1	<b>SSE</b> : Synchronous serial port enable: 0 SSP operation disabled. 1 SSP operation enabled.	RW	0x0
0	<b>LBM</b> : Loop back mode: 0 Normal serial port operation enabled. 1 Output of transmit serial shifter is connected to input of receive serial shifter internally.	RW	0x0

## SPI: SSPDR Register

Offset: 0x008

### Description

Data register, SSPDR on page 3-6

Table 1102. SSPDR Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	<b>DATA</b> : Transmit/Receive FIFO: Read Receive FIFO. Write Transmit FIFO. You must right-justify data when the PrimeCell SSP is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by transmit logic. The receive logic automatically right-justifies.	RWF	-

## SPI: SSPSR Register

Offset: 0x00c

### Description

Status register, SSPSR on page 3-7

Table 1103. SSPSR Register

Bits	Description	Type	Reset
31:5	Reserved.	-	-
4	<b>BSY</b> : PrimeCell SSP busy flag, RO: 0 SSP is idle. 1 SSP is currently transmitting and/or receiving a frame or the transmit FIFO is not empty.	RO	0x0
3	<b>RFF</b> : Receive FIFO full, RO: 0 Receive FIFO is not full. 1 Receive FIFO is full.	RO	0x0
2	<b>RNE</b> : Receive FIFO not empty, RO: 0 Receive FIFO is empty. 1 Receive FIFO is not empty.	RO	0x0
1	<b>TNF</b> : Transmit FIFO not full, RO: 0 Transmit FIFO is full. 1 Transmit FIFO is full.	RO	0x1
0	<b>TFE</b> : Transmit FIFO empty, RO: 0 Transmit FIFO is not empty. 1 Transmit FIFO is empty.	RO	0x1

表 1101. SSPCR1  
寄存器

位	描述	类型	复位
31:4	保留。	-	-
3	<b>SOD</b> : 从模式输出禁用。此位仅在从模式 (MS=1) 下有效。在多从设备系统中, PrimeCell SSP 主设备可向系统内所有从设备广播消息, 同时确保仅有 一台从设备驱动其串行输出线上的数据。在此类系统中, 多个从设备的 RXD 线可共用连线。为使系统正常运行, 当 PrimeCell SSP 从设备不应驱动 SSPTXD 线上信号时, 可置位 SOD 位: 0 表示 SSP 可在从模式下驱动 SSPTXD 输出; 1 表示 SSP 在从模式下不得驱动 SSPTXD 输出。	读写	0x0
2	<b>MS</b> : 主/从模式选择。此位仅在 PrimeCell SSP 被禁用时 (SSE=0) 允许修改: 0 表示设备配置为主设备 (默认); 1 表示设备配置为从设备。	读写	0x0
1	<b>SSE</b> : 同步串行端口使能: 0 表示 SSP 操作禁用; 1 表示 SSP 操作启用。	读写	0x0
0	<b>LBM</b> : 环回模式: 0 启用正常串行端口操作; 1 传输串行移位器的输出在内部连接至接收串行移位器的输入。	读写	0x0

## SPI: SSPDR 寄存器

## 12.4. ADC and Temperature Sensor

RP2350 has an internal analogue-digital converter (ADC) with the following features:

- SAR ADC (see [Section 12.4.3](#))
- 500 kS/s (using an independent 48 MHz clock)
- 12-bit with 9.2 ENOB (see [Section 12.4.4](#))
- Five or nine input mux:
  - Four inputs available on QFN-60 package pins shared with [GPIO\[29:26\]](#)
  - Eight inputs available on QFN-80 package pins shared with [GPIO\[47:40\]](#)
  - One input dedicated to the internal temperature sensor (see [Section 12.4.6](#))

## 12.4. ADC 与温度传感器

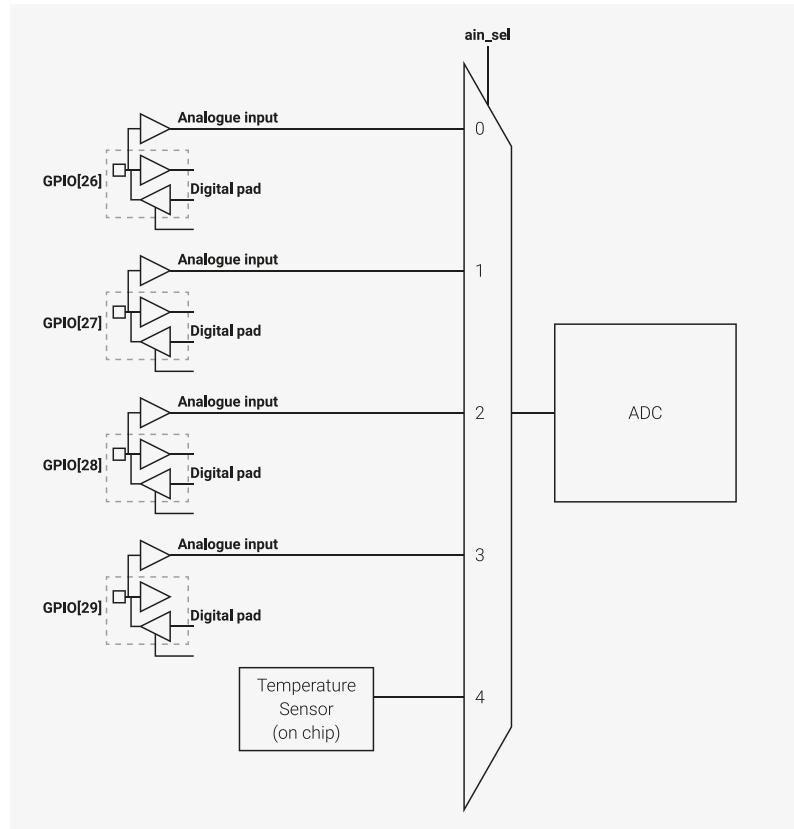

RP2350内置的模数转换器（ADC）具备以下特性：

- SAR ADC（参见第12.4.3节）
- 500 kS/s（使用独立的48 MHz时钟）
- 12位分辨率, 9.2 ENOB（参见第12.4.4节）
- 五路或九路输入多路复用器：
  - QFN-60封装引脚上有四个输入, 与GPIO[29:26]共用
  - QFN-80封装引脚上有八个输入, 与GPIO[47:40]共用
  - 一个输入专用于内部温度传感器（参见第12.4.6节）

- Eight element receive sample FIFO
- Interrupt generation
- DMA interface (see [Section 12.4.3.5](#))

[Figure 107](#) shows the arrangement of ADC channels in the QFN-60 package. [Figure 108](#) shows the same for QFN-80.

**Figure 107. ADC Connection Diagram for QFN-60.** This package features four external ADC inputs (0 through 3), on Bank 0 GPIOs 26 through 29. The internal temperature sensor connects to a fifth channel (channel 4). This is functionally the same ADC arrangement as RP2040, although the underlying hardware is different, to support the additional channels on QFN-80.

- 八级接收采样FIFO
- 中断生成
- DMA接口（参见第12.4.3.5节）

图107展示了QFN-60封装中ADC通道的排列。图108展示了QFN-80封装中相同的排列。

图107。QFN-60的ADC连接图。  
该封装具有四个外部ADC输入（  
编号0至3），对应Bank 0中GPIO 26至29  
。内部温度  
传感器连接至第五通道（通道4  
）。其功能与RP2040的ADC配置  
相同，尽管底层硬件不同，以支持  
QFN-80上的额外通道。  
通道。

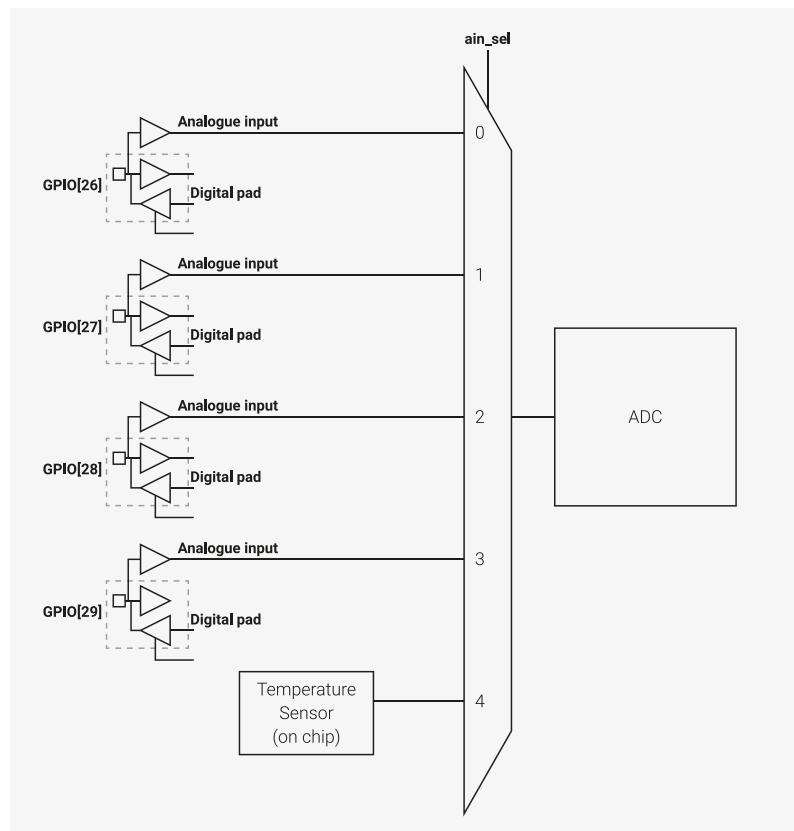

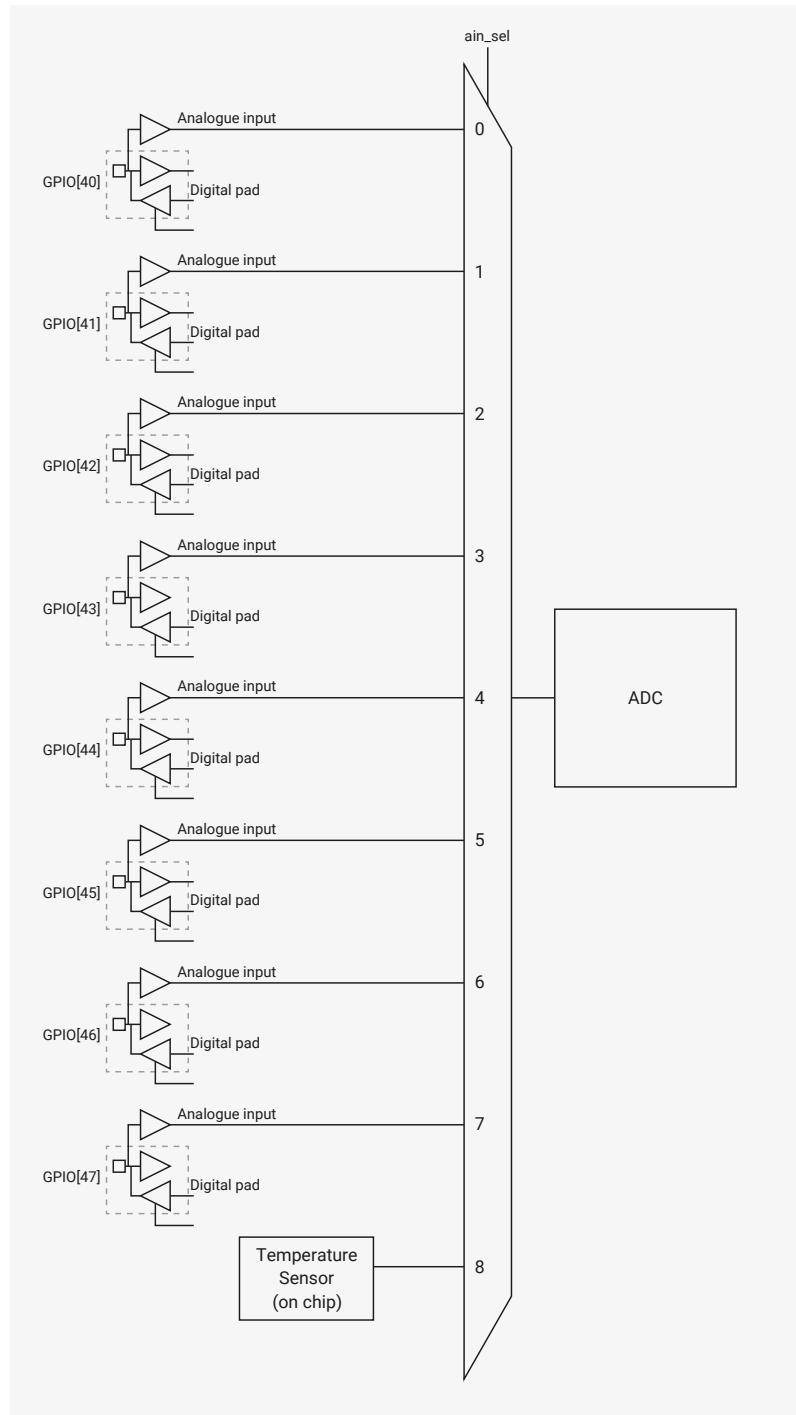

Figure 108. ADC Connection Diagram for QFN-80. This package features eight external ADC inputs (0 through 7), on Bank 0 GPIOs 40 through 47. The internal temperature sensor connects to a ninth channel (channel 8). Like in QFN-60, each ADC input shares a package pin with a digital Bank 0 GPIO: generally the digital functions are disabled when the ADC is in use.

When using an ADC input shared with a GPIO pin, always disable the pin's digital functions by setting **IE** low and **OD** high in the pin's pad control register. See [Section 9.11.3, "Pad Control - User Bank"](#) for details.

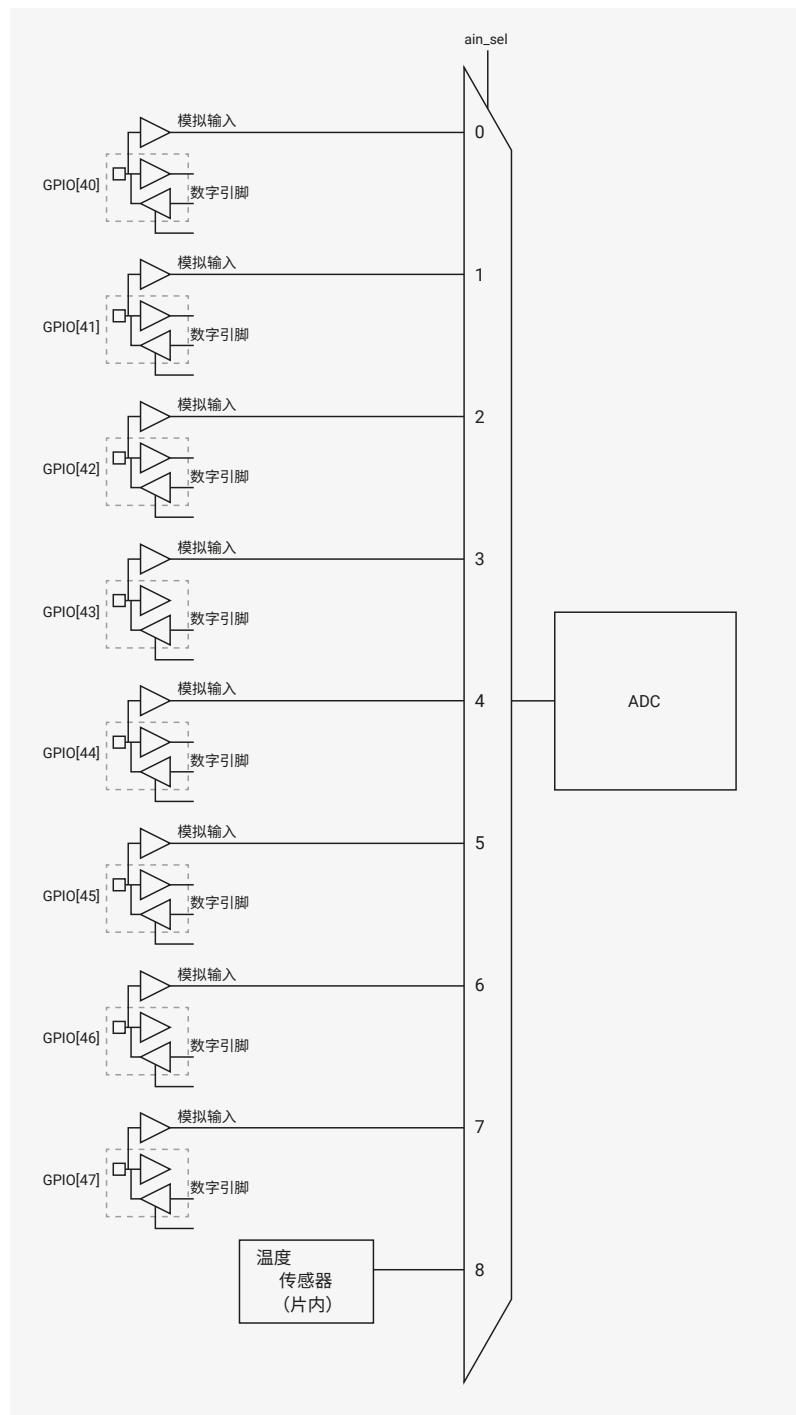

The maximum ADC input voltage is determined by the digital IO supply voltage (**IOVDD**), not the ADC supply voltage (**ADC\_AVDD**). For example, if **IOVDD** is powered at 1.8 V, the voltage on the ADC inputs should not exceed 1.8 V + 10% even if **ADC\_AVDD** is powered at 3.3 V. Voltages greater than **IOVDD** will result in leakage currents through the ESD protection diodes. See [Section 14.9, "Electrical specifications"](#) for details.

### 12.4.1. Changes from RP2040

- Removed spikes in differential nonlinearity at codes **0x200**, **0x600**, **0xa00** and **0xe00**, as documented by erratum RP2040-E11, improving the ADC's precision by around 0.5 ENOB.

图108。QFN-80 ADC连接图。该封装提供八个外部ADC输入（通道0至7），位于Bank 0的GPIO 40至47引脚。内部温度传感器连接至第九通道（通道8）。与QFN-60类似，每个ADC输入与Bank 0的数字GPIO共用封装引脚：

通常，当ADC正在使用时，数字功能会被禁用。

使用与GPIO引脚共用的ADC输入时，务必通过在引脚的管脚控制寄存器中将 **IE**置低且将 **OD**置高，以禁用该引脚的数字功能。详情请参见第9.11.3节，“管脚控制 - 用户组”。

最大ADC输入电压由数字IO电源电压 (**IOVDD**) 决定，非ADC电源电压。

(**ADC\_AVDD**)。例如，若 **IOVDD**电源电压为1.8 V，则ADC输入端电压不应超过1.8 V + 10%，即使ADC\_AVDD供电为3.3 V。电压超出 **IOVDD**范围将导致通过ESD保护二极管的漏电流。详情请参见第14.9节，“电气规格”。

### 12.4.1. 与 RP2040 的变化

- 如勘误表RP2040-E11所示，已消除码0x200、0x600、0xa00及0xe00处差分非线性中的尖峰，ADC精度提升约0.5 ENOB。

- Increased the number of external ADC input channels from 4 to 8 channels, in the QFN-80 package only.

### 12.4.2. ADC controller

A digital controller manages the details of operating the RP2350 ADC, and provides additional functionality:

- One-shot or free-running capture mode
- Sample FIFO with DMA interface
- Pacing timer (16 integer bits, 8 fractional bits) for setting free-running sample rate
- Round-robin sampling of multiple channels in free-running capture mode
- Optional right-shift to 8 bits in free-running capture mode, so samples can be DMA'd to a byte buffer in system memory

#### 12.4.2.1. Channel connections

The ADC channels are connected to the following GPIOs in QFN-60

*Table 1118. ADC channel connections on QFN-60*

Channel	Connection
0	GPIO[26]
1	GPIO[27]
2	GPIO[28]
3	GPIO[29]
4	Temperature Sensor

The ADC channels are connected to the following GPIOs in QFN-80

*Table 1119. ADC channel connections on QFN-80*

Channel	Connection
0	GPIO[40]
1	GPIO[41]
2	GPIO[42]
3	GPIO[43]
4	GPIO[44]
5	GPIO[45]
6	GPIO[46]
7	GPIO[47]
8	Temperature Sensor

### 12.4.3. SAR ADC

The Successive Approximation Register Analogue to Digital Converter (SAR ADC) is a combination of digital controller and analogue circuit as shown in [Figure 109](#) and [Figure 110](#).

- 仅在QFN-80封装中，外部ADC输入通道数量由4个增加至8个。

### 12.4.2. ADC 控制器

数字控制器负责管理RP2350 ADC的操作细节，并提供以下附加功能：

- 单次触发或自由运行采样模式
- 具有DMA接口的采样FIFO
- 定时器（16位整数部分，8位小数部分）用于设置自由运行采样速率
- 自由运行采样模式下的多通道循环采样
- 自由运行采样模式中，采样数据可选择右移至8位，以便通过DMA传输至系统字节缓冲区内存

#### 12.4.2.1 通道连接

QFN-60中ADC通道对应的GPIO连接如下

表1118 QFN-60  
封装上的ADC通道  
连接

通道	连接
0	GPIO[26]
1	GPIO[27]
2	GPIO[28]
3	GPIO[29]
4	温度传感器

ADC通道连接至QFN-80封装中的以下GPIO端口

表1119。QFN-  
80封装上的ADC通  
道连接

通道	连接
0	GPIO[40]
1	GPIO[41]

3	GPIO[43]
4	GPIO[44]
5	GPIO[45]
6	GPIO[46]
7	GPIO[47]
8	温度传感器

### 12.4.3. SAR ADC

逐次逼近寄存器模拟-数字转换器（SAR ADC）是数字控制器与模拟电路的组合，如图109和图110所示。

Figure 109. SAR ADC  
Block diagram QFN-60

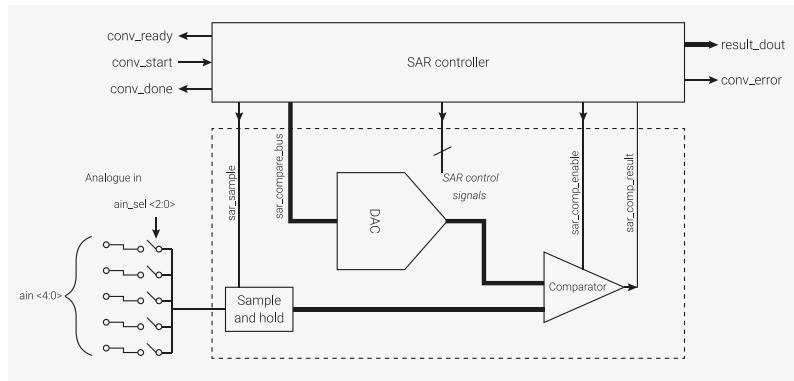

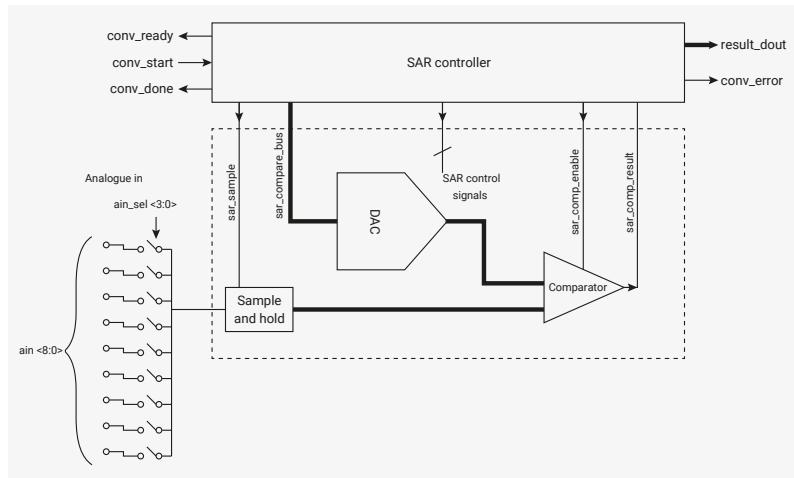

Figure 110. SAR ADC  
Block diagram QFN-80

The ADC requires a 48 MHz clock (`clk_adc`), which could come from the USB PLL. Capturing a sample takes 96 clock cycles ( $96 \times 1/48 \text{ MHz} = 2 \mu\text{s}$  per sample (500 kS/s). The clock must be set up correctly before enabling the ADC.

When the ADC block is provided with a clock, and its reset has been removed, writing a 1 to `CS.EN` will start a short internal power-up sequence for the ADC's analogue hardware. After a few clock cycles, `CS.READY` will go high, indicating the ADC is ready to start its first conversion.

To save power, you can disable the ADC at any time by clearing `CS.EN`. `CS.EN` does not enable the temperature sensor bias source; it is controlled separately, see [Section 12.4.6](#) for details.

The ADC input is capacitive. When sampling, the ADC places about 1pF across the input. Packaging, PCB routing, and other external factors introduce additional capacitance. The effective impedance, even when sampling at 500 kS/s, is over 100 kΩ. DC measurements have no need to buffer.

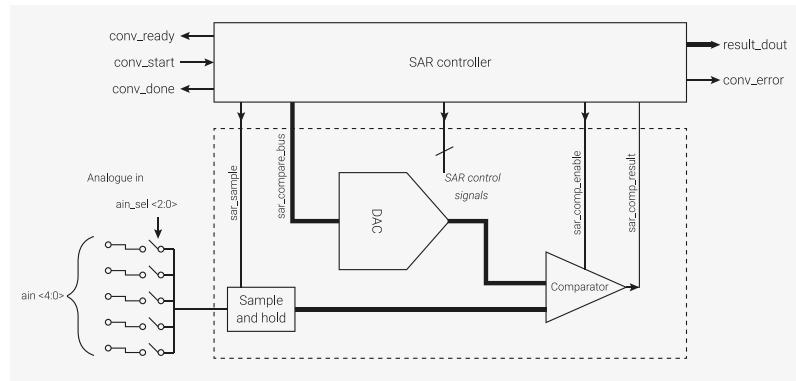

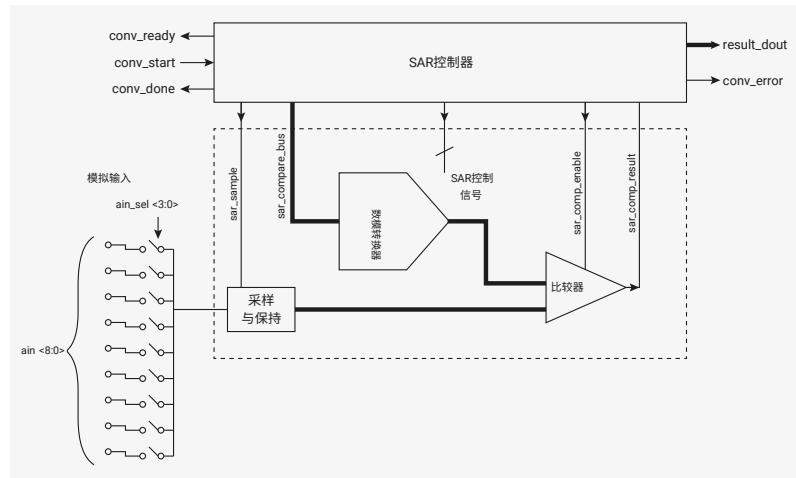

### 12.4.3.1. One-shot sample

To select an ADC input, write to `CS.AINSEL`:

- On QFN-60, there are 4 external inputs, with an `AINSEL` value of 0 → 3 mapping to the ADC input on GPIO26 → GPIO29. Set `AINSEL` to 4 to select the internal temperature sensor.
- On QFN-80, there are 8 external inputs, with an `AINSEL` value of 0 → 7 mapping to the ADC input on GPIO40 → GPIO47. Set `AINSEL` to 8 to select the internal temperature sensor.

Switching `AINSEL` requires no settling time.

Write a 1 to `CS.START_ONCE` to immediately start a new conversion. `CS.READY` will go low to show that a conversion is currently in progress. After 96 cycles of `clk_adc`, `CS.READY` will go high. The 12-bit conversion result is available in `RESULT`.

图109。SAR ADC  
方框图 QFN-60图110。SAR ADC  
方框图 QFN-80

ADC需要一个48 MHz时钟（`clk_adc`），该时钟可由USB PLL提供。采样过程需96个时钟周期（ $96 \times 1/48 \text{ MHz} = 2\text{微秒}$ 每样本（500 kS/s）。启用ADC前，必须正确设置时钟信号。

当ADC模块提供时钟且复位已解除时，向CS.EN写入1将启动ADC模拟硬件的短暂内部上电序列。经过几个时钟周期后，CS.READY将置高，表示ADC已准备好开始首次转换。

为节省功耗，您可随时通过清除CS.EN来禁用ADC。CS.EN不启用温度传感器偏置源；该偏置源由独立控制，详情请参见第12.4.6节。

ADC输入端为电容性。采样时，ADC在输入端并联约1pF电容。封装、PCB布线及其他外部因素会引入额外电容。即使在500 kS/s采样速率下，有效阻抗仍超过100 kΩ。直流测量无需缓冲。

### 12.4.3.1. 单次采样

要选择ADC输入，请写入CS.AINSEL：

- 在QFN-60封装上，有4个外部输入，AINSEL值为0→3对应GPIO26→GPIO29上的ADC输入。将AINSEL设置为4即选用内部温度传感器。
- 在QFN-80封装上，有8个外部输入，AINSEL值为0→7对应GPIO40→GPIO47上的ADC输入。将AINSEL设置为8即选用内部温度传感器。

切换AINSEL无需等待稳定时间。

向CS.START\_ONCE写入1以立即启动一次新的转换。CS.READY会拉低，表示转换正在进行。经过96个`clk_adc`周期后，CS.READY会拉高。12位转换结果可在RESULT中读取。

### 12.4.3.2. Free-running sampling

When `CS.START_MANY` is set, the ADC automatically starts new conversions at regular intervals. The most recent conversion result is always available in `RESULT`, but for IRQ or DMA-driven streaming of samples, you must enable the ADC FIFO ([Section 12.4.3.4](#)).

By default (`DIV` = 0), new conversions start immediately after the previous conversion finishes, producing a new sample every 96 cycles. At a clock frequency of 48 MHz, this produces 500 kS/s.

Set `DIV.INT` to a positive value `n` to trigger the ADC once per `n + 1` cycles. The ADC ignores this if a conversion is currently in progress, so generally `n` will be  $\geq 96$ . For example, setting `DIV.INT` to 47999 runs the ADC at 1 kS/s, if running from a 48 MHz clock.

The pacing timer supports fractional-rate division (first order delta sigma). When setting `DIV.FRAC` to a non-zero value,

the ADC starts a new conversion once per  $1 + \text{INT} + \frac{\text{FRAC}}{256}$  cycles on average, by changing the sample interval between `INT + 1` and `INT + 2`.

### 12.4.3.3. Sampling multiple inputs

`CS.RROBIN` allows the ADC to sample multiple inputs in an interleaved fashion while performing free-running sampling. Each bit in `RROBIN` corresponds to one of the five possible values of `CS.AINSEL`. When the ADC completes a conversion, `CS.AINSEL` automatically cycles to the next input whose corresponding bit is set in `RROBIN`.

To disable the round-robin sampling feature, write all-zeroes to `CS.RROBIN`.

For example, if `AINSEL` is initially 0, and `RROBIN` is set to 0x06 (bits 1 and 2 are set), the ADC samples channels in the following order:

1. Channel 0
2. Channel 1
3. Channel 2
4. Channel 1
5. Channel 2
6. Channel 1
7. Channel 2

The ADC continues to sample channels 1 and 2 indefinitely.

**NOTE**

The initial value of `AINSEL` does not need to correspond with a set bit in `RROBIN`.

### 12.4.3.4. Sample FIFO

You can read ADC samples directly from the `RESULT` register or store them in a local 8-entry FIFO and read out from `FIFO`. Use the `FCS` register to control FIFO operation.

When `FCS.EN` is set, the ADC writes each conversion result to the FIFO. A software interrupt handler or the RP2350 DMA can read this sample from the FIFO when notified by the ADC's `IRQ` or `DREQ` signals. Alternatively, software can poll the status bits in `FCS` to wait for each sample to become available.

If the FIFO is full when a conversion completes, the sticky error flag `FCS.OVER` is set. When the FIFO is full, the current FIFO contents do not change, so any conversions that complete during this time are lost.

Two flags control the data written to the FIFO by the ADC:

### 12.4.3.2. 自由运行采样模式

设置 CS.START\_MANY 后，ADC 会自动按照固定间隔启动新转换。最新的转换结果始终保存在RESULT中，但对于IRQ或DMA驱动的样本流，必须启用ADC FIFO（参见第12.4.3.4节）。

默认情况下（DIV = 0），新转换在前一次转换结束后立即启动，每96个周期产生一个新样本。在48 MHz时钟频率下，此设置产生500 kS/s的采样率。

将DIV.INT设置为正值 n以每 n+ 1个周期触发一次ADC转换。如果当前转换正在进行，ADC将忽略该设置，因此通常 n应≥ 96。例如，以48 MHz时钟运行时，将DIV.INT设置为47999可使ADC以1 kS/s速度运行。

节拍定时器支持分数速率分频（一阶增量调制）。当将DIV.FRAC设置为非零值时，

$$\text{ADC平均每 } \frac{1 + \text{INT} + \frac{\text{FRAC}}{256}}{256} \text{ 个周期启动一次新转换，通过改变采样间隔实现。}$$

介于 INT + 1 and INT + 2.

### 12.4.3.3. 采样多个输入

CS.RROBIN 允许 ADC 在执行自由运行采样时以轮询方式采样多个输入。

RROBIN 的每个位对应 CS.AINSEL 的五个可能值之一。当 ADC 完成转换后，CS.AINSEL 会自动切换至 RROBIN 中对应位被设置的下一个输入通道。

若要禁用轮询采样功能，请向 CS.RROBIN 写入全零值。

例如，若AINSEL 初始值为 0，且 RROBIN 设置为 0x06（即第1和第2位被设置），则 ADC 会按以下顺序采样通道：

1. 通道 0
2. 通道 1
3. 通道 2
4. 通道 1
5. 通道 2
6. 通道 1
7. 通道 2

ADC 会无限期持续采样通道 1 和通道 2。

#### 注意

AINSEL的初始值无需与RROBIN中的置位位对应。

### 12.4.3.4. FIFO示例

您可以直接从RESULT寄存器读取ADC样本，或将其存储在本地8条目的FIFO中，并从FIFO读取。使用FCS寄存器控制FIFO操作。

当FCS.EN被设置时，ADC会将每次转换结果写入FIFO。ADC通过 IRQ或 DREQ信号通知时，软件中断处理程序或RP2350 DMA可以从FIFO读取该样本。或者，软件可通过轮询FCS中的状态位等待每个样本可用。

若转换完成时FIFO已满，粘性错误标志FCS.OVER将被置位。FIFO满载时，当前内容保持不变，因此在此期间完成的任何转换结果将丢失。

有两个标志用于控制ADC写入FIFO的数据：

- [FCS.SHIFT](#) right-shifts the FIFO data to eight bits in size (i.e. FIFO bits 7:0 are conversion result bits 11:4). This is suitable for 8-bit DMA transfer to a byte buffer in memory, allowing deeper capture buffers, at the cost of some precision.
- [FCS.ERR](#) sets the [FIFO.ERR](#) flag of each FIFO value, showing that a conversion error took place, i.e. the SAR failed to converge.

Conversion errors indicate that the comparison of one or more bits failed to complete in the time allowed. Conversion errors are typically caused by comparator metastability: the closer to the comparator threshold the input signal is, the longer it takes to make a decision. The higher the comparator gain, the lower the probability of conversion errors.

#### CAUTION

Because conversion errors produce undefined results, you should always discard samples that contain conversion errors.

#### 12.4.3.5. DMA

The RP2350 DMA ([Section 12.6](#)) can fetch ADC samples from the sample FIFO, by performing a normal memory-mapped read on the [FIFO](#) register, paced by the [ADC\\_DREQ](#) system data request signal. Before you can use the DMA to fetch ADC samples, you must:

- Enable the sample FIFO ([FCS.EN](#)) so that samples are written to it; the FIFO is disabled by default so that it does not inadvertently fill when the ADC is used for one-shot conversions. Configure the ADC sample rate ([Section 12.4.3.2](#)) before starting the ADC.
- Enable the ADC's data request handshake ([DREQ](#)) via [FCS.DREQ\\_EN](#).
- In the DMA channel used for the transfer, select the [DREQ\\_ADC](#) data request signal ([Section 12.6.4.1](#)).
- Set the threshold for [DREQ](#) assertion ([FCS.THRESH](#)) to 1, so that the DMA transfers as soon as a single sample is present in the FIFO. This is also the threshold used for IRQ assertion, so non-DMA use cases might prefer a higher value for less frequent interrupts.
- If the DMA transfer size is set to 8 bits (so that the DMA transfers to a byte array in memory), set [FCS.SHIFT](#) to pre-shift the FIFO samples to 8 bits of significance.
- To sample multiple input channels, write a mask of those channels to [CS.RROBIN](#). Additionally, select the first channel to sample with [CS.AINSEL](#).

Once the ADC is suitably configured, start the DMA channel first, then the ADC conversion via [CS.START\\_MANY](#). Once the DMA completes, you can halt the ADC if you are finished sampling, or promptly start a new DMA transfer before the FIFO fills up. After clearing [CS.START\\_MANY](#) to halt the ADC, software should poll [CS.READY](#) to make sure the last conversion has finished, then drain any stray samples from the FIFO.

#### 12.4.3.6. Interrupts

Use [INTE](#) to generate an interrupt when the FIFO level reaches a threshold defined in [FCS.THRESH](#).

Use [INTS](#) to read the interrupt status. To clear the interrupt, drain the FIFO to a level lower than [FCS.THRESH](#).

#### 12.4.3.7. Supply

RP2350 separates the ADC supply out on its own pin to allow noise filtering.

- FCS.SHIFT将FIFO数据右移至8位大小（即FIFO的位7:0对应转换结果的位11:4）。该功能适用于向内存中的字节缓冲区执行8位DMA传输，从而实现更深层次的捕获缓冲区，代价是牺牲部分精度。

- FCS.ERR会设置每个FIFO值的FIFO.ERR标志，表明发生了转换错误，即SAR未能收敛。

转换错误表示一个或多个位的比较未能在规定时间内完成。转换错误通常由比较器亚稳态引起：输入信号越接近比较器阈值，做出决策所需时间越长。比较器增益越高，转换错误的概率越低。

#### 警告

由于转换错误会导致未定义结果，您应始终丢弃包含转换错误的样本。

#### 12.4.3.5. DMA

RP2350 DMA（见第12.6节）能够通过对FIFO寄存器执行正常的内存映射读取，从样本FIFO中获取ADC样本，该读取由 **AD\_C\_DREQ** 系统数据请求信号控制。在使用DMA获取ADC样本之前，您必须：

- 启用样本FIFO（FCS.EN），以便将样本写入其中；FIFO默认处于禁用状态，以防止在ADC用于单次转换时意外填满。在启动ADC之前，配置ADC采样率（第12.4.3.2节）。
- 通过FCS.DREQ\_EN启用ADC的数据请求握手（**DREQ**）。
- 在所用的DMA通道中，选择 **DREQ\_ADC** 数据请求信号（第12.6.4.1节）。
- 将 **DREQ** 断言阈值（FCS.THRESH）设置为1，使DMA在FIFO中存在单个样本时立即传输。此阈值同样用于IRQ断言，因此非DMA应用场景可能偏好设置较高值以降低中断频率。
- 如果DMA传输大小设置为8位（即DMA传输至内存中的字节数组），则需设置FCS.SHIFT以预移位FIFO样本至8位有效位。
- 要对多个输入通道进行采样，请将这些通道的掩码写入 CS.RROBIN。同时，使用 CS.AINSEL 选择第一个采样通道。

ADC配置完成后，先启动DMA通道，然后通过 CS.START\_MANY 启动ADC转换。DMA传输完成后，如采样结束，可停止ADC；否则，应在 FIFO 填满前立即启动新一轮DMA传输。清除 CS.START\_MANY 以停止ADC后，软件须轮询 CS.REady 以确认最后一次转换已完成，并清空 FIFO 中的任何残留样本。

#### 12.4.3.6. 中断

使用 INTE 以便在 FIFO 水平达到 FCS.THRESH 所定义的阈值时生成中断。

使用 INTS 读取中断状态。要清除中断，必须将 FIFO 排空至低于 FCS.THRESH 的水平。

#### 12.4.3.7. 电源

RP2350 将 ADC 电源引脚分离出来，以便进行噪声滤波。

#### 12.4.4. ADC ENOB

ADC ENOB details are shown in [Table 1438](#).

#### 12.4.5. INL and DNL

Details to follow.

#### 12.4.6. Temperature sensor

The temperature sensor measures the  $V_{be}$  voltage of a biased bipolar diode, connected to the fifth ADC channel ( $AINSEL=4$ ) on QFN-60 or the ninth ADC channel ( $AINSEL=8$ ) on QFN-80. Typically,  $V_{be} = 0.706$  V at 27 °C, with a slope of -1.721 mV per degree. Therefore the temperature in °C can be approximated as follows:

$$T = 27 - \frac{(ADC\_voltage - 0.706)}{0.001721}$$

As the  $V_{be}$  and the  $V_{be}$  slope can vary over the temperature range, and from device to device, some user calibration may be required if accurate measurements are required.

The temperature sensor's bias source must be enabled before use, via `CS.TS_EN`. This increases current consumption on `ADC_AVDD` by approximately 40 µA.

##### NOTE

The on board temperature sensor is very sensitive to errors in reference voltage. At 3.3 V, a value of 891 returned by the ADC corresponds to a temperature of 20.1°C. At a reference voltage 1% lower than 3.3 V, the same reading of 891 correspond to a temperature of 24.3°C: a temperature change of over 4°C. To improve the accuracy of the internal temperature sensor, consider adding an external reference voltage.

