.	-	-
0	<b>ACK_GEN_CALL:</b> ACK General Call. When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. Otherwise, DW_apb_i2c responds with a NACK (by negating ic_data_oe).	RW	0x1
	Enumerated values:		
	0x0 → DISABLED: Generate NACK for a General Call		
	0x1 → ENABLED: Generate ACK for a General Call		

**I2C: IC\_ENABLE\_STATUS Register**

**Offset:** 0x9c

**Description****I2C Enable Status Register**

The register is used to report the DW\_apb\_i2c hardware status when the IC\_ENABLE[0] register is set from 1 to 0; that is, when DW\_apb\_i2c is disabled.

If IC\_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.

If IC\_ENABLE[0] has been set to 0, bits 2:1 is only valid as soon as bit 0 is read as '0'.

Note: When IC\_ENABLE[0] has been set to 0, a delay occurs for bit 0 to be read as 0 because disabling the DW\_apb\_i2c depends on I2C bus activities.

**说明**

I2C SDA 设置寄存器

该寄存器控制在 DW\_apb\_i2c 作为从机发送器响应读请求时，SCL 上升沿相对于 SDA 变化所引入的延迟时间（单位为 ic\_clk 时钟周期数）。相关的I2C要求为tSU:DAT（注4），详见I2C总线规范。该寄存器须编程为等于或大于2的值。

仅当IC\_ENABLE[0] = 0时，写入该寄存器操作方能成功。

注：设定时间长度计算公式为[(IC\_SDA\_SETUP - 1) \* (ic\_clk\_period)]，因此若用户需求为10个ic\_clk周期的设定时间，则应编程为11。 IC\_SDA\_SETUP寄存器仅用于DW\_apb\_i2c作为从设备发送器时。

表1090。  
IC\_SDA\_SETUP  
寄存器

位	描述	类型	复位
31:8	保留。	-	-
7:0	<b>SDA_SETUP：</b> SDA设定。建议当所需延迟为1000ns时，且ic_clk频率为10 MHz，IC_SDA_SETUP应编程为11。 IC_SDA_SETUP的最小编程值为2。	读写	0x64

## I2C: IC\_ACK\_GENERAL\_CALL 寄存器

偏移: 0x98

**描述**

I2C 应答通用呼叫寄存器

该寄存器用于控制 DW\_apb\_i2c 在接收到 I2C 通用呼叫地址时，是否以 ACK 或 NACK 响应。

该寄存器仅在 DW\_apb\_i2c 处于从模式时适用。

表 1091。  
IC\_ACK\_GENERAL\_CA  
LL 寄存器

位	描述	类型	复位
31:1	保留。	-	-
0	<b>ACK_GEN_CALL：</b> ACK 通用呼叫。设置为 1 时，DW_apb_i2c 在接收到通用呼叫时通过断言 ic_data_oe 以 ACK 响应。否则，DW_apb_i2c 通过否定 ic_data_oe 以 NACK 响应。	读写	0x1
	枚举值：		
	0x0 → 禁用：对通用呼叫生成 NACK		
	0x1 → 启用：对通用呼叫生成 ACK		

## I2C: IC\_ENABLE\_STATUS 寄存器

偏移量: 0x9c

**描述**

I2C 使能状态寄存器

该寄存器用于报告在 IC\_ENABLE[0] 寄存器由 1 变为 0 时，DW\_apb\_i2c 硬件的状态；即，当DW\_apb\_i2c被禁用时。

如果IC\_ENABLE[0]已设置为1，则位2:1被强制清零，且位0被强制置1。

若IC\_ENABLE[0]已设置为0，则仅当位0被读取为“0”时，位2:1才有效。

注意：当IC\_ENABLE[0]设置为0时，位0被读取为0存在延迟，这因禁用DW\_apb\_i2c取决于I2C总线活动情况。

Table 1092.  
IC\_ENABLE\_STATUS  
Register

Bits	Description	Type	Reset
31:3	Reserved.	-	-
2	<p><b>SLV_RX_DATA_LOST:</b> Slave Received Data Lost. This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting bit 0 of IC_ENABLE from 1 to 0. When read as 1, DW_apb_i2c is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK.</p> <p>Note: If the remote I2C master terminates the transfer with a STOP condition before the DW_apb_i2c has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit is also set to 1.</p> <p>When read as 0, DW_apb_i2c is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer.</p> <p>Note: The CPU can safely read this bit when IC_EN (bit 0) is read as 0.</p> <p>Reset value: 0x0</p>	RO	0x0
	Enumerated values:

## I2C: IC\_FS\_SPKLEN Register

Offset: 0xa0

### Description

I2C SS, FS or FM+ spike suppression limit

This register is used to store the duration, measured in ic\_clk cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS, FS or FM+ modes. The relevant I2C requirement is tSP (table 4) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1.

Table 1093.  
IC\_FS\_SPKLEN  
Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	<b>IC_FS_SPKLEN:</b> This register must be set before any I2C bus transaction can take place to ensure stable operation. This register sets the duration, measured in ic_clk cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic. This register can be written only when the I2C interface is disabled which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 1 being set. or more information, refer to 'Spike Suppression'.	RW	0x07

## 12.3. SPI

### Arm Documentation

Excerpted from the [ARM PrimeCell Synchronous Serial Port \(PL022\) Technical Reference Manual](#). Used with permission.

RP2350 has two identical SPI controllers, both based on an Arm Primecell Synchronous Serial Port (SSP) (PL022) (Revision r1p4). This is distinct from the QSPI memory interface covered in [Section 12.14](#).

Each controller supports the following features:

- Master or Slave modes
  - Motorola SPI-compatible interface
  - Texas Instruments synchronous serial interface
  - National Semiconductor Microwire interface
- 8-location TX and RX FIFOs
- Interrupt generation to service FIFOs or indicate error conditions
- Can be driven from DMA
- Programmable clock rate
- Programmable data size 4-16 bits

Each controller can be connected to a number of GPIO pins as defined in the Bank 0 GPIO function table, [Table 646 \(Section 9.4\)](#).

The entries in the GPIO function table, such as "SPI0 TX", specify the SPI instance and the SPI signal for that instance which are available on that GPIO. The signals in the table are described as:

#### SCK

Serial clock. Connects to the SPI peripheral clock signals described as [SSPCLKOUT](#) and [SSPCLKIN](#) in the following sections. These pins are inputs in slave mode, and outputs in master mode.

#### TX

Serial data output. Connects to the SPI peripheral [SSPTXD](#) (data out) and [nSSPOE](#) (output enable) signals described in the following sections. This is always a data output, independent of the bus role. The SPI peripheral controls tristating depending on chip select status.

#### RX

Serial data input. Connects to the SPI peripheral [SSPRXD](#) data input described in the following sections. This is always a data input, independent of the bus role.

#### CSn

Active-low chip select. Connects to the SPI peripheral signals [SSPFSSOUT](#) and [SSPFSSIN](#) described in the following sections. These pins are inputs in slave mode, and outputs in master mode.

The SPI uses [clk\\_peri](#) as its reference clock for SPI timing, and is referred to as [SSPCLK](#) in the following sections. [clk\\_sys](#) is used as the bus clock, and is referred to as PCLK in the following sections (also see [Figure 33](#)).

## 12.3. SPI

Arm 文档

摘自 ARM PrimeCell 同步串行端口 (PL022) 技术参考手册。经授权使用。

RP2350 配备两个相同的 SPI 控制器，均基于 Arm PrimeCell 同步串行端口 (SSP) (PL022) (版本 r1p4)。该接口不同于第 12.14 节中介绍的 QSPI 存储器接口。

每个控制器支持以下功能：

- 主模式或从模式
  - Motorola SPI 兼容接口
  - Texas Instruments 同步串行接口
  - National Semiconductor Microwire 接口
- 8位置的TX和RX FIFO
- 生成中断以服务FIFO或指示错误状态
- 支持 DMA 驱动
- 可编程时钟速率
- 可编程数据宽度4-16位

每个控制器可连接至银行0 GPIO功能表 (表646, 第9.4节) 中定义的若干GPIO引脚。

GPIO功能表中的条目，如“SPI0 TX”，指定该GPIO引脚上的SPI实例及对应的SPI信号。表中信号描述如下：

### SCK

串行时钟。连接到以下章节中描述的SPI外设时钟信号 *SSPCLKOUT* 和 *SSPCLKIN*。在从设备模式下，该引脚为输入；在主设备模式下为输出。

### TX

串行数据输出。连接到以下章节中描述的SPI外设信号 *SSPTXD* (数据输出) 和 *nSSPOE* (输出使能)。该信号始终为数据输出，与总线角色无关。SPI 外设根据芯片选择信号状态控制三态输出。

### RX

串行数据输入。连接至 SPI 外设的 *SSPRXD* 数据输入，如后续章节所述。该信号始终作为数据输入，与总线角色无关。

### CSn

低电平有效芯片选择信号。连接至 SPI 外设信号 *SSPFSSOUT* 和 *SSPFSSIN*，如后续章节所述。在从设备模式下，该引脚为输入；在主设备模式下为输出。

SPI 使用 *clk\_peri* 作为 SPI 定时的参考时钟，以下章节中称为 *SSPCLK*。 *clk\_sys* 用作总线时钟，以下章节中称为 *PCLK* (另见图 33)。

### 12.3.1. Changes from RP2040

The output enable of the **SSPTXD** data output (connecting to pins listed as SPI0 TX and SPI1 TX in the GPIO function tables) is controlled by the SPI peripheral **nSSPOE** signal. The peripheral automatically tristates its output when deselected in slave mode. This makes software control of the output enable unnecessary even when multiple slaves share the data lines.

### 12.3.2. Overview

The PrimeCell SSP is a master or slave interface for synchronous serial communication with peripheral devices that have Motorola SPI, National Semiconductor Microwire, or Texas Instruments synchronous serial interfaces.

The PrimeCell SSP performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information through the AMBA APB interface. The transmit and receive paths are buffered with internal FIFO memories, enabling up to eight 16-bit values to be stored independently in both transmit and receive modes. Serial data transmits on **SSPTXD** and is received on **SSPRXD**.

The PrimeCell SSP includes a programmable bit rate clock divider and prescaler to generate the serial output clock, **SSPCLKOUT**, from the input clock, **SSPCLK**. Bit rates are supported to 2MHz and higher, subject to choice of frequency for **SSPCLK**, and the maximum bit rate is determined by peripheral devices.

You can use the control registers **SSPCR0** and **SSPCR1** to program the PrimeCell SSP operating mode, frame format, and size.

The following individually maskable interrupts are generated:

- **SSPTXINTR** requests servicing of the transmit buffer
- **SSPRXINTR** requests servicing of the receive buffer
- **SSPRORINTR** indicates an overrun condition in the receive FIFO
- **SSPRTINTR** indicates that a timeout period expired while data was present in the receive FIFO.

A single combined interrupt is asserted if any of the individual interrupts are asserted and unmasked. This interrupt is connected to the processor interrupt controllers in RP2350.

In addition to the above interrupts, a set of DMA signals are provided for interfacing with a DMA controller.

Depending on the operating mode selected, the **SSPFSSOUT** output operates as:

- an active-HIGH frame synchronization output for Texas Instruments synchronous serial frame format
- an active-LOW slave select for SPI and Microwire.