#### 12.4.7. List of registers

The ADC registers start at a base address of `0x400a0000` (defined as `ADC_BASE` in SDK).

Table 1120. List of ADC registers

Offset	Name	Info
0x00	<code>CS</code>	ADC Control and Status
0x04	<code>RESULT</code>	Result of most recent ADC conversion
0x08	<code>FCS</code>	FIFO control and status
0x0c	<code>FIFO</code>	Conversion result FIFO
0x10	<code>DIV</code>	Clock divider. If non-zero, <code>CS_START_MANY</code> will start conversions at regular intervals rather than back-to-back. The divider is reset when either of these fields are written. Total period is $1 + INT + FRAC / 256$
0x14	<code>INTR</code>	Raw Interrupts
0x18	<code>INTE</code>	Interrupt Enable
0x1c	<code>INTF</code>	Interrupt Force
0x20	<code>INTS</code>	Interrupt status after masking & forcing

#### 12.4.4. ADC ENOB

ADC 的有效位数（ENOB）详细信息见表 1438。

#### 12.4.5. INL 与 DNL

详细信息将随后提供。

#### 12.4.6. 温度传感器

温度传感器测量偏置双极性二极管的  $V_{be}$  电压，该二极管连接至 QFN-60 的第五 ADC 通道 ( $A_{INSEL}=4$ ) 或 QFN-80 的第九 ADC 通道 ( $A_{INSEL}=8$ )。通常， $V_{be}=0.706\text{ V}$  ( $27^\circ\text{C}$ )，斜率为每摄氏度  $-1.721\text{ mV}$ 。因此，温度（单位： $^\circ\text{C}$ ）可近似表示为：

$$T = 27 - \frac{(\text{ADC\_voltage} - 0.706)}{0.001721}$$

由于  $V_{be}$  及其斜率在不同温度范围内及不同器件间可能存在变化，如需准确测量，可能需要用户校准。

使用前必须通过 CS.TS\_EN 使能温度传感器的偏置电源，此举会使  $\text{ADC\_AVDD}$  的电流消耗增加约  $40\mu\text{A}$ 。

##### ① 注意

板载温度传感器对参考电压误差极为敏感。在  $3.3\text{ V}$  参考电压下，ADC 返回值 891 对应温度  $20.1^\circ\text{C}$ 。若参考电压比  $3.3\text{ V}$  低 1%，相同读数 891 对应温度将变为  $24.3^\circ\text{C}$ ，温差超过  $4^\circ\text{C}$ 。为提高内部温度传感器的准确度，建议添加外部参考电压。

#### 12.4.7. 寄存器列表

ADC 寄存器起始地址为  $0x400a0000$ （在 SDK 中定义为  $\text{ADC\_BASE}$ ）。

表1120.  
ADC寄存器列表

偏移量	名称	说明
0x00	CS	ADC控制与状态
0x04	RESULT	最近一次ADC转换结果
0x08	FCS	FIFO控制与状态
0x0c	FIFO	转换结果FIFO
0x10	DIV	时钟分频器。若非零，CS_START_MANY将在固定间隔而非连续启动转换。 写入任一字段时，分频器将被复位。 总周期为 $1 + \text{INT} + \text{FRAC} / 256$
0x14	中断	原始中断
0x18	INTE	中断使能
0x1c	INTF	中断触发
0x20	INTS	掩码与强制后的中断状态

## ADC: CS Register

## 12.5. PWM

## 12.5.1. Overview

Pulse width modulation (PWM) smoothly varies the average voltage of a digital signal using controlled-width positive pulses at regular intervals. The fraction of time spent high is known as the duty cycle. This may be used to approximate an analogue output or control switchmode power electronics.

The RP2350 PWM block has 12 identical slices. Each slice can drive two PWM output signals, or measure the frequency or duty cycle of an input signal. The two outputs on each slice have the same period, but independently varying duty cycles, so this gives a total of 24 controllable PWM outputs in the QFN-80 package.

**Figure 111.** A single PWM slice. A 16-bit counter counts from 0 up to some programmed value, and then wraps to zero, or counts back down again, depending on PWM mode. The A and B outputs transition high and low based on the current count value and the preprogrammed A and B thresholds. The counter advances based on a number of events: it may be free-running, or gated by level or edge of an input signal on the B pin. A fractional divider slows the overall count rate for finer control of output frequency.

Each PWM slice is equipped with the following:

- 16-bit counter
- 8.4 fractional clock divider
- Two independent output channels, duty cycle from 0% to 100% **inclusive**
- Dual slope and trailing edge modulation
- Edge-sensitive input mode for frequency measurement
- Level-sensitive input mode for duty cycle measurement
- Configurable counter wrap value
  - Wrap and level registers are double buffered and can be changed race-free while PWM is running
- Interrupt request and DMA request on counter wrap
- Phase can be precisely advanced or retarded while running (increments of one count)

Slices can be enabled or disabled simultaneously via a single global control register. Slices then run in lockstep, so that more complex power circuitry can be switched by the outputs of multiple slices.

### 12.5.1.1. Changes from RP2040

- Increased the number of slices from 8 to 12, with the 4 additional slices available on GPIOs 32 through 47 in the QFN-80 package.
- Added a second shared interrupt line (controlled by [IRQ1\\_INTE](#)), to aid use of PWM slices as simple repeating timers.

## 12.5.2. Programmer's model

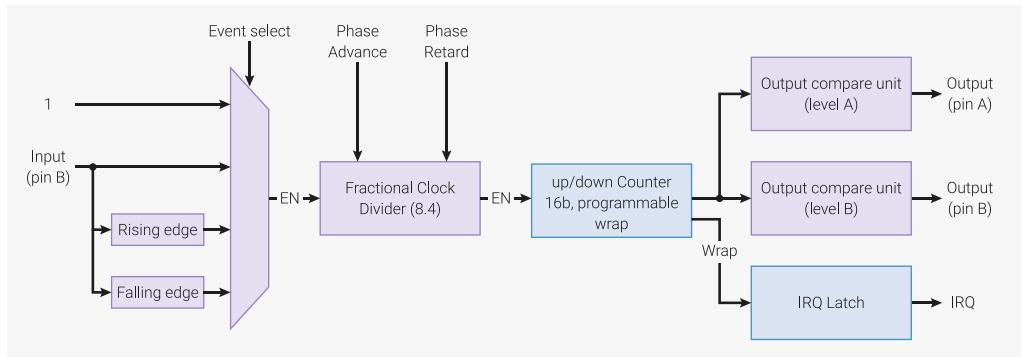

All GPIO pins on RP2350 can be used for PWM:

## 12.5.1. 概述

脉冲宽度调制（PWM）通过在规律间隔内使用受控宽度的正脉冲，平滑地调整数字信号的平均电压。高电平所占时间的比例称为占空比。这可用于近似模拟输出或控制开关式电源电子设备。

RP2350的PWM模块包含12个相同的切片。每个切片可驱动两个PWM输出信号，或测量输入信号的频率或占空比。每个切片的两个输出具有相同周期，但占空比独立变化，因此QFN-80封装中共计有24个可控PWM输出。

图111. 单个PWM切片。16位计数器从0计数至某个预设值后，根据PWM模式回绕至零，或反向计数。A和B输出根据当前计数值及预设的A和B阈值实现高低电平切换。计数器依据多种事件进行递增：可自由运行，亦可由B引脚输入信号的电平或边沿门控。分数除频器用于降低整体计数速率，以实现对输出频率的更精细控制。

每个 PWM 分片配备以下功能：

- 16 位计数器
- 8.4 分数时钟除频器
- 两个独立输出通道，占空比范围为 0% 至 100%（含）
- 双斜率及尾随边调制
- 用于频率测量的边沿敏感输入模式
- 用于占空比测量的电平敏感输入模式
- 可配置的计数器回绕值
  - 回绕与电平寄存器采用双缓冲设计，可在 PWM 运行时无竞争条件修改
- 计数器回绕时产生中断请求及 DMA 请求
- 运行期间可精确提前或延迟相位（按计数单位递增）

分片可通过单个全局控制寄存器同时启用或禁用分片随后以锁步模式运行，便于通过多个分片输出切换更复杂的电源电路。

### 12.5.1.1. 来自 RP2040 的变更

- 将切片数量从 8 个增加至 12 个，QFN-80 封装中新增的 4 个切片位于 GPIO 32 至 47。
- 新增第二条共享中断线（由 IRQ1\_INTE 控制），以辅助 PWM 切片作为简单重复计时器的使用。

## 12.5.2. 程序员模型

RP2350 上的所有 GPIO 引脚均可用于 PWM：

Table 1130. Mapping of PWM channels to GPIO pins on RP2350.  
This is also shown in the main GPIO function table, Table 646

GPIO	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
PWM Channel	0A	0B	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A	6B	7A	7B
GPIO	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
PWM Channel	0A	0B	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A	6B	7A	7B
GPIO	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
PWM Channel	8A	8B	9A	9B	10A	10B	11A	11B	8A	8B	9A	9B	10A	10B	11A	11B

- The first 16 PWM channels ( $8 \times 2$ -channel slices) appear on GPIOs 0 through 15, in the order **PWM0 A**, **PWM0 B**, **PWM1 A**, and so on.
- This pattern repeats for GPIOs 16 through 31. GPIO16 is **PWM0 A**, GPIO17 is **PWM0 B**, and so on up to **PWM7 B** on GPIO31. GPIO30 and above are available only in the QFN-80 package.
- The remaining 8 PWM channels ( $4 \times 2$ -channel slices) appear on GPIOs 32 through 39, and then repeat on GPIOs 40 through 47.
- If you select the same PWM output on two GPIO pins, the same signal appears on both.
- If you use **B** pin as an input and select it on multiple GPIO pins, the PWM slice sees the logical OR of those two GPIO inputs.

#### **NOTE**

GPIOs 0 through 29 have the same channel assignment as RP2040 for pinout compatibility. This reduces the maximum number of independent PWM outputs in the QFN-60 package option of RP2350, but you can still use slices 8 through 11 for repeating timer interrupts in this package.

### 12.5.2.1. Pulse width modulation (PWM)

The PWM hardware continuously compares an input value to a free-running counter. This produces a toggling output; the amount of time spent at the high output level corresponds to the input value. The fraction of time spent at the high signal level is known as the duty cycle of the signal.

The counting period is controlled by the **TOP** register, with a maximum possible period of 65536 cycles, as the counter and **TOP** are 16 bits in size. Use the **CC** register to configure input values.

表 1130。RP2350 上 PWM 通道与 GPIO 引脚的映射。  
该映射亦显示于主 GPIO 功能表，表 646。

GPIO	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
PWM 通道	0A	0B	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A	6B	7A	7B
GPIO	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
PWM 通道	0A	0B	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A	6B	7A	7B
GPIO	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
PWM 通道	8A	8B	9A	9B	10A	10B	11A	11B	8A	8B	9A	9B	10A	10B	11A	11B

- 前16个PWM通道（8个2通道切片）依次显示于GPIO0至GPIO15，顺序为 **PWM0 A**、**PWM0 B**、**PWM1 A**，依此类推。
- 该排列在GPIO16至GPIO31之间重复。GPIO16对应**PWM0 A**，GPIO17对应**PWM0 B**，依此类推至GPIO31的**PWM7 B**。GPIO30及以上仅在QFN-80封装中支持。
- 剩余8个PWM通道（4个2通道切片）分布于GPIO32至GPIO39，并在GPIO40至GPIO47上重复出现。
- 如果您在两个GPIO引脚上选择相同的PWM输出，则两个引脚上的信号相同。
- 如果您使用 **B**引脚作为输入并在多个GPIO引脚上选择该引脚，PWM切片将感知这两个GPIO输入的逻辑或。

### ① 注意

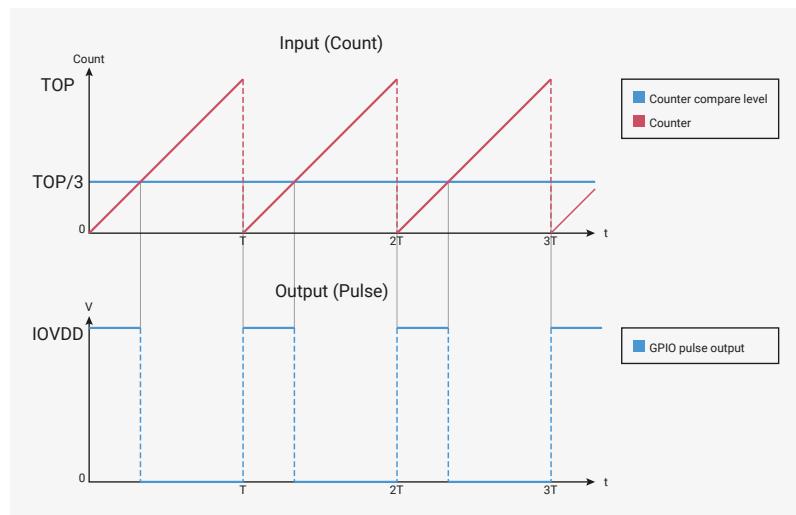

GPIO0至GPIO29的通道分配与RP2040相同，以保证引脚兼容性。这减少了RP2350 QFN-60封装选项中独立PWM输出的最大数量，但在此封装中，您仍可使用切片8至11实现定时器中断的重复。

#### 12.5.2.1. 脉宽调制 (PWM)

PWM硬件持续比较输入值与自由运行计数器的计数值。由此产生切换输出；高电平输出的持续时间与输入值相对应。高电平信号持续时间占总时间的比例称为信号的占空比。

计数周期由 **TOP**寄存器控制，最大周期为65536个计数周期，因计数器和 **TOP**寄存器均为16位。使用 **CC**寄存器配置输入值。

Figure 112. The counter repeatedly counts from 0 to TOP, forming a sawtooth shape. The counter is continuously compared with some input value. When the input value is higher than the counter, the output is driven high. Otherwise, the output is low. The output period T is defined by the TOP value of the counter, and how fast the counter is configured to count. The average output voltage, as a fraction of the IO power supply, is the input value divided by the counter period ( $TOP + 1$ )

This example shows the counting period and the A and B counter compare levels being configured on one of RP2350's PWM slices.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pwm/hello\\_pwm/hello\\_pwm.c](https://github.com/raspberrypi/pico-examples/blob/master/pwm/hello_pwm/hello_pwm.c) Lines 14 - 29

```

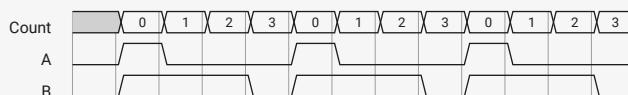

14 // Tell GPIO 0 and 1 they are allocated to the PWM
15 gpio_set_function(0, GPIO_FUNC_PWM);
16 gpio_set_function(1, GPIO_FUNC_PWM);
17
18 // Find out which PWM slice is connected to GPIO 0 (it's slice 0)
19 uint slice_num = pwm_gpio_to_slice_num(0);
20
21 // Set period of 4 cycles (0 to 3 inclusive)
22 pwm_set_wrap(slice_num, 3);
23 // Set channel A output high for one cycle before dropping
24 pwm_set_chan_level(slice_num, PWM_CHAN_A, 1);
25 // Set initial B output high for three cycles before dropping
26 pwm_set_chan_level(slice_num, PWM_CHAN_B, 3);
27 // Set the PWM running
28 pwm_set_enabled(slice_num, true);

```

Figure 113 shows how the PWM hardware operates once it has been configured.

Figure 113. The slice counts repeatedly from 0 to 3, which is configured as the TOP value. The output waves therefore have a period of 4. Output A is high for 1 cycle in 4, so the average output voltage is 1/4 of the IO supply voltage.

Output B is high for 3 cycles in every 4. The rising edges of A and B are always aligned.

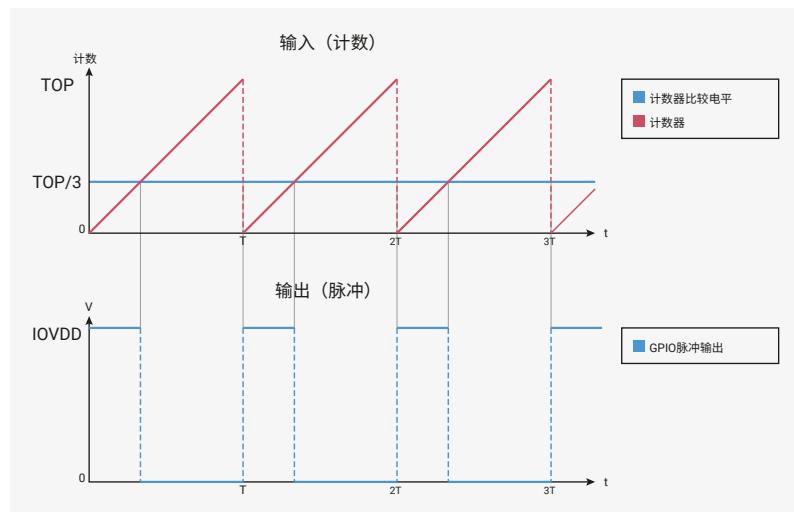

By default, PWM slices count upward until they reach the value of the TOP register. After they reach the TOP value, they wrap to 0. Alternatively, set **CSR\_PH\_CORRECT** to 1 to enable **phase-correct mode**, where the counter counts downward after reaching TOP, until it reaches 0 again.

Phase-correct mode centres the pulse on the same point no matter the duty cycle; its phase is not a function of duty cycle. When phase-correct mode is enabled, the output frequency is halved. The slice spends two cycles at a count of TOP and two cycles at a count of 0 each PWM period.

图112。计数器重复从0计数到TOP，形成锯齿波形。计数器持续与某输入值进行比较。当输入值高于计数器时，输出为高电平。

否则，输出为低电平。输出周期 $T$ 由计数器的TOP值及计数速度决定。

平均输出电压（占IO电源电压的比例）等于输入值除以计数周期 $(TOP + 1)$ 。

本示例演示了在RP2350的一个PWM切片上配置计数周期以及A、B计数比较电平。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pwm/hello\\_pwm/hello\\_pwm.c](https://github.com/raspberrypi/pico-examples/blob/master/pwm/hello_pwm/hello_pwm.c) 第14行至第29行

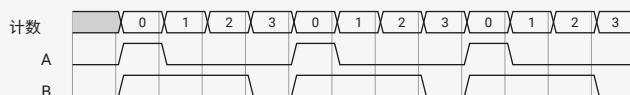

```

14 // 指示GPIO 0和1分配给PWM功能
15 gpio_set_function(0, GPIO_FUNC_PWM);
16 gpio_set_function(1, GPIO_FUNC_PWM);
17
18 // 查询连接到GPIO 0的PWM切片编号 (为切片0)
19 uint slice_num = pwm_gpio_to_slice_num(0);
20
21 // 设定计数周期为4 (含0至3)
22 pwm_set_wrap(slice_num, 3);
23 // 设置通道A输出高电平持续1个周期后降低
24 pwm_set_chan_level(slice_num, PWM_CHAN_A, 1);
25 // 在下降之前将初始B输出设置为高电平，持续三个周期
26 pwm_set_chan_level(slice_num, PWM_CHAN_B, 3);
27 // 启动PWM
28 pwm_set_enabled(slice_num, true);

```

图113展示了配置完成后的PWM硬件运行情况。

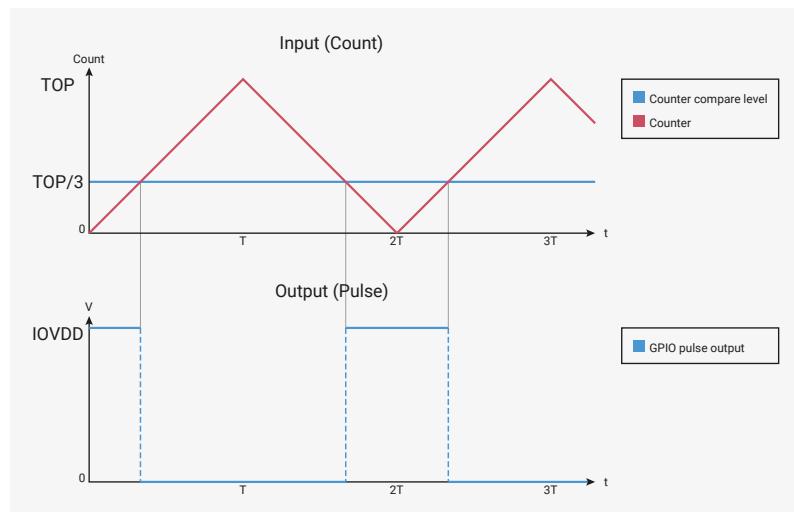

图113。该片段计数器反复从0计数至3，该值被设置为TOP。因此输出波形的周期为4。输出A在4个周期中高电平持续1个周期，故平均输出电压为IO供电电压的1/4。

默认情况下，PWM片段计数器向上计数，直到达到TOP寄存器的数值。达到TOP数值后，计数器回绕至0。或者，将CSR\_P\_H\_CORRECT设置为1以启用相位校正模式，在该模式下计数器在达到TOP后向下计数，直至再次达到0。

输出B在每4个周期中高电平持续3个周期。A和B的上升沿始终保持同步。

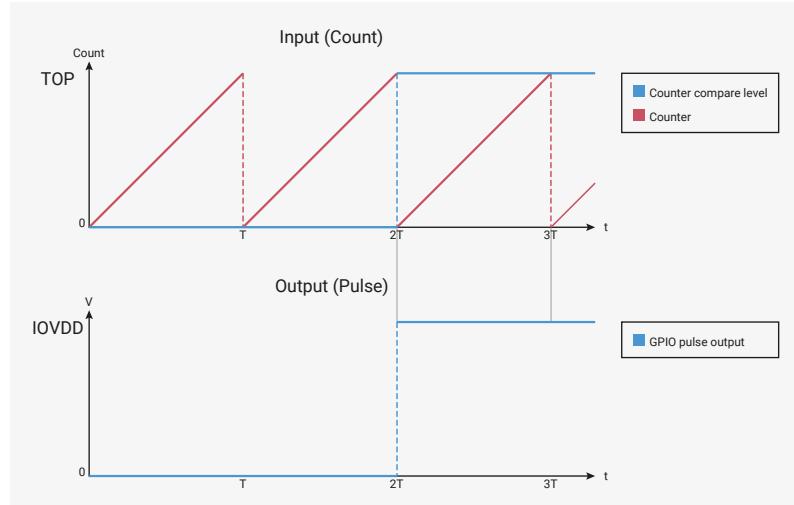

Figure 114. In phase-correct mode, the counter counts back down from TOP to 0 once it reaches TOP.

### 12.5.2.2. 0% and 100% Duty Cycle

The RP2350 PWM can produce toggle-free 0% and 100% duty cycle output.

Figure 115. Glitch-free 0% duty cycle output for CC = 0, and glitch-free 100% duty cycle output for CC = TOP + 1

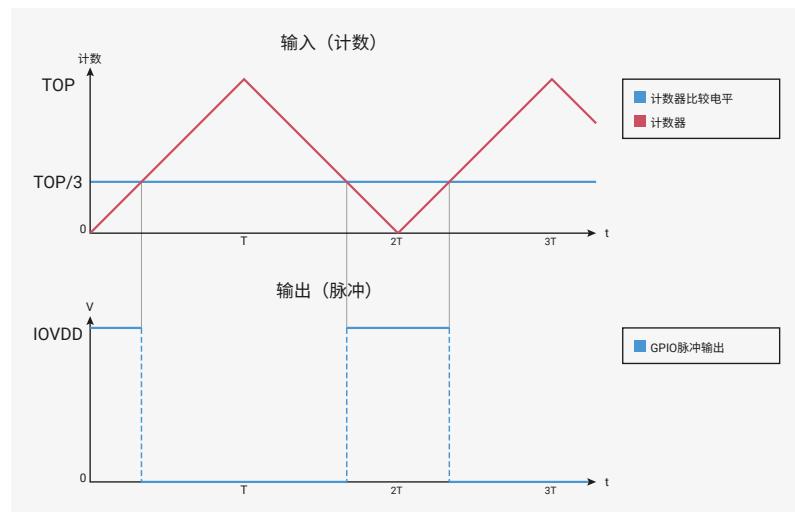

A **CC** value of 0 produces a 0% output: the output signal is always low. A **CC** value of **TOP** + 1 (equal to the period when not phase-corrected) produces a 100% output. If **TOP** is 254, the counter has a period of 255 cycles, and **CC** values in the range of 0 to 255 inclusive will produce duty cycles in the range 0% to 100% inclusive.

Glitch-free output at 0% and 100% helps avoid switching losses, for instance, when a MOSFET is controlled at its minimum and maximum current levels.

### 12.5.2.3. Double buffering

Figure 116 shows how a change in input value produces a change in output duty cycle. This can approximate analogue waveforms such as a sine wave.

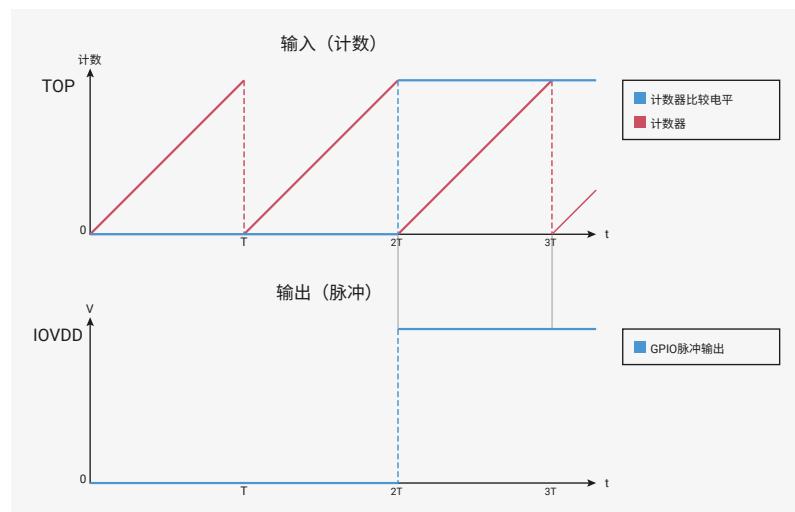

图114。在相位校正模式下，计数器达到TOP后，将从TOP向0倒计数。

### 12.5.2.2. 0%与100%占空比

RP2350 PWM能够产生无跳变的0%与100%占空比输出。

图115。当CC=0时，输出为无波动的0%占空比；当CC=TOP + 1时，输出为无波动的100%占空比。  
1

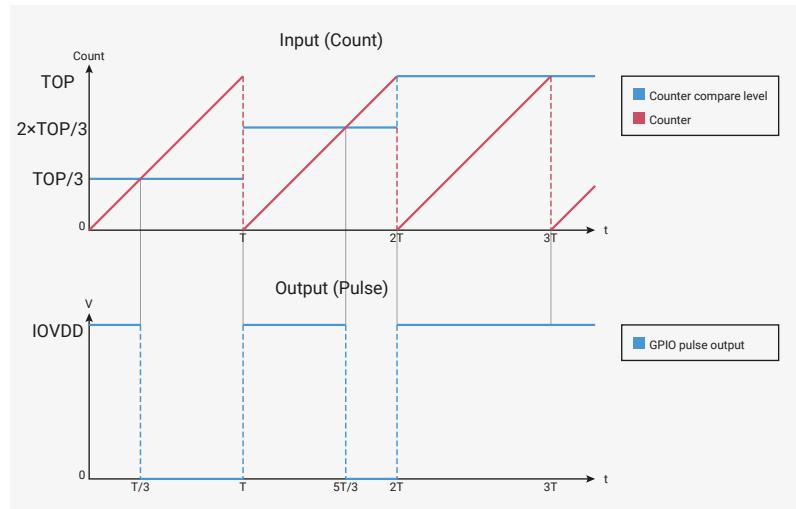

CC值为0产生0%输出：输出信号始终为低电平。CC值为TOP + 1（对应非相位校正时的周期）产生100%输出。如果 TOP为254，则计数器周期为255个计数，且 CC值在0至255（含）范围内将生成占空比在0%至100%（含）范围内。

在0%和100%时实现无毛刺输出，有助于避免开关损耗，例如当MOSFET被控制在其最小和最大电流等级时。

### 12.5.2.3. 双缓冲

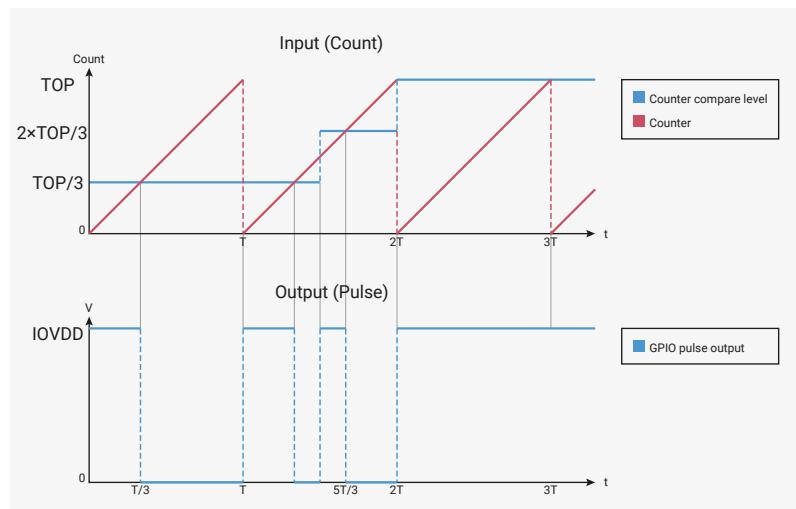

图116显示输入值变化如何引起输出占空比的变化。此方法可近似模拟波形，如正弦波。

**Figure 116.** The input value varies with each counter period: first  $\text{TOP}/3$ , then  $2 \times \text{TOP}/3$ , and finally  $\text{TOP} + 1$  for 100% duty cycle. Each increase in the input value causes a corresponding increase in the output duty cycle.

In Figure 116, the input value only changes at the instant where the counter wraps through 0. Figure 117 shows what happens if the input value is allowed to change at any other time: an unwanted glitch is produced at the output.

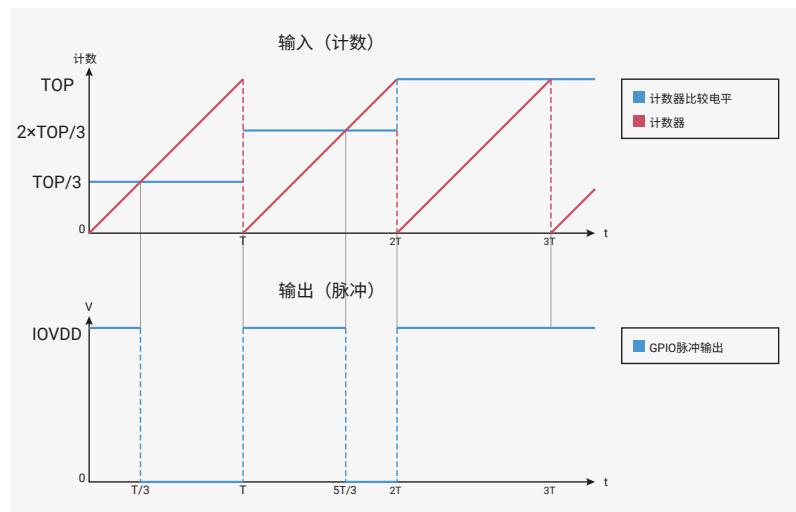

**Figure 117.** The input value changes whilst the counter is mid-ramp. This produces additional toggling at the output.

The behaviour becomes even more perplexing if the `TOP` register is also modified. It would be difficult for software to write to `CC` or `TOP` with the correct timing. To solve this, each slice has two copies of the `CC` and `TOP` registers: one copy that software can modify, and another, internal copy that is updated from the first register at the instant the counter wraps. Software can modify its copy of the register at will, but the changes are not captured by the PWM output until the next wrap.

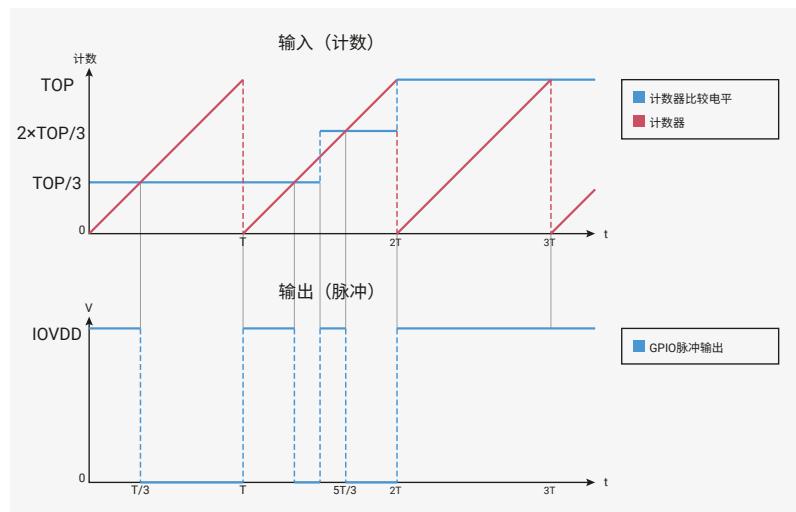

Figure 118 shows the sequence of events where a software interrupt handler changes the value of `CC_A` each time the counter wraps.

图116。输入值随每个计数周期变化：依次为 $TOP/3$ 、 $2 \times TOP/3$ ，最后为 $TOP + 1$ ，对应100%的占空比。  
输入值的每次增加都会导致输出占空比的相应增加。

在图116中，输入值仅在计数器绕回至0的瞬间发生变化。图117展示了如果允许输入值在其他时间变化时，输出端将产生不期望的毛刺。

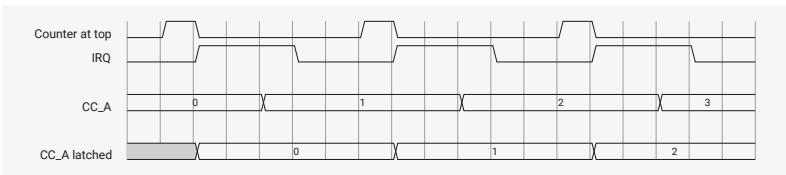

图117。输入值在计数器处于中间斜坡阶段时发生变化。这会导致输出端产生额外的跳变。

若同时修改 `TOP` 寄存器，行为将更加复杂难以分析。软件难以在准确时刻写入 `CC` 或 `TOP` 寄存器。为解决此问题，每个切片设有两份 `CC` 和 `TOP` 寄存器：一份供软件修改，另一份为内部副本，在计数器绕回时由第一份寄存器更新。软件可以自由修改自身寄存器副本，但 PWM 输出直到下一次绕回才应用这些更改。

图118展示了软件中断处理程序在每次计数器绕回时更改 `CC_A` 值的事件序列。

Figure 118. Each counter wrap causes the interrupt request signal to assert. The processor enters its interrupt handler, writes to its copy of the CC register, and clears the interrupt. When the counter wraps again, the latched version of the CC register is instantaneously updated with the most recent value written by software, and this value controls the duty cycle for the next period. The IRQ is reasserted so that software can write another fresh value to its copy of the CC register.

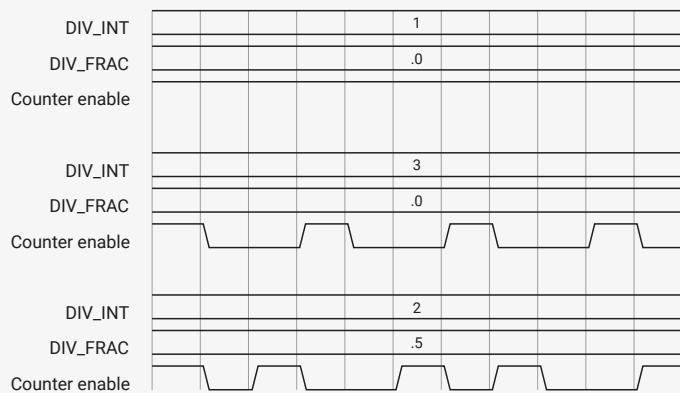

There is no limitation on what values can be written to **CC** or **TOP**, or when they are written. In normal PWM mode (**CSR\_PH\_CORRECT** is 0), the latched copies update when the counter wraps to 0, which occurs once every **TOP + 1** cycles. In phase-correct mode (**CSR\_PH\_CORRECT** is 1), the latched copies update on the 0 to 0 count transition, when the counter stops counting downward and begins to count upward again.

#### 12.5.2.4. Clock divider

Each slice has a 8 integer bit, 4 fractional bit fractional clock divider configured by the **DIV** register. The clock divider allows you to slow the count rate by a factor of up to 256. To do this, the PWM generates an enable signal that gates counter operation. This allows you to achieve output frequencies significantly lower than the system clock. For instance, from a 125MHz system clock, the clock divider can slow the count rate to approximately 7.5Hz. Lower frequencies than this require a system timer interrupt (Section 12.8).

Figure 119. The clock divider generates an enable signal. The counter only counts on cycles where this signal is high. A clock divisor of 1 causes the enable to be asserted on every cycle, so the counter counts by one on every system clock cycle. Higher divisors cause the count enable to be asserted less frequently. Fractional division achieves an average fractional counting rate by spacing some enable pulses further apart than others.

The fractional divider is a first-order delta-sigma type.

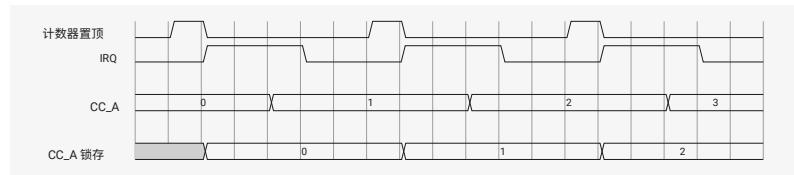

The clock divider also extends the effective count range when using level-sensitive or edge-sensitive modes to take duty cycle or frequency measurements.

#### 12.5.2.5. Level-sensitive and edge-sensitive triggering

The PWM provides the following counter modes:

- Default free-running, counting continuously whenever the slice is enabled (free-running)
- Count continuously when a high level is detected on the B pin (level sensitive)
- Count once with each rising edge detected on the B pin (rising edge-sensitive)
- Count once with each falling edge detected on the B pin (falling edge-sensitive)

图118。每次计数器循环都会触发中断请求信号置位。处理器进入中断处理程序，写入其CC寄存器副本，并清除中断。

计数器再次循环时，CC寄存器的锁存副本会瞬间更新为软件写入的新数值，该数值控制下一周期的占空比。IRQ信号被重新置位，以便软件向其CC寄存器副本写入新的数值。

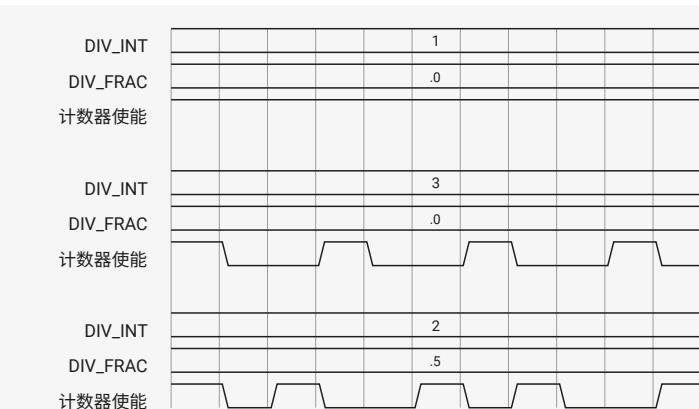

对CC或TOP的写入数值及时间不受限制。在正常PWM模式下（当CSR\_PH\_CORRECT为0时），锁存副本在计数器循环至0时更新，该过程每TOP+1个周期发生一次。在相位校正模式下（CSR\_PH\_CORRECT为1），锁存副本会在计数从0回到0的转换时更新，即计数器停止向下计数并开始向上计数时。

#### 12.5.2.4. 时钟分频器

每个切片包含一个由DIV寄存器配置的8位整数部分和4位小数部分的分数时钟分频器。时钟分频器允许您将计数速率降低最多256倍。为此，PWM会生成一个使能信号以控制计数器的运行。这使您能够实现远低于系统时钟的输出频率。例如，对于125MHz的系统时钟，时钟分频器可将计数速率降低至约7.5Hz。低于此频率则需要系统定时器中断（参见第12.8节）。

图119。时钟分频器生成使能信号。计数器仅在该信号为高电平时的周期内计数。分频值为1时，使能信号在每个周期均被断言，计数器在每个系统时钟周期内计数加一。更高的分频值会减少计数使能信号断言的频率。

分数除法通过拉长某些使能脉冲间隔，实现平均分数计数率。

分数分频器为一阶 $\Delta$ - $\Sigma$ 型。

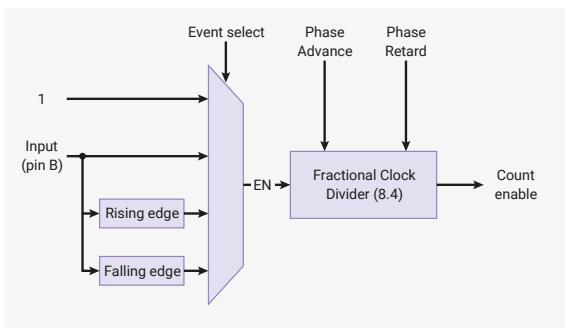

时钟分频器在采用电平敏感或边沿敏感模式进行占空比或频率测量时，可扩展有效计数范围。

#### 12.5.2.5. 电平敏感与边沿敏感触发

PWM 提供以下计数模式：

- 默认自由运行模式，片段启用时持续计数（自由运行）
- 当B引脚为高电平时持续计数（电平敏感）
- 对B引脚的每个上升沿计数一次（上升沿敏感）
- 对B引脚的每个下降沿计数一次（下降沿敏感）

Figure 120. PWM slice event selection. The counter advances when its enable input is high. This enable is generated by two sequential stages. First, any one of four event types (always on, pin B high, pin B rise, pin B fall) can generate enable pulses for the fractional clock divider. The divider can reduce the rate of the enable pulses, before passing them on to the counter.