### 12.3.3. Functional description

### 12.3.1. 与 RP2040 的变更

`SSPTXD`数据输出（连接至 GPIO 功能表中列出的 SPI0 TX 和 SPI1 TX 引脚）的输出使能由 SPI 外设信号 `nSSPOE` 控制。外设在从属模式下被取消选择时自动进入三态输出。即使多个从设备共享数据线，也无需软件控制输出使能。

### 12.3.2. 概述

PrimeCell SSP 是用于与具备 Motorola SPI、National Semiconductor Microwire 或 Texas Instruments 同步串行接口的外围设备进行同步串行通信的主从接口。

PrimeCell SSP 对从外围设备接收的数据执行串行转并行转换。CPU 通过 AMBA APB 接口访问数据、控制及状态信息。传输和接收路径均采用内部 FIFO 缓冲器，允许在传输和接收模式下分别独立存储最多八个 16 位值。串行数据通过 `SSPTXD` 发送，并通过 `SSPRXD` 接收。

PrimeCell SSP 配备可编程位速率时钟分频器和预分频器，用于从输入时钟 `SSPCLK` 生成串行输出时钟 `SSPCLKOUT`。位速率支持达到 2MHz 及更高，具体取决于 `SSPCLK` 频率的选择，最大位速率由外围设备决定。

您可以使用控制寄存器 `SSPCR0` 和 `SSPCR1` 来配置 PrimeCell SSP 的操作模式、帧格式及其大小。

会产生以下可单独屏蔽的中断：

- `SSPTXINTR` 请求对发送缓冲区进行服务
- `SSPRXINTR` 请求对接收缓冲区进行服务
- `SSPRORINTR` 指示接收 FIFO 产生溢出情况
- `SSPRTINTR` 指示在接收 FIFO 中有数据时超时时间已到。

若任一单独中断被断言且未被屏蔽，则会断言单一组合中断。该中断连接至 RP2350 处理器的中断控制器。

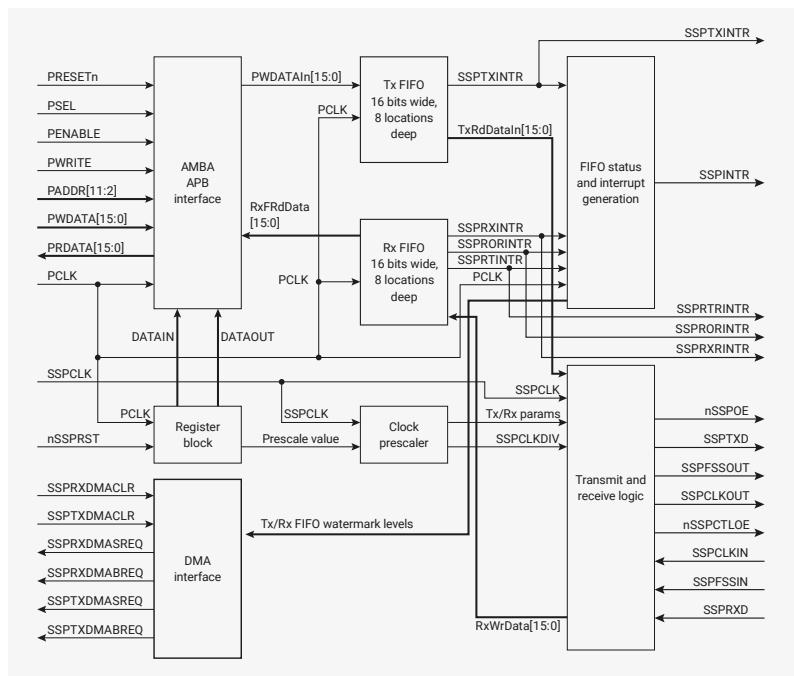

除了上述中断外，还提供一组 DMA 信号以实现与 DMA 控制器的接口。

根据所选操作模式，`SSPFSSOUT` 输出的功能如下：

- 作为德州仪器同步串行帧格式的高电平有效帧同步输出
- 作为 SPI 和 Microwire 的低电平有效从机选择信号。

### 12.3.3. 功能描述

Figure 91. PrimeCell SSP block diagram.  
For clarity, does not show the test logic.

### 12.3.3.1. AMBA APB interface

The AMBA APB interface generates read and write decodes for accesses to status and control registers, and transmit and receive FIFO memories.

### 12.3.3.2. Register block

The register block stores data written, or to be read, across the AMBA APB interface.

### 12.3.3.3. Clock prescaler

When configured as a master, an internal prescaler, comprising two free-running reloadable serially linked counters, provides the serial output clock **SSPCLKOUT**.

You can program the clock prescaler, using the **SSPCPSR** register, to divide **SSPCLK** by a factor of 2-254 in steps of two. By not utilizing the least significant bit of the **SSPCPSR** register, division by an odd number is not possible; this ensures that a symmetrical clock with equal mark-space ratio is generated. See **SSPCPSR**.

The output of the prescaler is divided again by a factor of 1-256, by programming the **SSPCR0** control register, to give the final master output clock **SSPCLKOUT**.

#### **NOTE**

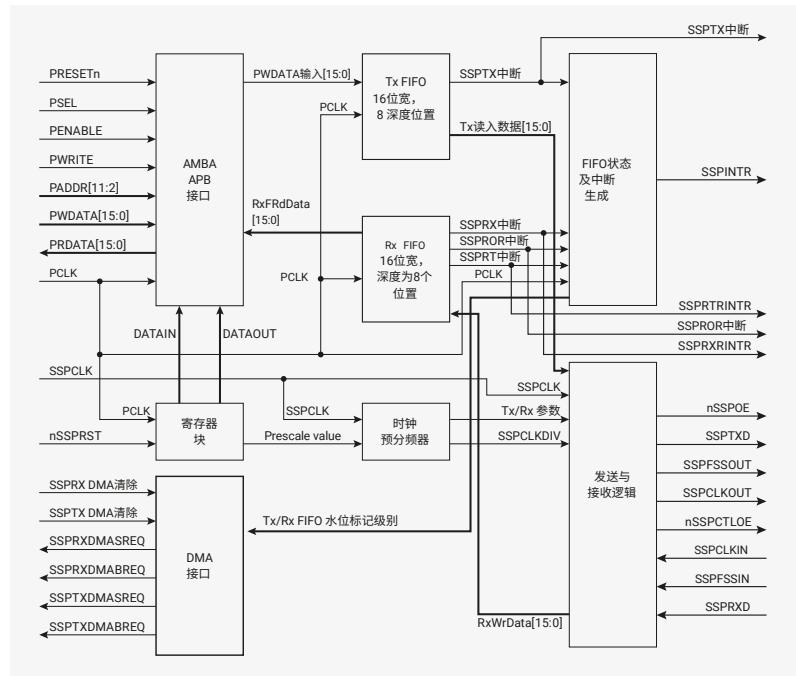

The PCLK and SSPCLK clock inputs in Figure 91 are connected to the **clk\_sys** and **clk\_peri** system-level clock nets on RP2350, respectively. By default, **clk\_peri** attaches directly to the system clock. However, you can detach it to maintain constant SPI frequency if the system clock is varied dynamically. See Figure 33 for an overview of the RP2350 clock architecture.

### 12.3.3.4. Transmit FIFO

The common transmit (TX) FIFO is a 16-bit wide, 8-location deep memory buffer. CPU data written across the AMBA

图91。PrimeCell SSP框图。

为清晰起见，不显示测试逻辑。

### 12.3.3.1. AMBA APB接口

AMBA APB接口为访问状态和控制寄存器以及发送与接收FIFO存储器生成读写译码。

### 12.3.3.2. 寄存器块

寄存器块用于通过AMBA APB接口存储已写入或待读取的数据。

### 12.3.3.3. 时钟分频器

当配置为主设备时，内部分频器由两个串联的自由运行可重载计数器组成，提供串行输出时钟 **SSPCLKOUT**。

您可以通过 **SSPCPSR** 寄存器对时钟分频器进行编程，以两个为步长将 **SSPCLK** 分频为2至254的倍数。由于未使用 **SSPCPSR** 寄存器的最低有效位，无法实现奇数分频；这确保生成的时钟具有对称的高低电平占空比。详见**SSPCPSR**。

分频器的输出通过编程**SSPCRO**控制寄存器，再次按1-256的因子分频，以生成最终的主输出时钟 **SSPCLKOUT**。

#### ① 注意

图91中，PCLK和SSPCLK时钟输入分别连接至RP2350的系统级时钟网络 **clk\_sys**和**clk\_peri**。默认情况下，**clk\_peri**直接连接至系统时钟。但若系统时钟动态变化，可将其断开以保持SPI频率恒定。有关RP2350时钟架构的整体概述，请参见图33。

### 12.3.3.4. 发送FIFO

通用发送（TX）FIFO为16位宽、深度为8个位置的内存缓冲区。通过AMBA接口写入的CPU数据

APB interface is stored in the buffer until read out by the transmit logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion, and transmission to the attached slave or master respectively, through the **SSPTXD** pin.

#### 12.3.3.5. Receive FIFO

The common receive (RX) FIFO is a 16-bit wide, 8-location deep memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU across the AMBA APB interface.

When configured as a master or slave, serial data received through the **SSPRXD** pin is registered prior to parallel loading into the attached slave or master receive FIFO respectively.

#### 12.3.3.6. Transmit and receive logic

When configured as a master, the clock for the attached slaves is derived from a divided-down version of **SSPCLK** through the previously described prescaler operations. The master transmit logic successively reads a value from its transmit FIFO and performs parallel to serial conversion on it. Then, the serial data stream and frame control signal, synchronized to **SSPCLKOUT**, outputs through the **SSPTXD** pin to the attached slaves. The master receive logic performs serial to parallel conversion on the incoming synchronous **SSPRXD** data stream, extracting and storing values into its receive FIFO for subsequent reading through the APB interface.

When configured as a slave, the **SSPCLKIN** clock is provided by an attached master and used to time transmission and reception sequences. The slave transmit logic, under control of the master clock, successively:

1. Reads a value from its transmit FIFO.
2. Performs parallel to serial conversion.
3. Outputs the serial data stream and frame control signal through the slave **SSPTXD** pin.

The slave receive logic performs serial to parallel conversion on the incoming **SSPRXD** data stream, extracting and storing values into its receive FIFO, for subsequent reading through the APB interface.

#### 12.3.3.7. Interrupt generation logic

The PrimeCell SSP generates four individual maskable, active-HIGH interrupts. A combined interrupt output is generated as an OR function of the individual interrupt requests.

The transmit and receive dynamic data-flow interrupts, **SSPTXINTR** and **SSPRXINTR**, are separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels.

#### 12.3.3.8. DMA interface

The PrimeCell SSP provides an interface to connect to a DMA controller, see [Section 12.3.4.16](#).

#### 12.3.3.9. Synchronizing registers and logic

The PrimeCell SSP supports both asynchronous and synchronous operation of the clocks, **PCLK** and **SSPCLK**. Synchronization registers and handshaking logic have been implemented, and are active at all times. Synchronization of control signals is performed on both directions of data flow, that is:

- from the **PCLK** to the **SSPCLK** domain
- from the **SSPCLK** to the **PCLK** domain.

APB接口的写入数据存储于缓冲区中，直到由发送逻辑读取。

配置为主机或从机时，平行数据写入发送FIFO，随后进行串行转换，通过 **SSPTXD**引脚分别传输至连接的从机或主机。

### 12.3.3.5. 接收FIFO

通用接收（RX）FIFO是一个16位宽、8个位置深的存储缓冲区。从串行接口接收的数据会存储在缓冲区中，直到CPU通过AMBA APB接口将其读取。

配置为主设备或从设备时，通过 **SSPRXD**引脚接收的串行数据，在并行装载到所连接的从设备或主设备接收FIFO之前，会被寄存。

### 12.3.3.6. 发送和接收逻辑

配置为主设备时，所连接从设备的时钟来源于经过上述分频器操作处理的 **SSPCLK**分频信号。主设备发送逻辑依次从发送FIFO读取数据，并进行并行转串行转换。随后，同步于 **SSPCLKOUT**的串行数据流及帧控制信号通过 **SSPTXD**引脚输出至所连接的从设备。主设备接收逻辑对输入的同步 **SSPRXD**串行数据流执行串行转并行转换，提取并存储数据至接收FIFO，供后续通过APB接口读取。

当配置为从属设备时，**SSPCLKIN**时钟由连接的主设备提供，用于定时传输和接收序列。在主时钟控制下，从属发送逻辑依次执行：

1. 从其发送FIFO中读取一个值。
2. 执行并行转串行转换。
3. 通过从属设备的 **SSPTXD**引脚输出串行数据流和帧控制信号。

从属接收逻辑对输入的 **SSPRXD**数据流执行串行转并行转换，提取并存储值至其接收FIFO，以供后续通过APB接口读取。

### 12.3.3.7. 中断生成逻辑

PrimeCell SSP产生四个独立的可屏蔽、有效高电平中断。组合中断输出由各单独中断请求的逻辑或产生。

发送和接收动态数据流中断，分别为 **SSPTXINTR**和 **SSPRXINTR**，与状态中断分离，以便根据FIFO触发级别进行数据的读写操作。

### 12.3.3.8. DMA接口

PrimeCell SSP提供了一个连接DMA控制器的接口，详见第12.3.4.16节。

### 12.3.3.9. 寄存器及逻辑同步

PrimeCell SSP支持时钟的异步和同步操作，分别为 **PCLK**和 **SSPCLK**。

同步寄存器及握手机制已实现，并始终处于激活状态。控制信号的同步在数据流的两个方向均进行，即：

- 从 **PCLK**域到 **SSPCLK**域
- 从 **SSPCLK**域到 **PCLK**域。

## 12.3.4. Operation

### 12.3.4.1. Interface reset

The PrimeCell SSP is reset by the global reset signal, `PRESETn`, and a block-specific reset signal, `nSSPRST`. The device reset controller asserts `nSSPRST` asynchronously and negates it synchronously to `SSPCLK`.

### 12.3.4.2. Configuring the SSP

Following reset, the PrimeCell SSP logic is disabled and must be configured when in this state. It is necessary to program control registers `SSPCR0` and `SSPCR1` to configure the peripheral as a master or slave operating under one of the following protocols:

- Motorola SPI
- Texas Instruments SSI
- National Semiconductor

The bit rate, derived from the external `SSPCLK`, requires the programming of the clock prescale register `SSPCPSR`.

### 12.3.4.3. Enable PrimeCell SSP operation

You can either prime the transmit FIFO, by writing up to eight 16-bit values when the PrimeCell SSP is disabled, or permit the transmit FIFO service request to interrupt the CPU. Once enabled, transmission or reception of data begins on the transmit, `SSPTXD`, and receive, `SSPRXD`, pins.

### 12.3.4.4. Clock ratios

There is a constraint on the ratio of the frequencies of `PCLK` to `SSPCLK`. The frequency of `SSPCLK` must be less than or equal to that of `PCLK`. This ensures that control signals from the `SSPCLK` domain to the `PCLK` domain are guaranteed to get synchronized before one frame duration:

$$F_{SSPCLK} \leq F_{PCLK}$$

In the slave mode of operation, the `SSPCLKIN` signal from the external master is double-synchronized and then delayed to detect an edge. It takes three `SSPCLKs` to detect an edge on `SSPCLKIN`. `SSPTXD` has less setup time to the falling edge of `SSPCLKIN` on which the master is sampling the line.

The setup and hold times on `SSPRXD`, with reference to `SSPCLKIN`, must be more conservative to ensure that it is at the right value when the actual sampling occurs within the `SSPMS`. To ensure correct device operation, `SSPCLK` must be at least 12 times faster than the maximum expected frequency of `SSPCLKIN`.

The frequency selected for `SSPCLK` must accommodate the desired range of bit clock rates. The ratio of minimum `SSPCLK` frequency to `SSPCLKOUT` maximum frequency in the case of the slave mode is 12, and for the master mode, it is two.

For example, at the maximum `SSPCLK` (`clk_peri`) frequency on RP2350 of 150MHz, the maximum peak bit rate in master mode is 70.5Mb/s. This is achieved with the `SSPCPSR` register programmed with a value of 2, and the `SCR[7:0]` field in the `SSPCR0` register programmed with a value of 0.

In slave mode, the same maximum `SSPCLK` frequency of 150MHz can achieve a peak bit rate of  $150 / 12 = 12.5\text{Mb/s}$ . The `SSPCPSR` register can be programmed with a value of 12, and the `SCR[7:0]` field in the `SSPCR0` register can be programmed with a value of 0. Similarly, the ratio of `SSPCLK` maximum frequency to `SSPCLKOUT` minimum frequency is  $254 \times 256$ .

The minimum frequency of `SSPCLK` is governed by the following inequalities, both of which must be satisfied:

$$F_{SSPCLK}(\min) \geq 2 \times F_{SSPCLKOUT}(\max), \text{ for master mode}$$

## 12.3.4. 操作

### 12.3.4.1. 接口复位

PrimeCell SSP由全局复位信号 `PRESETn`以及模块专用复位信号 `nSSPRST`复位。设备复位控制器异步断言 `nSSPRST`，并在与 `SSPC_LK`同步时取消断言。

### 12.3.4.2. 配置SSP

复位后，PrimeCell SSP逻辑被禁用，必须在此状态下进行配置。必须编程控制寄存器 `SSPCR0`和 `SSPCR1`，以配置外设为主设备或从设备，并使其按照以下协议之一工作：

- 摩托罗拉 SPI
- 德州仪器 SSI
- 国家半导体

位速率由外部 `SSPCLK`派生，需编程时钟预分频寄存器 `SSPCPSR`。

### 12.3.4.3. 启用PrimeCell SSP操作

您可以在PrimeCell SSP禁用时，通过写入最多八个16位值来预置发送FIFO，或允许发送FIFO服务请求中断CPU。一旦启用，数据的传输或接收即通过发送引脚 `SSPTXD`和接收引脚 `SSPRXD`开始。

### 12.3.4.4. 时钟比率

对 `PCLK`与 `SSPCLK`的频率比存在约束。`SSPCLK`的频率必须小于或等于 `PCLK`的频率。这确保来自 `SSPCLK`域到 `PCLK`域的控制信号在一个帧周期内得到同步：

$$F_{SSPCLK} \leq F_{PCLK}$$

在从机工作模式下，来自外部主机的 `SSPCLKIN`信号经过双重同步处理后再延迟，以用于边缘检测。检测 `SSPCLKIN`上的边缘需要三个 `SSPCLK`周期。`SSPTXD`相对于主机采样线路的 `SSPCLKIN`下降沿具有较短的建立时间。

相对于 `SSPCLKIN`的 `SSPRXD`建立和保持时间必须更加保守，以确保在 `SSPMS`内的实际采样时信号值正确。为确保设备正确运行，`SSPCLK`的频率必须至少是最大预期 `SSPCLKIN`频率的12倍。

所选的 `SSPCLK`频率必须满足所需的位时钟速率范围。在从属模式下，最小 `SSPCLK`频率与 `SSPCLKOUT`最大频率的比率为12，主模式下该比率为2。

例如，在RP2350的最大 `SSPCLK`频率（`clk_peri`）150MHz下，主模式的最大峰值比特率为70.5Mb/s。此值通过将 `SSPCPSR`寄存器设置为2，以及将 `SSPCR0`寄存器中的`SCR[7:0]`字段设置为0实现。

在从属模式下，最大 `SSPCLK`频率同为150MHz，可实现峰值比特率为 $150 \div 12 = 12.5$ Mb/s。将 `SSPCPSR`寄存器设置为12，并将 `SSPCR0`寄存器中的`SCR[7:0]`字段设置为0即可。类似地，`SSPCLK`最大频率与 `SSPCLKOUT`最小频率的比率为 $254 \times 256$ 。

`SSPCLK`的最小频率受以下不等式约束，且必须同时满足：

$$F_{SSPCLK}(min) \geq 2 \times F_{SSPCLKOUT}(max), \text{ 适用于主模式}$$

$$F_{SSPCLK}(min) \geq 12 \times F_{SSPCLKIN}(max), \text{ for slave mode.}$$

The maximum frequency of **SSPCLK** is governed by the following inequalities, both of which must be satisfied:

$$F_{SSPCLK}(max) \leq 254 \times 256 \times F_{SSPCLKOUT}(min), \text{ for master mode}$$

$$F_{SSPCLK}(max) \leq 254 \times 256 \times F_{SSPCLKIN}(min), \text{ for slave mode.}$$

#### 12.3.4.5. Programming the SSPCR0 control register

The **SSPCR0** register is used to:

- program the serial clock rate
- select one of the three protocols
- select the data word size, where applicable.

The Serial Clock Rate (SCR) value, in conjunction with the **SSPCPSR** clock prescale divisor value, **CPSDVS**, is used to derive the PrimeCell SSP transmit and receive bit rate from the external **SSPCLK**.

The frame format is programmed through the FRF bits, and the data word size through the **DSS** bits.

Bit phase and polarity, applicable to Motorola SPI format only, are programmed through the **SPH** and **SPO** bits.

#### 12.3.4.6. Programming the SSPCR1 control register

The **SSPCR1** register is used to:

- select master or slave mode
- enable a loop back test feature
- enable the PrimeCell SSP peripheral.

To configure the PrimeCell SSP as a master, clear the **SSPCR1** register master or slave selection bit, MS, to 0. This is the default value on reset.

Setting the **SSPCR1** register MS bit to 1 configures the PrimeCell SSP as a slave. When configured as a slave, use the **SSPCR1** slave mode **SSPTXD** output disable bit (**SOD**) to enable or disable of the PrimeCell SSP **SSPTXD** signal. You can use this in some multi-slave environments where masters might parallel broadcast.

To enable the PrimeCell SSP, set the Synchronous Serial Port Enable (**SSE**) bit to 1.

##### 12.3.4.6.1. Bit rate generation

The serial bit rate is derived by dividing down the input clock, **SSPCLK**. The clock is first divided by an even prescale value **CPSDVS** in the range 2-254, and is programmed in **SSPCPSR**. The clock is divided again by a value in the range 1-256, that is  $1 + SCR$ , where **SCR** is the value programmed in **SSPCR0**.

The following equation defines the frequency of the output signal bit clock, **SSPCLKOUT**:

$$F_{SSPCLKOUT} = \frac{F_{SSPCLK}}{CPSDVS \times (1 + SCR)}$$

For example, if **SSPCLK** is 125MHz, and **CPSDVS** = 2, then **SSPCLKOUT** has a frequency range from 244kHz - 62.5MHz.

#### 12.3.4.7. Frame format

Each data frame is between 4-16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. You can select the following basic frame types:

$F_{SSPCLK}(min) \geq 12 \times F_{SSPCLKIN}(max)$ , 适用于从模式。

SSPCLK的最大频率受以下不等式约束, 且必须同时满足:

$F_{SSPCLK}(max) \leq 254 \times 256 \times F_{SSPCLKOUT}(min)$ , 适用于主模式

$F_{SSPCLK}(max) \leq 254 \times 256 \times F_{SSPCLKIN}(min)$ , 适用于从模式。

#### 12.3.4.5. 编程 SSPCR0 控制寄存器

SSPCR0寄存器用于:

- 编程串行时钟速率
- 选择三种协议中的一种
- 选择数据字长 (如适用)

串行时钟速率 (SCR) 值结合 SSPCSR时钟预分频因子值 CPSDVS, 用于从外部 SSPCLK派生PrimeCell SSP的发送与接收比特率。

帧格式通过FRF位设置, 数据字长通过 DSS位配置。

位相和极性, 仅适用于Motorola SPI格式, 通过 SPH和 SPO位进行配置。

#### 12.3.4.6. SSPCR1控制寄存器的编程

SSPCR1寄存器用于:

- 选择主模式或从模式
- 启用环回测试功能
- 启用PrimeCell SSP外设。

要将PrimeCell SSP配置为主模式, 请将SSPCR1寄存器中的主从选择位MS清零。该值为复位时的默认值。

将SSPCR1寄存器中的MS位置1, 可将PrimeCell SSP配置为从模式。配置为从模式时, 使用SSPCR1寄存器中从模式SSPTXD输出禁用位 (S0D) 启用或禁用PrimeCell SSP的SSPTXD信号。该功能适用于某些多从设备环境中, 主设备可能进行并行广播的场合。

要启用PrimeCell SSP, 请将同步串行端口使能位 (SSE) 置位为1。

##### 12.3.4.6.1. 比特率生成

串行比特率通过对输入时钟 SSPCLK进行分频得出。时钟首先通过一个范围为2至254的偶数预分频值CPSDVS分频, 该值在 SSPCSR中设置。时钟随后由1至256范围内的值再次分频, 即 $1 + SCR$ , SCR的值由 SSPCR0中设置。

以下公式定义了输出信号比特时钟 SSPCLKOUT 的频率:

$$F_{SSPCLKOUT} = \frac{F_{SSPCLK}}{CPSDVS \times (1 + SCR)}$$

例如, 当 SSPCLK为125MHz且 CPSDVS= 2时, SSPCLKOUT的频率范围为244kHz至62.5MHz。

#### 12.3.4.7. 帧格式

每个数据帧长为4至16位, 具体取决于所编程的数据大小, 且从最高有效位 (MSB) 开始传输。您可以选择以下基本帧类型:

- Texas Instruments synchronous serial
- Motorola SPI
- National Semiconductor Microwire.

For all formats, the serial clock, **SSPCLKOUT**, is held inactive while the PrimeCell SSP is idle, and transitions at the programmed frequency only during active transmission or reception of data. The idle state of **SSPCLKOUT** is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Motorola SPI and National Semiconductor Microwire frame formats, the serial frame, **SSPFSSOUT**, pin is active-LOW, and is asserted, pulled-down, during the entire transmission of the frame.