Use the `DIVMODE` field in each slice's `CSR` to select a mode. In free-running mode, the A and B pins are both outputs. In any other mode, the B pin becomes an input that controls counter operation. `CC_B` is ignored when not in free-running mode.

You can measure the duty cycle or frequency of an input signal by running the slice for a fixed amount of time in level-sensitive or edge-sensitive mode. Due to the type of edge-detect circuit used, the low period and high period of the measured signal must both be strictly greater than the system clock period when taking frequency measurements.

The clock divider still operates in level-sensitive and edge-sensitive modes. At maximum division (`DIV_INT` is 0), the counter only advances once per 256 high input cycles in level-sensitive modes, or once per 256 edges in edge-sensitive mode. This allows you to take longer-running measurements, although the resolution is still 16 bits.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pwm/measure\\_duty\\_cycle/measure\\_duty\\_cycle.c](https://github.com/raspberrypi/pico-examples/blob/master/pwm/measure_duty_cycle/measure_duty_cycle.c) Lines 19 - 37

```

19 float measure_duty_cycle(uint gpio) {
20 // Only the PWM B pins can be used as inputs.
21 assert(pwm_gpio_to_channel(gpio) == PWM_CHAN_B);
22 uint slice_num = pwm_gpio_to_slice_num(gpio);
23
24 // Count once for every 100 cycles the PWM B input is high
25 pwm_config cfg = pwm_get_default_config();
26 pwm_config_set_clkdiv_mode(&cfg, PWM_DIV_B_HIGH);
27 pwm_config_set_clkdiv(&cfg, 100);
28 pwm_init(slice_num, &cfg, false);
29 gpio_set_function(gpio, GPIO_FUNC_PWM);
30
31 pwm_set_enabled(slice_num, true);
32 sleep_ms(10);
33 pwm_set_enabled(slice_num, false);
34 float counting_rate = clock_get_hz(clk_sys) / 100;
35 float max_possible_count = counting_rate * 0.01;
36 return pwm_get_counter(slice_num) / max_possible_count;
37 }

```

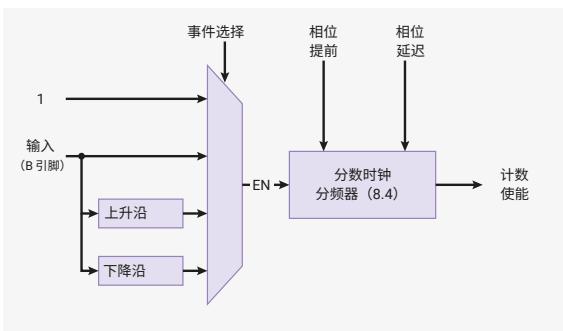

### 12.5.2.6. Configuring PWM period

When free-running, use the following three parameters to control the period of a PWM slice's output (measured in system clock cycles):

- The `TOP` register, which controls the maximum value of the counting period
- The `CSR_PH_CORRECT` bit, which enables phase-correct mode
- The `DIV` register, which controls the clock divider

The slice counts from 0 to `TOP`, then either wraps or begins counting backward, depending on the setting of `CSR_PH_CORRECT`. The clock divider slows the rate of counting, with a maximum speed of one count per cycle, and a minimum speed of one count per 256 cycles. Calculate the period in clock cycles with the following equation:

图120。 PWM 片段事件选择。当使能输入为高电平时，计数器递增。该使能信号由两个连续级产生。  
首先，四种事件类型中的任意一种（始终开启、引脚 B 为高电平、引脚 B 上升沿、引脚 B 下降沿）都可为分数时钟分频器生成使能脉冲。分频器可降低使能脉冲的频率，然后将其传递至计数器。

请使用各片段 CSR 中的 DIVMODE 字段选择模式。在自由运行模式下，A 和 B 引脚均为输出。在其他任何模式下，B 引脚变为控制计数器操作的输入。非自由运行模式下，CC\_B 信号被忽略。

您可以通过在电平敏感或边沿敏感模式下，使片段运行固定时间来测量输入信号的占空比或频率。由于所采用的边沿检测电路类型，频率测量时，被测信号的低电平周期和高电平周期均须严格大于系统时钟周期。

时钟分频器仍以电平敏感和边沿敏感模式运行。在最大分频 (DIV\_INT 为 0) 情况下，计数器仅在电平敏感模式下的每 256 个高电平输入周期，或边沿敏感模式下的每 256 个边沿时递增一次。这使您能够进行更长时间的测量，尽管分辨率仍保持 16 位。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pwm/measure\\_duty\\_cycle/measure\\_duty\\_cycle.c](https://github.com/raspberrypi/pico-examples/blob/master/pwm/measure_duty_cycle/measure_duty_cycle.c) 第 19 至 37 行

```

19 float measure_duty_cycle(uint gpio) {
20 // 仅 PWM 通道 B 的引脚可用作输入。
21 assert(pwm_gpio_to_channel(gpio) == PWM_CHAN_B);
22 uint slice_num = pwm_gpio_to_slice_num(gpio);
23
24 // PWM 通道 B 输入高电平的每 100 个周期计数一次
25 pwm_config cfg = pwm_get_default_config();
26 pwm_config_set_clkdiv_mode(&cfg, PWM_DIV_B_HIGH);
27 pwm_config_set_clkdiv(&cfg, 100);
28 pwm_init(slice_num, &cfg, false);
29 gpio_set_function(gpio, GPIO_FUNC_PWM);
30
31 pwm_set_enabled(slice_num, true);
32 sleep_ms(10);
33 pwm_set_enabled(slice_num, false);
34 float counting_rate = clock_get_hz(clk_sys) / 100;
35 float max_possible_count = counting_rate * 0.01;
36 return pwm_get_counter(slice_num) / max_possible_count;
37 }

```

### 12.5.2.6 配置 PWM 周期

在自由运行模式下，使用以下三个参数控制 PWM 切片输出的周期（以系统时钟周期计）：

- TOP 寄存器，用于控制计数周期的最大值
- CSR\_PH\_CORRECT 位，用于启用相位校正模式
- DIV 寄存器，用于控制时钟分频

切片从 0 计数至 TOP，随后根据 CSR\_PH\_CORRECT 设置，或回绕，或开始反向计数。时钟分频器降低计数速率，最大速度为每个周期计数一次，最小速度为每 256 个周期计数一次。使用以下公式计算时钟周期中的周期数：

$$\text{period} = (\text{TOP} + 1) \times (\text{CSR\_PH\_CORRECT} + 1) \times \left( \text{DIV\_INT} + \frac{\text{DIV\_FRAC}}{16} \right)$$

To determine the output frequency based on the system clock frequency, use the following equation:

$$f_{PWM} = \frac{f_{sys}}{\text{period}} = \frac{f_{sys}}{(\text{TOP} + 1) \times (\text{CSR\_PH\_CORRECT} + 1) \times \left( \text{DIV\_INT} + \frac{\text{DIV\_FRAC}}{16} \right)}$$

Set `DIV_INT` to 0 to divide the count rate by the maximum possible value of 256. You must not set any `DIV_FRAC` bits when `DIV_INT` is 0.

### 12.5.2.7. Interrupt Request (IRQ) and DMA Data Request (DREQ)

The PWM block has two IRQ outputs. The interrupt status registers `INTR`, `INTS0`, `INTS1`, `INTE0` and `INTE1` allow software to:

- Control which slices assert each of the two IRQs
- Check which slices caused the assertion of an IRQ
- Clear and acknowledge the interrupt

A slice generates an interrupt request each time its counter wraps (or, in phase-correct mode, each time the counter returns to 0). This sets the flag corresponding to this slice in the raw interrupt status register, `INTR`. If this slice's interrupt is enabled in `INTE`, this flag causes the PWM block's IRQ to be asserted, and the flag also appears in the masked interrupt status register `INTS`.

To clear flags, write a mask back to `INTR`. This is demonstrated in the LED fade SDK example below:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/pwm/led\\_fade/pwm\\_led\\_fade.c](https://github.com/raspberrypi/pico-examples/blob/master/pwm/led_fade/pwm_led_fade.c)

```

4 * SPDX-License-Identifier: BSD-3-Clause
5 */
6
7 // Fade an LED between low and high brightness. An interrupt handler updates
8 // the PWM slice's output level each time the counter wraps.
9
10 #include "pico/stdc.h"
11 #include <stdio.h>
12 #include "pico/time.h"
13 #include "hardware/irq.h"
14 #include "hardware/pwm.h"
15
16 void on_pwm_wrap() {
17 static int fade = 0;
18 static bool going_up = true;
19 // Clear the interrupt flag that brought us here
20 pwm_clear_irq(pwm_gpio_to_slice_num(PICO_DEFAULT_LED_PIN));
21
22 if (going_up) {
23 ++fade;
24 if (fade > 255) {
25 fade = 255;
26 going_up = false;
27 }
28 } else {
29 --fade;
30 if (fade < 0) {
31 fade = 0;
32 going_up = true;
33 }
34 }
35 }
```

$$\text{period} = (\text{TOP} + 1) \times (\text{CSR\_PH\_CORRECT} + 1) \times \left( \text{DIV\_INT} + \frac{\text{DIV\_FRAC}}{16} \right)$$

根据系统时钟频率确定输出频率，请使用以下公式：

$$f_{PWM} = \frac{f_{sys}}{\text{period}} = \frac{f_{sys}}{(\text{TOP} + 1) \times (\text{CSR\_PH\_CORRECT} + 1) \times \left( \text{DIV\_INT} + \frac{\text{DIV\_FRAC}}{16} \right)}$$

将 `DIV_INT` 设置为 0，以将计数速率分频至最大值 256。当 `DIV_INT` 为 0 时，不得设置任何 `DIV_FRAC` 位。

### 12.5.2.7. 中断请求 (IRQ) 与DMA数据请求 (DREQ)

PWM 模块具有两个 IRQ 输出端口。中断状态寄存器 `INTR`、`INTS0`、`INTS1`、`INTE0` 和 `INTE1` 允许软件：

- 控制各切片触发两个 IRQ 之一
- 检查导致 IRQ 触发的切片
- 清除并确认中断

每当计数器回绕（或在相位校正模式下，计数器返回至 0）时，切片将生成中断请求。该操作会在原始中断状态寄存器 `INT_R` 中设置对应于此片段的标志位。如果该片段的中断在 `INTE` 中已启用，则此标志将触发 PWM 模块的 IRQ，同时该标志也会出现在屏蔽中断状态寄存器 `INTS` 中。

要清除标志，请向 `INTR` 写入掩码值。如下 LED 渐变 SDK 示例所示：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/pwm/led\\_fade/pwm\\_led\\_fade.c](https://github.com/raspberrypi/pico-examples/blob/master/pwm/led_fade/pwm_led_fade.c)

```

7 // 在低亮度与高亮度之间渐变 LED。中断处理程序会更新
8 // 计数器每次回绕时 PWM 片段的输出电平。
9
10 #include "pico/stdc.h"
11 #include <stdio.h>
12 #include "pico/time.h"
13 #include "hardware/irq.h"
14 #include "hardware/pwm.h"
15
16 void on_pwm_wrap() {
17 static int fade = 0;
18 static bool going_up = true;
19 // 清除导致中断的标志
20 pwm_clear_irq(pwm_gpio_to_slice_num(PICO_DEFAULT_LED_PIN));
21
22 if (going_up) {
23 ++fade;
24 if (fade > 255) {
25 fade = 255;
26 going_up = false;
27 }
28 } else {
29 --fade;
30 if (fade < 0) {
31 fade = 0;
32 going_up = true;
33 }
34 }
35 }
```

```

33 }
34 }
35 // Square the fade value to make the LED's brightness appear more linear
36 // Note this range matches with the wrap value
37 pwm_set_gpio_level(PICO_DEFAULT_LED_PIN, fade * fade);
38 }
39
40 int main() {
41 #ifndef PICO_DEFAULT_LED_PIN
42 #warning pwm/led_fade example requires a board with a regular LED
43 #else
44 // Tell the LED pin that the PWM is in charge of its value.
45 gpio_set_function(PICO_DEFAULT_LED_PIN, GPIO_FUNC_PWM);
46 // Figure out which slice we just connected to the LED pin
47 uint slice_num = pwm_gpio_to_slice_num(PICO_DEFAULT_LED_PIN);
48
49 // Mask our slice's IRQ output into the PWM block's single interrupt line,
50 // and register our interrupt handler
51 pwm_clear_irq(slice_num);
52 pwm_set_irq_enabled(slice_num, true);
53 irq_set_exclusive_handler(PWM_DEFAULT_IRQ_NUM(), on_pwm_wrap);
54 irq_set_enabled(PWM_DEFAULT_IRQ_NUM(), true);
55
56 // Get some sensible defaults for the slice configuration. By default, the
57 // counter is allowed to wrap over its maximum range (0 to 2**16-1)
58 pwm_config config = pwm_get_default_config();
59 // Set divider, reduces counter clock to sysclock/this value
60 pwm_config_set_clkdiv(&config, 4.f);
61 // Load the configuration into our PWM slice, and set it running.
62 pwm_init(slice_num, &config, true);
63
64 // Everything after this point happens in the PWM interrupt handler, so we
65 // can twiddle our thumbs
66 while (1)
67 tight_loop_contents();
68 #endif
69 }
```

This scheme allows multiple slices to generate interrupts concurrently. A system interrupt handler determines which slices caused the most recent interruption, and handles them appropriately. Normally, this means reloading those slices' **TOP** or **CC** registers, but the PWM block can also be used as a source of regular interrupt requests for non-PWM purposes.

The same pulse which sets the interrupt flag in **INTR** is also available as a one-cycle data request to the RP2350 system DMA. For each cycle the DMA sees a DREQ asserted, it makes one data transfer to its programmed location in as timely a manner as possible. Combined with the double-buffered behaviour of **CC** and **TOP**, the DMA can efficiently stream data to a PWM slice at a rate of one transfer per counter period. Alternatively, a PWM slice could serve as a pacing timer for DMA transfers to some other memory-mapped hardware.

### 12.5.2.8. On-the-fly phase adjustment

For some applications, it is necessary to control the phase relationship between two PWM outputs on different slices.

The global enable register **EN** contains an alias of the **CSR\_EN** flag for each slice. Use this register to start and stop several slices simultaneously. If two slices with the same output frequency start at the same time, they run in perfect lockstep, with a fixed phase relationship determined by the initial counter values.

The **CSR\_PH\_ADV** and **CSR\_PH\_RET** fields advance or retard a slice's output phase by one count whilst it is running. They do so by inserting or deleting pulses from the clock enable (the output of the clock divider), as shown in [Figure 121](#).

```

33 }
34 }
35 // 对淡入淡出值进行平方处理，使LED亮度呈现更线性的变化
36 // 此范围与wrap值对应
37 pwm_set_gpio_level(PICO_DEFAULT_LED_PIN, fade * fade);
38 }
39
40 int main() {
41 #ifndef PICO_DEFAULT_LED_PIN
42 #warning pwm/led_fade 示例要求开发板配备标准LED
43 #else
44 // 告知LED引脚由PWM负责其数值控制。
45 gpio_set_function(PICO_DEFAULT_LED_PIN, GPIO_FUNC_PWM);
46 // 确定刚连接到LED引脚的切片编号
47 uint slice_num = pwm_gpio_to_slice_num(PICO_DEFAULT_LED_PIN);
48
49 // 将该切片的IRQ输出掩码映射到PWM模块的单一中断线，
50 // 并注册中断处理程序
51 pwm_clear_irq(slice_num);
52 pwm_set_irq_enabled(slice_num, true);
53 irq_set_exclusive_handler(PWM_DEFAULT_IRQ_NUM(), on_pwm_wrap);
54 irq_set_enabled(PWM_DEFAULT_IRQ_NUM(), true);
55
56 // 获取该切片配置的合理默认值。默认情况下，
57 // 计数器允许在其最大范围内循环（0至 $2^{16}-1$ ）
58 pwm_config config = pwm_get_default_config();
59 // 设置分频，降低计数器时钟至 sysclock 除以该值
60 pwm_config_set_clkdiv(&config, 4.f);
61 // 将配置加载至 PWM 分片，并启动运行。
62 pwm_init(slice_num, &config, true);
63
64 // 从此处起，所有操作均在 PWM 中断处理程序中进行，因此我们可以
65 // 无所事事
66 while (1)
67 tight_loop_contents();
68 #endif
69 }

```

该方案允许多个分片同时产生中断。系统中断处理程序确定最近中断的分片，并对其作出适当处理。通常，这意味着重新加载这些分片的 TOP 或 CC 寄存器，但 PWM 模块也可作为非 PWM 目的的定期中断请求源。

同一脉冲既设置了 INTR 中断标志，也作为 RP2350 系统 DMA 的一周期数据请求。每当 DMA 检测到 DREQ 信号被置位时，会尽快向其预设位置传输一笔数据。结合 CC 和 TOP 的双缓冲特性，DMA 能够以每个计数周期一次传输的速率高效地将数据流传输至 PWM 切片。或者，PWM 切片可以用作 DMA 传输至其他内存映射硬件的节奏计时器。

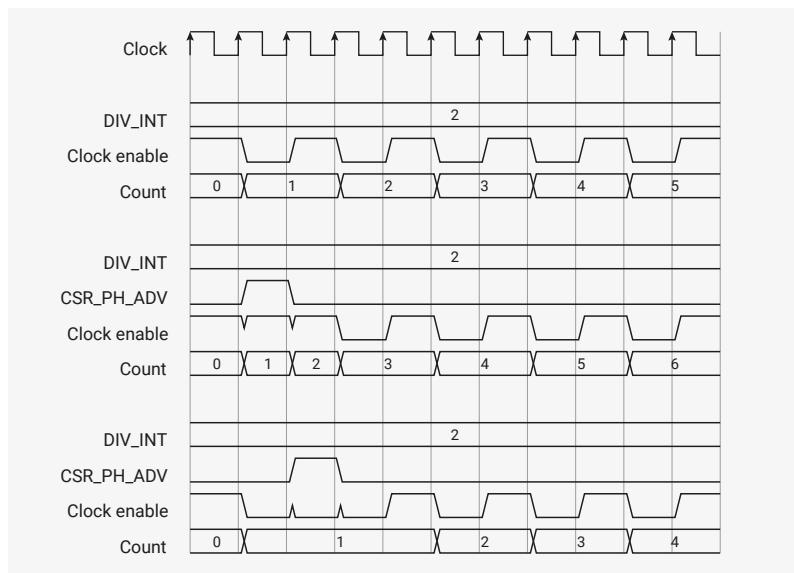

### 12.5.2.8. 动态相位调整

对于某些应用，必须控制两个不同切片上的 PWM 输出之间的相位关系。

全局使能寄存器 EN 包含每个切片的 CSR\_EN 标志的别名。可使用此寄存器同时启动和停止多个切片。如果两个具有相同输出频率的切片同时启动，它们将完美同步运行，其固定相位关系由初始计数值决定。

寄存器字段 CSR\_PH\_ADV 和 CSR\_PH\_RET 可在切片运行时将其输出相位提前或延迟一个计数。其方式是通过向时钟使能信号（时钟分频器输出）插入或删除脉冲，如图 121 所示。

Figure 121. The clock enable signal, output by the clock divider, controls the rate of counting. Phase advance forces the clock enable high on cycles where it is low, causing the counter to jump forward by one count. Phase retard forces the clock enable low when it would be high, holding the counter back by one count.

The counter cannot count faster than once per cycle, so **PH\_ADV** requires **DIV\_INT** > 1 or **DIV\_FRAC** > 0. Likewise, the counter will not start to count backward if **PH\_RET** is asserted when the clock enable is permanently low.

To advance or retard the phase by one count, software writes 1 to **PH\_ADV** or **PH\_RET**. Once an enable pulse has been inserted or deleted, the **PH\_ADV** or **PH\_RET** register bit returns to 0. Software can poll **CSR** until this happens. **PH\_ADV** always inserts a pulse into the next available gap; **PH\_RET** always deletes the next available pulse.

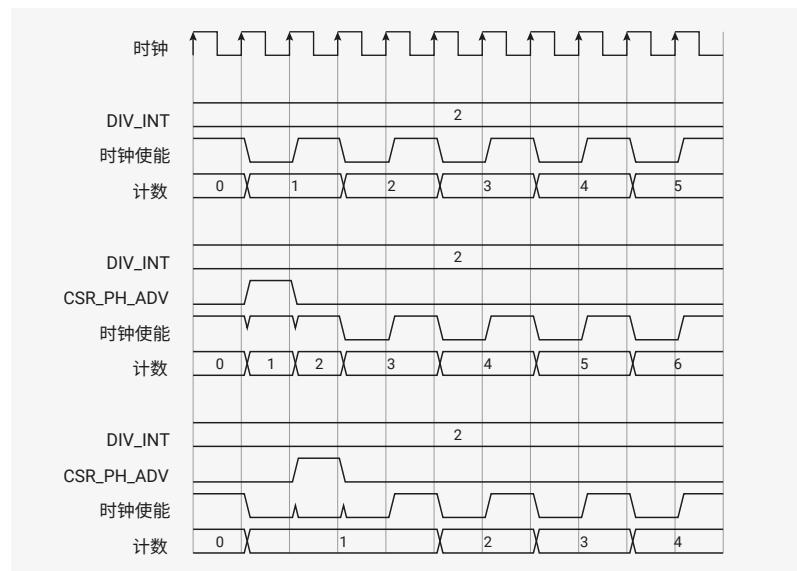

### 12.5.3. List of registers

The PWM registers start at a base address of **0x400a8000** (defined as **PWM\_BASE** in the SDK).

Table 1131. List of PWM registers

Offset	Name	Info
0x000	<b>CH0_CSR</b>	Control and status register
0x004	<b>CH0_DIV</b>	INT and FRAC form a fixed-point fractional number. Counting rate is system clock frequency divided by this number. Fractional division uses simple 1st-order sigma-delta.
0x008	<b>CH0_CTR</b>	Direct access to the PWM counter
0x00c	<b>CH0_CC</b>	Counter compare values
0x010	<b>CH0_TOP</b>	Counter wrap value
0x014	<b>CH1_CSR</b>	Control and status register
0x018	<b>CH1_DIV</b>	INT and FRAC form a fixed-point fractional number. Counting rate is system clock frequency divided by this number. Fractional division uses simple 1st-order sigma-delta.
0x01c	<b>CH1_CTR</b>	Direct access to the PWM counter
0x020	<b>CH1_CC</b>	Counter compare values
0x024	<b>CH1_TOP</b>	Counter wrap value
0x028	<b>CH2_CSR</b>	Control and status register
0x02c	<b>CH2_DIV</b>	INT and FRAC form a fixed-point fractional number. Counting rate is system clock frequency divided by this number. Fractional division uses simple 1st-order sigma-delta.

图121。由时钟分频器输出的时钟使能信号控制计数速率。相位提前在时钟使能为低的周期内强制使其为高，导致计数器向前跳过一次计数。相位滞后在时钟使能为高时强制使其为低，使计数器回退一次计数。

计数器计数速度不能超过每个周期一次，因此 `PH_ADV` 要求 `DIV_INT > 1` 或 `DIV_FRAC > 0`。同样，如果在时钟使能永久为低时断言 `PH_RET`，计数器不会开始向后计数。

要使相位提前或滞后一个计数，软件需向 `PH_ADV` 或 `PH_RET` 写入1。一旦插入或删除了一个使能脉冲，`PH_ADV` 或 `PH_RET` 寄存器位将自动恢复为0。软件可轮询 `CSR` 直至该过程完成。`PH_ADV` 始终在下一个可用间隙中插入一个脉冲；`PH_RET` 始终删除下一个可用脉冲。

### 12.5.3. 寄存器列表

PWM寄存器的起始基址为 `0x400a8000`（在SDK中定义为 `PWM_BASE`）。

0x10c	IRQ1_INTS	Interrupt status after masking & forcing for irq1

偏移量	名称	说明
0x0a4	CH8_DIV	INT与FRAC共同构成固定点小数。 计数频率为系统时钟频率除以该数值。 分数除法采用简单的一阶Σ-Δ调制。
0x0a8	CH8_CTR	对PWM计数器的直接访问
0x0ac	CH8_CC	计数器比较值
0x0b0	CH8_TOP	计数器回绕值
0x0b4	CH9_CSR	控制与状态寄存器
0x0b8	CH9_DIV	INT与FRAC共同构成固定点小数。 计数频率为系统时钟频率除以该数值。 分数除法采用简单的一阶Σ-Δ调制。
0x0bc	CH9_CTR	对PWM计数器的直接访问
0x0c0	CH9_CC	计数器比较值
0x0c4	CH9_TOP	计数器回绕值
0x0c8	CH10_CSR	控制与状态寄存器
0x0cc	CH10_DIV	INT与FRAC共同构成固定点小数。 计数频率为系统时钟频率除以该数值。 分数除法采用简单的一阶Σ-Δ调制。
0x0d0	CH10_CTR	对PWM计数器的直接访问
0x0d4	CH10_CC	计数器比较值
0x0d8	CH10_TOP	计数器回绕值
0x0dc	CH11_CSR	控制与状态寄存器
0x0e0	CH11_DIV	INT与FRAC共同构成固定点小数。 计数频率为系统时钟频率除以该数值。 分数除法采用简单的一阶Σ-Δ调制。
0x0e4	CH11_CTR	对PWM计数器的直接访问
0x0e8	CH11_CC	计数器比较值
0x0ec	CH11_TOP	计数器回绕值
0x0f0	EN	此寄存器为所有通道的CSR_EN位的别名。 写入此寄存器可同时启用或禁用多个通道，实现完全同步运行。 每个通道仅有一个物理EN寄存器位， 可通过此处或CHx_CSR进行访问。
0x0f4	中断	原始中断
0x0f8	IRQ0_INTE	irq0 中断使能
0x0fc	IRQ0_INTF	irq0 中断强制
0x100	IRQ0_INTS	irq0 掩码及强制后的中断状态
0x104	IRQ1_INTE	用于 irq1 的中断使能
0x108	IRQ1_INTF	用于 irq1 的中断强制
0x10c	IRQ1_INTS	irq1 掩码和强制后的中断状态

## PWM: CH0\_CSR, CH1\_CSR, ..., CH10\_CSR, CH11\_CSR Registers

**Offsets:** 0x000, 0x014, ..., 0x0c8, 0x0dc

### Description

Control and status register

Table 1132. CH0\_CSR, CH1\_CSR, ..., CH10\_CSR, CH11\_CSR Registers

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7	<b>PH_ADV</b> : Advance the phase of the counter by 1 count, while it is running. Self-clearing. Write a 1, and poll until low. Counter must be running at less than full speed ( $\text{div\_int} + \text{div\_frac} / 16 > 1$ )	SC	0x0
6	<b>PH_RET</b> : Retard the phase of the counter by 1 count, while it is running. Self-clearing. Write a 1, and poll until low. Counter must be running.	SC	0x0
5:4	<b>DIVMODE</b>	RW	0x0
	Enumerated values:		
	0x0 → DIV: Free-running counting at rate dictated by fractional divider		
	0x1 → LEVEL: Fractional divider operation is gated by the PWM B pin.		
	0x2 → RISE: Counter advances with each rising edge of the PWM B pin.		
	0x3 → FALL: Counter advances with each falling edge of the PWM B pin.		
3	<b>B_INV</b> : Invert output B	RW	0x0
2	<b>A_INV</b> : Invert output A	RW	0x0
1	<b>PH_CORRECT</b> : 1: Enable phase-correct modulation. 0: Trailing-edge	RW	0x0
0	<b>EN</b> : Enable the PWM channel.	RW	0x0

## PWM: CH0\_DIV, CH1\_DIV, ..., CH10\_DIV, CH11\_DIV Registers

**Offsets:** 0x004, 0x018, ..., 0x0cc, 0x0e0

### Description

INT and FRAC form a fixed-point fractional number.

Counting rate is system clock frequency divided by this number.

Fractional division uses simple 1st-order sigma-delta.

Table 1133. CH0\_DIV, CH1\_DIV, ..., CH10\_DIV, CH11\_DIV Registers

Bits	Description	Type	Reset
31:12	Reserved.	-	-
11:4	<b>INT</b>	RW	0x01
3:0	<b>FRAC</b>	RW	0x0

## PWM: CH0\_CTR, CH1\_CTR, ..., CH10\_CTR, CH11\_CTR Registers

**Offsets:** 0x008, 0x01c, ..., 0x0d0, 0x0e4

## PWM: CH0\_CSR, CH1\_CSR, ..., CH10\_CSR, CH11\_CSR寄存器

偏移地址: 0x000, 0x014, ..., 0x0c8, 0x0dc

### 描述

控制与状态寄存器

表 1132。CH0\_CSR, CH1\_CSR, ..., CH10\_CSR, CH11\_CSR 寄存器

位	描述	类型	复位
31:8	保留。	-	-
7	<b>PH_ADV</b> : 在计数器运行时, 将相位提前1个计数。 自动清零。写入1, 并轮询直至为低。计数器必须以低于全速运行 (div_int + div_frac / 16 > 1)。	SC	0x0
6	<b>PH_RET</b> : 在计数器运行时, 将相位延迟1个计数。 自动清零。写入1, 并轮询直至为低。计数器必须正在运行。	SC	0x0
5:4	<b>DIVMODE</b>	读写	0x0
	枚举值:		
	0x0 → DIV: 以分数分频器确定的速率自由运行计数。		
	0x1 → LEVEL: 分数分频器操作由PWM B引脚控制。		
	0x2 → RISE: 计数器随PWM B引脚的上升沿递增。		
	0x3 → FALL: 计数器随PWM B引脚的下降沿递增。		
3	<b>B_INV</b> : 反转输出B	读写	0x0
2	<b>A_INV</b> : 反转输出A	读写	0x0
1	<b>PH_CORRECT</b> : 1: 启用相位校正调制; 0: 后沿	读写	0x0
0	<b>EN</b> : 使能PWM通道。	读写	0x0

## PWM: CH0\_DIV、CH1\_DIV、...、CH10\_DIV、CH11\_DIV寄存器

偏移量: 0x004, 0x018, ..., 0x0cc, 0x0e0

### 描述

INT与FRAC共同构成固定点小数。  
计数频率为系统时钟频率除以该数值。  
分数除法采用简单的一阶Σ-Δ调制。

## PWM: EN Register

**Offset:** 0x0f0

### Description

This register aliases the CSR\_EN bits for all channels.

Writing to this register allows multiple channels to be enabled or disabled simultaneously, so they can run in perfect sync.

For each channel, there is only one physical EN register bit, which can be accessed through here or CHx\_CSR.

*Table 1137. EN Register*

## 12.6. DMA

The RP2350 Direct Memory Access (DMA) controller performs bulk data transfers on a processor's behalf. This leaves processors free to attend to other tasks or enter low-power sleep states. The DMA dual bus manager ports can issue one read and one write access per cycle. The data throughput is therefore far greater than one of RP2350's processors.

## 12.6. DMA

RP2350直接内存访问（DMA）控制器代表处理器执行批量数据传输。这使处理器得以专注于其他任务或进入低功耗睡眠状态。DMA双总线管理端口每个周期可同时发起一次读取和一次写入访问。因此，其数据吞吐量远超单个RP2350处理器。

**Figure 122. DMA Architecture Overview.**  
The read manager can read data from some address every clock cycle. Likewise, the write manager can write to another address. The address generator produces matched pairs of read and write addresses, which the managers consume through the address FIFOs. The DMA can run up to 16 transfer sequences simultaneously, supervised by software via the control and status registers.

The DMA can perform one read access and one write access, up to 32 bits in size, every clock cycle. There are 16 independent channels, each of which supervises a sequence of bus transfers in one of the following scenarios:

#### Memory-to-peripheral

a peripheral signals the DMA when it needs more data to transmit. The DMA reads data from an array in RAM or flash, and writes to the peripheral's data FIFO.

#### Peripheral-to-memory

a peripheral signals the DMA when it has received data. The DMA reads this data from the peripheral's data FIFO, and writes it to an array in RAM.

#### Memory-to-memory

the DMA transfers data between two buffers in RAM, as fast as possible.

Each channel has its own control and status registers (CSRs) that software can use to program and monitor the channel's progress. When multiple channels are active at the same time, the DMA shares bandwidth evenly between the channels, with round-robin over all channels that are currently requesting data transfers.

The transfer size can be either 32, 16, or 8 bits. This is configured once for each channel: source transfer size and destination transfer size are the same. The DMA performs byte lane replication on narrow writes, so byte data is available in all 4 bytes of the databus, and halfword data in both halfwords.

Channels can be combined in varied ways for more sophisticated behaviour and greater autonomy. For example, one channel can configure another, loading configuration data from a sequence of control blocks in memory, and the second can then call back to the first via the `CHAIN_TO` option when it needs to be reconfigured.

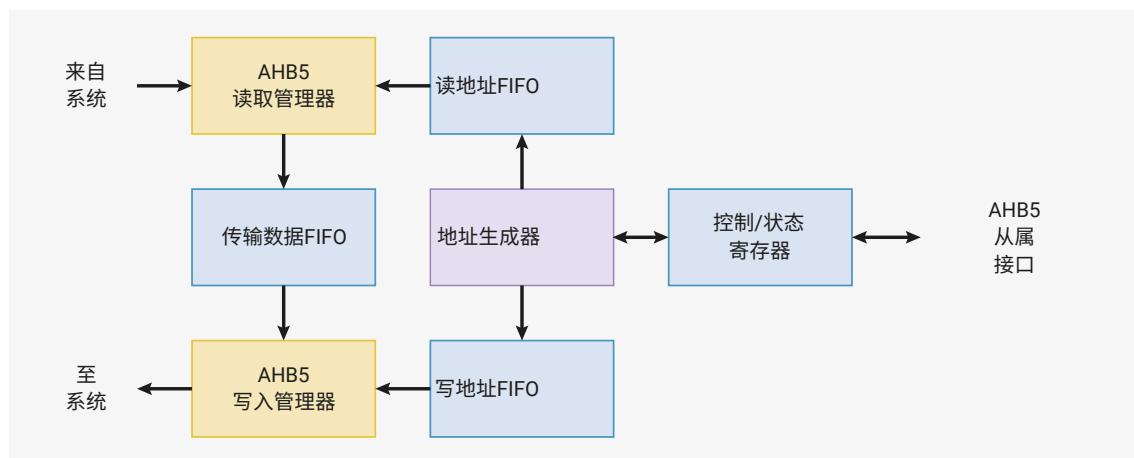

Making the DMA more autonomous means that much less processor supervision is required: overall this allows the system to do more at once, or to dissipate less power.

### 12.6.1. Changes from RP2040

The following new features have been added:

- Increased the number of DMA channels from 12 to 16.
- Increased the number of shared IRQ outputs from 2 to 4.
- Channels can be assigned to security domains using `SECCFG_CH0` through `SECCFG_CH15`.
- The DMA now filters bus accesses using the built-in memory protection unit (Section 12.6.3).
- Interrupts can be assigned to security domains using `SECCFG_IRQ0` through `SECCFG_IRQ3`.
- Pacing timers and the CRC sniffer can be assigned to security domains using the `SECCFG_MISC` register.
- The four most-significant bits of `TRANS_COUNT` (`CH0_TRANS_COUNT`) are redefined as the `MODE` field, which defines what happens when `TRANS_COUNT` reaches zero:

图122。 DMA  
架构概述。  
读管理器可在每个时钟周期从某个地址读取数据。同样，写管理器可向另一个地址写入数据。地址生成器产生匹配的读写地址对，管理器通过地址FIFO读取这些地址。DMA最多可同时运行16个传输序列，并通过控制与状态寄存器由软件监控。

DMA每个时钟周期可执行一次读访问和一次写访问，数据宽度最高为32位。共有16个独立通道，每个通道监督以下场景之一的总线传输序列：

#### 内存至外设

当外设需要更多传输数据时，会向DMA发出信号。DMA从RAM或闪存中的数组读取数据，并写入外设的数据FIFO。

#### 外设至内存

当外设已接收数据时，会向DMA发出信号。DMA从外设的数据FIFO读取数据，并写入RAM中的数组。

#### 内存到内存

DMA在两个RAM缓冲区之间尽可能快速地传输数据。

每个通道均设有专属控制和状态寄存器（CSR），软件可通过该寄存器对通道进行编程及监控其状态。当多个通道同时激活时，DMA会在这些通道之间均分带宽，并对所有当前请求数据传输的通道采用循环分配策略。

传输大小可为32位、16位或8位。每个通道仅配置一次：源传输大小与目标传输大小须保持一致。DMA对窄写操作执行字节通道复制，因此字节数据在数据总线的所有4个字节中均可用，半字数据亦在两个半字内均可用。

通道可通过多种组合方式实现更加复杂的行为及更高的自主性。例如，一个通道可配置另一个通道，通过内存中一系列控制块载入配置信息，当第二个通道需重新配置时，可通过[CHAIN\\_TO](#)选项回调第一个通道。

使DMA更加自主意味着处理器监督需求显著减少：整体上，这使系统能够同时处理更多任务，或降低功耗。

### 12.6.1. 与 RP2040 的变化

新增以下功能：

- 将DMA通道数量从12增加至16。
- 将共享中断（IRQ）输出数量从2增加至4。
- 通道可通过SECCFG\_CH0至SECCFG\_CH15分配至安全域。
- DMA现利用内置内存保护单元（第12.6.6.3节）过滤总线访问。
- 中断可通过SECCFG\_IRQ0至SECCFG\_IRQ3分配至安全域。
- 节奏计时器和CRC嗅探器可通过SECCFG\_MISC寄存器分配至安全域。
- `TRANS_COUNT` (`CHO_TRANS_COUNT`) 的最高四位重新定义为`MODE`字段，用于定义当`TRANS_COUNT`达到零时的操作：

- This backward-incompatible change reduces the maximum transfers in one sequence from  $2^{32}-1$  to  $2^{28}-1$ .
- Mode **0x0** has the same behaviour as RP2040, so there is no need to modify software that performs less than 256 million transfers at a time.
- Mode **0x1**, "trigger self", allows a channel to automatically restart itself after finishing a transfer sequence, in addition to the usual end-of-sequence actions like raising an interrupt or triggering other channels. This can be used for example to get periodic interrupts from streaming ring buffer transfers.
- Mode **0xf**, "endless", allows a channel to run forever: **TRANS\_COUNT** does not decrement.
- New **CH0\_CTRL\_TRIG.INCR\_READ\_REV** and **CH0\_CTRL\_TRIG.INCR\_WRITE\_REV** fields allow addresses to decrement rather than increment, or to increment by two.
  - Some existing fields in the **CTRL** registers, such as **CH0\_CTRL\_TRIG.BUSY**, have moved to accommodate the new fields.

Some existing behaviour has been refined:

- The logic that adjusts values read from **WRITE\_ADDR** and **READ\_ADDR** according to the number of in-flight transfers is disabled for address-wrapping and non-incrementing transfers (erratum RP2040-E12).
- You can now poll the **ABORT** register to wait for completion of an aborted channel (erratum RP2040-E13).
- DMA completion actions such as **CHAIN\_TO** are now strictly ordered against the last write completion, so a **CHAIN\_TO** on a channel whose registers you write to is a well-defined operation.
  - This enables the use of control blocks that don't include one of the four trigger register aliases.
  - Previously, a channel was considered to complete on the *first* cycle of its last write's data phase. Now, a channel is considered to complete on the *last* cycle of its last write's data phase. This is usually the same cycle, but it can be later when the DMA encounters a write data-phase bus stall.
- Previously, the DMA's internal arbitration logic inserted an idle cycle after completing a round of active high-priority channels (**CH0\_CTRL\_TRIG.HIGH\_PRIORITY**), even if there were no active low-priority requests. This reduced DMA throughput when lightly loaded. This idle cycle has been removed, eliminating lost throughput.
- IRQ assertion latency has been reduced by one cycle.

## 12.6.2. Configuring channels

Each channel has four control/status registers:

- **READ\_ADDR** (**CH0\_READ\_ADDR**) is the address of the next memory location to read.
- **WRITE\_ADDR** (**CH0\_WRITE\_ADDR**) is the address of the next memory location to write.
- **TRANS\_COUNT** (**CH0\_TRANS\_COUNT**) shows the number of transfers remaining in the current transfer sequence and programs the number of transfers in the next transfer sequence (see [Section 12.6.2.2](#)).
- **CTRL** (**CH0\_CTRL\_TRIG**) configures all other aspects of the channel's behaviour, enables/disables the channel, and provides completion status.

To directly instruct the DMA channel to perform a data transfer, software writes to these four registers, and then triggers the channel ([Section 12.6.3](#)). To make the DMA more autonomous, you can also program one DMA channel to write to another channel's configuration registers, queueing up many transfer sequences in advance.

All four are live registers; they update their status continuously as the channel progresses.