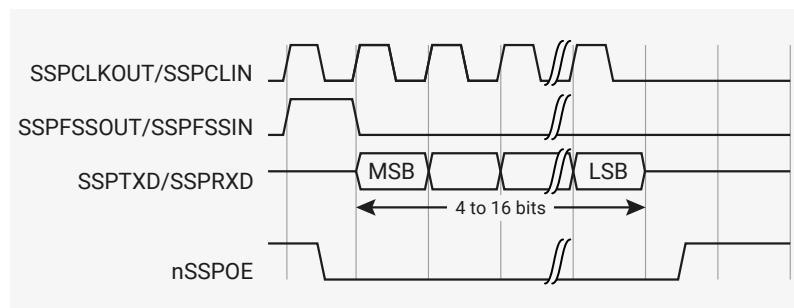

For Texas Instruments synchronous serial frame format, the **SSPFSSOUT** pin is pulsed for one serial clock period, starting at its rising edge, prior to the transmission of each frame. For this frame format, both the PrimeCell SSP and the off-chip slave device drive their output data on the rising edge of **SSPCLKOUT**, and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the National Semiconductor Microwire format uses a special master-slave messaging technique that operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, the SSS receives no incoming data. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4-16 bits in length, making the total frame length in the range 13-25 bits.

#### 12.3.4.8. Texas Instruments synchronous serial frame format

Figure 92 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

Figure 92. Texas Instruments synchronous serial frame format, single transfer

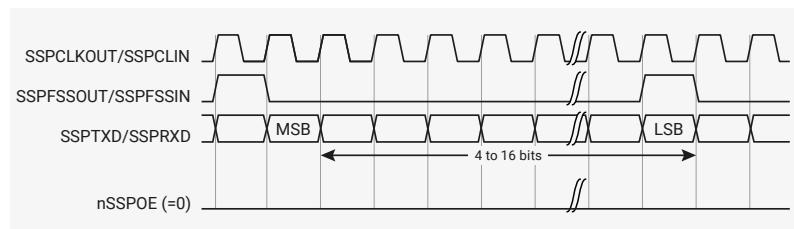

In this mode, **SSPCLKOUT** and **SSPFSSOUT** are forced LOW, and the transmit data line, **SSPTXD** is tristated whenever the PrimeCell SSP is idle. When the bottom entry of the transmit FIFO contains data, **SSPFSSOUT** is pulsed HIGH for one **SSPCLKOUT** period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of **SSPCLKOUT**, the MSB of the 4-bit to 16-bit data frame is shifted out on the **SSPTXD** pin. In a similar way, the MSB of the received data is shifted onto the **SSPRXD** pin by the off-chip serial slave device.

Both the PrimeCell SSP and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each **SSPCLKOUT**. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of **PCLK** after the LSB has been latched.

Figure 93 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 93. Texas Instruments synchronous serial frame format, continuous transfer

- 德州仪器同步串行
- 摩托罗拉 SPI
- 国家半导体Microwire。

对于所有格式，串行时钟 **SSPCLKOUT** 在 PrimeCell SSP 空闲时保持非活动状态，仅在数据的主动传输或接收期间以设定频率跳变。利用 **SSPFSSOUT** 的空闲状态提供接收超时指示，该指示发生于接收 FIFO 在超时期限后仍含有数据时。

对于 Motorola SPI 和国家半导体 Microwire 帧格式，串行帧信号 **SSPFSSOUT** 引脚为有效低电平，且在整个帧传输期间被拉低。

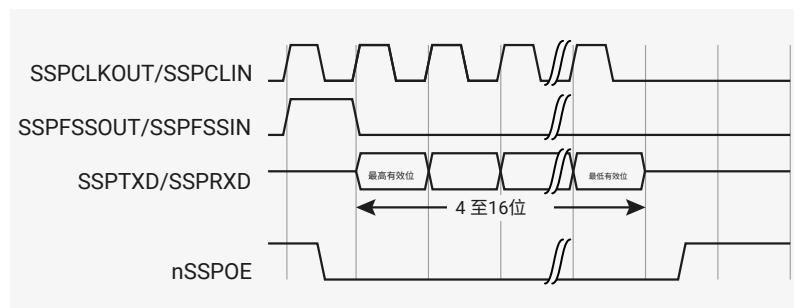

对于德州仪器同步串行帧格式，**SSPFSSOUT** 引脚在每个帧传输前的上升沿开始脉冲一个串行时钟周期。对于此帧格式，PrimeCell SSP 及片外从设备均在 **SSPCLKOUT** 上升沿驱动输出数据，并在下降沿锁存来自对方设备的数据。

与其他两种帧格式的全双工传输不同，National Semiconductor Microwire 格式采用一种特殊的主从通信技术，运行于半双工模式。在此模式下，帧开始时，会向片外从设备发送一个 8 位的控制消息。在该传输过程中，SSS 不接收任何输入数据。消息发送完成后，片外从设备会进行解码，并在 8 位控制消息最后一位发送后等待一个串行时钟周期，然后返回所请求的数据。返回的数据长度可为 4 至 16 位，使总帧长度处于 13 至 25 位之间。

#### 12.3.4.8. Texas Instruments 同步串行帧格式

图92显示了Texas Instruments单帧同步串行帧格式。

图92. 德州仪器同步串行帧格式，单次传输

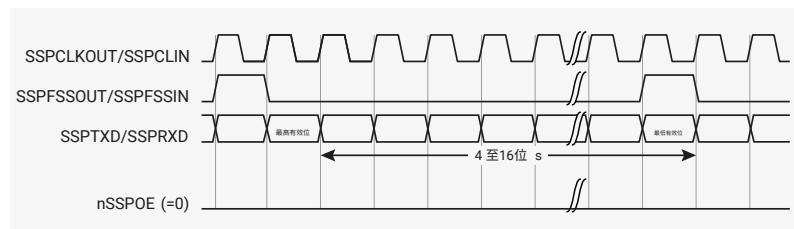

在此模式下，**SSPCLKOUT** 和 **SSPFSSOUT** 被强制拉低，且 PrimeCell SSP 空闲时，发送数据线 **SSPTXD** 处于三态状态。当发送 FIFO 底部条目包含数据时，**SSPFSSOUT** 会被拉高一个 **SSPCLKOUT** 周期的脉冲。传输的数据也从发送 FIFO 传送至发送逻辑的串行移位寄存器。在下一次 **SSPCLKOUT** 的上升沿，4 位至 16 位数据帧的最高有效位（MSB）通过 **SSPTXD** 引脚移出。类似地，接收数据的最高有效位由片外串行从设备加载到 **SSPRXD** 引脚。

随后，PrimeCell SSP 和片外串行从设备均在每个 **SSPCLKOUT** 的下降沿将各数据位时钟进入其串行移位寄存器。接收的数据在锁存最低有效位（LSB）后，于 **PCLK** 的首个上升沿从串行移位寄存器传输至接收 FIFO。

图93显示了德州仪器在背靠背帧传输时的同步串行帧格式。

图93. 德州仪器同步串行帧格式，连续传输

### 12.3.4.9. Motorola SPI frame format

The Motorola SPI interface is a four-wire interface where the **SSPFSSOUT** signal behaves as a slave select. The main feature of the Motorola SPI format is that you can program the inactive state and phase of the **SSPCLKOUT** signal using the **SPO** and **SPH** bits of the **SSPSCR0** control register.

#### 12.3.4.9.1. **SPO**, clock polarity

When the **SPO** clock polarity control bit is LOW, it produces a steady state LOW value on the **SSPCLKOUT** pin. If the **SPO** clock polarity control bit is HIGH, a steady state HIGH value is placed on the **SSPCLKOUT** pin when data is not being transferred.

#### 12.3.4.9.2. **SPH**, clock phase

The **SPH** control bit selects the clock edge that captures data and enables it to change state. It has the most impact on the first bit transmitted by either permitting or not permitting a clock transition before the first data capture edge.

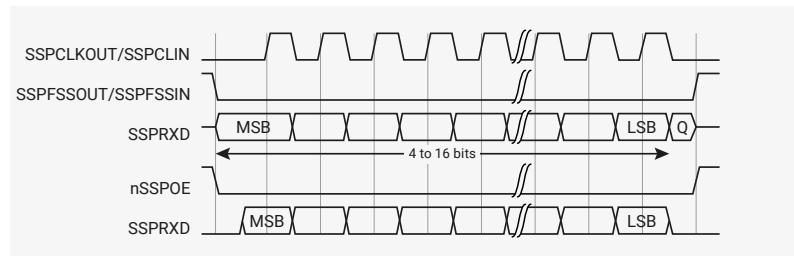

When the **SPH** phase control bit is LOW, data is captured on the first clock edge transition.

When the **SPH** clock phase control bit is HIGH, data is captured on the second clock edge transition.

### 12.3.4.10. Motorola SPI format with **SPO=0**, **SPH=0**

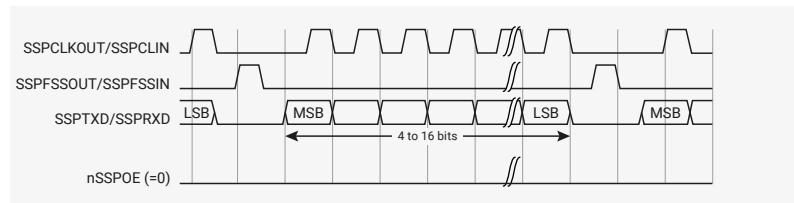

[Figure 94](#) and [Figure 95](#) shows a continuous transmission signal sequence for Motorola SPI frame format with **SPO=0**, **SPH=0**. [Figure 94](#) shows a single transmission signal sequence for Motorola SPI frame format with **SPO=0**, **SPH=0**.

Figure 94. Motorola SPI frame format, single transfer, with **SPO=0** and **SPH=0**

[Figure 95](#) shows a continuous transmission signal sequence for Motorola SPI frame format with **SPO=0**, **SPH=0**.

Figure 95. Motorola SPI frame format, single transfer, with **SPO=0** and **SPH=0**

In this configuration, during idle periods:

- the **SSPCLKOUT** signal is forced LOW
- the **SSPFSSOUT** signal is forced HIGH
- the transmit data line **SSPTXD** is arbitrarily forced LOW
- the **nSSPOE** pad enable signal is forced HIGH (this is not connected to the pad in RP2350)
- when the PrimeCell SSP is configured as a master, the **nSSPCTL0E** line is driven LOW, enabling the **SSPCLKOUT** pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the **nSSPCTL0E** line is driven HIGH, disabling the **SSPCLKOUT** pad, active-LOW enable

### 12.3.4.9. 摩托罗拉SPI帧格式

摩托罗拉SPI接口为四线接口，其中 **SSPFSSOUT**信号用作从设备选择信号。摩托罗拉SPI格式的主要特点是可以通过 **SSPSCRO** 控制寄存器中的**SP0**和**SPH**位，配置**SSPCLKOUT**信号的无效状态及相位。

#### 12.3.4.9.1. **SP0**, 时钟极性

当 **SP0**时钟极性控制位为低电平时，**SSPCLKOUT**引脚保持稳定的低电平；当 **SP0**时钟极性控制位为高电平，且无数据传输时，**SSPCLKOUT**引脚保持稳定的高电平。

#### 12.3.4.9.2. **SPH**, 时钟相位

该 **SPH**控制位选择捕获数据的时钟边缘，并允许其状态发生变化。它对首比特的传输影响最大，决定是否允许在第一个数据捕获边缘之前发生时钟跳变。

当 **SPH**相位控制位为低电平时，数据在第一个时钟边缘跳变处被捕获。

当 **SPH**时钟相位控制位为高电平时，数据在第二个时钟边缘跳变处被捕获。

### 12.3.4.10. **SPO=0, SPH=0**的Motorola SPI格式

图94和图95展示了**SPO=0, SPH=0**的Motorola SPI帧格式的连续传输信号序列。图94展示了**SPO=0, SPH=0**的Motorola SPI帧格式的单次传输信号序列。

图94。Motorola SPI帧格式，单次传输，**SP0=0**且**SPH=0**

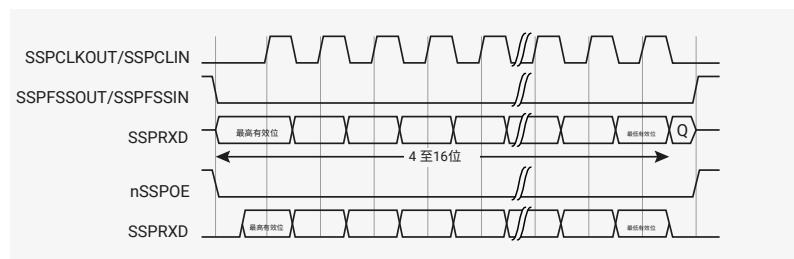

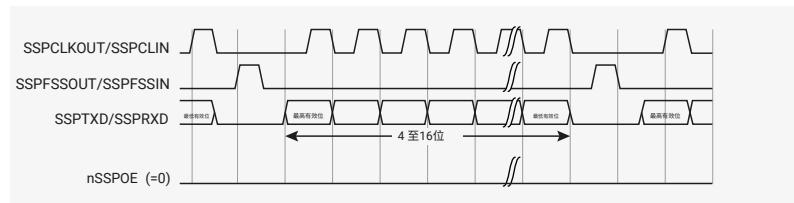

图95显示了摩托罗拉SPI帧格式下连续传输信号序列，**SP0=0, SPH=0**。

图95。Motorola SPI帧格式，单次传输，**SP0=0**且**SPH=0**

在该配置下，空闲期间：

- **SSPCLKOUT**信号被强制拉低
- **SSPFSSOUT**信号被强制拉高
- 传输数据线**SSPTXD**被任意强制拉低
- **nSSPOE**端口使能信号被强制拉高（该信号在RP2350中未连接至端口）
- 当PrimeCell SSP配置为主设备时，**nSSPCTL0E**线被拉低，启用**SSPCLKOUT**端口，低电平有效使能
- 当PrimeCell SSP配置为从设备时，**nSSPCTL0E**线被拉高，禁用**SSPCLKOUT**端口，低电平有效使能

If the PrimeCell SSP is enable, and there is valid data within the transmit FIFO, the start of transmission is signified by the **SSPFSSOUT** master signal being driven LOW. This causes slave data to be enabled onto the **SSPRXD** input line of the master. The **nSSPOE** line is driven LOW, enabling the master **SSPTXD** output pad.

One-half **SSPCLKOUT** period later, valid master data is transferred to the **SSPTXD** pin. Now that both the master and slave data have been set, the **SSPCLKOUT** master clock pin goes HIGH after one additional half **SSPCLKOUT** period.

The data is now captured on the rising and propagated on the falling edges of the **SSPCLKOUT** signal.

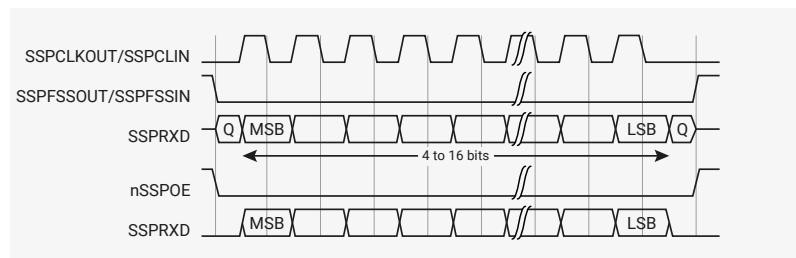

In the case of a single word transmission, after all bits of the data word have been transferred, the **SSPFSSOUT** line is returned to its idle HIGH state one **SSPCLKOUT** period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the **SSPFSSOUT** signal pulse HIGH between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not permit it to be altered if the **SPH** bit is logic zero. Therefore, the master device must raise the **SSPFSSIN** pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the **SSPFSSOUT** pin is returned to its idle state one **SSPCLKOUT** period after the last bit has been captured.

#### 12.3.4.11. Motorola SPI format with **SPO=0, SPH=1**

Figure 96 shows the transfer signal sequence for Motorola SPI format with **SPO=0, SPH=1**, and it covers both single and continuous transfers.

*Figure 96. Motorola SPI frame format with **SPO=0 and SPH=1**, single and continuous transfers*

In this configuration, during idle periods:

- the **SSPCLKOUT** signal is forced LOW
- The **SSPFSSOUT** signal is forced HIGH
- the transmit data line **SSPTXD** is arbitrarily forced LOW
- the **nSSPOE** pad enable signal is forced HIGH (not connected to the pad in RP2350)
- when the PrimeCell SSP is configured as a master, the **nSSPCTLOE** line is driven LOW, enabling the **SSPCLKOUT** pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the **nSSPCTLOE** line is driven HIGH, disabling the **SSPCLKOUT** pad, active-LOW enable

If the PrimeCell SSP is enabled, and there is valid data within the transmit FIFO, the start of transmission is signified by the **SSPFSSOUT** master signal being driven LOW. The **nSSPOE** line is driven LOW, enabling the master **SSPTXD** output pad. After an additional one half **SSPCLKOUT** period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the **SSPCLKOUT** is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the **SSPCLKOUT** signal.

In the case of a single word transfer, after all bits have been transferred, the **SSPFSSOUT** line is returned to its idle HIGH state one **SSPCLKOUT** period after the last bit has been captured. For continuous back-to-back transfers, the **SSPFSSOUT** pin is held LOW between successive data words and termination is the same as that of the single word transfer.

若PrimeCell SSP处于使能状态且传输FIFO中有有效数据，传输开始由SSPFSSOUT主设备信号拉低指示，进而使从设备数据能够加载至主设备的SSPRXD输入线上。nSSPOE线被拉低，启用主控端SSPTXD输出引脚。

半个 SSPCLKOUT周期后，有效的主控数据传输到 SSPTXD引脚。主从数据均已设定后，主控时钟引脚 SSPCLKOUT在再过半个 SSP CLKOUT周期后拉高。

数据现于 SSPCLKOUT信号的上升沿捕获，并在下降沿传播。

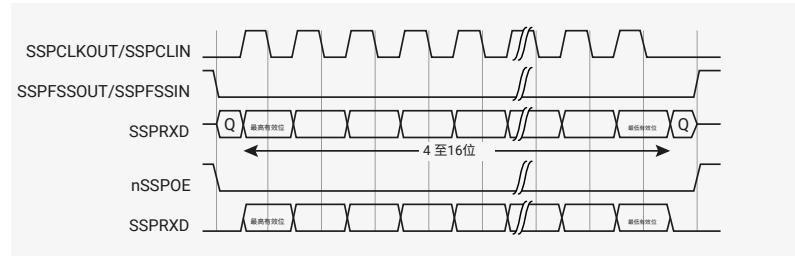

对于单字传输，所有数据位传输完成后，最后一位被捕获一个 SSPCLKOUT周期后， SSPFSSOUT线恢复至空闲高电平状态。

但在连续回连传输中， SSPFSSOUT信号在每个数据字传输间保持高电平脉冲。这是因为当 SPH位逻辑值为零时，从属选择引脚会冻结其串行外设寄存器中的数据，不允许修改。因此，主设备必须在每次数据传输之间将从设备的 SSPFSSIN引脚拉高，以启用串行外设数据写入。连续传输完成后，SSPFSSOUT引脚将在最后一位被捕获后一个SSPCLKOUT周期内恢复至空闲状态。

#### 12.3.4.11. SPO=0, SPH=1 的 Motorola SPI 格式

图96显示了 SPO=0、SPH=1 的 Motorola SPI 格式传输信号序列，涵盖单次传输和连续传输。

图96。 SPO=0 且  
SPH=1 的 Motorola S  
PI 帧格式，单次  
传输与连续传输

在该配置下，空闲期间：

- SSPCLKOUT信号被强制拉低
- SSPFSSOUT信号被强制置为高电平
- 传输数据线SSPTXD被任意强制拉低
- nSSPOE引脚使能信号被强制置为高电平（RP2350 中未连接至引脚）
- 当PrimeCell SSP配置为主设备时，nSSPC<sub>TLOE</sub>线被拉低，启用SSPCLKOUT端口，低电平有效使能
- 当PrimeCell SSP配置为从设备时，nSSPC<sub>TLOE</sub>线被拉高，禁用SSPCLKOUT端口，低电平有效使能

若启用 PrimeCell SSP 且发送 FIFO 中存在有效数据，传输开始即由将 SSPFSSOUT主信号拉低表示。nSSPOE线被拉低，启用主设备的SSPTXD输出引脚。再经过半个SSPCLKOUT周期后，主、从双方的有效数据被同时激活并传输至各自线路。同时，SSPCLKOUT通过上升沿触发被使能。

数据随后在 SSPCLKOUT信号的下降沿被捕获，并在上升沿传输。

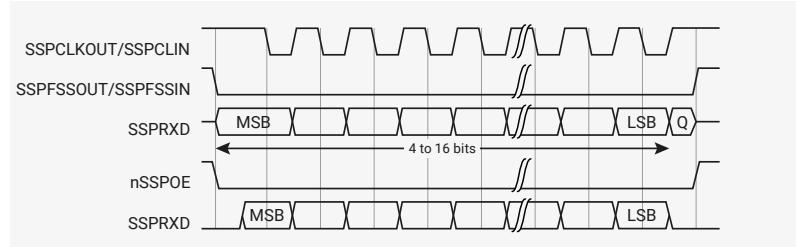

在单字传输的情况下，当所有位传输完成后，SSPFSSOUT线会在最后一位被捕获后的一个 SSPCLKOUT周期内恢复至其空闲的高电平状态。对于连续背靠背传输，SSPFSSOUT引脚在连续数据字之间保持低电平，终止方式与单字传输相同。

### 12.3.4.12. Motorola SPI format with SPO=1, SPH=0

[Figure 97](#) and [Figure 98](#) show single and continuous transmission signal sequences for Motorola SPI format with SPO=1, SPH=0.

[Figure 97](#) shows a single transmission signal sequence for Motorola SPI format with SPO=1, SPH=0.

Figure 97. Motorola SPI frame format, single transfer, with SPO=1 and SPH=0

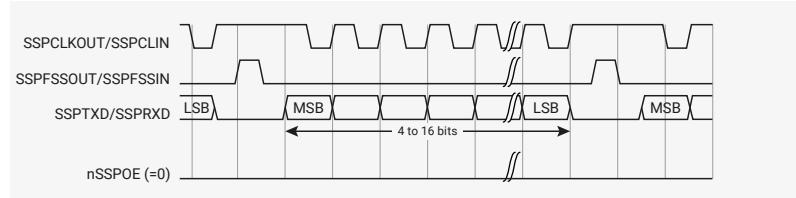

[Figure 98](#) shows a continuous transmission signal sequence for Motorola SPI format with SPO=1, SPH=0.

**i NOTE**

In [Figure 97](#), Q is an undefined signal.

Figure 98. Motorola SPI frame format, continuous transfer, with SPO=1 and SPH=0

In this configuration, during idle periods:

- the **SSPCLKOUT** signal is forced HIGH
- the **SSPFSSOUT** signal is forced HIGH
- the transmit data line **SSPTXD** is arbitrarily forced LOW
- the **nSSPOE** pad enable signal is forced HIGH (not connected to the pad in RP2350)
- when the PrimeCell SSP is configured as a master, the **nSSPCTLOE** line is driven LOW, enabling the **SSPCLKOUT** pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the **nSSPCTLOE** line is driven HIGH, disabling the **SSPCLKOUT** pad, active-LOW enable

If the PrimeCell SSP is enabled, and there is valid data within the transmit FIFO, the start of transmission is signified by the **SSPFSSOUT** master signal being driven LOW, and this causes slave data to be immediately transferred onto the **SSPRXD** line of the master. The **nSSPOE** line is driven LOW, enabling the master **SSPTXD** output pad.

One half period later, valid master data is transferred to the **SSPTXD** line. Now that both the master and slave data have been set, the **SSPCLKOUT** master clock pin becomes LOW after one additional half **SSPCLKOUT** period. This means that data is captured on the falling edges and be propagated on the rising edges of the **SSPCLKOUT** signal.

In the case of a single word transmission, after all bits of the data word are transferred, the **SSPFSSOUT** line is returned to its idle HIGH state one **SSPCLKOUT** period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the **SSPFSSOUT** signal must be pulsed HIGH between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not permit it to be altered if the **SPH** bit is logic zero. Therefore, the master device must raise the **SSPFSSIN** pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the **SSPFSSOUT** pin is returned to its idle state one **SSPCLKOUT** period after the last bit has been captured.