### 12.6.2.1. Read and write addresses

**READ\_ADDR** and **WRITE\_ADDR** contain the address the channel will next read from, and write to, respectively. These registers update automatically after each read/write access, incrementing to the next read/write address as required. The size of the increment varies according to:

- 此向后不兼容的更改将单序列最大传输次数从 $2^{32}-1$ 减少至 $2^{28}-1$ 。
- 模式 **0x0** 的行为与 RP2040 一致，因此无需修改执行每次传输少于 2.56 亿次的软件。
- 模式 **0x1**，“触发自身”，允许通道在完成传输序列后自动重启，除了通常的序列结束动作（例如触发中断或激发其他通道）之外。例如，可利用此模式通过流式环形缓冲区传输实现周期性中断。
- 模式 **0xf**，“无限”，允许通道永久运行：**TRANS\_COUNT** 不递减。
- 新增加的 CH0\_CTRL\_TRIG.INCR\_READ\_REV 和 CH0\_CTRL\_TRIG.INCR\_WRITE\_REV 字段允许地址递减，或按 2 递增。
  - 为容纳新字段，**CTRL** 寄存器中部分现有字段（如 CH0\_CTRL\_TRIG.BUSY）已重新调整位置。

部分现有行为已被优化：

- 针对地址环绕和非递增传输，调节从 **WRITE\_ADDR** 和 **READ\_ADDR** 读取值以反映在途传输数量的逻辑已被禁用（RP2040-E12勘误）。
- 您现在可以轮询 **ABORT** 寄存器，以等待被中止通道的完成（RP2040-E13缺陷修正）。
- DMA 完成操作如 **CHAIN\_TO** 现已严格按照最后写入完成的顺序执行，因此对写入其寄存器的通道执行 **CHAIN\_TO** 是一个明确规定操作。
  - 这使得能够使用不包含四个触发寄存器别名中的任意一个的控制块。
  - 此前，通道被视为在其最后一次写入数据阶段的第一个周期完成。现今，通道被视为在其最后一次写入数据阶段的最后一个周期完成。通常这两个周期相同，但当 DMA 遇到写数据阶段的总线阻塞时，完成周期可能会延后。
- 此前，DMA 的内部仲裁逻辑在完成一轮活动高优先级通道（CH0\_CTRL\_TRIG.HIGH\_PRIORITY）后插入一个空闲周期，即使无任何活动低优先级请求。这导致 DMA 在轻负载情况下吞吐量降低。该空闲周期已被移除，消除吞吐量损失。
- 中断请求（IRQ）断言延迟已减少一个周期。

## 12.6.2. 配置通道

每个通道均设有四个控制/状态寄存器：

- **READ\_ADDR** (CH0\_READ\_ADDR) 为下一次读取的内存地址。
- **WRITE\_ADDR** (CH0\_WRITE\_ADDR) 为下一次写入的内存地址。
- **TRANS\_COUNT** (CH0\_TRANS\_COUNT) 显示当前传输序列中剩余的传输次数，并设置下一传输序列的传输次数（详见第 12.6.2.2 节）。
- **CTRL** (CH0\_CTRL\_TRIG) 配置通道行为的所有其他方面，启用或禁用通道，并提供完成状态。

为直接指示 DMA 通道执行数据传输，软件需要写入这四个寄存器，然后触发该通道（详见第 12.6.3 节）。为增强 DMA 的自主性，您还可以编程使一个 DMA 通道写入另一个通道的配置寄存器，从而预先排队多个传输序列。

这四个均为活动寄存器；它们在通道执行过程中持续更新状态。

### 12.6.2.1 读写地址

**READ\_ADDR** 和 **WRITE\_ADDR** 分别存储通道下一次读取和写入的地址。这些寄存器在每次读写访问后会自动更新，按需递增至下一个读写地址。递增大小依据以下因素变化：

- the transfer size: 1, 2 or 4 byte bus accesses as per [CH0\\_CTRL\\_TRIG.DATA\\_SIZE](#)
- the increment enable for each address register: [CH0\\_CTRL\\_TRIG.INCR\\_READ](#) and [CH0\\_CTRL\\_TRIG.INCR\\_WRITE](#)
- the increment direction: [CH0\\_CTRL\\_TRIG.INCR\\_READ\\_REV](#) and [CH0\\_CTRL\\_TRIG.INCR\\_WRITE\\_REV](#)

Software should generally program these registers with new start addresses each time a new transfer sequence starts. If [READ\\_ADDR](#) and [WRITE\\_ADDR](#) are not reprogrammed, the DMA will use the current values as start addresses for the next transfer. For example:

- If the address does not increment (e.g. it is the address of a peripheral FIFO), and the next transfer sequence is to/from that *same* address, there is no need to write to the register again.
- When transferring to/from a consecutive series of buffers in memory (e.g. scattering and gathering), an address register will already have incremented to the start of the next buffer at the completion of a transfer.

By not programming all four CSRs for each transfer sequence, software can use shorter interrupt handlers, and more compact control block formats when used with channel chaining (see register aliases in [Section 12.6.3.1](#), chaining in [Section 12.6.3.2](#)).

#### 12.6.2.1.1. Address alignment

[READ\\_ADDR](#) and [WRITE\\_ADDR](#) must be aligned to the transfer size, specified in [CH0\\_CTRL\\_TRIG.DATA\\_SIZE](#). For 32-bit transfers, the address must be a multiple of four, and for 16-bit transfers, the address must be a multiple of two. Software is responsible for correctly aligning addresses written to [READ\\_ADDR](#) and [WRITE\\_ADDR](#): the DMA does not enforce alignment.

If software initially writes a correctly aligned address, the address will remain correctly aligned throughout the transfer sequence, because the DMA always increments [READ\\_ADDR](#) and [WRITE\\_ADDR](#) by a multiple of the transfer size. Specifically, it increments by transfer size times -1, 0, 1 or 2, depending on the values of [CH0\\_CTRL\\_TRIG.INCR\\_READ](#), [CH0\\_CTRL\\_TRIG.INCR\\_WRITE](#), [CH0\\_CTRL\\_TRIG.INCR\\_READ\\_REV](#) and [CH0\\_CTRL\\_TRIG.INCR\\_WRITE\\_REV](#).

The DMA MPU and system-level bus security filters perform protection checks on the lowest byte address of all bytes transferred on a given cycle (i.e. to the present value of [READ\\_ADDR/WRITE\\_ADDR](#)). RP2350 memory hardware ensures unaligned bus accesses do not cause data to be read/written from the other side of a protection boundary. This means that unaligned access can not be used to violate the memory protection model. Other than this, the result of an unaligned access is unspecified.

#### 12.6.2.2. Transfer count

Reading [TRANS\\_COUNT](#) ([CH0\\_TRANS\\_COUNT](#)) returns the number of transfers remaining in the current transfer sequence. This value updates continuously as the channel progresses. Writing to [TRANS\\_COUNT](#) sets the length of the *next* transfer sequence. Up to  $2^{28}-1$  transfers can be performed in one sequence ([0x0fffffff](#), approximately 256 million).

Each time the channel starts a new transfer sequence, the most recent value written to [TRANS\\_COUNT](#) is copied to the live transfer counter, which will then start to decrement again as the new transfer sequence makes progress. For debugging purposes, the [DBG\\_TCR](#) ([TRANS\\_COUNT](#) reload value) registers display the last value written to each channel's [TRANS\\_COUNT](#).

If the channel is triggered multiple times without intervening writes to [TRANS\\_COUNT](#), it performs the same number of transfers each time. For example, when chained to, one channel might load a fixed-size control block into another channel's CSRs. [TRANS\\_COUNT](#) would be programmed once by software, and then reload automatically every time.

Alternatively, [TRANS\\_COUNT](#) can be written with a new value before starting each transfer sequence. If [TRANS\\_COUNT](#) is the channel trigger (see [Section 12.6.3.1](#)), the channel will start immediately, and the value just written will be used, *not* the value currently in the reload register.

- 传输大小：依据CH0\_CTRL\_TRIG.DATA\_SIZE的1、2或4字节总线访问
- 各地址寄存器的递增使能标志：CH0\_CTRL\_TRIG.INCR\_READ和CH0\_CTRL\_TRIG.INCR\_WRITE
- 递增方向：CH0\_CTRL\_TRIG.INCR\_READ\_REV和CH0\_CTRL\_TRIG.INCR\_WRITE\_REV

软件通常应在每次新传输序列开始时，重新编程这些寄存器的起始地址。

若 `READ_ADDR` 和 `WRITE_ADDR` 未被重新编程，DMA 将使用当前值作为下一次传输的起始地址。例如：

- 如果地址不递增（例如，该地址为外围设备 FIFO 的地址），且下一传输序列仍针对该相同地址进行，则无需再次写入该寄存器。
- 当向内存中连续的一系列缓冲区传输数据时（例如，分散与聚集操作），地址寄存器在传输完成后将自动递增至下一缓冲区的起始地址。

通过不为每个传输序列编程所有四个CSR，软件能够使用更简短的中断处理程序，并在采用通道链时实现更紧凑的控制块格式（详见第12.6.3.1节寄存器别名及第12.6.3.2节链式结构）。

#### 12.6.2.1.1. 地址对齐

`READ_ADDR` 和 `WRITE_ADDR` 必须与传输大小对齐，传输大小由 `CH0_CTRL_TRIG.DATA_SIZE` 指定。对于32位传输，地址必须为4的倍数；对于16位传输，地址必须为2的倍数。

软件负责正确对齐写入 `READ_ADDR` 和 `WRITE_ADDR` 的地址；DMA 不执行对齐检查。

如果软件最初写入正确对齐的地址，则在整个传输序列中该地址将保持正确对齐，因为 DMA 始终以传输大小的整数倍递增 `READ_ADDR` 和 `WRITE_ADDR`。具体而言，递增量为传输大小乘以-1、0、1或2，具体取决于 `CH0_CTRL_TRIG.INCR_READ`、`CH0_CTRL_TRIG.INCR_WRITE`、`CH0_CTRL_TRIG.INCR_READ_REV` 和 `CH0_CTRL_TRIG.INCR_WRITE_REV` 的取值。

DMA MPU 及系统级总线安全过滤器对每个周期传输的所有字节的最低字节地址（即当前 `READ_ADDR` / `WRITE_ADDR` 的值）进行保护检查。RP2350 内存硬件确保未对齐的总线访问不会导致数据从保护边界的另一侧被读取或写入。这表明未对齐访问不能用来违反内存保护模型。除此之外，未对齐访问的结果是不确定的。

#### 12.6.2.2. 传输计数

读取 `TRANS_COUNT` (`CH0_TRANS_COUNT`) 返回当前传输序列中剩余的传输次数。

该数值随着通道的进度持续更新。写入 `TRANS_COUNT` 可设置下一次传输序列的长度。一次序列中最多可执行  $2^{28-1}$  次传输（即 `0xffffffff`，约 2.56 亿次）。

每当通道启动新的传输序列时，最近写入的 `TRANS_COUNT` 值会复制到当前的传输计数器，然后该计数器会随着新传输序列的进行再次递减。用于调试的 `DBG_TCR` (`TRANS_COUNT` 重载) 寄存器显示各通道最后写入的 `TRANS_COUNT` 值。

如果通道在未对 `TRANS_COUNT` 进行写入的情况下多次触发，则每次执行的传输次数相同。例如，当链式连接时，一个通道可能会将固定大小的控制块加载到另一个通道的CSR寄存器中。软件仅需编程一次 `TRANS_COUNT`，随后每次都会自动重载。

或者，可以在开始每次传输序列之前写入新的 `TRANS_COUNT` 值。如果 `TRANS_COUNT` 是通道触发器（参见第12.6.3.1节），通道会立即启动，并采用新写入的数值，而非重载寄存器中当前的数值。

### NOTE

The `TRANS_COUNT` is the number of *transfers* to be performed. The total number of bytes transferred is `TRANS_COUNT` times the size of each transfer in bytes, given by `CTRL.DATA_SIZE`.

#### 12.6.2.2.1. Count modes

The four most-significant bits of `TRANS_COUNT` contain the `MODE` field (`CHO_TRANS_COUNT.MODE`), which modifies the counting behaviour of `TRANS_COUNT`. Mode `0x0` is the default: `TRANS_COUNT` decrements once for every bus transfer, and the channel halts once `TRANS_COUNT` reaches zero and all in-flight transfers have finished. The value of `0x0` is chosen for backward-compatibility with RP2040 software, which expects the `TRANS_COUNT` register to contain a 32-bit count rather than a 4-bit mode and a 28-bit count. There are few use cases for a *finite* number of transfers greater than  $2^{28}$ , which is why the four most-significant bits have been reallocated for use with endless transfers.

Mode `0x1`, `TRIGGER_SELF`, behaves the same as mode `0x0`, except that rather than halting upon completion, the channel immediately re-triggers itself. This is equivalent to a trigger performed by any other mechanism (Section 12.6.3): `TRANS_COUNT` is reloaded, and the channel resumes from the current `READ_ADDR` and `WRITE_ADDR` addresses. A completion interrupt is still raised (if `CTRL.IRQ QUIET` is not set) and the specified `CHAIN_TO` operation is still performed. The main use for this mode is streaming through SRAM ring buffers, where some action is required at regular intervals, for example requesting the processor to refill an audio buffer once it is half-empty.

Mode `0xf`, `ENDLESS`, disables the decrement of `TRANS_COUNT`. This means a channel will generally run indefinitely without pause, though triggering a channel with a mode of `0xf` and a count of `0x0` will result in the channel halting immediately.

All other values are reserved for future use and their effect is unspecified.

#### 12.6.2.3. Control/Status

The `CTRL` register (`CHO_CTRL_TRIG`) has more, smaller fields than the other 3 registers. Among other things, `CTRL` is used to:

- Configure the size of this channel's data transfers through the `DATA_SIZE` field. Reads are always the same size as writes.
- Configure if and how `READ_ADDR` and `WRITE_ADDR` increment after each read or write through the `INCR_READ`, `INCR_READ_REV`, `INCR_WRITE`, `INCR_WRITE_REV`, `RING_SEL`, and `RING_SIZE` fields. Ring transfers are available, where one of the address pointers wraps at some power-of-2 boundary.
- Select another channel (or none) to trigger when this channel completes through the `CHAIN_TO` field.
- Select a peripheral data request (DREQ) signal to pace this channel's transfers, via the `TREQ_SEL` field.
- See when the channel is idle, using the `BUSY` flag.
- See if the channel has encountered a bus error in the `READ_ERROR` and `WRITE_ERROR` flags, or the combined error status in the `AHB_ERROR` flag.

#### 12.6.3. Triggering channels

After a channel has been correctly configured, you must trigger it. This instructs the channel to begin scheduling bus accesses, either paced by a peripheral data request signal (DREQ) or as fast as possible. The following events can trigger a channel:

- A write to a channel trigger register.
- Completion of another channel whose `CHAIN_TO` points to this channel.
- A write to the `MULTI_CHAN_TRIGGER` register (can trigger multiple channels at once).

Each trigger mechanism covers different use cases. For example, trigger registers are simple and efficient when

### ⓘ 注意

`TRANS_COUNT`表示将执行的传输次数。传输的字节总数等于`TRANS_COUNT`与每次传输字节大小（由`CTRL.DATA_SIZE`给出）的乘积。

#### 12.6.2.1. 计数模式

`TRANS_COUNT`的最高四位包含`MODE`字段（`CH0_TRANS_COUNT.MODE`），该字段会修改`TRANS_COUNT`的计数行为。模式`0x0`为默认模式：`TRANS_COUNT`每完成一次总线传输递减一次，当`TRANS_COUNT`归零且所有正在进行的传输完成后，通道停止工作。选择值`0x0`是为了向后兼容RP2040软件，该软件期望`TRANS_COUNT`寄存器包含32位计数，而非4位模式和28位计数。有限传输次数大于228的用例极少，因此最高四位已重新分配，用于支持无限次传输。

模式`0x1`，即`TRIGGER_SELF`，行为与模式`0x0`相同，但完成后通道不会停止，而是立即自我触发。这相当于通过其他机制执行的触发（参见第12.6.3节）：

重新加载`TRANS_COUNT`，通道从当前`READ_ADDR`和`WRITE_ADDR`地址继续运行。若`CTRL.IRQ QUIET`未设置，仍会产生完成中断，并且仍会执行指定的`CHAIN_TO`操作。此模式的主要用途是通过SRAM环形缓冲区进行流式传输，在其中需定期执行某些操作，例如在音频缓冲区使用至一半时请求处理器重新填充音频缓冲区。

模式`0xf`（`ENDLESS`）禁用`TRANS_COUNT`的递减。这意味着通道通常会无限期运行且不中断，但以模式`0x0`与计数`0x0`触发通道将导致通道立即停止。

所有其他数值均为保留以备将来使用，其效果未作说明。

#### 12.6.2.3 控制/状态

`CTRL`寄存器（`CH0_CTRL_TRIG`）包含比其他三个寄存器更多且更小的字段。除其他内容外，`CTRL`用于：

- 通过`DATA_SIZE`字段配置该通道数据传输的大小。读取操作的大小始终与写入操作相同。
- 通过`INCR_READ`、`INCR_READ_REV`、`INCR_WRITE`、`INCR_WRITE_REV`、`RING_SEL`和`RING_SIZE`字段，配置`READ_ADDR`和`WRITE_ADDR`在每次读写后的递增方式及是否递增。支持环形传输，即地址指针在2的幂边界处回绕。
- 通过`CHAIN_TO`字段选择另一个通道（或无）以在此通道完成时触发。
- 通过`TREQ_SEL`字段选择外设数据请求（DREQ）信号，以调节该通道的传输。
- 通过`BUSY`标志检测通道是否空闲。
- 通过`READ_ERROR`和`WRITE_ERROR`标志，或通过`AHB_ERROR`标志的综合错误状态，判断通道是否发生总线错误。

#### 12.6.3. 触发通道

通道配置完成后，须触发该通道。此操作指示其开始调度总线访问，方式为由外设数据请求信号（DREQ）节奏控制，或尽可能高速执行。以下事件可触发通道：

- 对通道触发寄存器进行写入。
- 另一个`CHAIN_TO`指向本通道的通道完成。
- 对`MULTI_CHAN_TRIGGER`寄存器进行写入（可同时触发多个通道）。

各触发机制适用于不同的使用场景。例如，当

configuring and starting a channel in an interrupt service routine because the channel is triggered by the last configuration write. `CHAIN_TO` allows one channel to callback to another channel, which can then reconfigure the first channel. `MULTI_CHAN_TRIGGER` allows software to simply start a channel without touching any of its configuration registers.

When triggered, the channel sets its `CTRL.BUSY` flag to indicate it is actively scheduling transfers. This remains set until the transfer count reaches zero, or the channel is aborted via the `CHAN_ABORT` register (Section 12.6.8.3).

When a channel is already running, indicated by `BUSY` = 1, it ignores additional triggers. A channel that is disabled (`CTRL.EN` is clear) also ignores triggers.

### 12.6.3.1. Aliases and triggers

*Table 1145. Control register aliases. Each channel has four control/status registers. Each register can be accessed at multiple different addresses. In each naturally-aligned group of four, all four registers appear, in different orders.*

Offset	+0x0	+0x4	+0x8	+0xc (Trigger)
0x00 (Alias 0)	READ_ADDR	WRITE_ADDR	TRANS_COUNT	CTRL_TRIG
0x10 (Alias 1)	CTRL	READ_ADDR	WRITE_ADDR	TRANS_COUNT_TRIG
0x20 (Alias 2)	CTRL	TRANS_COUNT	READ_ADDR	WRITE_ADDR_TRIG
0x30 (Alias 3)	CTRL	WRITE_ADDR	TRANS_COUNT	READ_ADD_TRIG

The four CSRs are aliased multiple times in memory. Each of the four aliases exposes the same four physical registers, but in a different order. The final register in each alias (at offset +0xc, highlighted) is a trigger register. Writing to the trigger register starts the channel.

Often, only alias 0 is used, and aliases 1 through 3 can be ignored. To configure and start the channel, write `READ_ADDR`, `WRITE_ADDR`, `TRANS_COUNT`, and finally `CTRL`. Since `CTRL` is the trigger register in alias 0, this starts the channel.

The other aliases allow more compact control block lists when using one channel to configure another, and more efficient reconfiguration and launch in interrupt handlers:

- Each CSR is a trigger register in one of the aliases:
  - When gathering fixed-size buffers into a peripheral, the DMA channel can be configured and launched by writing only `READ_ADDR_TRIG`.
  - When scattering from a peripheral to fixed-size buffers, the channel can be configured and launched by writing only `WRITE_ADDR_TRIG`.
- Useful combinations of registers appear as naturally-aligned tuples which contain a trigger register. In conjunction with channel chaining and address wrapping, these implement compressed control block formats, e.g.:
  - (`WRITE_ADDR`, `TRANS_COUNT_TRIG`) for peripheral scatter operations
  - (`TRANS_COUNT`, `READ_ADDR_TRIG`) for peripheral gather operations, or calculating CRCs on a list of buffers
  - (`READ_ADDR`, `WRITE_ADDR_TRIG`) for manipulating fixed-size buffers in memory

Trigger registers do not start the channel if:

- The channel is disabled via `CTRL.EN` (if the trigger is `CTRL`, the just-written value of `EN` is used, *not* the value currently in the `CTRL` register)
- The channel is already running
- The value 0 is written to the trigger register (useful for ending control block chains, see null triggers (Section 12.6.3.3))
- The bus access has a security level lower than the channel's security level (Section 12.6.6.1)

在中断服务例程中配置和启动通道时，触发寄存器简单且高效，因为通道由最后一次配置写操作触发。`CHAIN_TO` 允许一个通道回调到另一个通道，后者随后可以重新配置第一个通道。`MULTI_CHAN_TRIGGER` 允许软件简单启动一个通道，而无需修改其任何配置寄存器。

触发时，通道会设置其 `CTRL.BUSY` 标志，以指示该通道正在积极调度传输。该标志保持设置状态，直到传输计数归零，或通过 `CHAN_ABORT` 寄存器（第12.6.8.3节）中止该通道。

当通道已运行 (`BUSY = 1`) 时，会忽略额外的触发信号。已禁用的通道 (`CTRL.EN` 位清零) 同样会忽略触发信号。

### 12.6.3.1. 别名与触发

表1145。控制寄存器别名每个通道包含四个控制/状态寄存器。每个寄存器可通过多个不同地址进行访问。在每个自然对齐的四寄存器组内，所有四个寄存器均出现，但顺序不同。

偏移量	+0x0	+0x4	+0x8	+0xc (触发)
<code>0x00</code> (别名 0)	<code>READ_ADDR</code>	<code>WRITE_ADDR</code>	<code>TRANS_COUNT</code>	<code>CTRL_TRIG</code>
<code>0x10</code> (别名 1)	<code>CTRL</code>	<code>READ_ADDR</code>	<code>WRITE_ADDR</code>	<code>TRANS_COUNT_TRIG</code>
<code>0x20</code> (别名 2)	<code>CTRL</code>	<code>TRANS_COUNT</code>	<code>READ_ADDR</code>	<code>WRITE_ADDR_TRIG</code>
<code>0x30</code> (别名 3)	<code>CTRL</code>	<code>WRITE_ADDR</code>	<code>TRANS_COUNT</code>	<code>READ_ADD_TRIG</code>

这四个 CSR 在内存中被多次别名。每个别名均映射相同的四个物理寄存器，但顺序各异。每个别名中最后一个寄存器（偏移 +0xc，已高亮）为触发寄存器。向触发寄存器写入数据将启动该通道。

通常仅使用别名 0，别名 1 至 3 可予以忽略。配置并启动通道时，请依次写入 `READ_ADDR`、`WRITE_ADDR`、`TRANS_COUNT`，最后写入 `CTRL`。由于 `CTRL` 是别名 0 中的触发寄存器，因此它启动通道。

其他别名在使用一个通道配置另一个通道时，允许更紧凑的控制块列表，并能在中断处理程序中实现更高效的重新配置与启动：

- 每个CSR都是某一别名中的触发寄存器：
  - 在将固定大小的缓冲区聚集到外围设备时，DMA通道可通过仅写入 `READ_ADDR_TRIG` 来配置并启动。
  - 在将数据从外围设备分散至固定大小缓冲区时，通道可通过仅写入 `WRITE_ADDR_TRIG` 来配置并启动。
- 寄存器的有效组合表现为包含触发寄存器的自然对齐元组。结合通道链与地址环绕，这些组合实现了压缩控制块格式，例如：
  - (`WRITE_ADDR`, `TRANS_COUNT_TRIG`) 用于外围设备的分散操作
  - ((`TRANS_COUNT`,`READ_ADDR_TRIG`) 用于外围设备的聚集操作，或对缓冲区列表进行CRC计算
  - ((`READ_ADDR`,`WRITE_ADDR_TRIG`) 用于操作内存中的固定大小缓冲区

触发寄存器在以下情况下不会启动通道：

- 通过 `CTRL.EN` 禁用通道（若触发类型为 `CTRL`，则使用刚写入的 `EN` 值，而非 `CTRL` 寄存器中当前的值）
- 通道已处于运行状态
- 向触发寄存器写入值 0（用于结束控制块链，详见空触发器（第12.6.3.3节））
- 总线访问安全级别低于通道安全级别（第12.6.6.1节）

### 12.6.3.2. Chaining

When a channel completes, it can name a different channel to immediately be triggered. This can be used as a callback for the second channel to reconfigure and restart the first.

This feature is configured through the `CHAIN_TO` field in the channel `CTRL` register. This 4-bit value selects a channel that will start when this one finishes. A channel cannot chain to itself. Setting `CHAIN_TO` to a channel's own index prevents chaining.

Chain triggers behave the same as triggers from other sources, such as trigger registers. For example, they cause `TRANS_COUNT` to reload, and they are ignored if the targeted channel is already running.

One application for `CHAIN_TO` is for a channel to request reconfiguration by another channel from a sequence of control blocks in memory. Channel A is configured to perform a wrapped transfer from memory to channel B's control registers (including a trigger register), and channel B is configured to chain back to channel A when it completes each transfer sequence. This is shown explicitly in the DMA control blocks example ([Section 12.6.9.2](#)).

Use of the register aliases ([Section 12.6.3.1](#)) enables compact formats for DMA control blocks: as little as one word, in some cases.

Another use of chaining is a *ping-pong* configuration, where two channels each trigger one another. The processor can respond to the channel completion interrupts and reconfigure each channel after it completes. However, the chained channel, which has already been configured, starts immediately. In other words, channel configuration and channel operation are pipelined. This can improve performance dramatically when a usage pattern requires many short transfer sequences.

The [Section 12.6.9](#) goes into more detail on the possibilities of chain triggers in the real world.

### 12.6.3.3. Null triggers and chain interrupts

As mentioned in [Section 12.6.3.1](#), writing all-zeroes to a trigger register does not start the channel. This is called a null trigger, and it has two purposes:

- Cause a halt at the end of an array of control blocks, by appending an all-zeroes block.
- Reduce the number of interrupts generated when using control blocks.

By default, channels generate an interrupt each time they finish a transfer sequence, unless that channel's IRQ is masked in `INTE0` through `INTE3`. The rate of interrupts can be excessive, particularly as processor attention is generally not required while a sequence of control blocks are in progress. However, processor attention is required at the end of a chain.

The channel `CTRL` register has a field called `IRQ QUIET`. Its default value is 0. When set to 1, channels generate an interrupt when they receive a null trigger, but not on normal completion of a transfer sequence. The interrupt is generated by the channel that receives the trigger.

## 12.6.4. Data request (DREQ)

Peripherals produce or consume data at their own pace. If the DMA transferred data as fast as possible, loss or corruption of data would ensue. DREQs are a communication channel between peripherals and the DMA that enables the DMA to pace transfers according to the needs of the peripheral.

The `CTRL.TREQ_SEL` (transfer request) field selects an external DREQ. It can also be used to select one of the internal pacing timers, or select no TREQ at all (the transfer proceeds as fast as possible), e.g. for memory-to-memory transfers.

### 12.6.4.1. System DREQ table

DREQ numbers use the following global assignment to peripheral DREQ channels:

### 12.6.3.2. 链接

当通道完成时，可指定不同通道立即触发。此功能可作为第二通道的回调，用于重新配置并重新启动第一个通道。

通过通道 `CTRL` 寄存器中的 `CHAIN_TO` 字段配置该功能。该4位值选择在当前通道结束后将启动的通道。通道不得链接自身。将 `CHAIN_TO` 设置为通道自身的索引可防止链式连接。

链式触发的行为与其他来源的触发器相同，例如触发寄存器。例如，它们会导致 `TRANS_COUNT` 重新加载，且若目标通道已在运行，则会被忽略。

链式连接的一种应用是通道请求由内存中一系列控制块的另一个通道进行重新配置。通道A被配置为从内存向通道B的控制寄存器（包括触发寄存器）执行环形传输，通道B则配置为在完成每个传输序列后链回通道A。此情况在DMA控制块示例中有明确展示（第12.6.9.2节）。

使用寄存器别名（第12.6.3.1节）可实现DMA控制块的紧凑格式：某些情况下仅需一个字。

链式连接的另一种用途是乒乓配置，其中两个通道相互触发。处理器可以响应通道完成中断，并在每个通道完成后重新配置其参数。然而，已配置好的链式通道会立即开始运行。换言之，通道配置和通道操作是流水线并行的。当使用模式需要多次短传输序列时，此方式能极大提升性能。

第12.6.9节详细介绍了链式触发器在实际应用中的各种可能。

### 12.6.3.3. 空触发与链式中断

如第12.6.3.1节所述，向触发寄存器写入全零不会启动通道。这称为空触发器，具有以下两个目的：

- 通过附加一个全零控制块，实现在控制块数组末尾停止操作。
- 减少使用控制块时所产生的中断数量。

默认情况下，除非在 `INTE0` 至 `INTE3` 中屏蔽了该通道的IRQ，否则每完成一次传输序列，通道都会产生一次中断。中断频率可能过高，尤其是在连续执行一系列控制块时，通常不需要处理器介入。然而，链条末端需要处理器关注。

通道 `CTRL` 寄存器包含一个名为 `IRQ QUIET` 的字段。其默认值为0。当该字段设为1时，通道在接收到空触发时会产生中断，但在正常完成传输序列时不会产生中断。中断由接收到触发信号的通道触发。

## 12.6.4. 数据请求 (DREQ)

外设以其自身速率生成或消耗数据。如果DMA以最大速度传输数据，将导致数据丢失或损坏。DREQ是外设与DMA之间的通信通道，使DMA能够根据外设需求调节传输节奏。

字段`CTRL.TREQ_SEL`（传输请求）用于选择外部DREQ，亦可用于选择内部节奏定时器之一，或不选择任何TREQ（传输将尽可能快速进行），例如用于内存到内存的传输。

### 12.6.4.1 系统DREQ表

DREQ 编号按照以下方式全局分配至外设 DREQ 通道：

Table 1146. DREQs

DREQ	DREQ Channel	DREQ	DREQ Channel	DREQ	DREQ Channel	DREQ	DREQ Channel
0	DREQ_PI00_TX0	14	DREQ_PI01_RX2	28	DREQ_UART0_TX	42	DREQ_PWM_WRAP10
1	DREQ_PI00_TX1	15	DREQ_PI01_RX3	29	DREQ_UART0_RX	43	DREQ_PWM_WRAP11
2	DREQ_PI00_TX2	16	DREQ_PI02_TX0	30	DREQ_UART1_TX	44	DREQ_I2C0_TX
3	DREQ_PI00_TX3	17	DREQ_PI02_TX1	31	DREQ_UART1_RX	45	DREQ_I2C0_RX
4	DREQ_PI00_RX0	18	DREQ_PI02_TX2	32	DREQ_PWM_WRAP0	46	DREQ_I2C1_TX
5	DREQ_PI00_RX1	19	DREQ_PI02_TX3	33	DREQ_PWM_WRAP1	47	DREQ_I2C1_RX
6	DREQ_PI00_RX2	20	DREQ_PI02_RX0	34	DREQ_PWM_WRAP2	48	DREQ_ADC
7	DREQ_PI00_RX3	21	DREQ_PI02_RX1	35	DREQ_PWM_WRAP3	49	DREQ_XIP_STREAM
8	DREQ_PI01_TX0	22	DREQ_PI02_RX2	36	DREQ_PWM_WRAP4	50	DREQ_XIP_QMITX
9	DREQ_PI01_TX1	23	DREQ_PI02_RX3	37	DREQ_PWM_WRAP5	51	DREQ_XIP_QMIRX
10	DREQ_PI01_TX2	24	DREQ_SPI0_TX	38	DREQ_PWM_WRAP6	52	DREQ_HSTX
11	DREQ_PI01_TX3	25	DREQ_SPI0_RX	39	DREQ_PWM_WRAP7	53	DREQ_CORESIGHT
12	DREQ_PI01_RX0	26	DREQ_SPI1_TX	40	DREQ_PWM_WRAP8	54	DREQ_SHA256
13	DREQ_PI01_RX1	27	DREQ_SPI1_RX	41	DREQ_PWM_WRAP9		

#### 12.6.4.2. Credit-based DREQ Scheme

The RP2350 DMA is designed for systems where:

- The area and power cost of large peripheral data FIFOs is prohibitive.
- The bandwidth demands of individual peripherals can be high, for example, >50% bus injection rate for short periods.
- Bus latency is low, but multiple managers can compete for bus access.

In addition, the DMA's transfer FIFOs and dual-manager-port structure permit multiple accesses to the same peripheral to be in-flight at once to improve throughput. Choice of DREQ mechanism is therefore critical:

- The traditional "turn on the tap" method can cause overflow if multiple writes are backed up in the TDF. Some systems solve this by over-provisioning peripheral FIFOs and setting the DREQ threshold below the full level at the expense of precious area and power.
- The Arm-style single and burst handshake does not permit additional requests to be registered while the current request is being served. This limits performance when FIFOs are very shallow.

The RP2350 DMA uses a credit-based DREQ mechanism. For each peripheral, the DMA attempts to keep as many transfers in-flight as the peripheral has capacity for. This enables full bus throughput (1 word per clock) through an 8-deep peripheral FIFO with no possibility of overflow or underflow in the absence of fabric latency or contention.

For each channel, the DMA maintains a counter. Each 1-clock pulse on the `dreq` signal increments this counter. When non-zero, the channel requests a transfer from the DMA's internal arbiter. The counter decrements when the transfer is issued to the address FIFOs. At this point the transfer is in flight, but has not yet necessarily completed.

The counter is saturating, and six bits in size. The counter ignores increments at the maximum value or decrements at zero. The six-bit counter size supports counts up to the depth of any FIFO on RP2350.

表 1146. DREQs

DREQ	DREQ 通道	DREQ	DREQ 通道	DREQ	DREQ 通道	DREQ	DREQ 通道
0	DREQ_PI00_TX0	14	DREQ_PI01_RX2	28	DREQ_UART0_TX	42	DREQ_PWM_WRAP10
1	DREQ_PI00_TX1	15	DREQ_PI01_RX3	29	DREQ_UART0_RX	43	DREQ_PWM_WRAP11
2	DREQ_PI00_TX2	16	DREQ_PI02_TX0	30	DREQ_UART1_TX	44	DREQ_I2C0_TX
3	DREQ_PI00_TX3	17	DREQ_PI02_TX1	31	DREQ_UART1_RX	45	DREQ_I2C0_RX
4	DREQ_PI00_RX0	18	DREQ_PI02_TX2	32	DREQ_PWM_WRAP0	46	DREQ_I2C1_TX
5	DREQ_PI00_RX1	19	DREQ_PI02_TX3	33	DREQ_PWM_WRAP1	47	DREQ_I2C1_RX
6	DREQ_PI00_RX2	20	DREQ_PI02_RX0	34	DREQ_PWM_WRAP2	48	DREQ_ADC
7	DREQ_PI00_RX3	21	DREQ_PI02_RX1	35	DREQ_PWM_WRAP3	49	DREQ_XIP_STREAM
8	DREQ_PI01_TX0	22	DREQ_PI02_RX2	36	DREQ_PWM_WRAP4	50	DREQ_XIP_QMITX
9	DREQ_PI01_TX1	23	DREQ_PI02_RX3	37	DREQ_PWM_WRAP5	51	DREQ_XIP_QMIRX
10	DREQ_PI01_TX2	24	DREQ_SPI0_TX	38	DREQ_PWM_WRAP6	52	DREQ_HSTX
11	DREQ_PI01_TX3	25	DREQ_SPI0_RX	39	DREQ_PWM_WRAP7	53	DREQ_CORESIGHT
12	DREQ_PI01_RX0	26	DREQ_SPI1_TX	40	DREQ_PWM_WRAP8	54	DREQ_SHA256
13	DREQ_PI01_RX1	27	DREQ_SPI1_RX	41	DREQ_PWM_WRAP9		

#### 12.6.4.2. 基于信用的 DREQ 方案

RP2350 DMA 设计适用于如下系统环境：

- 大型外设数据 FIFO 的面积和功耗成本过高。
- 单个外设的带宽需求可能较大，例如短时间内总线注入率超过 50%。
- 总线延迟较低，但多个管理器可能竞争总线访问权。

此外，DMA 的传输 FIFO 及双管理器端口结构允许对同一外设的多次访问同时进行，以提升吞吐量。因此，DREQ 机制的选用至关重要：

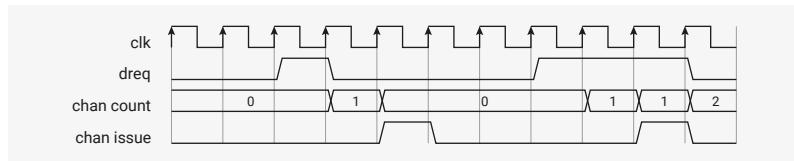

- 传统的“打开水龙头”方法在多个写入积压于 TDF 时可能导致溢出。部分系统通过超额配置外设 FIFO 并将 DR\_EQ 阈值设定在满容量以下解决此问题，尽管会牺牲宝贵的面积和功耗。
- Arm风格的单次和突发握手不允许在当前请求处理中注册额外请求。当FIFO深度较浅时，此限制会影响性能。

RP2350 DMA采用基于信用的DREQ机制。对于每个外设，DMA尝试保持尽可能多的传输同时进行，数量受外设容量限制。这使得在无结构延迟或争用的情况下，通过8级深度外设FIFO实现全总线吞吐量（每时钟1字）成为可能，且无溢出或欠载风险。

每个通道，DMA都会维护一个计数器。每个针对 `dreq`信号的1时钟脉冲都会使该计数器递增。当计数器非零时，通道向DMA内部仲裁器请求传输。当传输发往地址FIFO时计数器递减，此时传输已启动，但可能尚未完成。

该计数器为六位饱和计数器。计数器在达到最大值时忽略递增操作，在为零时忽略递减操作。六位计数器支持计数至RP2350上任意FIFO的深度。

Figure 123. DREQ counting

The effect is to upper bound the number of in-flight transfers based on the amount of room or data available in the peripheral FIFO. In the steady state, this gives maximum throughput, but can't underflow or overflow. This approach has the following caveats:

- The user *must not* access a FIFO currently being serviced by the DMA. This causes the channel and peripheral to become desynchronised, and can cause corruption or loss of data.
- Multiple channels *must not* be connected to the same DREQ.

## 12.6.5. Interrupts

Each channel can generate interrupts; these can be masked on a per-channel basis using one of the four identical interrupt enable registers, `INTE0` through `INTE3`. There are three circumstances where a channel raises an interrupt request:

- On the completion of each transfer sequence, if `CTRL.IRQ_QUIET` is disabled
- On receiving a null trigger, if `CTRL.IRQ_QUIET` is enabled
- On a read or write bus error

The masked interrupt status is visible in the `INTS` registers; there is one bit for each channel. Interrupts are cleared by writing a bit mask to `INTS`. One idiom for acknowledging interrupts is to read `INTS`, then write the same value back, so only enabled interrupts are cleared.

The RP2350 DMA provides four system IRQs, with independent masking and status registers (e.g. `INTE0`, `INTE1`). Any combination of channel interrupt requests can be routed to each system IRQ, though generally software only routes each channel interrupt to a single system IRQ. For example:

- Some channels can be given a higher priority in the system interrupt controller, if they have particularly tight timing requirements.
- In multiprocessor systems, different channel interrupts can be routed independently to different cores.
- When channels are assigned to a mixture of security domains, IRQs can also be assigned, so that software in each security domain can get interrupts from its own channels.

For debugging purposes, the `INTF` registers can force any channel interrupt to be asserted, which will cause assertion of any system IRQs that have that channel interrupt's enable bit set in their respective `INTE` registers.

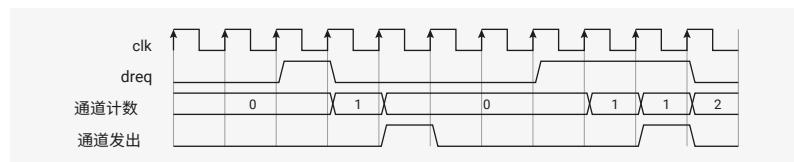

## 12.6.6. Security

RP2350's processors support partitioning of memory and peripherals into multiple security domains. This partitioning is extended into the DMA, so that different security contexts can safely use their assigned channels without breaking any of the security invariants laid out by the processor security model. For example, an Arm processor in the Non-secure state must not be able to use the DMA to access memory or peripherals owned by Secure software.

The DMA defines four **security levels** that map onto Arm or RISC-V processor security states:

- 3: SP (secure and privileged)
  - Equivalent to Arm processors in the Secure, Privileged state
  - Equivalent to RISC-V processors in Machine mode
- 2: SU (secure and unprivileged)

图123。DREQ  
计数

其效果是在外围设备FIFO中可用空间或数据量的基础上限制在途传输的最大数量。在稳态下，此方式保证最大吞吐量，且不会发生溢出或下溢。该方法具备以下注意事项：

- 用户不得访问DMA当前正在服务的FIFO，否则将导致通道与外围设备不同步，可能引发数据损坏或丢失。
- 多个通道不得连接至相同的DREQ。

### 12.6.5. 中断

每个通道均可产生中断；这些中断可通过四个相同的中断使能寄存器INTE0至INTE3按通道分别屏蔽。通道发出中断请求的情况有三种：

- 每个传输序列完成时，若`CTRL.IRQ.QUIET`未启用
- 在接收到空触发时，若启用了`CTRL.IRQ.QUIET`
- 发生读或写总线错误时

掩码中断状态可在 `INTS` 寄存器中查看；每个通道对应一位。通过向 `INTS` 寄存器写入位掩码以清除中断。确认中断的一种惯用做法是先读取 `INTS`，然后将相同的值写回，从而仅清除已启用的中断。

RP2350 DMA 提供四个系统 IRQ，配备独立的屏蔽和状态寄存器（例如 `INTE0` 和 `INTE1`）。任意组合的通道中断请求可路由至每个系统 IRQ，尽管通常软件只将每个通道中断路由至单个系统 IRQ。例如：

- 若某些通道具有特别严格的时序需求，则可在系统中断控制器中赋予其更高优先级。
- 在多处理器系统中，不同通道中断可独立路由至不同内核。
- 当通道分配至混合安全域时，IRQ 亦可分配，以使各安全域的软件能接收来自其自身通道的中断。

出于调试目的，`INTF` 寄存器可强制任意通道中断被激活，从而导致在对应 `INTE` 寄存器中设置了该通道中断使能位的任何系统 IRQ 被断言。

### 12.6.6. 安全性

RP2350 的处理器支持将内存和外设划分为多个安全域。此划分扩展至 DMA，使不同安全上下文能够安全地使用其分配的通道，而不破坏处理器安全模型所规定的任何安全不变量。例如，处于非安全态的 Arm 处理器不得通过 DMA 访问由安全软件拥有的内存或外设。

DMA 定义了四个安全级别，映射至 Arm 或 RISC-V 处理器的安全状态：

- 3: SP (安全且特权)
  - 等同于处于安全且特权态的 Arm 处理器
  - 等同于处于机器模式的 RISC-V 处理器
- 2: SU (安全且非特权)

- Equivalent to Arm processors in the Secure, Normal state
- 1: NSP (nonsecure and privileged)
  - Equivalent to Arm processors in the Non-secure, Privileged state
  - Equivalent to RISC-V processors in Supervisor mode
- 0: NSU (nonsecure and unprivileged)
  - Equivalent to Arm processors in the Non-secure, Normal state
  - Equivalent to RISC-V processors in User mode

So that the DMA can compare different security levels in a consistent way, they are considered ordered, with SP > SU > NSP > NSU. For example, when we say that a channel requires a *minimum* of SU to access its registers, this means that SP and SU are acceptable, and NSP and NSU are not. As a rule, every action has a reaction that is *at or below* the security level of the original action, and so the DMA can not be used to escalate accesses to a higher security level.