### 12.3.4.12. Motorola SPI格式，SPO=1，SPH=0

图97和图98显示了SPO=1，SPH=0配置下的Motorola SPI格式的单次及连续传输信号序列。

图97显示了SPO=1，SPH=0配置下的Motorola SPI格式的单次传输信号序列。

图97。Motorola SPI帧格式，单次传输，SPO=1且SPH=0

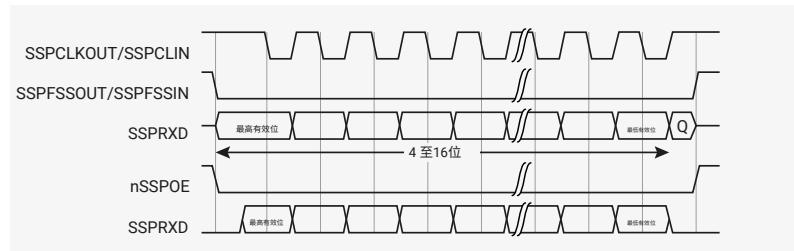

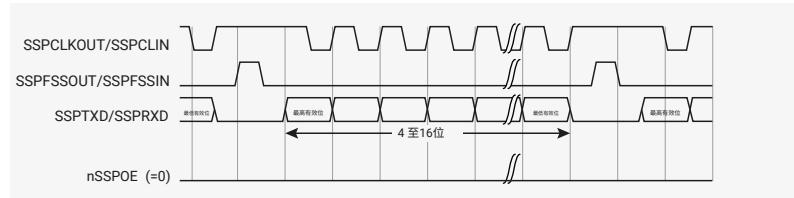

图98显示了Motorola SPI格式连续传输的信号序列，SPO=1，SPH=0。

#### **i 注意**

在图97中，Q为未定义信号。

图98。Motorola SPI帧格式，连续传输，SPO=1且SPH=0

在该配置下，空闲期间：

- SSPCLKOUT信号被强制置高
- SSPFSSOUT信号被强制拉高
- 传输数据线SSPTXD被任意强制拉低
- nSSPOE引脚使能信号被强制置为高电平（RP2350中未连接至引脚）
- 当PrimeCell SSP配置为主设备时，nSSPC<sub>TLOE</sub>线被拉低，启用SSPCLKOUT端口，低电平有效使能
- 当PrimeCell SSP配置为从设备时，nSSPC<sub>TLOE</sub>线被拉高，禁用SSPCLKOUT端口，低电平有效使能

若启用PrimeCell SSP且发送FIFO中有有效数据，传输启动由SSPFSSOUT主信号拉低表示，该操作使从设备数据立即传送至主设备的SSPRXD线。nSSPOE线被拉低，启用主控端SSPTXD输出引脚。

半周期后，有效的主设备数据被传输至SSPTXD线。既然主从设备数据均已设定，SSPCLKOUT主时钟引脚在额外经过半个SSPCLKOUT周期后变为低电平。这意味着数据在SSPCLKOUT信号的下降沿被采集，并在上升沿传输。

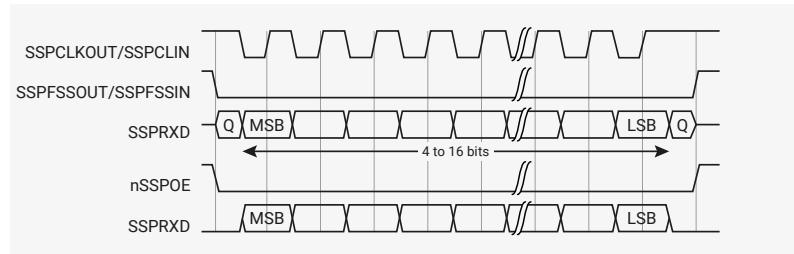

在单字传输的情况下，所有数据位传输完成后，SSPFSSOUT线路将在最后一位采集后的一个SSPCLKOUT周期内恢复为空闲高电平状态。

然而，在连续背靠背传输时，SSPFSSOUT信号必须在每个数据字传输之间产生高电平脉冲。这是因为当SPH位逻辑值为零时，从属选择引脚会冻结其串行外设寄存器中的数据，不允许修改。因此，主设备必须在每次数据传输之间将从设备的SSPFSSIN引脚拉高，以启用串行外设数据写入。连续传输结束后，SSPFSSOUT引脚将在最后一位采集后的一个SSPCLKOUT周期恢复至空闲状态。

### 12.3.4.13. Motorola SPI format with SPO=1, SPH=1

Figure 99 shows the transfer signal sequence for Motorola SPI format with  $SPO=1$ ,  $SPH=1$ , and it covers both single and continuous transfers.

Figure 99. Motorola SPI frame format with  $SPO=1$  and  $SPH=1$ , single and continuous transfers

#### **NOTE**

In Figure 99, Q is an undefined signal.

In this configuration, during idle periods:

- the **SSPCLKOUT** signal is forced HIGH
- the **SSPFSSOUT** signal is forced HIGH
- the transmit data line **SSPTXD** is arbitrarily forced LOW
- the **nSSPOE** pad enable signal is forced HIGH (not connected to the pad in RP2350)
- when the PrimeCell SSP is configured as a master, the **nSSPCTLOE** line is driven LOW, enabling the **SSPCLKOUT** pad, active-LOW enable
- when the PrimeCell SSP is configured as a slave, the **nSSPCTLOE** line is driven HIGH, disabling the **SSPCLKOUT** pad, active-LOW enable.

If the PrimeCell SSP is enabled, and there is valid data within the transmit FIFO, the start of transmission is signified by the **SSPFSSOUT** master signal being driven LOW. The **nSSPOE** line is driven LOW, enabling the master SSPTXD output pad. After an additional one half **SSPCLKOUT** period, both master and slave data are enabled onto their respective transmission lines. At the same time, the **SSPCLKOUT** is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the **SSPCLKOUT** signal.

After all bits have been transferred, in the case of a single word transmission, the **SSPFSSOUT** line is returned to its idle HIGH state one **SSPCLKOUT** period after the last bit has been captured.

For continuous back-to-back transmissions, the **SSPFSSOUT** pin remains in its active-LOW state, until the final bit of the last word has been captured, and then returns to its idle state as the previous section describes.

For continuous back-to-back transfers, the **SSPFSSOUT** pin is held LOW between successive data words and termination is the same as that of the single word transfer.

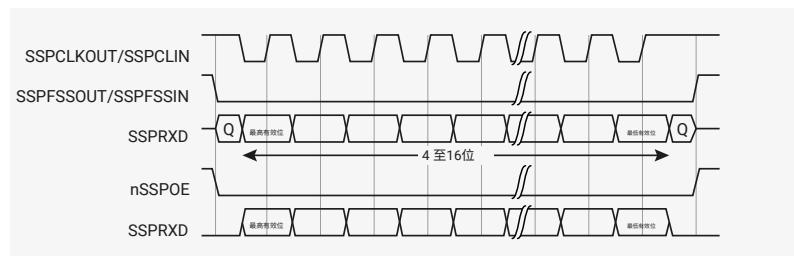

### 12.3.4.14. National Semiconductor Microwire frame format

Figure 100 shows the National Semiconductor Microwire frame format for a single frame. Figure 101 shows the same format when back to back frames are transmitted.

### 12.3.4.13. Motorola SPI 格式 (SPO=1, SPH=1)

图 99 展示了 SPO=1、SPH=1 条件下 Motorola SPI 格式的传输信号序列，涵盖单次及连续传输。

图 99。Motorola  
SPI 帧格式，SPO=1  
且 SPH=1，支持  
单次和连续传输。

**i 注意**

在图 99 中，信号 Q 未定义。

在该配置下，空闲期间：

- SSPCLKOUT 信号被强制置高
- SSPFSSOUT 信号被强制拉高
- 传输数据线 SSPTXD 被任意强制拉低
- nSSPOE 引脚使能信号被强制置为高电平 (RP2350 中未连接至引脚)
- 当 PrimeCell SSP 配置为主设备时，nSSPC<sub>TLOE</sub> 线被拉低，启用 SSPCLKOUT 端口，低电平有效使能
- 当 PrimeCell SSP 配置为从设备时，nSSPC<sub>TLOE</sub> 线被拉高，禁用 SSPCLKOUT 端口，低电平有效的使能信号。

若启用 PrimeCell SSP，且传输 FIFO 中存在有效数据，则传输开始时由 SSPFSSOUT 主控信号拉低。同时，nSSPOE 线路拉低，启用主控 SSPTXD 输出端。

再经过半个 SSPCLKOUT 周期后，主控与从控数据同时驱动至各自传输线。与此同时，SSPCLKOUT 由下降沿触发并被使能。数据随后在 SSPCLKOUT 信号的上升沿被采样，并在下降沿被传播。

所有位传输完成后，对于单词传输，最后一位采样完成后的 SSPCLKOUT 周期内，SSPFSSOUT 线路恢复至空闲高电平。

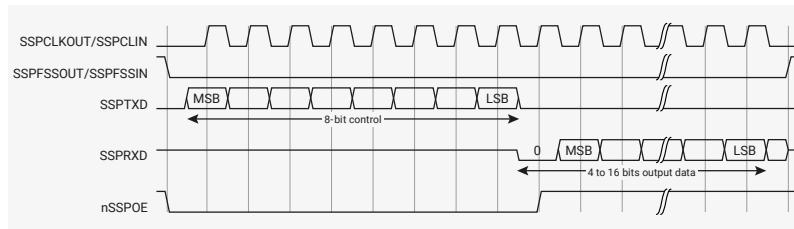

对于连续背靠背传输，SSPFSSOUT 引脚维持低电平有效状态，直至最后一个字的最后一帧被捕获，随后如前述部分所述恢复到空闲状态。

对于连续背靠背传输，SSPFSSOUT 引脚在连续数据字之间保持低电平，终止方式与单字传输相同。

### 12.3.4.14. 国家半导体Microwire帧格式

图100展示了单帧国家半导体Microwire帧格式。图101展示了连续帧传输时的相同帧格式。

Figure 100. Microwire frame format, single transfer

Microwire format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the PrimeCell SSP to the off-chip slave device. During this transmission, the PrimeCell SSP receives no incoming data. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length in the range 13-25 bits.

In this configuration, during idle periods:

- **SSPCLKOUT** is forced LOW
- **SSPFSSOUT** is forced HIGH
- the transmit data line, **SSPTXD**, is arbitrarily forced LOW
- the **nSSPOE** pad enable signal is forced HIGH (not connected to the pad in RP2350)

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of **SSPFSSOUT** causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the **SSPTXD** pin. **SSPFSSOUT** remains LOW for the duration of the frame transmission. The **SSPRXD** pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each **SSPCLKOUT**. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the PrimeCell SSP. Each bit is driven onto **SSPRXD** line on the falling edge of **SSPCLKOUT**. The PrimeCell SSP in turn latches each bit on the rising edge of **SSPCLKOUT**. At the end of the frame, for single transfers, the **SSPFSSOUT** signal is pulled HIGH one clock period after the last bit has been latched in the receive serial shifter, that causes the data to be transferred to the receive FIFO.

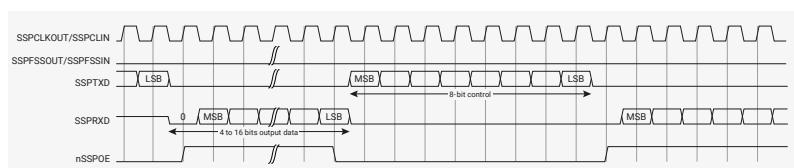

#### NOTE

The off-chip slave device can tristate the receive line either on the falling edge of **SSPCLKOUT** after the LSB has been latched by the receive shifter, or when the **SSPFSSOUT** pin goes HIGH.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the **SSPFSSOUT** line is continuously asserted, held LOW, and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge **SSPCLKOUT**, after the LSB of the frame has been latched into the PrimeCell SSP.

Figure 101 shows the National Semiconductor Microwire frame format when back-to-back frames are transmitted.

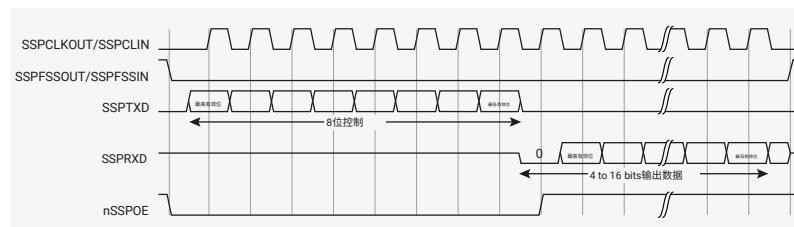

Figure 101. Microwire frame format, continuous transfers

In Microwire mode, the PrimeCell SSP slave samples the first bit of receive data on the rising edge of **SSPCLKIN** after **SSPFSSIN** has gone LOW. Masters that drive a free-running **SSPCLKIN** must ensure that the **SSPFSSIN** signal has sufficient setup and hold margins with respect to the rising edge of **SSPCLKIN**.

Figure 102 shows these setup and hold time requirements.

图100。Microwire  
帧格式，单次  
传输

Microwire格式与SPI格式极为相似，不同之处在于其传输为半双工而非全双工，采用主从消息传递机制。每次串行传输始于由PrimeCell SSP向片外从设备发送的8位控制字。在此传输过程中，PrimeCell SSP未接收任何输入数据。消息发送后，外部芯片从属设备对其进行解码，并在发送完8位控制消息的最后一一位后等待一个串行时钟周期，随后响应所需数据。返回的数据长度为4至16位，使总帧长度在13至25位之间。

在该配置下，空闲期间：

- **SSPCLKOUT** 被强制拉低
- **SSPFSSOUT** 被强制拉高
- 发送数据线 **SSPTXD**被任意拉低
- **nSSPOE**引脚使能信号被强制置为高电平（RP2350 中未连接至引脚）

通过向发送FIFO写入控制字节触发传输。**SSPFSSOUT**的下降沿使发送FIFO底端的值传输至发送逻辑的串行移位寄存器，8位控制帧的最高有效位被移出至 **SSPTXD**引脚。**SSPFSSOUT**在帧传输期间保持低电平。**SSPRXD**引脚在此次传输中保持三态状态。

片外串行从设备在每个 **SSPCLKOUT**的上升沿将每个控制位锁存至其串行移位寄存器。在从设备锁存最后一位后，控制字节将在一个时钟等待状态内解码，从设备随后通过向PrimeCell SSP发送数据进行响应。每个位于**SSPCLKOUT**的下降沿驱动至 **SSPRXD**线上。PrimeCell SSP则于**SSPCLKOUT**的上升沿锁存每个位。在帧结束时，对于单次传输，**SSPFSSOUT**信号在接收串行移位寄存器锁存最后一位后一个时钟周期被拉高，从而将数据传输到接收FIFO。

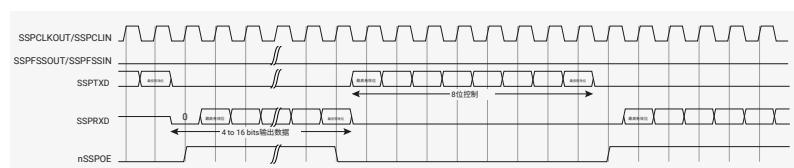

### **i 注意**

片外从设备可在接收移位器锁存LSB之后的 **SSPCLKOUT**下降沿，或 **SSPFSSOUT**引脚变高时，将接收线置于三态。

对于连续传输，数据传输的开始和结束方式与单次传输相同。然而，**SSPFSSOUT**线持续被拉低且被保持，数据传输紧密连续进行。下一帧的控制字节紧接在当前帧接收数据的最低有效位（LSB）之后。每个接收值均在**SSPCLKOUT**的下降沿从接收移位器传输，此时帧的LSB已锁存至PrimeCell SSP。

图101展示了National Semiconductor Microwire在连续帧传输时的帧格式。

图101。Microwire  
帧格式，连  
续传输

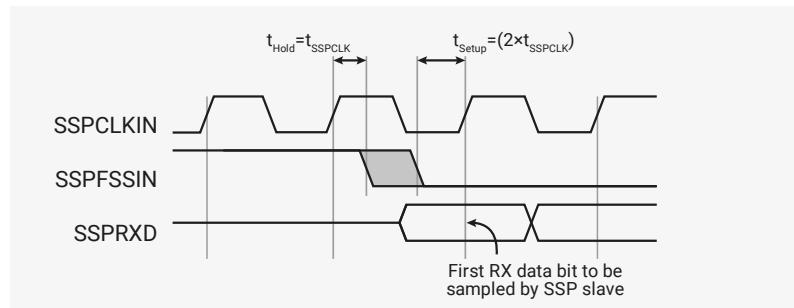

在Microwire模式下，PrimeCell SSP从机于SSPFSSIN信号拉低后，在SSPCLKIN的上升沿采样接收数据的首位。驱动自由运行SSPCLKIN的主机必须确保SSPFSSIN信号相较于SSPCLKIN的上升沿具备足够的建立时间和保持时间裕度。

图102显示了这些建立时间和保持时间的要求。

With respect to the **SSPCLKIN** rising edge on which the first bit of receive data is to be sampled by the PrimeCell SSP slave, **SSPFSSIN** must have a setup of at least two times the period of **SSPCLK** on which the PrimeCell SSP operates.

With respect to the **SSPCLKIN** rising edge previous to this edge, **SSPFSSIN** must have a hold of at least one **SSPCLK** period.

Figure 102. Microwire frame format, **SSPFSSIN** input setup and hold requirements

#### 12.3.4.15. Examples of master and slave configurations

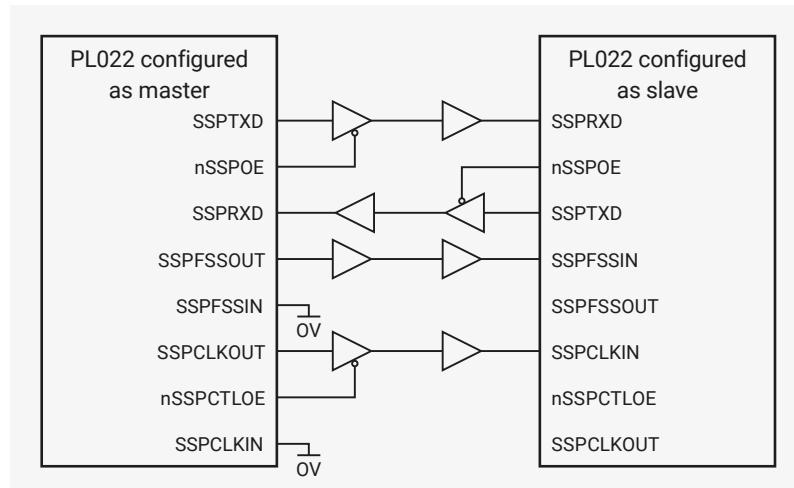

[Figure 103](#), [Figure 104](#), and [Figure 105](#) shows how you can connect the PrimeCell SSP ([PL022](#)) peripheral to other synchronous serial peripherals, when it is configured as a master or a slave.

##### **NOTE**

The SSP ([PL022](#)) does not support dynamic switching between master and slave in a system. Each instance is configured and connected either as a master or slave.

[Figure 103](#) shows the PrimeCell SSP ([PL022](#)) instanced twice, as a single master and one slave. The master can broadcast to the slave through the master **SSPTXD** line. In response, the slave drives its **nSSPOE** signal HIGH, enabling its **SSPTXD** data onto the **SSPRXD** line of the master.

Figure 103. PrimeCell SSP master coupled to a PL022 slave

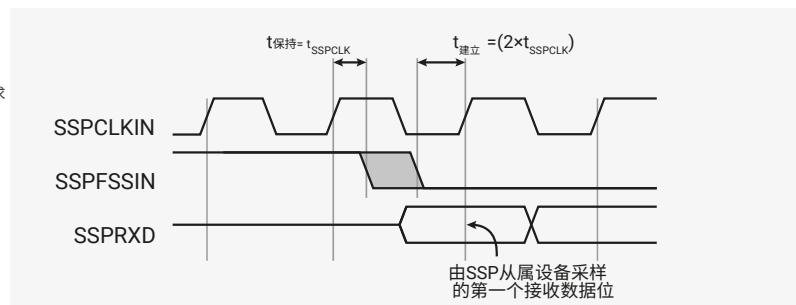

[Figure 104](#) shows how an PrimeCell SSP ([PL022](#)), configured as master, interfaces to a Motorola SPI slave. The SPI Slave Select (**SS**) signal is permanently tied LOW and configures it as a slave. Similar to the above operation, the master can broadcast to the slave through the master PrimeCell SSP **SSPTXD** line. In response, the slave drives its SPI **MISO** port onto the **SSPRXD** line of the master.

关于PrimeCell SSP从属设备采样第一个接收数据位的 **SSPCLKIN**上升沿，**SSPFSSIN**必须满足至少为PrimeCell SSP工作 **SSPCLK**周期两倍的建立时间。

关于该边沿之前的 **SSPCLKIN**上升沿，**SSPFSSIN**必须满足至少一个 **SSPCLK**周期的保持时间。

图102。Microwire

帧格式  
**SSPFSSIN**输入的建  
立时间和保持时间要求

#### 12.3.4.15. 主设备与从设备配置示例

图103、图104和图105展示了在PrimeCell SSP（PL022）外设被配置为主设备或从设备时，如何连接至其他同步串行外设。

**i 注意**

SSP（PL022）不支持系统中主从动态切换。每个实例均配置并连接为主设备或从设备。

图103展示了PrimeCell SSP（PL022）两次实例化，分别作为一个主设备和一个从设备。主设备可以通过其 SSPTXD线向从设备广播。作为响应，从设备将其 nSSPOE信号置高，使其SSPTXD数据输出到主设备的 SSPRXD线上。

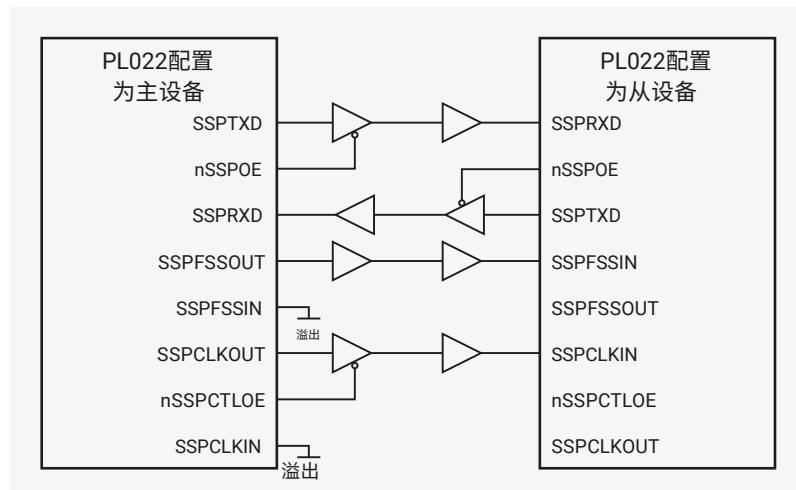

图103。PrimeCell  
SSP主设备连接至  
PL022从设备

图104展示了PrimeCell SSP（PL022）作为主设备时如何与摩托罗拉SPI从设备接口。SPI从设备选择（SS）信号被永久拉低，配置为从设备。类似上述操作，主设备可通过PrimeCell SSP主控的 SSPTXD线向从设备广播。作为响应，从设备将其 SPI MISO端口驱动至主设备的 SSPRXD线路。

Figure 104. PrimeCell SSP master coupled to an SPI slave

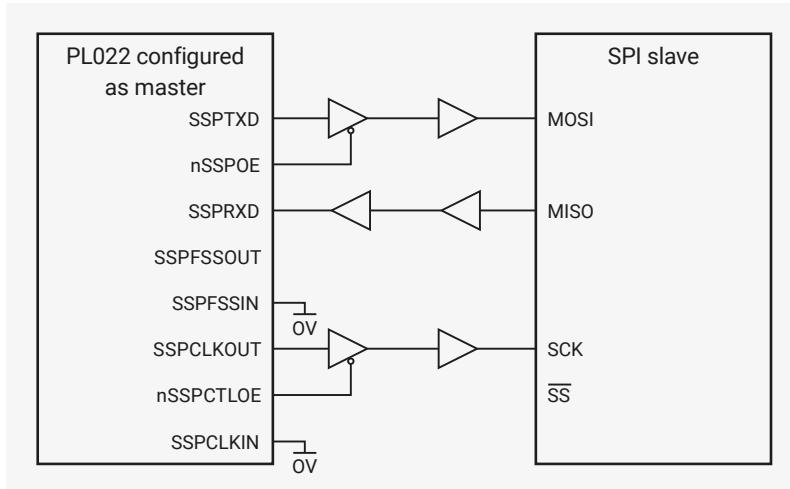

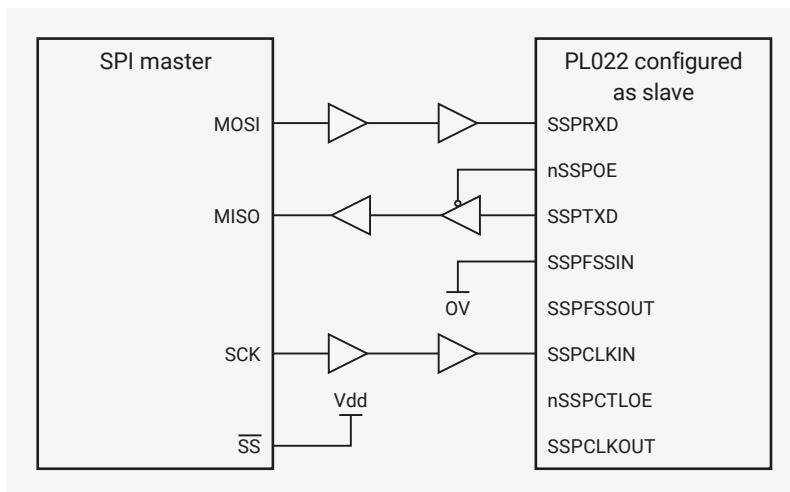

Figure 105 shows a Motorola SPI configured as a master and interfaced to an instance of a PrimeCell SSP (PL022) configured as a slave. In this case, the slave Select Signal (**SS**) is permanently tied HIGH to configure it as a master. The master can broadcast to the slave through the master SPI **MOSI** line and in response, the slave drives its **nSSPOE** signal LOW. This enables its **SSPTXD** data onto the **MISO** line of the master.