Software assigns internal DMA resources, like channels, interrupts, pacing timers and the CRC sniffer, to one of the four possible security levels. These resources are then accessible only at and above that level. Channel assignment in particular is discussed in [Section 12.6.6.1](#).

The DMA memory protection unit ([Section 12.6.6.3](#)) defines the minimum security level required to access up to eight programmable address ranges, so that channels of a given security level can not access memory beyond their means. This MPU is intended to mirror the SRAM and XIP memory protection boundaries configured in the processor SAU or PMP. In addition to the internal filtering performed by the DMA MPU, accesses are filtered by the system bus according to the ACCESSCTRL filter rules described in [Section 10.6.2](#).

The combination of these features allows the DMA to be safely shared by software running in different security domains. If this is not desired, the entire DMA block can instead be assigned wholesale to a single security domain using the ACCESSCTRL [DMA](#) register.

### 12.6.6.1. Channel security assignment

Channels are assigned to security domains using the channel [SECCFG](#) registers, [SECCFG\\_CH0](#) through [SECCFG\\_CH15](#). There is one register per channel. Each register contains a 2-bit security level, and a lock bit that prevents that [SECCFG](#) register from being changed once configured. At reset, all channels are assigned to the SP security level, which is the highest.

The security level of a channel defines:

- The security level of bus transfers performed by this channel, which is checked against both the DMA memory protection unit and the ACCESSCTRL bus-level filters described in [Section 10.6.2](#).
- The minimum security level required to read or write this channel's registers; access from a lower level returns a bus fault.
- The minimum security level that must be defined on a shared IRQ line for that IRQ to be able to observe this channel's interrupts ([Section 12.6.6.2](#)), or for this channel's interrupt to be set/cleared through that IRQ's registers.
- The minimum bus security level required to clear this channel's interrupts through the [INTR](#) register.
- Which DREQs a channel can observe: channels assigned to the NSP or NSU security levels can not observe DREQs of Secure-only peripherals (as defined by the ACCESSCTRL peripheral configuration).
- Which pacing timer TREQs can be observed; pacing timer security levels are configured by [SECCFG\\_MISC](#) and must be no higher than the channel security level for the channel in order to observe the TREQ.
- Whether the channel is visible to the CRC sniffer; the sniffer's security level is configured by [SECCFG\\_MISC](#) and must be no lower than the observed channel's security level.
- Which channels this channel can trigger with a [CHAIN\\_TO](#); chaining from lower to higher security levels is not permitted.

- 等同于处于安全且普通态的 Arm 处理器
- 1: NSP (非安全且特权)
  - 等同于处于非安全、特权态的 Arm 处理器
  - 等同于处于监督模式的 RISC-V 处理器
- 0: NSU (非安全且非特权)
  - 等同于处于非安全、正常态的 Arm 处理器
  - 等同于处于用户模式的 RISC-V 处理器

为使 DMA 能够以一致方式比较不同安全级别，安全级别被视为有序，顺序为 SP > SU > NSP > NSU。例如，当我们说某通道访问其寄存器所需的最低安全级别为 SU 时，表示 SP 和 SU 可接受，而 NSP 和 NSU 不可接受。通常，每个动作对应的响应安全级别不高于该动作，因此 DMA 不能用于提升访问权限至更高安全级别。

软件将内部 DMA 资源，如通道、中断、节奏定时器及 CRC 嗅探器，分配至四个可能的安全级别之一。这些资源随后仅在该安全级别及以上可访问。频道分配的具体内容详见第12.6.6.1节。

DMA内存保护单元（第12.6.6.3节）定义了访问多达八个可编程地址范围所需的最低安全级别，确保具有特定安全级别的通道无法访问超出其权限的内存区域。

该MPU旨在映射处理器SAU或PMP中配置的SRAM和XIP内存保护边界。除DMA MPU执行的内部过滤外，访问还会根据第10.6.2节中描述的ACCESSCTRL过滤规则，由系统总线进行过滤。

这些功能的结合使DMA能够安全地被运行于不同安全域的软件共享。如不希望如此，可通过ACCESSCTRL DMA寄存器将整个DMA模块完整分配至单一安全域。

### 12.6.6.1. 通道安全分配

通道通过通道SECCFG寄存器（SECCFG\_CH0至SECCFG\_CH15）分配至安全域。

每个通道对应一个寄存器。每个寄存器包含一个2位的安全级别和一个锁定位，该锁定位防止该 SECCFG 寄存器在配置后被更改。复位时，所有通道均被分配为SP安全级别，且该级别为最高。

通道的安全级别定义如下：

- 该通道执行的总线传输的安全级别，将同时与DMA内存保护单元及第10.6.2节所述的ACCESSCTRL总线级过滤器进行校验。
- 读取或写入该通道寄存器所需的最低安全级别；低于该级别的访问将返回总线错误。
- 共享IRQ线上必须定义的最低安全级别，以使该IRQ能够监视此通道的中断（见第12.6.6.2节），或通过该IRQ的寄存器设置/清除该通道中断。
- 通过INTR寄存器清除该通道中断所需的最低总线安全级别。
- 通道能够监视的DREQ信号：分配为NSP或NSU安全级别的通道无法监视仅限安全外设的DREQ（如ACCESSCTRL外设配置所定义）。
- 可以观察到哪些pacing timer TREQ；pacing timer的安全级别由SECCFG\_MISC配置，且不得高于该通道的通道安全级别，方可观察TREQ。
- 该通道是否对CRC嗅探器可见；嗅探器的安全级别由SECCFG\_MISC配置，且不得低于被观察通道的安全级别。
- 该通道可通过 CHAIN\_TO 触发哪些通道；不允许从较低安全级别向较高安全级别的链式触发。

- The minimum bus security level required to trigger this channel with a write to [MULTI\\_CHAN\\_TRIGGER](#).

The channel [SECCFG](#) registers require privileged writes (SP/NSP), and will generate a bus fault on an attempted unprivileged write (SU/NSU). Additionally, the [S](#) bit (MSB of the security level) and the [LOCK](#) bit are writable only by SP, whilst the [P](#) bit (LSB of the security level) is also writable by NSP, if and only if the [S](#) bit is clear. Reads are always allowed: it is always possible to query which channels are assigned to you by reading the channel [SECCFG](#) registers.

Each channel [SECCFG](#) register can be locked manually by writing a one to the [LOCK](#) bit in that register, and will also lock automatically upon a successful write to one of the channel's control registers such as [CH0\\_CTRL\\_TRIG](#). This automatic locking avoids any race conditions that can arise from a channel's security level changing after it has already started making transfers, or from leaking secure pointers that have been written to its control registers. After a channel [SECCFG](#) register has been locked, it becomes read-only. [LOCK](#) bits can be cleared only by a full reset of the DMA block.

[SECCFG](#) registers can be written multiple times before being locked, so the full assignment does not have to be known up front: for example, Secure Arm software can set spare channels to NSP before launching the Non-secure software context, and Non-secure, Privileged software can then set the remaining channels it does not need to NSU before returning to the Non-secure, Normal context.

### 12.6.6.2. Interrupt Security Assignment

The RP2350 DMA has four system-level interrupt request lines (IRQs), each of which can be asserted on any combination of channel interrupts, as defined by the channel masks in the interrupt enable registers [INTE0](#) through [INTE3](#). Because the timing of interrupts can leak information, and because it is possible to cause software to malfunction by deliberately manipulating its interrupts, access to the channel interrupt flags must be controlled.

The interrupt security configuration registers, [SECCFG\\_IRQ0](#) through [SECCFG\\_IRQ3](#), define the security level for each interrupt. This is one of the four security levels laid out in [Section 12.6.6](#). The security level of an IRQ defines:

- Which channels are visible in this IRQ's status registers; channels of a level higher than the IRQ's will read back as zero.
- Whether a bus access to this IRQ's control and status registers is permitted; bus accesses below this IRQ's security level will return bus faults and have no effect on the DMA.
- Which channels will assert this IRQ; channels of a level higher than this IRQ's level will not cause the interrupt to assert, even if relevant INTE bit is set.
- Whether a channel's interrupt can be cleared through this IRQ's INTS register, or set through this channel's INTF register; the interrupt flags of channels of higher security level than the IRQ can not be set or cleared.

The [INTR](#) register is shared between all IRQs, so it does not respect any of the IRQ security levels. Instead, it follows the security level of the bus access: reads of [INTR](#) will return the interrupt flags of all channels at or below the security level of the bus access (with higher-level channels reading back as zeroes), and writes to [INTR](#) have write-one-clear behaviour on channels which are at or below the security level of the bus access.

### 12.6.6.3. Memory protection unit

The DMA memory protection unit (MPU) monitors the addresses of all read/write transfers performed by the DMA, and notes the security level of the originating channel. The MPU is configured in advance with a user-defined security address map, which specifies the *minimum* security level required to access up to eight dynamically configured regions. This is one of the four security levels defined in [Section 12.6.6](#).

Transfers that fail to meet the minimum security level for their address are shot down before reaching the system bus, and a bus error is returned to the originating channel. This will be reported as either a read or write bus error in the channel's [CTRL](#) register, depending on whether it was a read or write address that failed the security check.

The intended use for the DMA MPU is to mirror the security definitions of SRAM and XIP memory from the processor SAU or PMP. The number of DMA MPU regions is not sufficient for assigning individual peripherals, so the ACCESSCTRL bus access registers ([Section 10.6.2](#)) are provided for this purpose.

- 通过向MULTI\_CHAN\_TRIGGER写入触发该通道所需的最低总线安全级别。

通道 **SECCFG** 寄存器要求特权写入（SP/NSP），非特权写入（SU/NSU）将导致总线错误。此外，**S**位（安全级别最高有效位）和**LOCK**位仅限SP写入；而**P**位（安全级别最低有效位）仅在**S**位为0时，方可由NSP写入。读取始终被允许：始终可以通过读取通道 **SECCFG** 寄存器查询分配给您的通道。

每个通道 **SECCFG** 寄存器可通过向该寄存器中的 **LOCK**位写入1来手动锁定，且在对该通道的任一控制寄存器（如CH0\_CTRL\_TRIG）成功写入后会自动锁定。此自动锁定避免了通道安全级别在开始传输后变化，或控制寄存器中已写入的安全指针泄露可能引发的竞态条件。通道**SECCFG** 寄存器锁定后即变为只读。**LOCK**位仅能通过对DMA模块进行完全复位来清除。

**SECCFG** 寄存器在锁定前可多次写入，因此无需预先完全确定分配方案：例如，安全Arm软件可在启动非安全软件上下文之前将备用通道设置为NSP，非安全特权软件随后可将不再需要的剩余通道设为NSU，之后返回至非安全普通上下文。

### 12.6.6.2. 中断安全分配

RP2350 DMA具有四条系统级中断请求线（IRQ），每条IRQ可由通道中断的任意组合触发，其组合由中断使能寄存器INT\_E0至INT\_E3中的通道掩码定义。鉴于中断时序可能泄露信息，且恶意操控中断可能导致软件异常，必须严格控制对通道中断标志的访问。

中断安全配置寄存器SECCFG IRQ0至SECCFG IRQ3定义了各中断的安全级别。该安全级别为第12.6.6节中列示的四个安全等级之一。IRQ的安全级别定义了：

- 该IRQ状态寄存器中哪些通道可见；安全级别高于该IRQ的通道将读回零值。
- 是否允许对该IRQ的控制和状态寄存器进行总线访问；低于该IRQ安全级别的总线访问将导致总线错误，且不会对DMA产生任何影响。
- 哪些通道会断言该IRQ；高于该IRQ级别的通道不会导致中断断言，即使相关的INTE位已设置。
- 某通道的中断是否可以通过该IRQ的INTS寄存器清除，或通过该通道的INTF寄存器设置；高于该IRQ安全级别的通道的中断标志无法被设置或清除。

INTR寄存器由所有IRQ共用，因此不遵守任何IRQ的安全级别。相反，其遵循总线访问的安全级别：读取INTR将返回所有处于总线访问安全级别及以下的通道的中断标志（高于该级别的通道读取结果为零），对INTR的写入具有写一清零行为，且仅针对处于总线访问安全级别及以下的通道生效。

### 12.6.6.3. 内存保护单元

DMA内存保护单元（MPU）监控DMA执行的所有读/写传输的地址，并记录源通道的安全级别。MPU预先配置了用户定义的安全地址映射，该映射指定了访问最多八个动态配置区域所需的最低安全级别。

这是第12.6.6节中定义的四个安全级别之一。

未达到其地址最低安全级别的传输在到达系统总线之前将被终止，并向起始通道返回总线错误。这将在通道的 **CTRL** 寄存器中报告为读或写总线错误，具体取决于安全检查失败的是读地址还是写地址。

DMA MPU的预期用途是反映处理器SAU或PMP中SRAM和XIP存储器的安全定义。由于DMA MPU区域数量不足以分配给各个外围设备，因此为此目的提供了ACCESSCTRL总线访问寄存器（第10.6.2节）。

Each of the eight MPU regions is configured with a base address, [MPU\\_BAR0](#) through [MPU\\_BAR7](#) for each region, and a limit address, [MPU\\_LAR0](#) through [MPU\\_LAR7](#).

MPU regions have a granularity of 32 bytes, so the base/limit addresses are configured by the 27 most-significant bits of each [BAR/LAR](#) register (bits 31:5). Addresses match MPU regions when the 27 most-significant bits of the address are greater than or equal to the [BAR](#) address bits, and less than or equal to the [LAR](#) address bits. For example, when [MPU\\_BAR0](#) and [MPU\\_LAR0](#) both have the value `0x1000000`, MPU region 0 matches on a 32-byte region extending from byte address `0x1000000` to `0x1000001f` (inclusive). Regions can be enabled or disabled using the [LAR.EN](#) bits – if a region is disabled, it matches no addresses.

The minimum security level required to access each region is defined by the [S](#) and [P](#) bits in the LSBs of that region's [LAR](#) register. When an address matches multiple regions, the lowest-numbered region applies. This matches the tie-break rules for the RISC-V PMP, but is different from the Arm SAU tie-break rules, so care must be taken when mirroring SAU mappings with overlapping regions. When none of the MPU regions are matched, the security level is defined by the global [MPU\\_CTRL.S](#) and [MPU\\_CTRL.P](#) bits.

The MPU configuration registers ([MPU\\_CTRL](#), [MPU\\_BAR0](#) through [MPU\\_BAR7](#) and [MPU\\_LAR0](#) through [MPU\\_LAR7](#)) do not permit unprivileged access. Bus accesses at the SU and NSU security levels will return a bus fault and have no other effect.

The MPU registers are also mostly read-only to NSP accesses, with the sole exception being the region [P](#) bits which are NSP-writable if and only if the corresponding region's [S](#) bit is clear. This delegates to Privileged, Non-secure software the decision of whether Non-secure regions are NSU-accessible.

### 12.6.7. Bus error handling

A bus error is an error condition flagged to one of the DMA's manager ports in response to an attempted read or write transfer, indicating the transfer was rejected for one of the following reasons:

- The DMA MPU forbids access to this address at the originating channel's security level ([Section 12.6.6.3](#)).
- The bus fabric failed to decode the address; the address did not match any known memory location (for example SIO is not visible from the DMA bus ports as it is tightly coupled to the processors).
- ACCESSCTRL forbids access to the addressed region at the originating channel's privilege level ([Section 10.6.2](#)).
- ACCESSCTRL forbids DMA access to the addressed region, irrespective of privilege.
- The APB bridge returned a timeout fault for a transfer exceeding 65535 cycles (e.g. accessed ADC whilst `clk_adc` was stopped).
- The downstream bus port returned an error response for any other device-specific reason, e.g. attempting to access configuration registers for a DMA channel with higher security level ([Section 12.6.6.1](#)).

#### 12.6.7.1. Response to bus errors

Upon encountering a bus error, the DMA halts the offending channel and reports the error through the channel's [CH0\\_CTRL\\_TRIG.READ\\_ERROR](#) and [WRITE\\_ERROR](#) flags. The channel stops scheduling bus accesses.

Bus errors are exceptional events which usually indicate misconfiguration of the DMA or some other system hardware. Therefore the DMA refuses to restart the offending channel until its error status is cleared by writing 1 to the relevant error flag. Other channels are not affected, and continue their transfer sequences uninterrupted.

A channel which encounters a bus error does not [CHAIN\\_TO](#) other channels.

Bus errors always cause the channel's interrupt request to be asserted. Whether or not this causes a system-level IRQ depends on the channel masks configured in interrupt enable registers [INTE0](#) through [INTE3](#).

八个MPU区域中的每一个均配置有基址，分别为MPU\_BAR0至MPU\_BAR7，以及限制地址，分别为MPU\_LAR0至MPU\_LAR7。

MPU区域的粒度为32字节，因此基址/限制地址由每个 BAR/LAR寄存器的27个最高有效位（位 31:5）配置。当地址的27个最高有效位大于或等于 BAR地址位且小于或等于 LAR地址位时，地址匹配MPU区域。例如，当MPU\_BAR0和MPU\_LAR0的值均为 0x10000000时，MPU区域0匹配一个从字节地址 0x10000000至 0x1000001f（含）扩展的32字节区域。区域可通过 LAR.E位启用或禁用——若区域被禁用，则不匹配任何地址。

访问每个区域所需的最低安全级别由该区域LAR寄存器最低有效位的S和P位定义。当地址匹配多个区域时，优先适用编号最低的区域。此规则符合RISC-V PMP的平局判定规则，但与Arm SAU的平局判定规则不同，因此在镜像具有重叠区域的SAU映射时务必谨慎。当没有任何MPU区域匹配时，安全级别由全局MPU\_CTRL.S和MPU\_CTRL.P位确定。

MPU配置寄存器（MPU\_CTRL、MPU\_BAR0至MPU\_BAR7及MPU\_LAR0至MPU\_LAR7）不允许非特权访问。在SU和NSU安全级别下的总线访问将产生总线错误且不产生其他影响。

MPU寄存器对NSP访问大多为只读，唯一例外是区域 P位，且仅当对应区域的 S位清零时，该P位可由NSP写入。此项委托特权非安全软件决定非安全区域是否允许NSU访问。

## 12.6.7. 总线错误处理

总线错误是指DMA管理端口之一所报告的错误状态，表明尝试的读写传输因下列原因之一被拒绝：

- DMA MPU禁止源通道在其安全级别访问该地址（见第12.6.3节）。
- 总线结构未能解码该地址；该地址未匹配任何已知内存位置（例如SIO因紧密耦合于处理器，从DMA总线端口不可见）。
- ACCESSCTRL禁止源通道在其特权级别访问所寻址区域（见第10.6.2节）。
- ACCESSCTRL不论特权级别，均禁止DMA访问所寻址区域。
- APB桥在传输超时超过65535周期时返回超时故障（例如访问ADC时 clk\_adc 已停止）。
- 下游总线端口因其他设备特定原因返回错误响应，例如尝试访问安全级别更高的DMA通道配置寄存器（见第12.6.1节）。

### 12.6.7.1. 总线错误响应

遇到总线错误时，DMA将停止违规通道，并通过该通道的CHO\_CTRL\_TRIG.READ\_ERROR及WRITE\_ERROR标志报告该错误。通道停止调度总线访问。

总线错误为异常事件，通常指示DMA或其他系统硬件配置错误。

因此，DMA拒绝重新启动故障通道，直到通过向相关错误标志写入 1清除其错误状态。其他通道不受影响，继续不间断地执行传输序列。

遇到总线错误的通道不会 CHAIN\_TO 其他通道。

总线错误必然会触发通道的中断请求。是否产生系统级IRQ取决于中断使能寄存器INTE0至INTE3中配置的通道屏蔽状态。

### 12.6.7.2. Recovery after bus errors

If an error is reported through `READ_ERR/WRITE_ERR` then, before restarting the channel, software must:

1. Poll for a low `BUSY` status to ensure that all in-flight transfers for this channel have been flushed from the DMA's bus pipeline.
2. Clear the error flags by writing `1` to each flag.

Generally the `BUSY` flag will already be low long before the processor enters its interrupt handler and checks the error status, but it is possible for these events to overlap when the DMA is accessing a slow device such as XIP with a high `SCK` divisor and processors are executing from SRAM.

`READ_ADDR` and `WRITE_ADDR` contain the approximate address where the bus error was encountered. This can be useful for the programmer to understand why the bus error occurred, and fix the software to avoid it in future.

Since the DMA performs reads and writes in parallel, it is possible for a channel to encounter both a read and write error simultaneously, and in this case the DMA sets both `READ_ERR` and `WRITE_ERR`. You must clear both.

### 12.6.7.3. Halt timing

The DMA halts the channel as soon as possible following a bus error. This suppresses future reads and writes. Because the request to access the bus is masked, the bus access has no side effects on the system. The timing relationships are not straightforward due to the DMA's pipelining and buffering. The DMA provides the following ordering guarantees between transfers originating from one channel:

- Read error → read suppression: Any reads scheduled to occur after a faulting read *will* be suppressed, but *can* still increment `READ_ADDR` up to two times total
- Write error → write suppression: Any writes scheduled to occur after a faulting write *will* be suppressed, but *can* still increment `WRITE_ADDR` up to four times total
- Read error → write suppression:
  - Any write paired with a faulting read *will* be suppressed, but *will* increment `WRITE_ADDR`
  - Any write following the first write paired with a faulting read *will* be suppressed, but *can* increment `WRITE_ADDR` up to three times total
  - Up to three writes immediately preceding the first write paired with a faulting read *can* be suppressed, but *will* increment `WRITE_ADDR`
- Write error → read suppression:
  - Reads paired with writes before the first faulting write *will not* be suppressed, and *will* increment `READ_ADDR`.
  - Up to two read transfers paired with writes after the first faulting write *can* be suppressed, and *can* increment `READ_ADDR`

"Paired with" in the above paragraph refers to *the write access which writes data originating from a particular read transfer*, or vice versa. The DMA always schedules read and write accesses in matched pairs.

Slight variability in halt behaviour is due to the buffering of in-flight transfers, and the parallel operation of the read and write bus ports. The values of `READ_ADDR/WRITE_ADDR` following a bus error can be slightly beyond the address that experienced the first error, but the difference is bounded, and usually this is still sufficient to diagnose the reason for the fault. Additionally, `READ_ADDR` and `WRITE_ADDR` are guaranteed to over-increment by the same amount, since reads and writes are always scheduled in pairs.

In addition to the increments mentioned above, `READ_ADDR/WRITE_ADDR` always point to the *next* address to be written, so always point slightly past the faulting address if address increment is enabled.

### 12.6.7.2. 总线错误后的恢复

若通过 `READ_ERR`/`WRITE_ERR` 报告错误，则在重启通道前，软件必须：

1. 轮询 `BUSY` 信号至低电平，确保该通道所有在执行中的传输已从 DMA 总线流水线中清除。
2. 通过向每个错误标志写入 1 以清除错误标志。

通常，处理器进入中断处理程序并检查错误状态前，`BUSY` 标志早已变为低电平，但当 DMA 访问诸如 XIP 这类高 `SCK` 分频慢速设备且处理器从 `SRAM` 执行时，这些事件可能存在重叠。

`READ_ADDR` 和 `WRITE_ADDR` 包含发生总线错误的大致地址。这有助于程序员理解总线错误发生的原因，并修正软件以避免将来再发生此类错误。

由于 DMA 并行执行读写操作，通道可能同时遇到读错误和写错误，在这种情况下，DMA 会同时设置 `READ_ERR` 和 `WRITE_ERR`。您必须同时清除两者。

### 12.6.7.3. 停止时序

DMA会在发生总线错误后尽快停止该通道。这将抑制后续的读写操作。由于访问总线的请求被屏蔽，访问总线对系统没有副作用。由于 DMA 的流水线和缓冲机制，时序关系较为复杂。DMA 对于来自同一通道的传输提供以下顺序保证：

- 读错误 → 读操作抑制：任何计划在故障读操作之后执行的读操作将被抑制，但仍可最多递增 `READ_ADDR` 两次
- 写入错误 → 写入抑制：任何计划在出错写入之后进行的写入将被抑制，但仍可最多增加 `WRITE_ADDR` 四次
- 读取错误 → 写入抑制：
  - 任何与出错读取配对的写入将被抑制，但会增加 `WRITE_ADDR`
  - 紧随与出错读取配对的首次写入之后的任何写入将被抑制，但最多可增加 `WRITE_ADDR` 三次
  - 紧接与出错读取配对的首次写入之前的最多三次写入可被抑制，但会增加 `WRITE_ADDR`
- 写入错误 → 读取抑制：
  - 与首次出错写入之前的写入配对的读取不会被抑制，且会增加 `READ_ADDR`。
  - 与首次出错写入之后的写入配对的最多两次读取传输可被抑制，且可增加 `READ_ADDR`

上述段落中的“配对”是指写入访问，即写入来自特定读取传输的数据，或反之亦然。DMA 始终按配对方式调度读写访问。

停机行为的细微差异源于在途传输的缓冲以及读写总线端口的并行运行。发生总线错误后，`READ_ADDR`/`WRITE_ADDR` 的值可能略超首次出错的地址，但此差异有界，通常仍足以诊断故障原因。此外，`READ_ADDR` 和 `WRITE_ADDR` 保证以相同增量超前，因为读写操作始终成对调度。

除上述增量外，`READ_ADDR`/`WRITE_ADDR` 始终指向下一个待写入地址，因此若启用地址递增，总会略超故障地址。

## 12.6.8. Additional features

### 12.6.8.1. Pacing timers

These allow transfer of data roughly once every  $n$  `clk_sys` clocks instead of using external peripheral DREQ to trigger transfers. A fractional (X/Y) divider is used, and will generate a maximum of 1 request per `clk_sys` cycle.

There are 4 timers available in RP2350. Each DMA channel is able to select any of these in `CTRL.TREQ_SEL`. There is one register used to configure the pacing coefficients for each timer, `TIMER0` through `TIMER3`.

Each timer's security level is defined by a register field in `SECCFG_MISC`. This defines the minimum bus security level required to configure that timer (lower levels will get a bus fault), and the minimum channel security level required to observe that timer's TREQ.

### 12.6.8.2. CRC calculation

The DMA can watch data from a given channel passing through the data FIFO, and calculate checksums based on this data. This is a purely passive affair: the data is not altered by this hardware, only observed.

The feature is controlled via the `SNIFF_CTRL` and `SNIFF_DATA` registers, and can be enabled/disabled per DMA transfer via the `CTRL.SNIFF_EN` field.

As this hardware cannot place back-pressure on the FIFO, it must keep up with the DMA's maximum transfer rate of 32 bits per clock.

The supported checksums are:

- CRC-32, MSB-first and LSB-first
- CRC-16-CCITT, MSB-first and LSB-first
- Simple summation (add to 32-bit accumulator)
- Even parity

The result register is both readable and writable, so that the initial seed value can be set.

Bit/byte manipulations are available on the result, which can aid specific use cases:

- Bit inversion
- Bit reversal
- Byte swap

These manipulations do not affect the CRC calculation, just how the data is presented in the result register.

The sniffer's security level is configured by the `SECCFG_MISC.SNIFF_S` and `SECCFG_MISC.SNIFF_P` bits. This determines the minimum bus security level required to access the sniffer's control registers, as well as the maximum channel security level that the sniffer can observe.

### 12.6.8.3. Channel abort

It is possible for a channel to get into an irrecoverable state. If commanded to transfer more data than a peripheral will ever request, the channel will never complete. Clearing the `CTRL.EN` bit pauses the channel, but does not solve the problem. This should not occur under normal circumstances, but it is important that there is a mechanism to recover without simply hard-resetting the entire DMA block.

In such a situation, use the `CHAN_ABORT` register to force the channel to complete early. There is one bit for each channel. Writing a 1 to the corresponding bit terminates the channel. This clears the transfer counter and forces the channel into an inactive state.

## 12.6.8. 附加功能

### 12.6.8.1. 节奏定时器

该定时器允许约每  $n$  个 `clk_sys` 时钟周期传输一次数据，无需使用外部外围设备 DREQ 触发传输。采用分数 (X/Y) 分频器，并在每个 `clk_sys` 周期内最多产生 1 次请求。

RP2350 中提供 4 个定时器。每个 DMA 通道可在 `CTRL.TREQ_SEL` 中选择其中任意一个定时器。有一个寄存器用于配置每个定时器 (TIMER0 至 TIMER3) 的步进系数。

每个定时器的安全级别由 SECCFG\_MISC 中的寄存器字段定义。该字段规定了配置该定时器所需的最低总线安全级别（较低级别将导致总线故障），以及观察该定时器 TREQ 所需的最低通道安全级别。

### 12.6.8.2. CRC 计算

DMA 可监视经数据 FIFO 的指定通道数据，并基于该数据计算校验和。该过程纯属被动：硬件不会更改数据，仅进行监控。

该功能通过 `SNIFF_CTRL` 和 `SNIFF_DATA` 寄存器控制，并可通过 `CTRL.SNIFF_EN` 字段针对每次 DMA 传输单独启用或禁用。

由于该硬件无法对 FIFO 施加背压，必须跟上 DMA 的最大传输速率，即每个时钟 32 位。

支持的校验和如下：

- CRC-32，MSB 优先和 LSB 优先
- CRC-16-CCITT，MSB 优先和 LSB 优先
- 简单求和（加至 32 位累加器）
- 偶校验

结果寄存器为可读可写，允许设置初始种子值。

结果寄存器支持位/字节操作，以协助特定使用场景：

- 位反转
- 位序反转
- 字节交换

这些操作不会影响 CRC 计算，仅会改变结果寄存器中数据的呈现形式。

嗅探器的安全级别由 `SECCFG_MISC.SNIFF_S` 和 `SECCFG_MISC.SNIFF_P` 位配置。此配置决定访问嗅探器控制寄存器时所需的最小总线安全级别，以及嗅探器可监视的最大通道安全级别。

### 12.6.8.3 通道中止

通道可能进入不可恢复的状态。如果指令要求传输的数据量超过外围设备的请求，通道将无法完成。清除 `CTRL.EN` 位会暂停通道，但不能解决该问题。正常情况下不会发生此问题，但必须具备在不对整个 DMA 模块进行硬复位的情况下恢复的机制。

在此情况下，应使用 `CHAN_ABORT` 寄存器强制通道提前完成。每个通道对应一个位。向对应位写入 1 将终止该通道。此操作清除传输计数器并使通道进入非活动状态。

At the time an abort is triggered, a channel might have bus transfers currently in flight between the read and write manager. These transfers cannot be revoked. The `CTRL.BUSY` flag stays high until these transfers complete, and the channel reaches a safe state. This generally takes only a few cycles. The channel must not be restarted until its `CTRL.BUSY` flag de-asserts. Starting a new sequence of transfers whilst transfers from an old sequence are still in flight will cause unpredictable behaviour.

The sequence to abort one or more channels in an unknown state (also accounting for the behaviour described in RP2350-E5) is:

1. Clear the `EN` bit and disable `CHAIN_TO` for all channels to be aborted.
2. Write the `CHAN_ABORT` register with a bitmap of those same channels.
3. Poll the `ABORT` register until all bits set by the previous write are clear.

When aborting a channel involved in a `CHAIN_TO`, it is recommended to simultaneously abort all other channels involved in the chain.

#### 12.6.8.4. Debug

Debug registers are available for each DMA channel to show the dreq counter `DBG_CTDREQ` and next transfer count `DBG_TCR`. These can also be used to reset a DMA channel if required.

### 12.6.9. Example use cases

#### 12.6.9.1. Using interrupts to reconfigure a channel

When a channel finishes a block of transfers, it becomes available for making more transfers. Software detects that the channel is no longer busy, and reconfigures and restarts the channel. One approach is to poll the `CTRL_BUSY` bit until the channel is done, but this loses one of the key advantages of the DMA, namely that it does *not* have to operate in lockstep with a processor. By setting the correct bit in `INTE0` through `INTE3`, you can instruct the DMA to raise one of its four interrupt request lines when a given channel completes. Rather than repeatedly asking if a channel is done, you are told.

**NOTE**

Having four system interrupt lines allows different channel completion interrupts to be routed to different cores, or to pre-empt one another on the same core if one channel is more time-critical. It also allows channel interrupts to target different security domains.

When the interrupt is asserted, the processor can be configured to drop whatever it is doing and call a user-specified handler function. The handler can reconfigure and restart the channel. When the handler exits, the processor returns to the interrupted code running in the foreground.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/dma/channel\\_irq/channel\\_irq.c](https://github.com/raspberrypi/pico-examples/blob/master/dma/channel_irq/channel_irq.c) Lines 35 - 52

```

35 void dma_handler() {
36 static int pwm_level = 0;
37 static uint32_t wavetable[N_PWM_LEVELS];
38 static bool first_run = true;
39 // Entry number `i` has `i` one bits and `(32 - i)` zero bits.
40 if (first_run) {
41 first_run = false;
42 for (int i = 0; i < N_PWM_LEVELS; ++i)
43 wavetable[i] = ~(~0u << i);
44 }
45 }
```

触发中止时，通道可能正处于读写管理器之间的总线传输过程中。这些传输无法撤销。直到这些传输完成且通道达到安全状态，**CTRL.BUSY**标志位保持高电平。这通常只需几个周期。通道在其**CTRL.BUSY**标志取消置位前不得重新启动。当旧序列的传输仍在进行中时启动新的传输序列，将导致不可预测的行为。

中止一个或多个处于未知状态的通道的操作序列（同时兼顾RP2350-E5中描述的行为）如下：

1. 清除所有需中止通道的**EN**位，并禁用**CHAIN\_TO**。
2. 向**CHAN\_ABORT**寄存器写入对应通道的位图。
3. 轮询**ABORT**寄存器，直至先前写入的所有位清除。

中止涉及**CHAIN\_TO**的通道时，建议同时中止该链中的所有其他通道。

#### 12.6.8.4. 调试

每个DMA通道均配有调试寄存器，用于显示dreq计数器**DBG\_CTDREQ**及下一个传输计数**DBG\_TCR**。如有需要，这些寄存器亦可用于重置DMA通道。

### 12.6.9. 示例用例

#### 12.6.9.1. 使用中断重新配置通道

当通道完成一段传输后，即变得可用于执行更多传输。软件检测到通道不再忙碌，随即重新配置并重新启动该通道。一种方法是轮询**CTRL\_BUSY**位，直到通道完成，但这会丧失DMA的一个关键优势，即无需与处理器同步操作。通过设置INTE0至INTE3中的相应位，可以指示DMA在特定通道完成时触发其四个中断请求线之一。您无需反复查询通道状态，而是会主动接收到通知。

##### 注意

四个系统中断线允许将不同通道的完成中断路由到不同核心，或在同一核心上优先中断更为关键的通道，且支持针对不同安全域的通道中断。

当中断触发时，处理器可配置为中断当前任务，调用用户指定的处理程序。该处理程序可重新配置并重启通道。当处理程序退出时，处理器将恢复运行中断前台代码。

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/dma/channel\\_irq/channel\\_irq.c](https://github.com/raspberrypi/pico-examples/blob/master/dma/channel_irq/channel_irq.c) 第35至52行

```

35 void dma_handler() {
36 static int pwm_level = 0;
37 static uint32_t wavetable[N_PWM_LEVELS];
38 static bool first_run = true;
39 // 条目编号`i`具有`i`个一位和`~(32 - i)`个零位。
40 if (first_run) {
41 first_run = false;
42 for (int i = 0; i < N_PWM_LEVELS; ++i)
43 wavetable[i] = ~(~0u << i);
44 }
45 }
```

```

46 // Clear the interrupt request.
47 dma_hw->ints0 = 1u << dma_chan;
48 // Give the channel a new wave table entry to read from, and re-trigger it
49 dma_channel_set_read_addr(dma_chan, &wavetable[pwm_level], true);
50
51 pwm_level = (pwm_level + 1) % N_PWM_LEVELS;
52 }

```

In many cases, most of the configuration can be done the first time the channel starts. This way, only addresses and transfer lengths need reprogramming in the interrupt handler.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/dma/channel\\_irq/channel\\_irq.c](https://github.com/raspberrypi/pico-examples/blob/master/dma/channel_irq/channel_irq.c) Lines 54 - 94

```

54 int main() {
55 #ifndef PICO_DEFAULT_LED_PIN
56 #warning dma/channel_irq example requires a board with a regular LED
57 #else
58 // Set up a PIO state machine to serialise our bits
59 uint offset = pio_add_program(pio0, &pio_serialiser_program);
60 pio_serialiser_program_init(pio0, 0, offset, PICO_DEFAULT_LED_PIN, PIO_SERIAL_CLKDIV);
61
62 // Configure a channel to write the same word (32 bits) repeatedly to PIO0
63 // SM0's TX FIFO, paced by the data request signal from that peripheral.
64 dma_chan = dma_claim_unused_channel(true);
65 dma_channel_config c = dma_channel_get_default_config(dma_chan);
66 channel_config_set_transfer_data_size(&c, DMA_SIZE_32);
67 channel_config_set_read_increment(&c, false);
68 channel_config_set_dreq(&c, DREQ_PI00_TX0);
69
70 dma_channel_configure(
71 dma_chan,
72 &c,
73 &pio0_hw->txf[0], // Write address (only need to set this once)
74 NULL, // Don't provide a read address yet
75 PWM_REPEAT_COUNT, // Write the same value many times, then halt and interrupt
76 false // Don't start yet
77);
78
79 // Tell the DMA to raise IRQ line 0 when the channel finishes a block
80 dma_channel_set_irq0_enabled(dma_chan, true);
81
82 // Configure the processor to run dma_handler() when DMA IRQ 0 is asserted
83 irq_set_exclusive_handler(DMA_IRQ_0, dma_handler);
84 irq_set_enabled(DMA_IRQ_0, true);
85
86 // Manually call the handler once, to trigger the first transfer
87 dma_handler();
88
89 // Everything else from this point is interrupt-driven. The processor has
90 // time to sit and think about its early retirement -- maybe open a bakery?
91 while (true)
92 tight_loop_contents();
93 #endif
94 }

```

One disadvantage of this technique is that you don't start to reconfigure the channel until some time after the channel makes its last transfer. If there is heavy interrupt activity on the processor, this can be quite a long time, and quite a large gap in transfers. This makes it difficult to sustain a high data throughput.

This is solved by using two channels, with their **CHAIN\_TO** fields crossed over, so that channel A triggers channel B when it completes, and vice versa. At any point in time, one of the channels is transferring data. The other is either already

```

46 // 清除中断请求。
47 dma_hw->ints0 = 1u << dma_chan;
48 // 赋予通道新的波形表条目进行读取，并重新触发其运行
49 dma_channel_set_read_addr(dma_chan, &wavetable[pwm_level], true);
50
51 pwm_level = (pwm_level + 1) % N_PWM_LEVELS;
52 }

```

在多数情况下，大部分配置可于通道首次启动时完成。如此，中断处理程序中仅需重新配置地址和传输长度。

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/dma/channel\\_irq/channel\\_irq.c](https://github.com/raspberrypi/pico-examples/blob/master/dma/channel_irq/channel_irq.c) 第54行至94行

```

54 int main() {
55 #ifndef PICO_DEFAULT_LED_PIN
56 //warning dma/channel_irq 示例需配备常规LED的开发板
57 #else
58 // 配置PIO状态机以实现位串行化
59 uint offset = pio_add_program(pio0, &pio_serialiser_program);
60 pio_serialiser_program_init(pio0, 0, offset, PICO_DEFAULT_LED_PIN, PIO_SERIAL_CLKDIV);
61
62 // 配置一个通道以重复写入相同数据（32位）到 PIO0
63 // SM0 的 TX FIFO，由该外设的数据请求信号节奏控制。
64 dma_chan = dma_claim_unused_channel(true);
65 dma_channel_config c = dma_channel_get_default_config(dma_chan);
66 channel_config_set_transfer_data_size(&c, DMA_SIZE_32);
67 channel_config_set_read_increment(&c, false);
68 channel_config_set_dreq(&c, DREQ_PI00_TX0);
69
70 dma_channel_configure(
71 dma_chan,
72 &c,
73 &pio0_hw->txf[0], // 写地址（仅需设置一次）
74 NULL, // 暂不提供读取地址
75 PWM_REPEAT_COUNT, // 多次写入相同数值，随后停止并触发中断
76 false // 暂不启动
77);
78
79 // 指示 DMA 在通道完成一个块传输时激活 IRQ 线 0
80 dma_channel_set_irq0_enabled(dma_chan, true);
81
82 // 配置处理器在 DMA IRQ 0 断言时执行dma_handler()
83 irq_set_exclusive_handler(DMA_IRQ_0, dma_handler);
84 irq_set_enabled(DMA_IRQ_0, true);
85
86 // 手动调用一次处理程序以触发第一次传输
87 dma_handler();
88
89 // 从此开始，其他所有操作均由中断驱动。处理器
90 // 有时间考虑提前退休——也许开家面包店？
91 while (true)
92 tight_loop_contents();
93 #endif
94 }

```

该技术的一个缺点是，直到通道完成最后一次传输后，才开始重新配置通道。若处理器中断活动频繁，这段时间可能较长，传输之间存在较大间隙。这使得持续保持高数据吞吐率变得困难。

通过使用两个通道及其 CHAIN\_TO 字段交叉设置实现此目的，使通道A在完成时触发通道B，反之亦然。在任何时间点，始终有一个通道正在传输数据。另一个通道要么已经

configured to start the next transfer immediately when the current one finishes, or it is in the process of being reconfigured. When channel A completes, it immediately starts the cued-up transfer on channel B. At the same time, the interrupt is fired, and the handler reconfigures channel A so that it is ready when channel B completes.