Figure 105. SPI master coupled to a PrimeCell SSP slave

#### 12.3.4.16. PrimeCell DMA interface

The PrimeCell SSP provides an interface to connect to the DMA controller. The PrimeCell SSP DMA control register, **SSPDMACTR** controls the DMA operation of the PrimeCell SSP.

The DMA interface includes the following signals, for receive:

##### **SSPRXDMASREQ**

Single-character DMA transfer request, asserted by the SSP. This signal is asserted when the receive FIFO contains at least one character.

##### **SSPRXDMAREQ**

Burst DMA transfer request, asserted by the SSP. This signal is asserted when the receive FIFO contains four or more characters.

##### **SSPRXDMACLR**

DMA request clear, asserted by the DMA controller to clear the receive request signals. If DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

The DMA interface includes the following signals, for transmit:

图104。连接至SPI  
从设备的PrimeCell SSP主设备

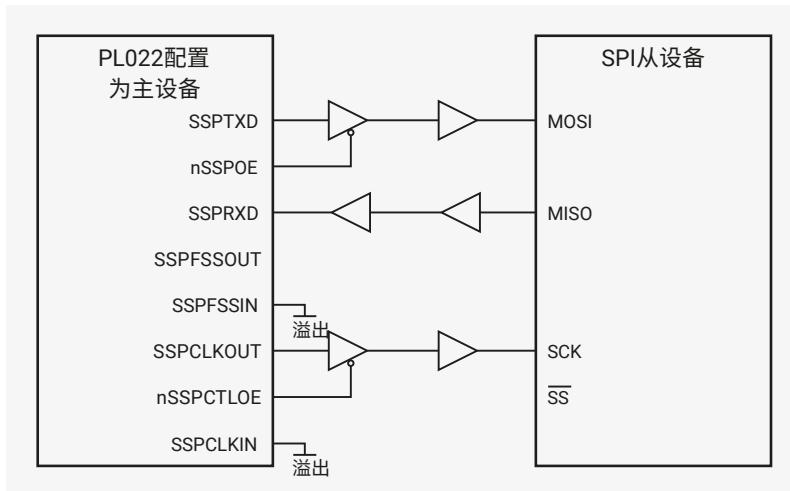

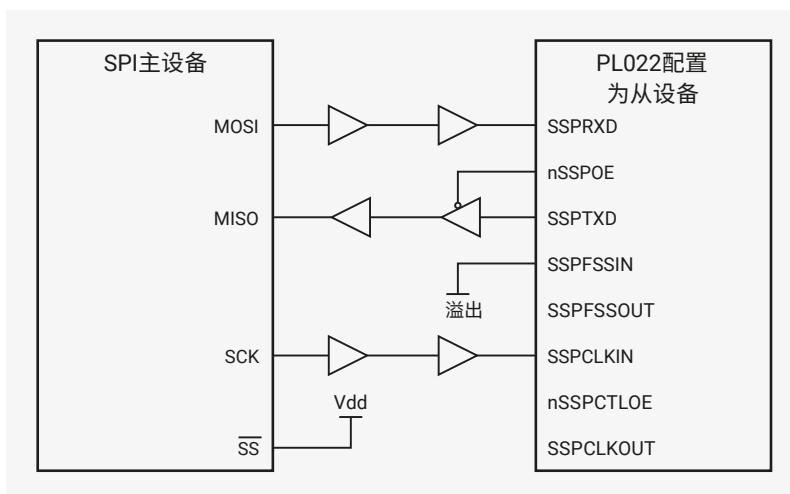

图105显示一个配置为主设备的摩托罗拉SPI，与配置为从设备的PrimeCell SSP（PL022）实例相连接。在此情况下，从设备选择信号（SS）永久拉高，以配置为主设备。主设备可通过SPI MOSI线向从设备广播，作为响应，从设备将其nSSPOE信号拉低，从而使其SSPTXD数据输出到主设备的MISO线。

图105。SPI主设备  
连接至PrimeCell  
SSP从设备

#### 12.3.4.16. PrimeCell DMA接口

PrimeCell SSP提供了连接DMA控制器的接口。PrimeCell SSP DMA控制寄存器SSPDMA<sub>R</sub>控制PrimeCell SSP的DMA操作。

DMA接口包括以下接收信号：

##### SSPRXDMASREQ

单字符DMA传输请求，由SSP发出。当接收FIFO中至少有一个字符时，该信号被激活。

##### SSPRXDMABREQ

突发DMA传输请求，由SSP发出。当接收FIFO中包含四个或更多字符时，该信号被激活。

##### SSPRX DMA清除

DMA请求清除信号，由DMA控制器发出，用以清除接收请求信号。若请求DMA突发传输，则在突发传输最后一条数据传送时，清除信号被发送。

DMA接口包括以下发送信号：

**SSPTXDMASREQ**

Single-character DMA transfer request, asserted by the SSP. This signal is asserted when there is at least one empty location in the transmit FIFO.

**SSPTXDMABREQ**

Burst DMA transfer request, asserted by the SSP. This signal is asserted when the transmit FIFO contains four characters or fewer.

**SSPTXDMACLR**

DMA request clear, asserted by the DMA controller, to clear the transmit request signals. If a DMA burst transfer is requested, the clear signal is asserted during the transfer of the last data in the burst.

The burst transfer and single transfer request signals are not mutually exclusive. They can both be asserted at the same time. For example, when there is more data than the watermark level of four in the receive FIFO, the burst transfer request, and the single transfer request, are asserted. When the amount of data left in the receive FIFO is less than the watermark level, the single request only is asserted. This is useful for situations where the number of characters left to be received in the stream is less than a burst.

For example, if 19 characters must be received, the DMA controller then transfers four bursts of four characters, and three single transfers to complete the stream.

**NOTE**

For the remaining three characters, the PrimeCell SSP does not assert the burst request.

Each request signal remains asserted until the relevant DMA clear signal is asserted. After the request clear signal is de-asserted, a request signal can become active again, depending on the conditions that previous sections describe. All request signals are de-asserted if the PrimeCell SSP is disabled, or the DMA enable signal is cleared.

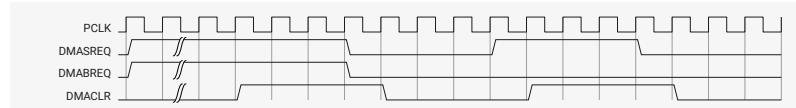

Table 1098 shows the trigger points for **DMABREQ**, for both the transmit and receive FIFOs.

*Table 1098. DMA trigger points for the transmit and receive FIFOs*

Burst length		
Watermark level	Transmit, number of empty locations	Receive, number of filled locations
1/2	4	4

Figure 106 shows the timing diagram for both a single transfer request, and a burst transfer request, with the appropriate DMA clear signal. The signals are all synchronous to PCLK.

*Figure 106. DMA transfer waveforms*

### 12.3.5. List of registers

The **SPI0** and **SPI1** registers start at base addresses of **0x40080000** and **0x40088000** respectively (defined as **SPI0\_BASE** and **SPI1\_BASE** in SDK).

*Table 1099. List of SPI registers*

Offset	Name	Info
0x000	<b>SSPCR0</b>	Control register 0, SSPCR0 on page 3-4
0x004	<b>SSPCR1</b>	Control register 1, SSPCR1 on page 3-5
0x008	<b>SSPDR</b>	Data register, SSPDR on page 3-6
0x00c	<b>SSPSR</b>	Status register, SSPSR on page 3-7
0x010	<b>SSPCPSR</b>	Clock prescale register, SSPCPSR on page 3-8

**SSPTXDMASREQ**

单字符DMA传输请求，由SSP发出。当发送FIFO中至少有一个空位时，该信号被激活。

**SSPTXDMABREQ**

突发DMA传输请求，由SSP发出。当发送FIFO中包含四个或更少字符时，该信号被激活。

**SSPTX DMA清除**

DMA请求清除信号由DMA控制器断言，用以清除传输请求信号。若请求DMA突发传输，则在突发传输的最后一数据传输期间断言清除信号。

突发传输请求信号与单次传输请求信号并非相互排斥。两者可同时断言。例如，当接收FIFO中的数据量超过四的水印水平时，突发传输请求信号与单次传输请求信号将同时被断言。当接收FIFO中剩余数据量低于水印水平时，仅断言单次请求信号。此情形适用于流中剩余待接收字符数少于一次突发的情况。

例如，如需接收19个字符，DMA控制器会先进行四次四字符的突发传输，随后进行三次单次传输以完成数据流。

**注意**

对于剩余的三个字符，PrimeCell SSP不会断言突发传输请求信号。

各请求信号在相应DMA清除信号断言前，均保持断言状态。在请求清除信号取消断言后，请求信号可根据前述章节描述的条件重新激活。若PrimeCell SSP被禁用或DMA使能信号被清除，所有请求信号将被取消断言。

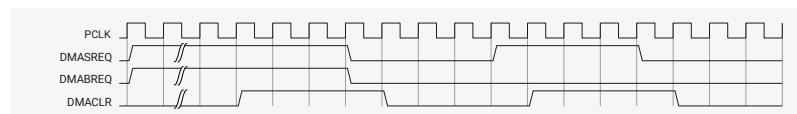

表1098显示了传输和接收FIFO的 DMABREQ 触发点。

表1098。发送和接收FIFO的DMA触发点

突发长度		
水位线水平	传输端，空闲位置数量	接收端，已填充位置数量

## SPI: SSPCR0 寄存器

偏移: 0x000

### 描述

控制寄存器 0, SSPCR0, 见第3-4页

表1100. SSPCR0  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:8	<b>SCR</b> : 串行时钟速率。SCR的值用于生成PrimeCell SSP的发送和接收比特率。比特率计算公式为: $F_{SSPCLK} = CPSDVSR \times (1+SCR)$ , 其中CPSDVSR为通过SSPCPSR寄存器设定的2至254之间的偶数, SCR取值范围为0至255。	读写	0x00
7	<b>SPH</b> : SSPCLKOUT 相位, 仅适用于 Motorola SPI 帧格式。详见第 2-10 页 Motorola SPI 帧格式。	读写	0x0
6	<b>SPO</b> : SSPCLKOUT 极性, 仅适用于 Motorola SPI 帧格式。详见第 2-10 页 Motorola SPI 帧格式。	读写	0x0
5:4	<b>FRF</b> : 帧格式: 00 Motorola SPI 帧格式; 01 TI 同步串行帧格式; 10 National Semiconductor Microwire 帧格式; 11 保留, 未定义操作。	读写	0x0
3:0	<b>DSS</b> : 数据大小选择: 0000 保留, 未定义操作; 0001 保留, 未定义操作; 0010 保留, 未定义操作; 0011 4 位数据。 0100 5 位数据; 0101 6 位数据; 0110 7 位数据; 0111 8 位数据; 1000 9 位数据; 1001 10 位数据; 1010 11 位数据; 1011 12 位数据; 1100 13 位数据; 1101 14 位数据; 1110 15 位数据; 1111 16 位数据。	读写	0x0

## SPI: SSPCR1 寄存器

偏移: 0x004

### 说明

控制寄存器 1, SSPCR1, 见第3-5页

Table 1101. SSPCR1 Register

Bits	Description	Type	Reset
31:4	Reserved.	-	-
3	<b>SOD</b> : Slave-mode output disable. This bit is relevant only in the slave mode, MS=1. In multiple-slave systems, it is possible for an PrimeCell SSP master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto its serial output line. In such systems the RXD lines from multiple slaves could be tied together. To operate in such systems, the SOD bit can be set if the PrimeCell SSP slave is not supposed to drive the SSPTXD line: 0 SSP can drive the SSPTXD output in slave mode. 1 SSP must not drive the SSPTXD output in slave mode.	RW	0x0
2	<b>MS</b> : Master or slave mode select. This bit can be modified only when the PrimeCell SSP is disabled, SSE=0: 0 Device configured as master, default. 1 Device configured as slave.	RW	0x0