### 12.6.9.2. DMA control blocks

Frequently, multiple smaller buffers must be gathered together and sent to the same peripheral. To address this use case, the RP2350 DMA can execute a long and complex sequence of transfers without processor control. One channel repeatedly reconfigures a second channel, and the second channel restarts the first each time it completes block of transfers.

Because the first DMA channel transfers data directly from memory to the second channel's control registers, the format of the control blocks in memory must match those registers. Each time, the last register written to will be one of the trigger registers ([Section 12.6.3.1](#)), which will start the second channel on its programmed block of transfers. The register aliases ([Section 12.6.3.1](#)) give some flexibility for the block layout, and more importantly allow some registers to be omitted from the blocks, so they occupy less memory and can be loaded more quickly.

This example shows how multiple buffers can be gathered and transferred to the UART, by reprogramming `TRANS_COUNT` and `READ_ADDR_TRIG`:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/dma/control\\_blocks/control\\_blocks.c](https://github.com/raspberrypi/pico-examples/blob/master/dma/control_blocks/control_blocks.c)

```

6
7 // Use two DMA channels to make a programmed sequence of data transfers to the
8 // UART (a data gather operation). One channel is responsible for transferring
9 // the actual data, the other repeatedly reprograms that channel.
10
11 #include <stdio.h>
12 #include "pico/stl.h"
13 #include "hardware/dma.h"
14 #include "hardware/structs/uart.h"
15
16 // These buffers will be DMA'd to the UART, one after the other.
17
18 const char word0[] = "Transferring ";
19 const char word1[] = "one ";
20 const char word2[] = "word ";
21 const char word3[] = "at ";
22 const char word4[] = "a ";
23 const char word5[] = "time.\n";
24
25 // Note the order of the fields here: it's important that the length is before
26 // the read address, because the control channel is going to write to the last
27 // two registers in alias 3 on the data channel:
28 // +0x0 +0x4 +0x8 +0xC (Trigger)
29 // Alias 0: READ_ADDR WRITE_ADDR TRANS_COUNT CTRL
30 // Alias 1: CTRL READ_ADDR WRITE_ADDR TRANS_COUNT
31 // Alias 2: CTRL TRANS_COUNT READ_ADDR WRITE_ADDR
32 // Alias 3: CTRL WRITE_ADDR TRANS_COUNT READ_ADDR
33 //
34 // This will program the transfer count and read address of the data channel,
35 // and trigger it. Once the data channel completes, it will restart the
36 // control channel (via CHAIN_TO) to load the next two words into its control
37 // registers.
38
39 const struct {uint32_t len; const char *data;} control_blocks[] = {

```

被配置为在当前传输结束后立即启动下一次传输，或处于重新配置过程中。通道A完成后立即启动通道B上排队的传输，同时触发中断，中断处理程序重新配置通道A，以确保其在通道B完成后准备就绪。

### 12.6.9.2. DMA控制块

经常需要将多个较小缓冲区汇总后发送至同一外设。为满足此需求，RP2350 DMA可执行无需处理器干预的长而复杂的传输序列。一个通道持续重新配置第二通道，第二通道每完成一块传输即重新启动第一个通道。

由于第一个DMA通道直接将数据从内存传输到第二通道的控制寄存器，内存中的控制块格式必须与这些寄存器相匹配。每次写入的最后一个寄存器均为触发寄存器之一（第12.6.3.1节），该寄存器将启动第二通道执行其编程的传输块。寄存器别名（第12.6.3.1节）为块布局提供一定灵活性，更重要的是允许省略某些寄存器，从而减少内存占用并加快加载速度。

本示例展示了如何通过重新编程TRANS\_COUNT和READ\_ADDR\_TRIG收集多个缓冲区并传输至UART：

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/dma/control\\_blocks/control\\_blocks.c](https://github.com/raspberrypi/pico-examples/blob/master/dma/control_blocks/control_blocks.c)

```

*...,*  
*CH14\_TRANS\_COUNT,*  
*CH15\_TRANS\_COUNT*  
*Registers*

Bits	Description	Type	Reset
31:28	<b>MODE:</b> When MODE is 0x0, the transfer count decrements with each transfer until 0, and then the channel triggers the next channel indicated by CTRL_CHAIN_TO.  When MODE is 0x1, the transfer count decrements with each transfer until 0, and then the channel re-triggers itself, in addition to the trigger indicated by CTRL_CHAIN_TO. This is useful for e.g. an endless ring-buffer DMA with periodic interrupts.  When MODE is 0xf, the transfer count does not decrement. The DMA channel performs an endless sequence of transfers, never triggering other channels or raising interrupts, until an ABORT is raised.  All other values are reserved.	RW	0x0
	Enumerated values:		
	0x0 → NORMAL		
	0x1 → TRIGGER_SELF		
	0xf → ENDLESS		
27:0	<b>COUNT:</b> 28-bit transfer count (256 million transfers maximum).  Program the number of bus transfers a channel will perform before halting. Note that, if transfers are larger than one byte in size, this is not equal to the number of bytes transferred (see CTRL_DATA_SIZE).  When the channel is active, reading this register shows the number of transfers remaining, updating automatically each time a write transfer completes.  Writing this register sets the RELOAD value for the transfer counter. Each time this channel is triggered, the RELOAD value is copied into the live transfer counter. The channel can be started multiple times, and will perform the same number of transfers each time, as programmed by most recent write.  The RELOAD value can be observed at CHx_DBG_TCR. If TRANS_COUNT is used as a trigger, the written value is used immediately as the length of the new transfer sequence, as well as being written to RELOAD.	RW	0x00000000

Bits	Description	Type	Reset
31	<b>AHB_ERROR:</b> Logical OR of the READ_ERROR and WRITE_ERROR flags. The channel halts when it encounters any bus error, and always raises its channel IRQ flag.	RO	0x0
30	<b>READ_ERROR:</b> If 1, the channel received a read bus error. Write one to clear. READ_ADDR shows the approximate address where the bus error was encountered (will not be earlier, or more than 3 transfers later)	WC	0x0
29	<b>WRITE_ERROR:</b> If 1, the channel received a write bus error. Write one to clear. WRITE_ADDR shows the approximate address where the bus error was encountered (will not be earlier, or more than 5 transfers later)	WC	0x0
28:27	Reserved.	-	-
26	<b>BUSY:</b> This flag goes high when the channel starts a new transfer sequence, and low when the last transfer of that sequence completes. Clearing EN while BUSY is high pauses the channel, and BUSY will stay high while paused.  To terminate a sequence early (and clear the BUSY flag), see CHAN_ABORT.	RO	0x0
25	<b>SNIFF_EN:</b> If 1, this channel's data transfers are visible to the sniff hardware, and each transfer will advance the state of the checksum. This only applies if the sniff hardware is enabled, and has this channel selected.  This allows checksum to be enabled or disabled on a per-control-block basis.	RW	0x0
24	<b>BSWAP:</b> Apply byte-swap transformation to DMA data. For byte data, this has no effect. For halfword data, the two bytes of each halfword are swapped. For word data, the four bytes of each word are swapped to reverse order.	RW	0x0
23	<b>IRQ QUIET:</b> In QUIET mode, the channel does not generate IRQs at the end of every transfer block. Instead, an IRQ is raised when NULL is written to a trigger register, indicating the end of a control block chain.  This reduces the number of interrupts to be serviced by the CPU when transferring a DMA chain of many small control blocks.	RW	0x0
22:17	<b>TREQ_SEL:</b> Select a Transfer Request signal. The channel uses the transfer request signal to pace its data transfer rate. Sources for TREQ signals are internal (TIMERS) or external (DREQ, a Data Request from the system). 0x0 to 0x3a → select DREQ n as TREQ	RW	0x00
	Enumerated values:		
	0x3b → TIMER0: Select Timer 0 as TREQ		
	0x3c → TIMER1: Select Timer 1 as TREQ		
	0x3d → TIMER2: Select Timer 2 as TREQ (Optional)		
	0x3e → TIMER3: Select Timer 3 as TREQ (Optional)		

## DMA: CH0\_CTRL\_TRIG, CH1\_CTRL\_TRIG, ..., CH14\_CTRL\_TRIG, CH15\_C TRL\_TRIG寄存器

偏移量: 0x00c, 0x04c, ..., 0x38c, 0x3cc

### 描述

DMA通道 N控制及状态

表1151。  
CH0\_CTRL\_TRIG,  
CH1\_CTRL\_TRIG, ...  
CH14\_CTRL\_TRIG,  
CH15\_CTRL\_TRIG  
寄存器

位	描述	类型	复位
31	<b>AHB_ERROR:</b> READ_ERROR和WRITE_ERROR标志的逻辑或运算结果。通道在遇到任何总线错误时将停止，并始终置位其通道中断请求（IRQ）标志。	只读	0x0
30	<b>READ_ERROR:</b> 若为1，表示通道发生读总线错误。写1以清除该标志。READ_ADDR 显示发生总线错误的大致地址（不会早于该地址，且不会超过3次传输之后）	WC	0x0
29	<b>WRITE_ERROR:</b> 若为1，表示通道收到写入总线错误。写入1以清除该标志。WRITE_ADDR 显示发生总线错误的大致地址（不会早于该地址，且不会超过5次传输之后）	WC	0x0
28:27	保留。	-	-
26	<b>BUSY:</b> 当通道开始新传输序列时，该标志置高，序列中最后一次传输完成时置低。在 BUSY 置高时清除 EN 会暂停通道，且暂停期间 BUSY 将保持置高状态。  如需提前终止序列（并清除 BUSY 标志），请参见 CHAN_ABORT。	只读	0x0
25	<b>SNIFF_EN:</b> 若为1，则该通道的数据传输对嗅探硬件可见，且每次传输将推进校验和状态。此项仅在启用嗅探硬件且选定该通道时适用。  该机制允许在每个控制块级别启用或禁用校验和。	读写	0x0
24	<b>BSWAP:</b> 对DMA数据应用字节交换转换。 对于字节数据，该操作无效。对于半字数据，每个半字的两个字节将被交换。对于字数据，每个字的四个字节按倒序交换。	读写	0x0
23	<b>IRQ QUIET:</b> 在静默模式下，通道不会在每个传输块结束时产生中断请求（IRQ）。取而代之的是，当向触发寄存器写入NULL时会产生中断请求，表示控制块链的结束。  这减少了在传输多个小控制块的DMA链时CPU需处理的中断数量。	读写	0x0
22:17	<b>TREQ_SEL:</b> 选择传输请求信号。 通道使用传输请求信号来调节数据传输速率。 TREQ信号源包括内部（定时器）或外部（系统的数据请求DREQ）。  0x0至0x3a → 选择DREQ n作为TREQ	读写	0x00
	枚举值：		
	0x3b → TIMER0：选择定时器0作为TREQ		
	0x3c → TIMER1：选择 Timer 1 作为 TREQ		
	0x3d → TIMER2：选择 Timer 2 作为 TREQ（可选）		
	0x3e → TIMER3：选择 Timer 3 作为 TREQ（可选）		

Bits	Description	Type	Reset
	0x3f → PERMANENT: Permanent request, for unpaced transfers.		
16:13	<b>CHAIN_TO:</b> When this channel completes, it will trigger the channel indicated by CHAIN_TO. Disable by setting CHAIN_TO = <i>(this channel)</i> .  Note this field resets to 0, so channels 1 and above will chain to channel 0 by default. Set this field to avoid this behaviour.	RW	0x0
12	<b>RING_SEL:</b> Select whether RING_SIZE applies to read or write addresses. If 0, read addresses are wrapped on a $(1 \ll \text{RING\_SIZE})$ boundary. If 1, write addresses are wrapped.	RW	0x0
11:8	<b>RING_SIZE:</b> Size of address wrap region. If 0, don't wrap. For values n > 0, only the lower n bits of the address will change. This wraps the address on a $(1 \ll n)$ byte boundary, facilitating access to naturally-aligned ring buffers.  Ring sizes between 2 and 32768 bytes are possible. This can apply to either read or write addresses, based on value of RING_SEL.	RW	0x0
	Enumerated values:		
	0x0 → RING_NONE		
7	<b>INCR_WRITE_REV:</b> If 1, and INCR_WRITE is 1, the write address is decremented rather than incremented with each transfer.  If 1, and INCR_WRITE is 0, this otherwise-unused combination causes the write address to be incremented by twice the transfer size, i.e. skipping over alternate addresses.	RW	0x0
6	<b>INCR_WRITE:</b> If 1, the write address increments with each transfer. If 0, each write is directed to the same, initial address.  Generally this should be disabled for memory-to-peripheral transfers.	RW	0x0
5	<b>INCR_READ_REV:</b> If 1, and INCR_READ is 1, the read address is decremented rather than incremented with each transfer.  If 1, and INCR_READ is 0, this otherwise-unused combination causes the read address to be incremented by twice the transfer size, i.e. skipping over alternate addresses.	RW	0x0
4	<b>INCR_READ:</b> If 1, the read address increments with each transfer. If 0, each read is directed to the same, initial address.  Generally this should be disabled for peripheral-to-memory transfers.	RW	0x0
3:2	<b>DATA_SIZE:</b> Set the size of each bus transfer (byte/halfword/word). READ_ADDR and WRITE_ADDR advance by this amount (1/2/4 bytes) with each transfer.	RW	0x0
	Enumerated values:		
	0x0 → SIZE_BYTE		
	0x1 → SIZE_HALFWORD		
	0x2 → SIZE_WORD		

位	描述	类型	复位
	0x3f → PERMANENT：永久请求，适用于无节奏传输。		
16:13	<p><b>CHAIN_TO</b>: 当该通道完成时，将触发由 CHAIN_TO 指示的通道。通过将 CHAIN_TO 设置为（本通道）来禁用此功能。</p> <p>注意，该字段会重置为 0，因此通道 1 及以上默认链至通道 0。设置该字段以避免此行为。</p>	读写	0x0
12	<p><b>RING_SEL</b>: 选择 RING_SIZE 应用于读地址还是写地址。</p> <p>如果为 0，读地址将在 <math>(1 \ll \text{RING\_SIZE})</math> 边界处回绕。如果为 1，则写入地址回绕。</p>	读写	0x0
11:8	<p><b>RING_SIZE</b>: 地址回绕区域大小。若为 0，则不回绕。当 <math>n &gt; 0</math> 时，仅地址的低 <math>n</math> 位会发生变化。该操作将在 <math>(1 \ll n)</math> 字节边界上对地址进行环绕，便于访问自然对齐的环形缓冲区。</p> <p>环形缓冲区的大小可在 2 至 32768 字节之间。此功能可应用于读地址或写地址，具体取决于 RING_SEL 的值。</p>	读写	0x0
	枚举值：		
	0x0 → RING_NONE		
7	<p><b>INCR_WRITE_REV</b>: 当其值为 1 且 INCR_WRITE 为 1 时，写地址会在每次传输时递减，而非递增。</p> <p>当其值为 1 且 INCR_WRITE 为 0 时，此未使用的组合会使写地址每次递增两倍传输大小，即跳过交替地址。</p>	读写	0x0
6	<p><b>INCR_WRITE</b>: 当其值为 1 时，写地址会在每次传输时递增。当其值为 0 时，每次写入均指向相同的初始地址。</p> <p>通常，应在内存到外设传输中禁用此功能。</p>	读写	0x0
5	<p><b>INCR_READ_REV</b>: 当其值为 1 且 INCR_READ 为 1 时，读地址会在每次传输时递减，而非递增。</p> <p>如果为 1 且 INCR_READ 为 0，则此原本未使用的组合会导致读取地址增加两倍传输大小，即跳过交替地址。</p>	读写	0x0
4	<p><b>INCR_READ</b>: 如果为 1，读取地址在每次传输时递增。如果为 0，则每次读取均指向相同的初始地址。</p> <p>通常应为外设到内存的传输禁用此选项。</p>	读写	0x0
3:2	<p><b>DATA_SIZE</b>: 设置每次总线传输的数据大小（字节/半字/字）。</p> <p>READ_ADDR 和 WRITE_ADDR 在每次传输时按此大小（1/2/4 字节）递增。</p>	读写	0x0
	枚举值：		
	0x0 → SIZE_BYTE		
	0x1 → SIZE_HALFWORD		
	0x2 → SIZE_WORD		

Bits	Description	Type	Reset
1	<b>HIGH_PRIORITY:</b> HIGH_PRIORITY gives a channel preferential treatment in issue scheduling: in each scheduling round, all high priority channels are considered first, and then only a single low priority channel, before returning to the high priority channels.  This only affects the order in which the DMA schedules channels. The DMA's bus priority is not changed. If the DMA is not saturated then a low priority channel will see no loss of throughput.	RW	0x0
0	<b>EN:</b> DMA Channel Enable. When 1, the channel will respond to triggering events, which will cause it to become BUSY and start transferring data. When 0, the channel will ignore triggers, stop issuing transfers, and pause the current transfer sequence (i.e. BUSY will remain high if already high)	RW	0x0

## DMA: INTR Register

Offset: 0x400

### Description

Interrupt Status (raw)

Table 1164. INTR Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	Raw interrupt status for DMA Channels 0..15. Bit n corresponds to channel n.  Ignores any masking or forcing. Channel interrupts can be cleared by writing a bit mask to INTR or INTS0/1/2/3.  Channel interrupts can be routed to either of four system-level IRQs based on INTE0, INTE1, INTE2 and INTE3.  The multiple system-level interrupts might be used to allow NVIC IRQ preemption for more time-critical channels, to spread IRQ load across different cores, or to target IRQs to different security domains.  It is also valid to ignore the multiple IRQs, and just use INTE0/INTS0/IRQ 0.  If this register is accessed at a security/privilege level less than that of a given channel (as defined by that channel's SECCFG_CHx register), then that channel's interrupt status will read as 0, ignore writes.	WC	0x0000

## DMA: INTE0 Register

Offset: 0x404

### Description

Interrupt Enables for IRQ 0

## DMA: INTR 寄存器

偏移: 0x400

### 描述

中断状态 (原始)

表1164. INTR  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	DMA通道0至15的原始中断状态。位n对应通道n。 忽略所有屏蔽或强制操作。通道中断可通过向INTR或INTS0/1/2/3写入位掩码来清除。  通道中断可根据INTE0、INTE1、INTE2和INTE3的配置，路由至四个系统级IRQ中的任意一个。  多路系统级中断可用于允许NVIC IRQ抢占更关键的通道，分散IRQ负载至不同内核，或将IRQ定向至不同的安全域。  忽略多个IRQ，仅使用INTE0/INTS0/IRQ 0，同样有效。  如果以低于某通道安全/权限级别（由该通道的SECCFG_CHx寄存器定义）的安全/权限级别访问此寄存器，则该通道的中断状态将读取为0，写入操作将被忽略。	WC	0x0000

## DMA: INT0 寄存器

偏移: 0x404

### 描述

IRQ0 中断使能

Table 1165. INTFO Register

Bits	Description	Type	Reset

## DMA: TIMER0, TIMER1, TIMER2, TIMER3 Registers

Offsets: 0x440, 0x444, 0x448, 0x44c

### Description

Pacing (X/Y) fractional timer

The pacing timer produces TREQ assertions at a rate set by  $((X/Y) * sys\_clk)$ . This equation is evaluated every sys\_clk cycles and therefore can only generate TREQs at a rate of 1 per sys\_clk (i.e. permanent TREQ) or less.

Table 1177. TIMER0, TIMER1, TIMER2, TIMER3 Registers

Bits	Description	Type	Reset
31:16	X: Pacing Timer Dividend. Specifies the X value for the (X/Y) fractional timer.	RW	0x0000
15:0	Y: Pacing Timer Divisor. Specifies the Y value for the (X/Y) fractional timer.	RW	0x0000

表1174. INTE3  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	设置位n以允许来自通道n的中断通过至DMA IRQ 3。  注意：当通道安全/权限级别（由SECCFG_CHx定义）高于IRQ安全/权限级别（由SECCFG_IRQ3定义）时，该位无效。	读写	0x0000

## DMA：INTF3寄存器

偏移: 0x438

### 描述

强制中断

表1175. INTF3  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	写入1以强制INTS3中相应位。中断将保持激活状态，直到清除INTF3。	读写	0x0000

## DMA：INTS3寄存器

偏移: 0x43c

### 描述

IRQ 3 的中断状态

表1176. INTS3  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	指示当前导致IRQ 3断言的活动通道中断请求。  可通过在此处写入位掩码来清除通道中断。  在本寄存器中，安全/权限(SECCFG_CHx)高于SECCFG_IRQ3的通道读取值恒为0，且忽略写入操作。	WC	0x0000

## DMA：TIMER0、TIMER1、TIMER2、TIMER3寄存器

偏移: 0x440, 0x444, 0x448, 0x44c

### 描述

节奏 (X/Y) 分数定时器

节奏定时器以 $((X/Y) \times \text{sys\_clk})$ 的速率产生TREQ断言。该公式每个sys\_clk周期计算一次，因此只能生成速率为每个sys\_clk周期不超过1次（即持续TREQ）或更低的TREQ。

表1177. TIMER0,  
TIMER1, TIMER2,  
TIMER3 寄存器

位	描述	类型	复位
31:16	X：步进定时器被除数。指定 (X/Y) 分数定时器中的 X 值。	读写	0x0000
15:0	Y：步进定时器除数。指定 (X/Y) 分数定时器中的 Y 值。	读写	0x0000

## DMA：MULTI\_CHAN\_TRIGGER 寄存器

偏移: 0x450

**Description**

Trigger one or more channels simultaneously

*Table 1178.*  
*MULTI\_CHAN\_TRIGGER*  
*R Register*

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	Each bit in this register corresponds to a DMA channel. Writing a 1 to the relevant bit is the same as writing to that channel's trigger register; the channel will start if it is currently enabled and not already busy.	SC	0x0000

**DMA: SNIFF\_CTRL Register**

**Offset:** 0x454

**Description**

Sniffer Control

*Table 1179.*  
*SNIFF\_CTRL Register*

Bits	Description	Type	Reset
31:12	Reserved.	-	-
11	<b>OUT_INV:</b> If set, the result appears inverted (bitwise complement) when read. This does not affect the way the checksum is calculated; the result is transformed on-the-fly between the result register and the bus.	RW	0x0
10	<b>OUT_REV:</b> If set, the result appears bit-reversed when read. This does not affect the way the checksum is calculated; the result is transformed on-the-fly between the result register and the bus.	RW	0x0
9	<b>BSWAP:</b> Locally perform a byte reverse on the sniffed data, before feeding into checksum.  Note that the sniff hardware is downstream of the DMA channel byteswap performed in the read master: if channel CTRL_BSWAP and SNIFF_CTRL_BSWAP are both enabled, their effects cancel from the sniffer's point of view.	RW	0x0
8:5	<b>CALC</b>  Enumerated values:  0x0 → CRC32: Calculate a CRC-32 (IEEE802.3 polynomial) 0x1 → CRC32R: Calculate a CRC-32 (IEEE802.3 polynomial) with bit reversed data 0x2 → CRC16: Calculate a CRC-16-CCITT 0x3 → CRC16R: Calculate a CRC-16-CCITT with bit reversed data 0xe → EVEN: XOR reduction over all data. == 1 if the total 1 population count is odd. 0xf → SUM: Calculate a simple 32-bit checksum (addition with a 32 bit accumulator)	RW	0x0
4:1	<b>DMACH:</b> DMA channel for Sniffer to observe	RW	0x0
0	<b>EN:</b> Enable sniffer	RW	0x0

**DMA: SNIFF\_DATA Register**

**Offset:** 0x458

**描述**

同时触发一个或多个通道

表1178。  
MULTI\_CHAN\_TRIGGER  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	该寄存器的每个位对应一个 DMA 通道。向相关位写入 1 等同于写入该通道的触发寄存器；只要该通道当前已启用且未占用，通道即会启动。	SC	0x0000

**DMA：SNIFF\_CTRL 寄存器**

偏移：0x454

**说明**

嗅探器控制

表1179。  
SNIFF\_CTRL 寄存器

位	描述	类型	复位
31:12	保留。	-	-
11	<b>OUT_INV</b> ：若设置，读取结果将以位反码形式显示。 这不影响校验和的计算方式；结果为在结果寄存器与总线之间实时转换。	读写	0x0
10	<b>OUT_REV</b> ：若设置，读取时结果以位反转形式显示。此操作不影响校验和的计算方式；结果在结果寄存器与总线之间实时转换。	读写	0x0
9	<b>BSWAP</b> ：在传入校验和计算之前，对嗅探数据执行局部字节反转。  请注意，嗅探硬件位于read master中DMA通道字节交换之后：若通道CTR_L_BSWAP和SNIFF_CTRL_BSWAP均启用，嗅探器视角下二者效果相互抵消。	读写	0x0
8:5	<b>CALC</b>  枚举值：  0x0 → CRC32：计算CRC-32（IEEE802.3多项式） 0x1 → CRC32R：计算带位反转数据的CRC-32（IEEE802.3多项式） 0x2 → CRC16：计算CRC-16-CCITT 0x3 → CRC16R：计算带位反转数据的CRC-16-CCITT 0xe → EVEN：对所有数据执行 XOR 归约。== 1 表示总的 1 的数量为奇数。 0xf → SUM：计算简单的 32 位校验和（采用 32 位累加器进行加法）。	读写	0x0
4:1	<b>DMACH</b> ：用于监听的 DMA 通道	读写	0x0
0	<b>EN</b> ：启用监听器	读写	0x0

**DMA：SNIFF\_DATA 寄存器**

Offset: 0x458

**Description**

Data accumulator for sniff hardware

*Table 1180.*  
SNIFF\_DATA Register

Bits	Description	Type	Reset
31:0	Write an initial seed value here before starting a DMA transfer on the channel indicated by SNIFF_CTRL_DMACH. The hardware will update this register each time it observes a read from the indicated channel. Once the channel completes, the final result can be read from this register.	RW	0x00000000

**DMA: FIFO\_LEVELS Register**

**Offset:** 0x460

**Description**

Debug RAF, WAF, TDF levels

*Table 1181.*  
FIFO\_LEVELS Register

Bits	Description	Type	Reset
31:24	Reserved.	-	-

**DMA: SECCFG\_CH0、SECCFG\_CH1、...、SECCFG\_CH14、SECCFG\_CH15  
寄存器**

偏移: 0x480、0x484、...、0x4b8、0x4bc

**Description**

Security configuration for channel  $N$ . Control whether this channel performs Secure/Non-secure and Privileged/Unprivileged bus accesses.

If this channel generates bus accesses of some security level, an access of at least that level (in the order S+P > S+U > NS+P > NS+U) is required to program, trigger, abort, check the status of, interrupt on or acknowledge the interrupt of this channel.

This register automatically locks down (becomes read-only) once software starts to configure the channel.

This register is world-readable, but is writable only from a Secure, Privileged context.

*Table 1184.  
SECCFG\_CH0,  
SECCFG\_CH1, ...,  
SECCFG\_CH14,  
SECCFG\_CH15  
Registers*

Bits	Description	Type	Reset
31:3	Reserved.	-	-
2	<b>LOCK:</b> LOCK is 0 at reset, and is set to 1 automatically upon a successful write to this channel's control registers. That is, a write to CTRL, READ_ADDR, WRITE_ADDR, TRANS_COUNT and their aliases.  Once its LOCK bit is set, this register becomes read-only.  A failed write, for example due to the write's privilege being lower than that specified in the channel's SECCFG register, will not set the LOCK bit.	RW	0x0
1	<b>S:</b> Secure channel. If 1, this channel performs Secure bus accesses. If 0, it performs Non-secure bus accesses.  If 1, this channel is controllable only from a Secure context.	RW	0x1
0	<b>P:</b> Privileged channel. If 1, this channel performs Privileged bus accesses. If 0, it performs Unprivileged bus accesses.  If 1, this channel is controllable only from a Privileged context of the same Secure/Non-secure level, or any context of a higher Secure/Non-secure level.	RW	0x1

**DMA: SECCFG\_IRQ0, SECCFG\_IRQ1, SECCFG\_IRQ2, SECCFG\_IRQ3 Registers**

**Offsets:** 0x4c0, 0x4c4, 0x4c8, 0x4cc

**Description**

Security configuration for IRQ  $N$ . Control whether the IRQ permits configuration by Non-secure/Unprivileged contexts, and whether it can observe Secure/Privileged channel interrupt flags.

*Table 1185.  
SECCFG\_IRQ0,  
SECCFG\_IRQ1,  
SECCFG\_IRQ2,  
SECCFG\_IRQ3  
Registers*

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>S:</b> Secure IRQ. If 1, this IRQ's control registers can only be accessed from a Secure context.  If 0, this IRQ's control registers can be accessed from a Non-secure context, but Secure channels (as per SECCFG_CHx) are masked from the IRQ status, and this IRQ's registers can not be used to acknowledge the channel interrupts of Secure channels.	RW	0x1

**描述**

信道 N 的安全配置。控制该信道是否执行安全/非安全及特权/非特权总线访问。

若该信道产生某一安全级别的总线访问，则在编程、触发、中止、状态检查、中断响应或中断确认时，必须至少具备该级别的访问权限（级别顺序为 S+P > S+U > NS+P > NS+U）。

一旦软件开始配置该信道，该寄存器将自动锁定（变为只读）。

该寄存器为全局可读，但仅允许在安全且具特权的上下文中写入。

31:0	Read to get channel TRANS_COUNT reload value, i.e. the length of the next transfer	RO	0x00000000

## 12.7. USB

### 12.7.1. Overview

#### NOTE

*Prerequisite knowledge required*

This section requires knowledge of the USB protocol. If you aren't yet familiar with the USB protocol, we recommend the archive of the very useful [USB Made Simple](#) website. For formal definitions of the terminology used in this section, see the [USB 2.0 Specification](#).

RP2350 contains a USB 2.0 controller that can operate as either:

- a Full Speed (FS) device (12 Mb/s)
- a host that can communicate with both Low Speed (LS) (1.5 Mb/s) and Full Speed devices, including multiple downstream devices connected to a USB hub

There is an integrated USB 1.1 PHY which interfaces the USB controller with the **DP** and **DM** pins of the chip. You may use this as 3.3 V GPIO when the USB controller is not in use.

位	描述	类型	复位
2	<b>S</b> : 若启用此区域，确定匹配该区域地址的安全/非安全 (=1/0) 状态。	读写	0x0
1	<b>P</b> : 若启用此区域，确定匹配该区域地址的特权/非特权 (=1/0) 状态。仅当 S 位清除时，方可从任何特权上下文写入。否则，仅能从安全的特权上下文写入。	读写	0x0
0	<b>EN</b> : 区域使能。若为 1，则基地址 (BAR_ADDR) 与限制地址 (LAR_A DDR) 指定范围内的任一地址均具有由 S 和 P 指定的属性。	读写	0x0

## DMA:CH0\_DBG\_CTDREQ, CH1\_DBG\_CTDREQ, ..., CH14\_DBG\_CTDREQ, CH15\_DBG\_CTDREQ 寄存器

31:0	读取以获取通道TRANS_COUNT的重载值，即下一次传输的长度	只读	0x00000000

## 12.7. USB

### 12.7.1. 概述

#### 注意

所需的先决知识

本节要求具备USB协议相关知识。若您尚未熟悉USB协议，建议参考非常实用的“USB简单入门”网站存档。有关本节术语的正式定义，请参阅USB 2.0规范。

RP2350包含一款USB 2.0控制器，能够以下列任一方方式运行：

- 全速 (FS) 设备 (12 Mb/s)
- 主机，可与低速 (LS) (1.5 Mb/s) 及全速设备通信，包括连接于USB集线器的多个下游设备

集成USB 1.1 PHY，用以连接USB控制器与芯片的DP和DM引脚。当USB控制器未使用时，可将其用作3.3 V GPIO。

### 12.7.1.1. Features

The USB controller hardware handles the low level USB protocol. The programmer must configure the controller, provide data buffers, and consume or provide data buffers in response to events on the bus. The controller interrupts the processor when it needs attention. The USB controller has 4 kB of dual-port SRAM (DPSRAM) used for configuration and data buffers.

#### 12.7.1.1.1. Device Mode

In Device Mode, the USB controller has the following characteristics:

- USB 2.0-compatible Full Speed device (12 Mb/s)
- Supports up to 32 endpoints (Endpoints 0 → 15 in both in and out directions)
- Supports Control, Isochronous (ISO), Bulk, and Interrupt endpoint types
- Supports double buffering
- 3840 bytes of usable buffer space in DPSRAM. This is equivalent to  $60 \times 64$ -byte buffers

#### 12.7.1.1.2. Host Mode

In Host Mode, the USB controller can:

- communicate with Full Speed (12 Mb/s) devices and Low Speed devices (1.5 Mb/s)
- communicate with multiple devices via a USB hub, including Low Speed devices connected to a Full Speed hub
- poll up to 15 interrupt endpoints in hardware (used by hubs to notify the host of connect/disconnect events, used by mice to notify the host of movement, etc.)

#### 12.7.1.1.3. USB DPRAM

The USB controller uses 4 kB of dual-port SRAM (DPSRAM) to exchange data and control information with the controller. This is also referred to as dual-port RAM (DPRAM). One port is accessible from the system bus, clocked by `clk_sys`. The other port is accessible from the controller, clocked by `clk_usb`. The DPRAM is mapped in the system address space starting from `0x50100000`, `USBCTRL_DPRAM_BASE`.

The USB DPRAM supports 32-bit, 16-bit and 8-bit reads and writes. Writes complete in one cycle. Reads complete in two cycles.

You can store general user data in USB DPRAM space not required for USB controller operation. When the controller is disabled, all 4 kB of DPRAM is available. Before accessing the DPRAM, you must take the USB controller out of reset.

Since the USB controller is in the peripheral address space, it is not accessible for processor instruction fetch. Attempting to fetch instructions from USB DPRAM unconditionally returns a bus error response, no matter the configuration of the processor SAU/MPU/PMP or the system ACCESSCTRL registers.

As peripheral addresses are marked Exempt in the IDAU (Section 10.2.2), the SAU configuration for this address range is ignored. Accesses to USB DPRAM are controlled only by the processor MPU/PMP and the ACCESSCTRL `USBCTRL` register.

### 12.7.2. Changes from RP2040

All changes from RP2040 are a superset of the RP2040 features. Existing software for the RP2040 USB controller will continue to work with one exception: you must clear the `MAIN_CTRL.PHY_ISO` bit at startup and after power down events. We recommend leaving the `LINESTATE_TUNING` register at its reset value. Software should not clear this register.

### 12.7.1.1. 功能特性

USB控制器硬件负责处理底层USB协议。程序员必须配置控制器、提供数据缓冲区，并根据总线事件消费或提供数据缓冲区。控制器在需要处理时会中断处理器。USB 控制器配备了 4 kB 双端口 SRAM (DPSRAM)，用于配置和数据缓冲。

#### 12.7.1.1.1. 设备模式

在设备模式下，USB 控制器具有以下特性：

- 兼容 USB 2.0 的全速设备 (12 Mb/s)
- 支持最多 32 个端点 (端点 0 → 15，包含输入和输出方向)
- 支持控制、同步 (ISO)、批量和中断端点类型
- 支持双缓冲
- DPSRAM 中有 3840 字节可用缓冲空间，相当于 60 个 64 字节缓冲区

#### 12.7.1.1.2. 主机模式

在主机模式下，USB 控制器能够：

- 与全速 (12 Mb/s) 设备和低速设备 (1.5 Mb/s) 通信
- 通过 USB 集线器与多个设备通信，包括连接到全速集线器的低速设备
- 硬件轮询最多 15 个中断端点 (用于集线器通知主机连接/断开事件，鼠标通知主机移动等)

#### 12.7.1.1.3. USB DPRAM

USB 控制器使用 4 kB 的双端口 SRAM (DPSRAM) 与控制器交换数据及控制信息。这也称为双端口 RAM (DPRAM)。一个端口可通过系统总线访问，由 `clk_sys` 时钟驱动。另一个端口可由控制器访问，由 `clk_usb` 时钟驱动。DPRAM 映射于系统地址空间，起始地址为 `0x50100000`, `USBCTRL_DPRAM_BASE`。

USB DPRAM 支持 32 位、16 位及 8 位的读写操作。写操作在一个时钟周期内完成。读操作在两个时钟周期内完成。

您可在 USB DPRAM 中存储不用于 USB 控制器操作的一般用户数据。当控制器被禁用时，4 kB 的 DPRAM 全部可用。访问 DPRAM 之前，必须先使 USB 控制器退出复位状态。

由于USB控制器位于外设地址空间，处理器无法通过指令读取该区域。

无论处理器的SAU/MPU/PMP或系统ACCESSCTRL寄存器如何配置，尝试从USB DPRAM读取指令均无条件返回总线错误响应。

由于外设地址在IDAU（第10.2.2节）中标记为豁免，故该地址范围的SAU配置将被忽略。对USB DPRAM的访问仅由处理器的MPU/PMP及ACCESSCTRL的USBCTRL寄存器控制。

### 12.7.2. RP2040的变更内容

RP2040的所有更改均为RP2040功能集的超集。RP2040 USB控制器的既有软件仍然兼容，但唯一例外是：必须在启动及断电事件后清除MAIN\_CTRL.PHY\_ISO位。建议将LINESTATE\_TUNING寄存器保持其复位值不变。软件不得清除此寄存器。

### 12.7.2.1. Errata fixes

RP2350 fixes all RP2040 USB errata. This includes fixes for the following RP2040B0 and B1 errata which are also fixed by RP2040B2:

- RP2040-E2: USB device endpoint abort is not cleared
- RP2040-E5: USB device fails to exit RESET state on busy USB bus

For more information about RP2040B2, see the RP2040 datasheet.

RP2350 fixes the following RP2040B2 errata, which require software workarounds on RP2040B2:

- RP2040-E3: USB host: interrupt endpoint buffer done flag can be set with incorrect buffer select
- RP2040-E4: USB host writes to upper half of buffer status in single buffered mode
- RP2040-E15: USB Device controller will hang if certain bus errors occur during an IN transfer (see [Section 12.7.2.2.4](#))

### 12.7.2.2. New features

#### 12.7.2.2.1. General

- The USB PHY **DP** and **DM** can be used as regular GPIO pins. See the GPIO muxing [Table 646](#) in [Section 9.4](#).
- A **MAIN\_CTRL.PHY\_ISO** control isolates the PHY from the switched core power domain while the switched core domain is powered down. The isolation control resets to 1, meaning the **MAIN\_CTRL.PHY\_ISO** bit needs to be cleared before the PHY can be used. For more information on isolation, see [Chapter 9](#).
- **SIE\_CTRL.PULLDOWN\_EN** defaults to a 1 to match the reset state of isolation latches in the USB PHY. Pulling the **DP** and **DM** pins down by default saves power by preventing them from floating when unused.
- The **USB\_MUXING.TO\_PHY** bit defaults to a 1 to match the reset state of isolation latches.
- Added **SM\_STATE**, which exposes the internal state of the controller's modules.

#### 12.7.2.2.2. Host

- You can now optionally stop a transaction if a **NAK** is received. This allows the USB host to stop a bulk transaction if the device is not able to transfer data. Some devices using bulk endpoints, such as a UART, will return **NAKs** until a character is received. Stopping the transaction in hardware rather than using software means the host can get a **NAK** and guarantee no data has been dropped. RP2350 adds two register bits and an interrupt to support this:
  - The **NAK\_POLL.STOP\_EPX\_ON\_NAK** control, which enables and disables the feature.
  - The **NAK\_POLL.EPX\_STOPPED\_ON\_NAK** status bit, which also has an associated interrupt **INTS.EPX\_STOPPED\_ON\_NAK**.
- RP2350 increases inter-packet and turnaround timeouts to accommodate worst-case hub delays. This issue, only seen with long chains of USB hubs, was never seen in practice. Timings in the host state machine have been corrected to match USB spec. This fix is enabled by [LINESTATE\\_TUNING.MULTI\\_HUB\\_FIX](#).

#### 12.7.2.2.3. Device

- Added wake from suspend fix: Any bus activity (defined as **K** or **SE0**) should cause a wake from suspend, not just a qualified period of resume signalling. This fix is enabled by default and can be disabled with [LINESTATE\\_TUNING.DEV\\_LS\\_WAKE\\_FIX](#) (**LS** means line state in this instance, not low speed).
- Added DPSRAM double read feature to ensure data consistency. This avoids the need to set the **AVAILABLE** bit in the buffer control register separate to the rest of the buffer information. This feature is enabled by default and controlled by [LINESTATE\\_TUNING.DEV\\_BUFF\\_CONTROL\\_DOUBLE\\_READ\\_FIX](#).

### 12.7.2.1. 勘误修正

RP2350修正了所有RP2040 USB相关的勘误。本修复包含了对以下RP2040B0及B1错误的修正，这些错误同样已由RP2040B2解决：

- RP2040-E2：USB设备端点中止信号未被清除
- RP2040-E5：USB设备在繁忙的USB总线上无法退出复位状态

有关RP2040B2的详细信息，请参阅RP2040数据手册。

RP2350修正了以下RP2040B2错误，这些错误在RP2040B2上需通过软件进行解决：

- RP2040-E3：USB主机模式下，中断端点缓冲结束标志可能因缓冲选择错误而被错误置位
- RP2040-E4：USB主机在单缓冲模式下错误写入缓冲区状态的上半部分
- RP2040-E15：在IN传输过程中发生特定总线错误时，USB设备控制器可能挂起（详见第12.7.2.4节）

### 12.7.2.2 新特性

#### 12.7.2.2.1 概述

- USB PHY 的 DP 和 DM 引脚可用作普通 GPIO 引脚。详见第9.4节中的GPIO复用表646。
- MAIN\_CTRL.PHY\_ISO 控制用于在切换核心电源域断电时，将 PHY 与该电源域隔离。隔离控制复位为1，意味着在使用PHY之前必须清除 MAIN\_CTRL.PHY\_ISO 位。有关隔离的详细信息，请参见第9章。
- SIE\_CTRL.PULLDOWN\_EN 默认值为1，以匹配USB PHY中隔离锁存器的复位状态。将DP和DM引脚默认下拉，可防止未使用时引脚悬空，从而节省能耗。
- USB\_MUXING.TO\_PHY 位默认值为1，以匹配隔离锁存器的复位状态。
- 新增 SM\_STATE，用于公开控制器各模块的内部状态。

#### 12.7.2.2.2. 主机

- 现在可选择在接收到 NAK 时停止事务。此功能允许USB主机在设备无法传输数据时停止批量传输。某些使用批量端点的设备，例如UART，会持续返回 NAK，直至接收到字符。通过硬件停止传输而非采用软件方式，主机可接收到 NAK，确保无数据丢失。RP2350新增了两个寄存器位及一个中断以支持该功能：
  - NAK\_POLL.STOP\_EPX\_ON\_NAK 控制位，用于启用或禁用此功能。
  - NAK\_POLL.EPX\_STOPPED\_ON\_NAK 状态位，亦配有相应中断 INTS.EPX\_STOPPED\_ON\_NAK。
- RP2350延长了包间及转换超时，以适应最恶劣的集线器延迟。该问题仅在长链USB集线器中出现，但实际应用中未曾观察到。主机状态机时序已修正以符合USB规范。此修正通过LINESTATE\_TUNING.MULTI\_HUB\_FIX启用。
  -

#### 12.7.2.2.3. 设备

- 添加了从挂起状态唤醒的修正：任何总线活动（定义为 K 或 SE0）都应触发从挂起状态唤醒，而不仅限于合格的恢复信号周期。该修正默认启用，可通过LINESTATE\_TUNING.DEV\_LS\_WAKE\_FIX禁用（此处的LS表示线路状态，而非低速）。
- 新增DPSRAM双重读取功能以确保数据一致性。此举避免了在缓冲区控制寄存器中需单独设置 AVAILABLE 位以外的缓冲区信息。该功能默认启用，由LINESTATE\_TUNING.DEV\_BUFF\_CONTROL\_DOUBLE\_READ\_FIX控制。

- Added ability to stop **DEVICE OUT FROM HOST** when a short packet is received. For **E0** this is controlled by **SIE\_CTRL.EP0\_STOP\_ON\_SHORT\_PACKET**. This is done by stopping the transaction and then not toggling the buffer if in double buffered mode. Also added **short\_packet** interrupt to notify software that a short packet has been received (**INTS.RX\_SHORT\_PACKET**)

#### 12.7.2.2.4. Device error handling

- Added **DEV\_RX\_ERR QUIESCE** feature: the device endpoint error count replicates the host's internal Cerr count so software can detect if the host has probably halted the endpoint after three consecutive errors. The various stages of RX decode generate their own error signals that propagate to the top level. These error signals arrive at different times, so two error interrupts generate for every failed transfer. Added an optional override for this behaviour by forcing the device RX controller to idle after the first instance of an error during a transfer. This fix is enabled with **LINESTATE\_TUNING.DEV\_RX\_ERR QUIESCE**.
- Added **SIE\_RX\_CHATTER\_SE0\_FIX**: the existing error recovery implementation waits for 8 FS idle bit-times before signalling a framing error and returning to idle. This works OK for random bus errors, but when a hub terminates a downstream packet, the hub forces a bit-stuff error followed by EOP. A valid token from the host may immediately follow this, but the device controller may ignore it due to the enforced delay. Optionally waits for either a valid EOP or 8 idle bit times before signalling a framing error. To enable the fix, use **LINESTATE\_TUNING.SIE\_RX\_CHATTER\_SE0\_FIX**.
- Fix RP2040-E15: the receive state machine doesn't always handle cases where the bitstream deserialiser can abort a transfer. If decoding terminates due to bitstuff errors during the middle phases of a packet, the device controller can lock up. Unconditionally disables RX if the deserialiser has flagged a bitstuff error and subsequently signalled framing error after linestate returns to idle. To enable this fix, use **LINESTATE\_TUNING.SIE\_RX\_BITSTUFF\_FIX**.
- Device state machine watchdog: added a watchdog so that if the device state machine gets stuck for a certain amount of time it can be forced to idle. This is to handle any other error cases not anticipated by the above fixes. To enable the watchdog, use **DEV\_SM\_WATCHDOG**.

### 12.7.3. Architecture

#### 12.7.3.1. Clock speed

This controller requires **clk\_usb** to be running at 48MHz.

**NOTE**

**clk\_sys** must also be running at > 48MHz. See [RP2350-E12](#).

#### 12.7.3.2. Overview

- 新增短包接收时停止设备从主机传出的功能。对于 EP0，该功能由 SIE\_CTRL.EP0\_STOP\_ON\_SHORT\_PACKET 控制，方法是停止事务并在双缓冲模式下不切换缓冲区。还新增 short\_packet 中断，用以通知软件已收到短包 (INTS.RX\_SHORT\_PACKET)。

#### 12.7.2.4. 设备错误处理

- 新增 DEV\_RX\_ERR QUIESCE 功能：设备端点错误计数会复制主机内部的 Cerr 计数，从而使软件能够检测主机是否在连续三次错误后可能已停止该端点。RX 解码的各个阶段会生成各自的错误信号，并传播至顶层。这些错误信号在不同时间到达，因此每次传输失败将产生两个错误中断。新增该行为的可选覆盖功能，通过在传输过程中首次发生错误时强制设备 RX 控制器进入空闲状态实现。该修复通过 LINESTATE\_TUNING.DEV\_RX\_ERR QUIESCE 启用。
- 新增 SIE\_RX\_CHATTER\_SE0\_FIX：现有错误恢复机制在发出帧错误信号并返回空闲状态前需等待 8 个 FS 空闲位时间。此方法对随机总线错误有效，但当集线器终止下行数据包时，集线器会强制产生位填充错误，随后是结束包 (EOP)。主机可能立即发送有效令牌，但设备控制器可能因该强制延迟而忽略该令牌。可选择等待有效的 EOP 或 8 个空闲位时间，然后发出帧错误信号。要启用该修复，请使用 LINESTATE\_TUNING.SIE\_RX\_CHATTER\_SE0\_FIX。
- 修复 RP2040-E15：接收状态机并非总能正确处理位流解串器中断传输的情况。若在数据包中期因位填充错误导致解码终止，设备控制器可能会锁死。若解串器标记了位填充错误并随后在位状态返回空闲后发出帧错误信号，则无条件禁用 RX。要启用该修复，请使用 LINESTATE\_TUNING.SIE\_RX\_BITSTUFF\_FIX。
- 设备状态机看门狗：新增看门狗功能，若设备状态机卡住超过设定时间，可强制其进入空闲状态。此项用于处理上述修复未覆盖的其他错误情况。  
要启用看门狗功能，请使用 DEV\_SM\_WATCHDOG。

### 12.7.3. 架构

#### 12.7.3.1 时钟速度

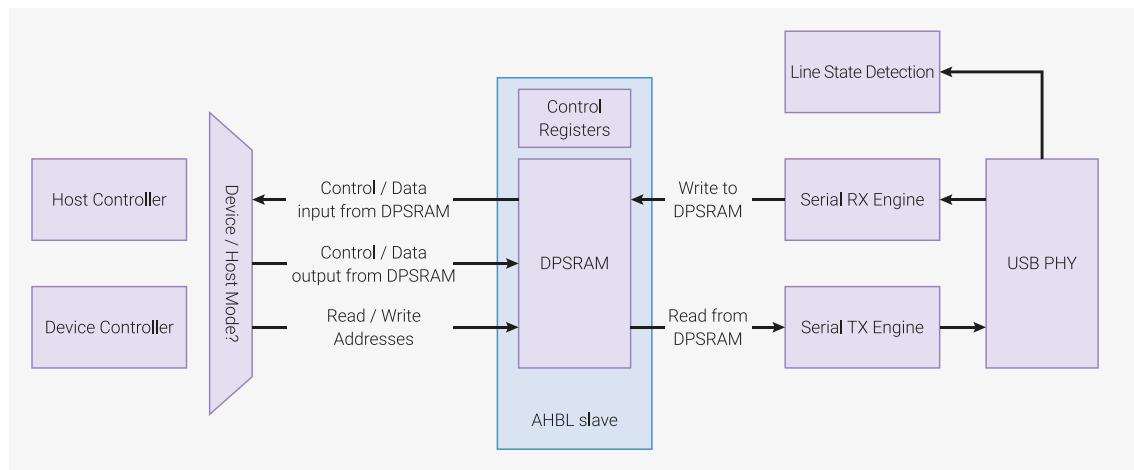

该控制器要求 `clk_usb` 以 48MHz 运行。

**注意**

`clk_sys` 也必须以超过 48MHz 的频率运行，详见 RP2350-E12。

#### 12.7.3.2 概述

Figure 124. A simplified overview of the USB controller architecture.

The USB controller is an area-efficient design that muxes a device controller or host controller onto a common set of components. Each component is detailed below.

#### 12.7.3.3. USB PHY

The USB PHY provides the electrical interface between the USB **DP** and **DM** pins and the digital logic of the controller. The **DP** and **DM** pins are a differential pair, meaning the values are always the inverse of each other, except to encode a specific line state (e.g. **SE0**). The USB PHY drives the **DP** and **DM** pins to transmit data and performs a differential receive of any incoming data. The USB PHY provides both single-ended and differential receive data to the line state detection module.

The USB PHY has built in pull-up and pull-down resistors. When the controller acts as a Full Speed device, the **DP** pin is pulled up to indicate to the host that a Full Speed device has been connected. In host mode, a weak pull-down is applied to **DP** and **DM** so that the lines are pulled to a logical zero until the device pulls up **DP** for Full Speed or **DM** for Low Speed.

#### 12.7.3.4. Line state detection

The [USB 2.0 Specification](#) defines several line states (Bus Reset, Connected, Suspend, Resume, Data 1, Data 0, etc.) that need to be detected. The line state detection module has several state machines to detect these states and signal events to the other hardware components. There is no shared clock signal in USB, so the RX data must be sampled by an internal clock. The maximum data rate of USB Full Speed is 12 Mb/s. The RX data is sampled at 48MHz, giving 4 clock cycles to capture and filter the bus state. The line state detection module distributes the filtered RX data to the Serial RX Engine.

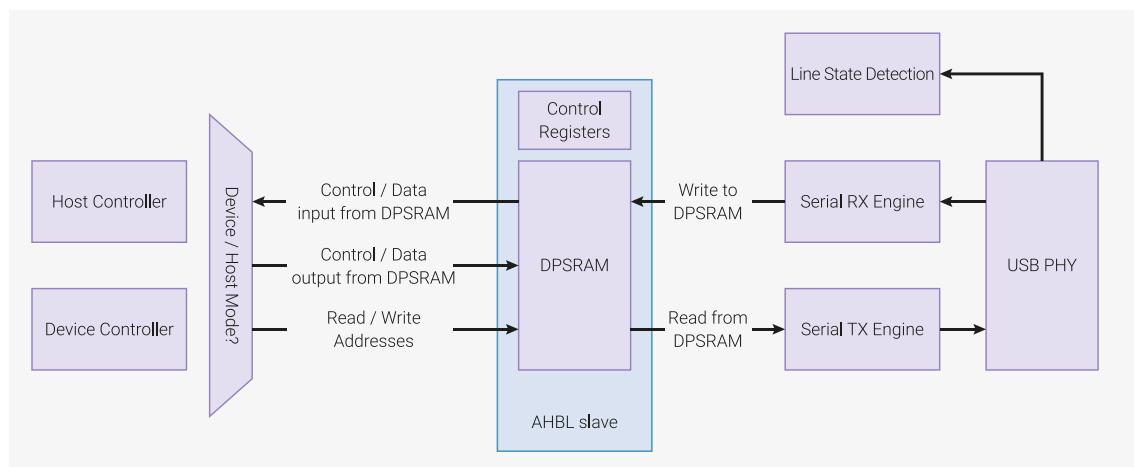

#### 12.7.3.5. Serial RX engine

The serial receive (RX) engine decodes receive data captured by the line state detection module. It produces the following information:

- The **PID** of the incoming data packet
- The device address for the incoming data
- The device endpoint for the incoming data
- Data bytes

The serial receive engine also detects errors in RX data by performing a CRC check on the incoming data. Any errors are signalled to the other hardware blocks and can raise an interrupt.

图124 USB  
控制器架构的简化  
概述。

USB控制器采用面积高效设计，将设备控制器或主机控制器复用到一组公共组件上。各组件详述如下。

### 12.7.3.3 USB PHY

USB PHY提供USB DP和DM引脚与控制器数字逻辑之间的电气接口。DP和DM引脚为差分对，意味着其信号值始终相反，除非用于编码特定线路状态（例如SE0）。USB PHY驱动DP和DM引脚传输数据，并对接收的数据进行差分接收。USB PHY向线路状态检测模块提供单端和差分接收的数据。

USB PHY内置上拉和下拉电阻。当控制器作为全速设备时，DP引脚被上拉，以向主机指示已连接全速设备。在主机模式下，对DP和DM引脚施加弱下拉，使线路保持逻辑低电平，直到设备对DP（全速）或DM（低速）进行上拉。

### 12.7.3.4. 线路状态检测

USB 2.0规范定义了多个线路状态（总线复位、已连接、挂起、恢复、数据1、数据0等），需被检测。线路状态检测模块包含多个状态机，用于检测这些状态并向其他硬件组件发送事件信号。USB中无共享时钟信号，接收数据必须由内部时钟采样。USB全速最大数据速率为12 Mb/s。接收数据以48 MHz采样，提供4个时钟周期用于采集和滤除总线状态。线路状态检测模块将已滤波的RX数据分配至串行RX引擎。

### 12.7.3.5. 串行RX引擎

串行接收（RX）引擎解码线路状态检测模块捕获的接收数据。其产生以下信息：

- 传入数据包的PID
- 传入数据的设备地址
- 传入数据的设备端点
- 数据字节

串行接收引擎还通过对传入数据执行CRC校验以检测RX数据中的错误。任何错误均会向其他硬件模块发出信号，并可能触发中断。

**NOTE**

If you disconnect the USB cable during packet transfer in either host or device mode, the hardware will raise errors. Software must account for this scenario if you enable error interrupts.

**12.7.3.6. Serial TX engine**

The serial transmit (TX) engine is a mirror of the serial receive engine. It is connected to the currently active controller (either device or host). It creates **TOKEN** and **DATA** packets, calculates the CRC, and transmits them on the bus.

**12.7.3.7. DPSRAM**

The USB controller uses 4 kB (4096 bytes) of Dual Port SRAM (DPSRAM) to store control registers and data buffers. The DPSRAM is accessible as a 32-bit wide memory at address 0 of the USB controller (**0x50100000**).

The DPSRAM has the following characteristics, which differ from most registers on RP2350:

- Supports 8-bit, 16-bit, and 32-bit accesses (typically, RP2350 registers only support 32-bit accesses)
- Does not support set/clear aliases. (typically, RP2350 registers support these)

Data Buffers are typically 64 bytes long, as this is the maximum normal packet size for most Full Speed packets. Isochronous endpoints support a maximum buffer size of 1023 bytes. For other packet types, the maximum size is 64 bytes per buffer.

**12.7.3.7.1. Concurrent access**

The DPSRAM in the USB controller is asynchronous. The **dual port** part of the name indicates that *both* the processor and the USB controller have ports to read and write, and these two ports are in different clock domains. As a result, the processor and USB controller can access the same memory address at the same time. One could write and one could read simultaneously. This could result in inconsistent data reads. You can avoid this scenario by following the rules outlined in this section.

The **AVAILABLE** bit in the buffer control register indicates who has ownership of a buffer. Set this bit to 1 from the processor to give the controller ownership of the buffer. When it has finished using the buffer, the controller sets the bit back to 0. Set the **AVAILABLE** bit separately from the rest of the data in the buffer control register so that the rest of the data in the buffer control register is accurate when the **AVAILABLE** bit is set.

This is necessary because the processor clock **clk\_sys** can run several times faster than the **clk\_usb** clock. Therefore **clk\_sys** can update the data *during* a USB controller read on a slower clock. The correct process is:

1. Write buffer information (length, etc.) to the buffer control register.
2. **nop** for some **clk\_sys** cycles to ensure that at least one **clk\_usb** cycle passes. Consider a scenario where **clk\_sys** runs at 125MHz and **clk\_usb** runs at 48MHz. Because  $\lceil \frac{125}{48} \rceil = 3$ , you should issue 3 **nop** instructions between the writes to guarantee that at least one **clk\_usb** cycle has passed.
3. Set the **AVAILABLE** bit.

If **clk\_sys** and **clk\_usb** run at the same frequency, then it is not necessary to set the **AVAILABLE** bit separately.

### ⓘ 注意

若在主机或设备模式下传输数据包过程中断开USB电缆，硬件将报告错误。  
若启用错误中断，软件必须考虑此情况。

#### 12.7.3.6. 串行TX引擎

串行发送（TX）引擎是串行接收引擎的镜像。其连接至当前活动控制器（设备或主机）。其创建 TOKEN和 DATA包，计算CRC，并在总线上发送。

#### 12.7.3.7. DPSRAM

USB控制器使用4KB（4096字节）的双端口SRAM（DPSRAM）用于存储控制寄存器和数据缓冲区。DPSRAM可作为USB控制器地址0（[0x50100000](#)）处的32位宽存储器访问。

DPSRAM具备以下特性，这些特性与RP2350上的大多数寄存器有所不同：

- 支持8位、16位及32位访问（一般而言，RP2350寄存器仅支持32位访问）
- 不支持置位/清除别名。（通常，RP2350寄存器支持此类功能）

数据缓冲区通常为64字节长度，此为大多数全速数据包的最大正常包大小。  
等时端点支持最大1023字节缓冲区大小。其他数据包类型的每个缓冲区最大为64字节。

##### 12.7.3.7.1. 并发访问

USB控制器中的DPSRAM为异步运行。名称中的**dual port**表明处理器和USB控制器均配备读写端口，并且这两个端口处于不同的时钟域。因此，处理器和USB控制器可同时访问相同的内存地址。一方可同时写入，而另一方可同时读取。这可能导致数据读取不一致。您可通过遵循本节所述规则避免此类情况发生。

缓冲区控制寄存器中的 **AVAILABLE**位指示缓冲区的所有权归属。处理器将此位设置为1，以将缓冲区所有权赋予控制器。控制器使用完缓冲区后，会将该位复位为0。应将 **AVAILABLE**位与缓冲区控制寄存器中的其他数据分开放置，确保设置 **AVAILABLE**位时其他数据依然准确。

这是因为处理器时钟 **clk\_sys**的频率可能是 **clk\_usb**时钟的数倍。因此，**clk\_sys**能够在较低频率时钟的USB控制器读取期间更新数据。正确的流程如下：

1. 将缓冲区信息（长度等）写入缓冲区控制寄存器。
2. 执行 **nop**指令，延续若干个 **clk\_sys**周期，以确保至少经历一个 **clk\_usb**周期。考虑一种情况，**clk\_sys**运行于125MHz，**clk\_usb**运行于48MHz。由于  $\lceil \frac{125}{48} \rceil = 3$ ，你应在两次写入之间发出3条 **nop**指令，以确保至少经历一个 **clk\_usb**周期。
3. 设置 **AVAILABLE**位。

若 **clk\_sys**与 **clk\_usb**频率相同，则无需单独设置 **AVAILABLE**位。

**NOTE**

When the USB controller writes the status back to the DPSRAM, it does a 16-bit write to the lower 2 bytes for buffer 0 and the upper 2 bytes for buffer 1. When using double-buffered mode, always treat the buffer control register as two 16-bit registers when updating it in software.

**12.7.3.7.2. Layout**

Addresses `0x0` → `0xff` are used for control registers containing configuration data. The remaining space, addresses `0x100` → `0xffff` (3840 bytes) can be used for data buffers. The controller has control registers that start at address `0x10000`.

The memory layout depends on the USB controller mode:

- In Device mode, the host can access multiple endpoints, so each endpoint must have endpoint control and buffer control registers.
- In Host mode, the host software running on the processor decides which endpoints and devices to access. This only requires one set of endpoint control and buffer control registers. As well as software-driven transfers, the host controller can poll up to 15 interrupt endpoints and has a register for each of these interrupt endpoints.

*Table 1192. DPSRAM layout*

Offset	Device Function	Host Function
<code>0x0</code>	Setup packet (8 bytes)	
<code>0x8</code>	EP1 in control	Interrupt endpoint control 1
<code>0xc</code>	EP1 out control	Spare
<code>0x10</code>	EP2 in control	Interrupt endpoint control 2
<code>0x14</code>	EP2 out control	Spare
<code>0x18</code>	EP3 in control	Interrupt endpoint control 3
<code>0x1c</code>	EP3 out control	Spare
<code>0x20</code>	EP4 in control	Interrupt endpoint control 4
<code>0x24</code>	EP4 out control	Spare
<code>0x28</code>	EP5 in control	Interrupt endpoint control 5
<code>0x2c</code>	EP5 out control	Spare
<code>0x30</code>	EP6 in control	Interrupt endpoint control 6
<code>0x34</code>	EP6 out control	Spare
<code>0x38</code>	EP7 in control	Interrupt endpoint control 7
<code>0x3c</code>	EP7 out control	Spare
<code>0x40</code>	EP8 in control	Interrupt endpoint control 8
<code>0x44</code>	EP8 out control	Spare
<code>0x48</code>	EP9 in control	Interrupt endpoint control 9
<code>0x4c</code>	EP9 out control	Spare
<code>0x50</code>	EP10 in control	Interrupt endpoint control 10
<code>0x54</code>	EP10 out control	Spare
<code>0x58</code>	EP11 in control	Interrupt endpoint control 11

### ⓘ 注意

当 USB 控制器将状态写回 DPSRAM 时，对缓冲区 0 执行低 2 字节的 16 位写操作，对缓冲区 1 执行高 2 字节的 16 位写操作。使用双缓冲模式时，软件更新缓冲区控制寄存器应始终将其视作两个独立的 16 位寄存器。

#### 12.7.3.7.2. 布局

地址 `0x0 → 0xff` 用于存放配置信息的控制寄存器。剩余空间，地址 `0x100 → 0xffff` (3840字节) 可用于数据缓冲区。控制器的控制寄存器起始于地址

`0x10000`。

内存布局取决于USB控制器的工作模式：

- 在设备模式下，主机会访问多个端点，因此每个端点必须拥有端点控制寄存器和缓冲区控制寄存器。
- 在主机模式下，运行于处理器上的主机软件决定访问哪些端点和设备。这仅需要一套端点控制寄存器和缓冲区控制寄存器。除了软件驱动的数据传输外，主机控制器可以轮询最多15个中断端点，并为每个中断端点配置相应寄存器。

表1192. DPSRAM  
布局

#### 12.7.3.7.3. Endpoint control register

The endpoint control register is used to configure an endpoint. It defines:

- The endpoint type
- The base address of the endpoint's data buffer (or data buffers if double-buffered)
- Which endpoint events trigger the controller interrupt output

A device must support Endpoint 0 so that it can reply to **SETUP** packets and be enumerated. As a result, there is no endpoint control register for **EP0**. Its buffers begin at **0x100**. All other endpoints can have either single or dual buffers and are mapped at the base address programmed. As **EP0** has no endpoint control register, the interrupt enable controls for **EP0** come from **SIE\_CTRL**.

Table 1193. Endpoint control register layout

Bit(s)	Device Function	Host Function
31	Endpoint enable	
30	Single buffered (64 bytes) = 0, Double buffered (64 bytes × 2) = 1	
29	Enable interrupt for every transferred buffer	
28	Enable interrupt for every 2 transferred buffers (valid for double-buffered only)	
27:26	Endpoint Type: Control = 0, Isochronous = 1, Bulk = 2, Interrupt = 3	
25:18	N/A	The interval the host controller should poll this endpoint. Only applicable for interrupt endpoints. Specified in ms - 1. For example: a value of 9 would poll the endpoint every 10ms.
17	Interrupt on <b>STALL</b>	
16	Interrupt on <b>NAK</b>	
15:6	Address base offset in DPSRAM of data buffer(s)	

#### NOTE

The data buffer base address must be 64-byte aligned, since bits 0 through 5 are ignored.

#### 12.7.3.7.4. Buffer control register

The buffer control register contains information about the state of the data buffers for that endpoint. It is shared between the processor and the controller. If the endpoint is configured to be single-buffered, only the first half (bits 0 through 15) of the buffer are used.

If double buffering, the buffer select starts at buffer 0. From then on, the buffer select flips between buffer 0 and 1

偏移量	设备功能	主机功能
0xec	EP13 出站缓冲区控制	备用

0xf4	EP14 出站缓冲区控制	备用
0xf8	EP15 入站缓冲区控制	中断端点缓冲区控制 15
0xfc	EP15 输出缓冲区控制	备用
0x100	EP0 缓冲区 0 (输入和输出共享)	EPx 控制
0x140	可选 EP0 缓冲区 1	备用
0x180	数据缓冲区	

#### 12.7.3.7.3. 端点控制寄存器

端点控制寄存器用于配置端点，包括：

- 端点类型
- 端点数据缓冲区的基址（双缓冲时为数据缓冲区）
- 触发控制器中断输出的端点事件

设备必须支持端点0，以便响应 **SETUP**包并完成枚举。因此，端点0不存在端点控制寄存器。其缓冲区起始地址为 0x100。所有其他端点可配置为单缓冲或双缓冲，并映射至所编程的基址。由于EP0无端点控制寄存器，其中断使能控制由 SIE\_CTRL 提供。

表 1193。端点控制寄存器布局

Bit (位)	设备功能	主机功能
31	端点启用	
30	单缓冲 (64字节) = 0，双缓冲 (64字节×2) = 1	
29	为每个传输缓冲区启用中断	
28	为每两个传输缓冲区启用中断 (仅适用于双缓冲)	
27:26	端点类型：控制 = 0，等时 = 1，批量 = 2，中断 = 3	
25:18	不适用	主机控制器轮询该端点的间隔时间。仅适用于中断端点。单位为毫秒，值减1。例如：值为9表示每10毫秒轮询一次该端点。
17	中断触发于 <b>STALL</b>	
16	中断触发于 <b>NAK</b>	
15:6	数据缓冲区在DPSRAM中的基址偏移量	

#### 注意

数据缓冲区基址必须64字节对齐，因位0至5被忽略。

#### 12.7.3.7.4. 缓冲区控制寄存器

缓冲区控制寄存器包含该端点数据缓冲区的状态信息。该寄存器由处理器与控制器共享。如果端点配置为单缓冲，则仅使用缓冲区的前半部分（第0至15位）。

若为双缓冲，则缓冲区选择从缓冲区0开始。此后，缓冲区选择在缓冲区0和缓冲区1之间切换，

unless the **reset buffer select** bit is set (which resets the buffer select to buffer 0). The value of the buffer select is internal to the controller and not accessible by the processor.

For host interrupt and isochronous packets on **EP<sub>x</sub>**, the buffer full bit will be set on completion even if the transfer was unsuccessful. To determine the error, read the error bits in the **SIE\_STATUS** register.

*Table 1194. Buffer control register layout*

Bit(s)	Function
31	Buffer 1 full. Should be set to 1 by the processor for an <b>IN</b> transaction and 0 for an <b>OUT</b> transaction. The controller sets this to 1 for an <b>OUT</b> transaction because it has filled the buffer. The controller sets it to 0 for an <b>IN</b> transaction because it has emptied the buffer. Only valid when double buffering.
30	Last buffer of transfer for buffer 1. Only valid when double buffering.
29	Data PID for buffer 1 - DATA0 = 0, DATA1 = 1. Only valid when double buffering.
27:28	Double buffer offset for isochronous mode (0 = 128, 1 = 256, 2 = 512, 3 = 1024).
26	Buffer 1 available. Whether the buffer can be used by the controller for a transfer. The processor sets this to 1 when the buffer is configured. The controller sets this to 0 after it has sent the data to the host for an <b>IN</b> transaction, or filled the buffer with data from the host for an <b>OUT</b> transaction. Only valid when double buffering.
25:16	Buffer 1 transfer length. Only valid when double buffering.
15	Buffer 0 full. Should be set to 1 by the processor for an <b>IN</b> transaction and 0 for an <b>OUT</b> transaction. The controller sets this to 1 for an <b>OUT</b> transaction because it has filled the buffer. The controller sets it to 0 for an <b>IN</b> transaction because it has emptied the buffer.
14	Last buffer of transfer for buffer 0.
13	Data PID for buffer 0 - DATA0 = 0, DATA1 = 1.
12	Reset buffer select to buffer 0 - cleared at end of transfer. For device <i>only</i> .
11	Send <b>STALL</b> for device, <b>STALL</b> received for host.
10	Buffer 0 available. Indicates whether the buffer can be used by the controller for a transfer. The processor sets this to 1 when the buffer is configured. The controller sets this to 0 after it has sent the data to the host for an <b>IN</b> transaction or filled the buffer with data from the host for an <b>OUT</b> transaction.
9:0	Buffer 0 transfer length.

### ⚠ WARNING

If you run **clk\_sys** and **clk\_usb** at different speeds, set the available and stall bits *after* the other data in the buffer control register. Otherwise, the controller may initiate a transaction with data from a previous packet. The controller could see the available bit set, but get the data PID or length from the previous packet.

### 12.7.3.8. Device controller

This section details how the device controller operates when it receives various packet types from the host.

#### 12.7.3.8.1. SETUP

The device controller **MUST** always accept a **SETUP** packet from the host. DPSRAM dedicates its first 8 bytes to the setup packet.

The [USB 2.0 Specification](#) states that receiving a setup packet also clears any stall bits on **EP0**. For this reason, the stall

除非设置了复位缓冲区选择位（该位将缓冲区选择重置为缓冲区0）。缓冲区选择的值为控制器内部状态，处理器不可访问。

对于主机中断和等时包于 EPx上的传输，即使传输失败，缓冲区满位在完成时仍被置位。要确定错误，请读取SIE\_STATU S寄存器中的错误位。

表1194。缓冲区控制寄存器布局

Bit (位)	功能
31	缓冲区1已满。对于 IN事务，处理器应将其置1；对于 OUT事务，应置0。控制器在 OUT事务中将其置为1，表明缓冲区已填满。 控制器将其设置为0，用于 IN事务，因为缓冲区已清空。仅在双缓冲模式下有效。
30	缓冲区1的最后一个传输缓冲。仅在双缓冲模式下有效。
29	缓冲区1的数据PID - DATA0 = 0, DATA1 = 1。仅在双缓冲模式下有效。
27:28	同步传输模式下的双缓冲偏移量 (0 = 128, 1 = 256, 2 = 512, 3 = 1024)。
26	缓冲区1可用。指示该缓冲区是否可被控制器用于传输。处理器在配置缓冲区时将其设置为1。控制器在将数据发送至主机以进行 IN事务，或从主机接收数据填充缓冲区以进行OUT事务后，将其设置为0。仅在双缓冲模式下有效。
25:16	缓冲区1传输长度。仅在双缓冲模式下有效。
15	缓冲区0已满。对于 IN事务，处理器应将其置1；对于 OUT事务，应置0。控制器在 OUT事务中将其置为1，表明缓冲区已填满。 控制器将其设置为0，用于 IN事务，因为缓冲区已清空。
14	缓冲区0的最后一个传输缓冲。
13	缓冲区0的数据PID—DATA0 = 0, DATA1 = 1。
12	将缓冲区选择重置为缓冲区0—在传输结束时清除，仅限设备使用。
11	向设备发送STALL，主机接收STALL。
10	缓冲区0可用。指示控制器是否可使用该缓冲区进行传输。 处理器在配置缓冲区时将其设置为1。控制器在向主机发送 IN事务数据后，或为 OUT事务从主机填充数据至缓冲区后，将此位清零。
9:0	缓冲区0传输长度。

### ● 警告

若您以不同速度运行 clk\_sys 和 clk\_usb，请在缓冲区控制寄存器中的其他数据之后设置available和stall位。否则，控制器可能会启动包含来自先前数据包的数据的事务。控制器可能检测到available位被设置，但获取的是先前数据包的数据PID或长度。

### 12.7.3.8. 设备控制器

本节详细说明设备控制器接收主机各类数据包时的操作方式。

#### 12.7.3.8.1. SETUP

设备控制器必须始终接受来自主机的SETUP数据包。DPSRAM将其前8个字节专用于存放设置数据包。

USB 2.0规范规定，接收设置数据包同时清除EP0上的任何阻塞位。因此，阻塞

bits for EP0 are gated with two bits in the EP\_STALL\_ARM register. These bits are cleared when a setup packet is received. This means that to send a stall on EP0, you must set both the stall bit in the buffer control register and the appropriate bit in EP\_STALL\_ARM.

Barring any errors, the setup packet will be put into the setup packet buffer at DPSRAM offset 0x0. The device controller will then reply with an ACK.

Finally, SIE\_STATUS.SETUP\_REC is set to indicate that a setup packet has been received. This will trigger an interrupt if the programmer has enabled the SETUP\_REC interrupt (see INT).

#### 12.7.3.8.2. IN

From the device's point of view, an IN transfer means transferring data *into* the host. When an IN token is received from the host, the request is handled as follows:

**TOKEN** phase:

1. If STALL is set in the buffer control register (and if EP0, the appropriate EP\_STALL\_ARM bit is set), send a STALL response and go to idle.
2. If AVAILABLE and FULL bits are set in buffer control, go to the DATA phase.
3. If this is an isochronous endpoint, go to idle.
  - o Otherwise, send NAK and go to the DATA phase.

**DATA** phase:

1. Send data.
2. If this is an isochronous endpoint, go to idle.
  - o Otherwise, go to the ACK phase.

**ACK** phase:

1. Wait for ACK packet from host.
2. If there is a timeout, raise a timeout error.
3. If ACK is received, the packet is done, so go to STATUS phase.

**STATUS** phase:

1. If this was the last buffer in the transfer (i.e. if the LAST\_BUFFER bit in the buffer control register was set), set SIE\_STATUS.TRANS\_COMPLETE.
2. If the endpoint is double buffered, flip the buffer select to the other buffer.
3. Set a bit in BUFF\_STATUS to indicate the buffer is done. When handling this event, the programmer should read BUFF\_CPU\_SHOULD\_HANDLE to see if it is buffer 0 or buffer 1 that is finished. If the endpoint is double-buffered, both buffers could be done. The cleared BUFF\_STATUS bit will be set again, and BUFF\_CPU\_SHOULD\_HANDLE will change in this instance.
4. Update status in the appropriate half of the buffer control register: length, pid, and last\_buff are set. Everything else is written to zero.

If the host receives a NAK, the host will retry again later.

#### 12.7.3.8.3. OUT

When an OUT token is received from the host, the request is handled as follows:

**TOKEN** phase:

1. If this is *not* an Isochronous endpoint and the data PID does not match the buffer control register, raise

位于EP0端点通过EP\_STALL\_ARM寄存器中的两个位进行控制。当接收到设置数据包时，这些位将被清除。这意味着，要在EP0端点发送阻塞信号，必须同时设置缓冲控制寄存器中的阻塞位和EP\_STALL\_ARM寄存器中的相应位。

在无误的情况下，设置数据包将被存放在DPSRAM偏移量0x0处的设置数据包缓冲区。设备控制器随后将回复ACK信号。

最后，SIE\_STATUS.SETUP\_REC位被置位，以指示已接收到设置数据包。如果程序员已启用 SETUP\_REC中断（参见INTE），则会触发中断。

#### 12.7.3.8.2. IN

从设备的角度来看，IN传输是指将数据传输到主机。当接收到来自主机的IN令牌时，请按以下方式处理：

**TOKEN** 阶段：

1. 如果缓冲区控制寄存器中设置了 STALL（且对于 EP0，相应的EP\_STALL\_ARM位已设置），则发送STALL响应并进入空闲状态。
2. 如果缓冲区控制中的 AVAILABLE 和 FULL 位均被设置，则进入 DATA阶段。
3. 若为等时端点，则进入空闲状态。
  - 否则，发送 NAK并进入 DATA阶段。

**DATA** 阶段：

1. 发送数据。
2. 若为等时端点，则进入空闲状态。
  - 否则，进入 ACK阶段。

**ACK** 阶段：

1. 等待来自主机的 ACK数据包。
2. 若发生超时，则触发超时错误。
3. 如果收到 ACK，数据包传输完成，则进入 STATUS阶段。

**STATUS** 阶段：

1. 若该缓冲区为传输中的最后一个（即缓冲区控制寄存器中的LAST\_BUFFER位已设置），则置位 SIE\_STATUS.TRANSACTION\_COMPLETE。
2. 若端点采用双缓冲，则切换缓冲区选择至另一缓冲区。
3. 在 BUFF\_STATUS 中设置相应位以指示缓冲区已完成。处理此事件时，程序应读取 BUFF\_CPU\_SHOULD\_HANDLE 以确定完成的是缓冲区 0 还是缓冲区 1。若端点为双缓冲，则两个缓冲区均可能已完成。被清除的 BUFF\_STATUS 位会被重新置位，且 BUFF\_CPU\_SHOULD\_HANDLE 会相应变化。
4. 在缓冲区控制寄存器的相应半区更新状态：length、pid 与 last\_buff 被设置，其余全部写入零。

若主机收到 NAK，将稍后重试。

#### 12.7.3.8.3. OUT

当从主机接收到 OUT令牌时，请按以下方式处理：

**TOKEN** 阶段：

1. 如果这不是一个等时端点，且数据 PID 与缓冲区控制寄存器不匹配，则触发

[SIE\\_STATUS](#).DATA\_SEQ\_ERROR (isochronous data is always sent with a [DATA0](#) pid).

- If the [AVAILABLE](#) bit is set and the [FULL](#) bit is clear, go to the [DATA](#) phase, unless the [STALL](#) bit is set in which case the device controller will reply with a [STALL](#).

[DATA](#) phase:

- Store received data in buffer. If this is an isochronous endpoint, go to the [STATUS](#) phase. Otherwise, go to the [ACK](#) phase.

[ACK](#) phase:

- Send [ACK](#). Go to the [STATUS](#) phase.

[STATUS](#) phase:

See [IN STATUS](#) phase: [\[usb-device-in-status-phase\]](#). There is one difference: the [FULL](#) bit is set in the buffer control register to indicate that data has been received. In the [IN](#) phase, the [FULL](#) bit is cleared to indicate that data has been sent.

#### 12.7.3.8.4. Suspend and resume

The USB device controller supports suspend, resume, and device-initiated remote resume (triggered with [SIE\\_CTRL](#).RESUME). There is an interrupt / status bit in [SIE\\_STATUS](#). It is not necessary to enable the suspend and resume interrupts, since suspend and resume are irrelevant to most devices.

The device goes into suspend when it does not see any start of frame packets (transmitted every 1ms) from the host.

**i NOTE**

If you enable the suspend interrupt, it is likely you will see a suspend interrupt when the device first connects, but the bus is idle. The bus can be idle for a few milliseconds before the host begins sending start of frame packets. If you do not have a VBUS detect circuit connected, you will also see a suspend interrupt when the device disconnects. Without VBUS detection, it is impossible to tell the difference between being disconnected and suspended.

#### 12.7.3.9. Host controller

The host controller design is similar to the device controller. The host starts all transactions, so the host always deals with transactions it has started. For this reason, there is only one set of endpoint control and endpoint buffer control registers. The host controller also contains additional hardware to poll interrupt endpoints in the background when there are no software controlled transactions taking place.

The host needs to send keep-alive packets to the device every 1ms to keep the device from suspending. Full Speed mode uses a [SOF](#) (start of frame) packet. Low Speed mode uses an [EOP](#) (end of packet) instead. Set [SIE\\_CTRL](#).KEEP\_ALIVE\_EN and [SIE\\_CTRL](#).SOF\_EN to enable these packets.

Several bits in [SIE\\_CTRL](#) are used to begin a host transaction:

- [SEND\\_SETUP](#) - Send a setup packet. Typically used with [RECEIVE\\_TRANS](#), so the setup packet will be sent followed by the additional data transaction expected from the device.
- [SEND\\_TRANS](#) - This transfer is [OUT](#) from the host.
- [RECEIVE\\_TRANS](#) - This transfer is [IN](#) to the host.
- [START\\_TRANS](#) - Start the transfer (non-latching).
- [STOP\\_TRANS](#) - Stop the current transfer (non-latching).
- [PREAMBLE\\_ENABLE](#) - Used to send a packet to a Low Speed device on a Full Speed hub. Sends a [PRE](#) token packet before every packet the host sends (i.e. [PRE](#), [TOKEN](#), [PRE](#), [DATA](#), [pre](#), [ACK](#)).
- [SOF\\_SYNC](#) - Used to delay the transaction until after the next [SOF](#). Useful for interrupt and isochronous endpoints. The host controller prevents a transaction of 64 bytes from clashing with the [SOF](#) packets. For longer isochronous

**SIE\_STATUS.DATA\_SEQ\_ERROR** (等时数据始终以 DATA0 PID 发送)。

2. 如果 **AVAILABLE**位被置位且 **FULL**位被清除，则进入 **DATA**阶段；除非 **STALL**位被置位，此时设备控制器将回复一个 **STALL**。

**DATA** 阶段：

1. 将接收的数据存储于缓冲区。若为等时端点，则进入 **STATUS**阶段。否则，进入 **ACK**阶段。

**ACK** 阶段：

1. 发送 **ACK**。进入 **STATUS**阶段。

**STATUS** 阶段：

参见 **IN STATUS**阶段：[usb-device-in-status-phase]。有一点不同之处：缓冲区控制寄存器中的 **FULL**位被置位，以指示数据已接收。在 **IN**阶段，**FULL**位被清除以指示数据已发送。

#### 12.7.3.8.4. 挂起与恢复

USB 设备控制器支持挂起、恢复以及设备发起的远程恢复（由 **SIE\_CTRL.RESUME** 触发）。**SIE\_STATUS** 中含有中断/状态位。无需启用挂起和恢复中断，因为挂起与恢复对大多数设备而言无关紧要。

当设备未检测到主机发送的任何帧起始包（每隔1毫秒发送一次）时，设备将进入挂起状态。

##### ① 注意

启用挂起中断时，设备首次连接可能会产生挂起中断，但总线处于空闲状态。主机开始发送帧起始包前，总线可能空闲数毫秒。若未连接 VBUS 检测电路，设备断开时亦会出现挂起中断。

未连接 VBUS 检测电路时，无法区分断开连接与挂起状态。

#### 12.7.3.9. 主机控制器

主机控制器的设计与设备控制器类似。主机发起所有事务，因此主机始终处理其发起的事务。因此，仅存在一组端点控制和端点缓冲控制寄存器。主机控制器还配备了额外硬件，在无软件控制事务进行时，可在后台轮询中断端点。

主机需每1毫秒向设备发送保持活动包，以防止设备进入挂起状态。全速模式使用 **SOF**（帧开始）包。低速模式则使用 **EOP**（包结束）包。通过设置 **SIE\_CTRL.KEEP\_ALIVE\_EN** 和 **SIE\_CTRL.SOF\_EN** 来启用这些包。

**SIE\_CTRL** 寄存器中的若干位用于启动主机事务：

- **SEND\_SETUP**- 发送设置包。通常与**RECEIVE\_TRANS**配合使用，先发送设置包，随后执行设备预期的额外数据事务。
- **SEND\_TRANS** - 此传输为 **OUT** 方向，来源于主机。
- **RECEIVE\_TRANS** - 此传输为 **IN** 方向，进入主机。
- **START\_TRANS** - 启动传输（非锁存）。
- **STOP\_TRANS** - 停止当前传输（非锁存）。
- **PREAMBLE\_ENABLE**- 用于向全速集线器上的低速设备发送数据包。主机会在发送的每个数据包前附加一个 **PRE**令牌包（即 **PRE**、**TOKEN**、**PRE**、**DATA**、**pre**、**ACK**）。
- **SOF\_SYNC**- 用于延迟事务，直到下一个 **SOF**之后。适用于中断端点和同步端点。主机控制器防止64字节长度的事务与 **SOF**数据包冲突。对于更长的同步

packets, software is responsible for preventing collisions. To prevent collisions in software, use `SOF_SYNC` and limit the number of packets sent in one frame. If a transaction is set up with multiple packets, `SOF_SYNC` only applies to the first packet.

The `START_TRANS` bit is synchronised separately from other control bits in the `SIE_CTRL` register because the processor clock `clk_sys` can be asynchronous to the `clk_usb` clock. Always set the `START_TRANS` bit separately from the rest of the data in the `SIE_CTRL` register. Always ensure that at least two `clk_usb` cycles pass between writing to `START_TRANS` and other bits in `SIE_CTRL`. This ensures that the register contents are stable when the controller is prompted to start a transfer.

Consider a scenario where `clk_sys` runs at 125MHz and `clk_usb` runs at 48MHz. Because  $\lceil \frac{125}{48} \rceil \times 2 = 6$ , you should issue 6 `nop` instructions between the writes to guarantee that at least two `clk_usb` cycles have passed.

#### 12.7.3.9.1. SETUP

The `SETUP` packet sent from the host always comes from the dedicated 8 bytes of space at offset `0x0` of the DPSRAM. Like the device controller, there are no control registers associated with the setup packet. The parameters are hard-coded and loaded into the hardware when you write to `START_TRANS` with the `SEND_SETUP` bit set. Once the setup packet has been sent, the host state machine waits for an `ACK` from the device. If there is a timeout, an `RX_TIMEOUT` error will be raised. If the `SEND_TRANS` bit is set, the host state machine will move to the `OUT` phase. Typically, the `SEND_SETUP` packet is used with the `RECEIVE_TRANS` bit, so the controller moves to the `IN` phase after sending a setup packet.

#### 12.7.3.9.2. IN

An `IN` transfer is triggered with the `RECEIVE_TRANS` bit set when the `START_TRANS` bit is set. If the `SEND_SETUP` bit was set, this may be preceded by a `SETUP` packet.

**CONTROL** phase:

1. Read the `EPx` control register located at `0x80` to get the following endpoint information:
  - o Is it double buffered?
  - o What interrupts are enabled?
  - o Base address of the data buffer (data buffers if in double-buffered mode)
  - o What is the endpoint type?
2. Read the `EPx` buffer control register at `0x100` to get endpoint buffer information, such as transfer length and data PID.
3. Set the `AVAILABLE` bit (the host state machine checks for it).
4. Clear the `FULL` bit.

**TOKEN** phase:

1. Send the `IN` token packet to the device. The target device address and endpoint come from the `ADDR_ENDP` register.

**DATA** phase:

1. Receive the first data packet from the device.
2. Raise RX timeout error if the device doesn't reply.
3. If this is *not* an Isochronous endpoint and the data PID does not match the buffer control register, raise `SIE_STATUS.DATA_SEQ_ERROR` (isochronous data is always sent with a `DATA0` pid).

**ACK** phase:

1. Send `ACK` to device.

**STATUS** phase:

数据包，软件层负责避免冲突。为避免软件冲突，请使用 **SOF\_SYNC** 并限制每帧发送的数据包数量。如果事务由多个数据包组成，**SOF\_SYNC** 仅适用于第一个数据包。

**START\_TRANS** 位与 **SIE\_CTRL** 寄存器中的其他控制位分别同步，因为处理器时钟 **clk\_sys** 可能与 **clk\_usb** 时钟异步。务必在写入 **START\_TRANS** 和 **SIE\_CTRL** 中其他位之间至少经过两个 **clk\_usb** 周期。此举确保当控制器被触发启动传输时，寄存器内容保持稳定。

考虑一种情况，**clk\_sys** 运行于 125MHz，**clk\_usb** 运行于 48MHz。由于  $\lceil \frac{125}{48} \rceil \times 2 = 6$  应在写入之间插入 6 条 **nop** 指令，以确保至少经过两个 **clk\_usb** 周期。

#### 12.7.3.9.1. SETUP

主机发送的 **SETUP** 数据包始终来源于 DPSRAM 偏移地址 **0x0** 处专用的 8 字节空间。

与设备控制器类似，**setup** 数据包不对应任何控制寄存器。当写入 **START\_TRANS** 且设置了 **SEND\_SETUP** 位时，参数将被硬编码并加载至硬件。一旦设置包发送完毕，主机状态机将等待设备的 **ACK** 响应。若发生超时，将触发一个 **RX\_TIMEOUT** 错误。

若设置了 **SEND\_TRANS** 位，主机状态机将进入 **OUT** 阶段。通常，**SEND\_SETUP** 包与 **RECEIVE\_TRANS** 位共同使用，因此控制器在发送设置包后进入 **IN** 阶段。

#### 12.7.3.9.2. IN

当设置 **START\_TRANS** 且 **RECEIVE\_TRANS** 位时，将触发一次 **IN** 传输。如设置了 **SEND\_SETUP** 位，可能会先发送一个 **SETUP** 包。

**CONTROL** 阶段：

1. 读取位于 **0x80** 地址的 **EPx** 控制寄存器以获取以下端点信息：
  - 是否为双缓冲？
  - 启用了哪些中断？
  - 数据缓冲区的基址（双缓冲模式下为数据缓冲区）
  - 端点类型是什么？
2. 读取位于 **0x100** 的 **EPx** 缓冲区控制寄存器，以获取端点缓冲信息，如传输长度和数据 PID。
3. 设置 **AVAILABLE** 位（主机状态机将检查该位）。
4. 清除 **FULL** 位。

**TOKEN** 阶段：

1. 向设备发送 **IN** 令牌包。目标设备地址和端点信息来源于 **ADDR\_ENDP** 寄存器。

**DATA** 阶段：

1. 接收来自设备的第一个数据包。
2. 如果设备未响应，则触发 RX 超时错误。
3. 如果不是同步端点，且数据 PID 与缓冲区控制寄存器不匹配，则触发 **SIE\_STATUS.DATA\_SEQ\_ERROR**（同步数据始终使用 DATA0 pid 发送）。

**ACK** 阶段：

1. 向设备发送 **ACK**。

**STATUS** 阶段：

1. Set the **BUFF\_STATUS** bit and update the buffer control register.
2. Set **FULL**, **DATA\_PID**, **WR\_LEN**, and **LAST\_BUFF** if applicable.
3. If this is the last buffer in the transfer, set **TRANS\_COMPLETE**.

**CONTROL** phase (continued):

The host state machine performs **IN** transactions until **LAST\_BUFF** is seen in the **buffer\_control** register.

If the host is in double buffered mode, the host controller toggles between the **BUF0** and **BUF1** sections of the buffer control register.

Otherwise, the controller reads the buffer control register for buffer 0, then waits for **FULL** to be clear and **AVAILABLE** to be set before starting the next **IN** transaction, waiting in the **CONTROL** phase.

If the host receives a zero length packet, the device has no more data. The host state machine stops listening for more data regardless of if the **LAST\_BUFF** flag was set or not. To detect this from host software, check **BUFF\_DONE** for a data length of 0 in the buffer control register.

**12.7.3.9.3. OUT**

An **OUT** transfer is triggered with the **SEND\_TRANS** bit set when the **START\_TRANS** bit is set. This may be preceded by a **SETUP** packet if the **SEND\_SETUP** bit was set.

**CONTROL** phase:

1. Read the **EPx** control register to get endpoint information (same as [Section 12.7.3.9.2](#)).
2. Read the **EPx** buffer control register to get the transfer length and data PID. **AVAILABLE** and **FULL** must be set before the transfer can start.

**TOKEN** phase

1. Send an **OUT** packet to the device. The target device address and endpoint come from the **ADDR\_ENDP** register.

**DATA** phase:

1. Send the first data packet to the device. If the endpoint type is isochronous, there is no **ACK** phase, so the host controller goes straight to status phase. If **ACK** is received, go to status phase. Otherwise:
  - o If the host receives no reply, raise **SIE\_STATUS.RX\_TIMEOUT**.
  - o If the host receives **NAK**, raise **SIE\_STATUS.NAK\_REC** and send the data packet again.
  - o If the host receives **STALL**, raise **SIE\_STATUS.STALL\_REC** and go to idle.

**STATUS** phase:

1. Set the **BUFF\_STATUS** bit and update the buffer control register. **FULL** will be set to 0. **TRANS\_COMPLETE** will be set if this is the last buffer in the transfer.

**CONTROL** phase (continued):

1. If this isn't the last buffer in the transfer, wait for **FULL** and **AVAILABLE** to be set in the **EPx** buffer control register again.

**12.7.3.9.4. Interrupt endpoints**

The host controller can poll interrupt endpoints on a maximum of 15 endpoints. To enable interrupt endpoints, the programmer must:

- Pick the next free interrupt endpoint slot on the host controller (starting at 1, to a maximum of 15).
- Program the appropriate endpoint control register and buffer control register like you would with a normal **IN** or **OUT** transfer. Because interrupt endpoints are single-buffered, the **BUF1** part of the buffer control register is invalid.
- Set the address and endpoint of the device in the appropriate **ADDR\_ENDP** register (**ADDR\_ENDP1** to **ADDR\_ENDP15**).

1. 设置BUFF\_STATUS位，并更新缓冲区控制寄存器。
2. 如适用，设置 FULL、DATA\_PID、WR\_LEN和 LAST\_BUFF。
3. 若这是传输中的最后一个缓冲区，请设置TRANS\_COMPLETE。

**CONTROL** 阶段（续）：

主机状态机执行 IN 事务，直到在buffer\_control 寄存器中检测到 LAST\_BUFF 标志。

若主机处于双缓冲模式，主机控制器将在缓冲区控制寄存器的 BUF0 和 BUF1部分之间切换。

否则，控制器读取缓冲区0的缓冲区控制寄存器，然后等待 FULL 清除且 AVAILABLE被置位后，开始下一次 IN 事务，在 CONTROL 阶段等待。

若主机收到零长度数据包，表示设备无更多数据。无论 LAST\_BUFF 标志是否被设置，主机状态机会停止监听更多数据。若需从主机软件检测此情况，请检查缓冲区控制寄存器中 BUFF\_DONE 对应的数据长度是否为0。

#### 12.7.3.9.3. OUT

当 START\_TRANS 被设置时，SEND\_TRANS位触发一次OUT传输。若 SEND\_SETUP位被设置，则可能先发送一个 SETUP数据包。

**CONTROL** 阶段：

1. 读取 EPx 控制寄存器以获取端点信息（同第12.7.3.9.2节）。
2. 读取 EPx 缓冲区控制寄存器以获取传输长度和数据PID。AVAILABLE 和 FULL 必须在传输开始前设置。

**TOKEN** 阶段

1. 向设备发送 OUT 包。目标设备地址和端点信息来源于ADDR\_ENDP 寄存器。

**DATA** 阶段：

1. 向设备发送第一个数据包。如果端点类型为同步传输（isochronous），则无 ACK 阶段，主控器直接进入状态阶段。若收到 ACK，则进入状态阶段。否则：
  - 若主机未收到回复，触发 SIE\_STATUS.RX\_TIMEOUT。
  - 若主机收到 NAK，触发 SIE\_STATUS.NAK\_REC，并重新发送数据包。
  - 若主机收到 STALL，触发 SIE\_STATUS.STALL\_REC，并进入空闲状态。

**STATUS** 阶段：

1. 设置 BUFF\_STATUS 位并更新缓冲区控制寄存器。FULL 将被置为0。若这是传输中的最后一个缓冲区，则将设置TRANS\_COMPLETE 标志。

**CONTROL** 阶段（续）：

1. 如非传输中的最后缓冲区，请等待 FULL 和 AVAILABLE 标志在 EPx 缓冲区控制寄存器中再次被置位。

#### 12.7.3.9.4. 中断端点

主机控制器最多可轮询15个中断端点。启用中断端点，程序员必须：

- 在主机控制器上选择下一个空闲的中断端点槽（起始编号为1，最大可达15）。
- 如同处理普通的 IN 或 OUT 传输，设置相应的端点控制寄存器和缓冲区控制寄存器。由于中断端点为单缓冲，缓冲区控制寄存器中的BUF1位无效。
- 在对应的 ADDR\_ENDP 寄存器（ADDR\_ENDP1 至 ADDR\_ENDP15）中设置设备地址及端点号。

If the device is Low Speed but attached to a Full Speed hub, the preamble bit should be set. The endpoint `direction` bit should also be set.

- Set the corresponding interrupt endpoint active bit (one of bits 1 through 15) in `INT_EP_CTRL`.

Typically, interrupt endpoints use an `IN` transfer. The host might poll a USB hub to see if the state of any of its ports have changed. If there is no change, the hub replies with a `NAK` to the controller, and nothing happens. Similarly, a mouse replies with a `NAK` unless the mouse has been moved since the last time the interrupt endpoint was polled.

Interrupt endpoints are polled by the controller once a `SOF` packet has been sent by the host controller.

The controller loops from 1 to 15 and attempts to poll any interrupt endpoint with the `EP_ACTIVE` bit set to 1 in `INT_EP_CTRL`. The controller will then read the endpoint control register and the buffer control register to see if there is an available buffer (i.e. `FULL + AVAILABLE` if an `OUT` transfer and `NOT FULL + AVAILABLE` for an `IN` transfer). If not, the controller will move onto the next interrupt endpoint slot.

If there is an available buffer, the transfer is dealt with the same as a normal `IN` or `OUT` transfer and the `BUFF_DONE` flag in `BUFF_STATUS` will be set when the interrupt endpoint has a valid buffer.

### 12.7.3.10. VBUS control

The USB controller can be connected to GPIO pins (see [Chapter 9](#)) for the following VBUS controls:

- **VBUS enable**, used to enable VBUS in host mode. Set in `SIE_CTRL`.
- **VBUS detect**, used to detect that VBUS is present in device mode. Set via a bit in `SIE_STATUS`. Can also raise a `VBUS_DETECT` interrupt enabled in `INTE`.
- **VBUS overcurrent**, used to detect an overcurrent event. Applicable to both device and host. VBUS overcurrent is a bit in `SIE_STATUS`.

It is not necessary to connect up any of these pins to GPIO. The host can permanently supply VBUS and detect a device being connected when either the `DP` or `DM` pin is pulled high. VBUS detect can be forced in `USB_PWR`.

### 12.7.4. Programmer's model

#### 12.7.4.1. TinyUSB

The RP2350 TinyUSB port is the reference implementation for this USB controller. This port can be found in the following files of the [pico-sdk](#) GitHub repository:

```
dcd_rp2040.c
hcd_rp2040.c
rp2040_usb.h
```

#### 12.7.4.2. Standalone device example

A standalone USB device example, `dev_lowlevel`, makes it easier to understand how to interact with the USB controller without needing to understand the TinyUSB abstractions. In addition to endpoint 0, the standalone device has two bulk endpoints: `EP1 OUT` and `EP2 IN`. The device is designed to send whatever data it receives on `EP1` to `EP2`. The example comes with a small Python script that writes "Hello World" into `EP1` and checks that it is correctly received on `EP2`.

The code included in this section explains setting up the USB device controller to receive. It also shows how software responds to a setup packet received from the host.

如果设备为低速且连接至全速集线器，应设置前导码位，同时设置端点方向位。

- 在INT\_EP\_CTRL中设置相应中断端点的活动位（位1至位15之一）。

通常，中断端点使用 IN传输。主机可能轮询USB集线器，以检测其任一端口状态是否发生变化。若无变化，集线器向控制器返回 NAK，且不会执行任何操作。同样，除非自上次轮询该中断端点以来鼠标已移动，否则鼠标会回复 NAK。

主机控制器发送 SOF数据包后，控制器将对中断端点进行轮询。

控制器从1循环至15，尝试轮询INT\_EP\_CTRL中将 EP\_ACTIVE位设置为1的任何中断端点。随后，控制器读取端点控制寄存器与缓冲区控制寄存器，以确认是否存在可用缓冲区（即，对于OUT传输，缓冲区应为FULL且AVAILABLE；对于IN传输，应为NOT FULL且AVAILABLE）。若无，则控制器将切换至下一个中断端点槽。

如有可用缓冲区，传输将按常规 IN或 OUT传输处理，当中断端点拥有有效缓冲区时，BUFF\_STATUS中的 BUFF\_DONE标志将被置位。

### 12.7.3.10. VBUS 控制

USB 控制器可连接至 GPIO 引脚（详见第9章）以实现以下 VBUS 控制：

- **VBUS 使能**，用于主机模式下启用 VBUS。在 SIE\_CTRL 中设置。
- **VBUS 检测**，用于设备模式下检测 VBUS 是否存在。通过 SIE\_STATUS 中的某个位设置。亦可触发 INTE 中启用的 VBUS\_DETECT中断。
- **VBUS 过流**，用于检测过流事件。适用于设备模式和主机模式。VBUS 过流为 SIE\_STATUS 中的一个位。

无须将这些引脚连接至 GPIO。主机可持续供应 VBUS，且当 DP或 DM引脚被拉高时，能检测到设备连接。VBUS 检测可通过 USB\_PWR 强制执行。

### 12.7.4. 程序员模型

#### 12.7.4.1. TinyUSB

RP2350 TinyUSB 端口为该 USB 控制器的参考实现。该端口可在 [pico-sdk GitHub](#) 仓库的以下文件中找到：

```
dcd_rp2040.c
hcd_rp2040.c
rp2040_usb.h
```

#### 12.7.4.2. 独立设备示例

独立 USB 设备示例dev\_lowlevel便于理解如何与 USB 控制器交互，无需掌握 TinyUSB 的抽象层。除端点 0 外，该独立设备还有两个批量端点：EP1 OUT和EP2 IN。此设备设计为将其在 EP1接收的任何数据发送到 EP2。该示例附带一个小型 Python 脚本，向 EP1写入“Hello World”，并验证其是否正确接收至 EP2。

本节中包含的代码解释了如何设置USB设备控制器以实现接收功能。同时展示了软件如何响应从主机接收到的设置包。

Figure 125. USB analyser trace of the dev\_lowlevel USB device example. The control transfers are the device enumeration. The first bulk OUT (out from the host) transfer, highlighted in blue, is the host sending "Hello World" to the device. The second bulk transfer IN (in to the host), is the device returning "Hello World" to the host.

#### 12.7.4.2.1. Device controller initialisation

The following code initialises the USB device:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) Lines 183 - 217

```

183 void usb_device_init() {
184 // Reset usb controller
185 reset_unreset_block_num_wait_blocking(RESET_USBCTRL);
186
187 // Clear any previous state in dpram just in case
188 memset(usb_dpram, 0, sizeof(*usb_dpram)); ①
189
190 // Enable USB interrupt at processor
191 irq_set_enabled(USBCTRL_IRQ, true);
192
193 // Mux the controller to the onboard usb phy
194 usb_hw->muxing = USB_USB_MUXING_TO_PHY_BITS | USB_USB_MUXING_SOFTCON_BITS;
195
196 // Force VBUS detect so the device thinks it is plugged into a host
197 usb_hw->pwr = USB_USB_PWR_VBUS_DETECT_BITS | USB_USB_PWR_VBUS_DETECT_OVERRIDE_EN_BITS;
198
199 // Enable the USB controller in device mode.
200 usb_hw->main_ctrl = USB_MAIN_CTRL_CONTROLLER_EN_BITS;
201
202 // Enable an interrupt per EP0 transaction
203 usb_hw->sie_ctrl = USB_SIE_CTRL_EP0_INT_1BUF_BITS; ②
204
205 // Enable interrupts for when a buffer is done, when the bus is reset,
206 // and when a setup packet is received
207 usb_hw->inte = USB_INTS_BUFF_STATUS_BITS |
208 USB_INTS_BUS_RESET_BITS |
209 USB_INTS_SETUP_REQ_BITS;
210
211 // Set up endpoints (endpoint control registers)
212 // described by device configuration
213 usb_setup_endpoints();
214
215 // Present full speed device by enabling pull up on DP

```

图125。 dev\_lowlevel USB设备示例的USB分析仪跟踪。控制传输即设备枚举过程。第一个批量OUT（主机输出）传输，用蓝色标记，表示主机向设备发送“Hello World”。第二个批量/N（主机输入）传输，表示设备向主机返回“Hello World”。

#### 12.7.4.2.1. 设备控制器初始化

以下代码用于初始化USB设备：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) 第183至217行

```

183 void usb_device_init() {
184 // 重置USB控制器
185 reset_unreset_block_num_wait_blocking(RESET_USBCTRL);
186
187 // 清除dpram中任何先前状态以防意外
188 memset(usb_dpram, 0, sizeof(*usb_dpram)); ①
189
190 // 在处理器上启用 USB 中断
191 irq_set_enabled(USBCTRL_IRQ, true);
192
193 // 将控制器复用至板载 USB 物理层
194 usb_hw->muxing = USB_USB_MUXING_TO_PHY_BITS | USB_USB_MUXING_SOFTCON_BITS;
195
196 // 强制VBUS 检测，使设备误认为已连接至主机
197 usb_hw->pwr = USB_USB_PWR_VBUS_DETECT_BITS | USB_USB_PWR_VBUS_DETECT_OVERRIDE_EN_BITS;
198
199 // 以设备模式启用 USB 控制器
200 usb_hw->main_ctrl = USB_MAIN_CTRL_CONTROLLER_EN_BITS;
201
202 // 为每次 EP0 事务启用中断
203 usb_hw->sie_ctrl = USB_SIE_CTRL_EP0_INT_1BUF_BITS; ②
204
205 // 启用中断，适用于缓冲区完成、总线重置以及接收设置包时
206 //
207 usb_hw->inte = USB_INTS_BUFF_STATUS_BITS |
208 USB_INTS_BUS_RESET_BITS |
209 USB_INTS_SETUP_REQ_BITS;
210
211 // 配置端点（端点控制寄存器）
212 // 由设备配置描述
213 usb_setup_endpoints();
214
215 // 通过在DP线上使能上拉电阻展示全速设备

```

```
216 usb_hw_set->sie_ctrl = USB_SIE_CTRL_PULLUP_EN_BITS;
217 }
```

#### 12.7.4.2.2. Configuring the endpoint control registers for EP1 and EP2

The function `usb_configure_endpoints` loops through each endpoint defined in the device configuration (including EP0 in and EP0 out, which don't have an endpoint control register defined) and calls the `usb_configure_endpoint` function. This sets up the endpoint control register for that endpoint:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) Lines 149 - 164

```
149 void usb_setup_endpoint(const struct usb_endpoint_configuration *ep) {
150 printf("Set up endpoint 0x%x with buffer address 0x%p\n", ep->descriptor-
>bEndpointAddress, ep->data_buffer);
151
152 // EP0 doesn't have one so return if that is the case
153 if (!ep->endpoint_control) {
154 return;
155 }
156
157 // Get the data buffer as an offset of the USB controller's DPRAM
158 uint32_t dpram_offset = usb_buffer_offset(ep->data_buffer);
159 uint32_t reg = EP_CTRL_ENABLE_BITS
160 | EP_CTRL_INTERRUPT_PER_BUFFER
161 | (ep->descriptor->bmAttributes << EP_CTRL_BUFFER_TYPE_LSB)
162 | dpram_offset;
163 *ep->endpoint_control = reg;
164 }
```

#### 12.7.4.2.3. Receiving a setup packet

An interrupt is raised when a setup packet is received, so the interrupt handler must handle this event:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) Lines 494 - 504

```
494 void isr_usbcctrl(void) {
495 // USB interrupt handler
496 uint32_t status = usb_hw->ints;
497 uint32_t handled = 0;
498
499 // Setup packet received
500 if (status & USB_INTS_SETUP_REQ_BITS) {
501 handled |= USB_INTS_SETUP_REQ_BITS;
502 usb_hw_clear->sie_status = USB_SIE_STATUS_SETUP_REC_BITS;
503 usb_handle_setup_packet();
504 }
}
```

The controller writes the `SETUP` packet to the first 8 bytes of the DPSRAM, so the setup packet handler casts that area of memory to `struct usb_setup_packet *`:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) Lines 383 - 427

```
383 void usb_handle_setup_packet(void) {
384 volatile struct usb_setup_packet *pkt = (volatile struct usb_setup_packet *) &usb_dpram
->setup_packet;
385 uint8_t req_direction = pkt->bmRequestType;
```

```
216 usb_hw_set->sie_ctrl = USB_SIE_CTRL_PULLUP_EN_BITS;
217 }
```

#### 12.7.4.2.2. 配置 EP1和 EP2的端点控制寄存器

函数`usb_configure_endpoints`遍历设备配置中定义的所有端点（包括没有端点控制寄存器的 EP0输入和 EP0输出）并调用`usb_configure_endpoint`函数。该操作用于配置该端点的端点控制寄存器：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) 第149-164行

```
149 void usb_setup_endpoint(const struct usb_endpoint_configuration *ep) {
150 printf("设置端点 0x%x, 缓冲区地址 0x%p\n", ep->descriptor->bEndpointAddress, ep->data_buffer); 151
152
153 // EP0 无缓冲区, 若如此则返回
154 if (!ep->endpoint_control) {
155 return;
156 }
157
158 // 获取数据缓冲区在 USB 控制器 DPRAM 中的偏移量
159 uint32_t dpram_offset = usb_buffer_offset(ep->data_buffer);
160 uint32_t reg = EP_CTRL_ENABLE_BITS
161 | EP_CTRL_INTERRUPT_PER_BUFFER
162 | (ep->descriptor->bmAttributes << EP_CTRL_BUFFER_TYPE_LSB)
163 | dpram_offset;
164 *ep->endpoint_control = reg;
165 }
```

#### 12.7.4.2.3. 接收设置包

当接收到设置包时，会触发中断，故中断处理程序必须对此事件进行处理：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) 第494至504行

```
494 void isr_usbcctrl(void) {
495 // USB中断处理函数
496 uint32_t status = usb_hw->ints;
497 uint32_t handled = 0;
498
499 // 已接收设置包
500 if (status & USB_INTS_SETUP_REQ_BITS) {
501 handled |= USB_INTS_SETUP_REQ_BITS;
502 usb_hw_clear->sie_status = USB_SIE_STATUS_SETUP_REC_BITS;
503 usb_handle_setup_packet();
504 }
505 }
```

控制器将`SETUP`包写入DPSRAM的前8字节，因此设置包处理程序将该内存区域转换为`struct usb_setup_packet *`类型：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) 第383至427行

```
383 void usb_handle_setup_packet(void) {
384 volatile struct usb_setup_packet *pkt = (volatile struct usb_setup_packet *) &usb_dpram
385 ->setup_packet;
386 uint8_t req_direction = pkt->bmRequestType;
```

```

386 uint8_t req = pkt->bRequest;
387
388 // Reset PID to 1 for EP0 IN
389 usb_get_endpoint_configuration(EP0_IN_ADDR)->next_pid = 1u;
390
391 if (req_direction == USB_DIR_OUT) {
392 if (req == USB_REQUEST_SET_ADDRESS) {
393 usb_set_device_address(pkt);
394 } else if (req == USB_REQUEST_SET_CONFIGURATION) {
395 usb_set_device_configuration(pkt);
396 } else {
397 usb_acknowledge_out_request();
398 printf("Other OUT request (0x%x)\r\n", pkt->bRequest);
399 }
400 } else if (req_direction == USB_DIR_IN) {
401 if (req == USB_REQUEST_GET_DESCRIPTOR) {
402 uint16_t descriptor_type = pkt->wValue >> 8;
403
404 switch (descriptor_type) {
405 case USB_DT_DEVICE:
406 usb_handle_device_descriptor(pkt);
407 printf("GET DEVICE DESCRIPTOR\r\n");
408 break;
409
410 case USB_DT_CONFIG:
411 usb_handle_config_descriptor(pkt);
412 printf("GET CONFIG DESCRIPTOR\r\n");
413 break;
414
415 case USB_DT_STRING:
416 usb_handle_string_descriptor(pkt);
417 printf("GET STRING DESCRIPTOR\r\n");
418 break;
419
420 default:
421 printf("Unhandled GET_DESCRIPTOR type 0x%x\r\n", descriptor_type);
422 }
423 } else {
424 printf("Other IN request (0x%x)\r\n", pkt->bRequest);
425 }
426 }
427 }
```

#### 12.7.4.2.4. Replying to a setup packet on EP0 IN

The host first requests the device descriptor. The following code handles that setup request:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) Lines 266 - 273

```

266 void usb_handle_device_descriptor(volatile struct usb_setup_packet *pkt) {
267 const struct usb_device_descriptor *d = dev_config.device_descriptor;
268 // EP0 in
269 struct usb_endpoint_configuration *ep = usb_get_endpoint_configuration(EP0_IN_ADDR);
270 // Always respond with pid 1
271 ep->next_pid = 1;
272 usb_start_transfer(ep, (uint8_t *) d, MIN(sizeof(struct usb_device_descriptor), pkt-
273 >wLength));
273 }
```

The `usb_start_transfer` function copies data to be sent into the appropriate hardware buffer and configures the buffer

```

386 uint8_t req = pkt->bRequest;
387
388 // 将EP0 IN的PID重置为1
389 usb_get_endpoint_configuration(EP0_IN_ADDR)->next_pid = 1u;
390
391 if (req_direction == USB_DIR_OUT) {
392 if (req == USB_REQUEST_SET_ADDRESS) {
393 usb_set_device_address(pkt);
394 } else if (req == USB_REQUEST_SET_CONFIGURATION) {
395 usb_set_device_configuration(pkt);
396 } else {
397 usb_acknowledge_out_request();
398 printf("其他 OUT 请求 (0x%x)\r\n", pkt->bRequest);
399 }
400 } else if (req_direction == USB_DIR_IN) {
401 if (req == USB_REQUEST_GET_DESCRIPTOR) {
402 uint16_t descriptor_type = pkt->wValue >> 8;
403
404 switch (descriptor_type) {
405 case USB_DT_DEVICE:
406 usb_handle_device_descriptor(pkt);
407 printf("获取设备描述符\r\n");
408 break;
409
410 case USB_DT_CONFIG:
411 usb_handle_config_descriptor(pkt);
412 printf("获取配置描述符\r\n");
413 break;
414
415 case USB_DT_STRING:
416 usb_handle_string_descriptor(pkt);
417 printf("获取字符串描述符\r\n");
418 break;
419
420 default:
421 printf("未处理的 GET_DESCRIPTOR 类型 0x%x\r\n", descriptor_type);
422 }
423 } else {
424 printf("其他 IN 请求 (0x%x)\r\n", pkt->bRequest);
425 }
426 }
427 }

```

#### 12.7.4.2.4. 回复 EP0 IN端点上的设置包

主机首先请求设备描述符。以下代码处理该设置请求：

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c), 第266至273行

```

266 void usb_handle_device_descriptor(volatile struct usb_setup_packet *pkt) {
267 const struct usb_device_descriptor *d = dev_config.device_descriptor;
268 // EP0 IN端点
269 struct usb_endpoint_configuration *ep = usb_get_endpoint_configuration(EP0_IN_ADDR);
270 // 始终响应pid为1
271 ep->next_pid = 1;
272 usb_start_transfer(ep, (uint8_t *) d, MIN(sizeof(struct usb_device_descriptor), pkt-
273 >wLength));
273 }

```

usb\_start\_transfer函数将待发送数据复制至相应硬件缓冲区，并对缓冲区进行配置。

control register. Once the buffer control register has been written to, the device controller responds to the host with the data. Before this point, the device replies with a **NAK**:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) Lines 238 - 260

```

238 void usb_start_transfer(struct usb_endpoint_configuration *ep, uint8_t *buf, uint16_t len) {
239 // We are asserting that the length is <= 64 bytes for simplicity of the example.
240 // For multi packet transfers see the tinyusb port.
241 assert(len <= 64);
242
243 printf("Start transfer of len %d on ep addr 0x%x\n", len, ep->descriptor-
>bEndpointAddress);
244
245 // Prepare buffer control register value
246 uint32_t val = len | USB_BUF_CTRL_AVAIL;
247
248 if (ep_is_tx(ep)) {
249 // Need to copy the data from the user buffer to the usb memory
250 memcpy((void *) ep->data_buffer, (void *) buf, len);
251 // Mark as full
252 val |= USB_BUF_CTRL_FULL;
253 }
254
255 // Set pid and flip for next transfer
256 val |= ep->next_pid ? USB_BUF_CTRL_DATA1_PID : USB_BUF_CTRL_DATA0_PID;
257 ep->next_pid ^= 1u;
258
259 *ep->buffer_control = val;
260 }
```

## 12.7.5. List of registers

The USB registers start at a base address of **0x50110000** (defined as **USBCTRL\_REGS\_BASE** in SDK).

Table 1195. List of USB registers

Offset	Name	Info
0x000	ADDR_ENDP	Device address and endpoint control
0x004	ADDR_ENDP1	Interrupt endpoint 1. Only valid for HOST mode.
0x008	ADDR_ENDP2	Interrupt endpoint 2. Only valid for HOST mode.
0x00c	ADDR_ENDP3	Interrupt endpoint 3. Only valid for HOST mode.
0x010	ADDR_ENDP4	Interrupt endpoint 4. Only valid for HOST mode.
0x014	ADDR_ENDP5	Interrupt endpoint 5. Only valid for HOST mode.
0x018	ADDR_ENDP6	Interrupt endpoint 6. Only valid for HOST mode.
0x01c	ADDR_ENDP7	Interrupt endpoint 7. Only valid for HOST mode.
0x020	ADDR_ENDP8	Interrupt endpoint 8. Only valid for HOST mode.
0x024	ADDR_ENDP9	Interrupt endpoint 9. Only valid for HOST mode.
0x028	ADDR_ENDP10	Interrupt endpoint 10. Only valid for HOST mode.
0x02c	ADDR_ENDP11	Interrupt endpoint 11. Only valid for HOST mode.
0x030	ADDR_ENDP12	Interrupt endpoint 12. Only valid for HOST mode.
0x034	ADDR_ENDP13	Interrupt endpoint 13. Only valid for HOST mode.

控制寄存器。缓冲区控制寄存器一旦被写入，设备控制器即向主机响应数据。在此之前，设备将回复 NAK：

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev\\_lowlevel/dev\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/usb/device/dev_lowlevel/dev_lowlevel.c) 第238至260行

```

238 void usb_start_transfer(struct usb_endpoint_configuration *ep, uint8_t *buf, uint16_t len) {
239 // 为简化示例，断言长度不超过64字节。
240 // 多包传输请参见 tinyusb 移植层。
241 assert(len <= 64);
242
243 printf("开始传输，长度为 %d，端点地址为 0x%x\n", len, ep->descriptor->bEndpointAddress); 244
244
245 // 准备缓冲区控制寄存器的值
246 uint32_t val = len | USB_BUF_CTRL_AVAIL;
247
248 if (ep_is_tx(ep)) {
249 // 需要将数据从用户缓冲区复制到USB存储器
250 memcpy((void *) ep->data_buffer, (void *) buf, len);
251 // 标记为已满
252 val |= USB_BUF_CTRL_FULL;
253 }
254
255 // 设置pid并切换以用于下一次传输
256 val |= ep->next_pid ? USB_BUF_CTRL_DATA1_PID : USB_BUF_CTRL_DATA0_PID;
257 ep->next_pid ^= 1u;
258
259 *ep->buffer_control = val;
260 }
```

## 12.7.5. 寄存器列表

USB寄存器起始地址为 **0x50110000**（在SDK中定义为USBCTRL\_REGS\_BASE）。

表1195。  
USB寄存器列表

偏移量	名称	说明
0x000	ADDR_ENDP	设备地址及端点控制
0x004	ADDR_ENDP1	中断端点1。仅适用于主机模式。
0x008	ADDR_ENDP2	中断端点2。仅适用于主机模式。
0x00c	ADDR_ENDP3	中断端点3。仅适用于主机模式。
0x010	ADDR_ENDP4	中断端点4。仅适用于主机模式。
0x014	ADDR_ENDP5	中断端点5。仅适用于主机模式。
0x018	ADDR_ENDP6	中断端点6。仅适用于主机模式。
0x01c	ADDR_ENDP7	中断端点7。仅适用于主机模式。
0x020	ADDR_ENDP8	中断端点8。仅适用于主机模式。
0x024	ADDR_ENDP9	中断端点9。仅适用于主机模式。
0x028	ADDR_ENDP10	中断端点10。仅适用于主机模式。
0x02c	ADDR_ENDP11	中断端点11。仅适用于主机模式。
0x030	ADDR_ENDP12	中断端点12。仅适用于主机模式。
0x034	ADDR_ENDP13	中断端点13。仅适用于主机模式。

Offset	Name	Info
0x038	ADDR_ENDP14	Interrupt endpoint 14. Only valid for HOST mode.
0x03c	ADDR_ENDP15	Interrupt endpoint 15. Only valid for HOST mode.
0x040	MAIN_CTRL	Main control register
0x044	SOF_WR	Set the SOF (Start of Frame) frame number in the host controller. The SOF packet is sent every 1ms and the host will increment the frame number by 1 each time.
0x048	SOF_RD	Read the last SOF (Start of Frame) frame number seen. In device mode the last SOF received from the host. In host mode the last SOF sent by the host.
0x04c	SIE_CTRL	SIE control register
0x050	SIE_STATUS	SIE status register
0x054	INT_EP_CTRL	interrupt endpoint control register
0x058	BUFF_STATUS	Buffer status register. A bit set here indicates that a buffer has completed on the endpoint (if the buffer interrupt is enabled). It is possible for 2 buffers to be completed, so clearing the buffer status bit may instantly re set it on the next clock cycle.
0x05c	BUFF_CPU_SHOULD_HANDLE	Which of the double buffers should be handled. Only valid if using an interrupt per buffer (i.e. not per 2 buffers). Not valid for host interrupt endpoint polling because they are only single buffered.
0x060	EP_ABORT	Device only: Can be set to ignore the buffer control register for this endpoint in case you would like to revoke a buffer. A NAK will be sent for every access to the endpoint until this bit is cleared. A corresponding bit in EP_ABORT_DONE is set when it is safe to modify the buffer control register.
0x064	EP_ABORT_DONE	Device only: Used in conjunction with EP_ABORT. Set once an endpoint is idle so the programmer knows it is safe to modify the buffer control register.
0x068	EP_STALL_ARM	Device: this bit must be set in conjunction with the STALL bit in the buffer control register to send a STALL on EP0. The device controller clears these bits when a SETUP packet is received because the USB spec requires that a STALL condition is cleared when a SETUP packet is received.
0x06c	NAK_POLL	Used by the host controller. Sets the wait time in microseconds before trying again if the device replies with a NAK.
0x070	EP_STATUS_STALL_NAK	Device: bits are set when the IRQ_ON_NAK or IRQ_ON_STALL bits are set. For EP0 this comes from SIE_CTRL. For all other endpoints it comes from the endpoint control register.
0x074	USB_MUXING	Where to connect the USB controller. Should be to_phy by default.
0x078	USB_PWR	Overrides for the power signals in the event that the VBUS signals are not hooked up to GPIO. Set the value of the override and then the override enable to switch over to the override value.

偏移量	名称	说明
0x038	ADDR_ENDP14	中断端点14。仅适用于主机模式。
0x03c	ADDR_ENDP15	中断端点15。仅适用于主机模式。
0x040	MAIN_CTRL	主控寄存器
0x044	SOF_WR	设置主机控制器中的SOF（帧开始）帧编号。 SOF包每1毫秒发送一次，主机会每次将帧编号递增1。
0x048	SOF_RD	读取最近一次检测到的SOF（帧开始）帧编号。设备模式下，接收到的主机最后一个SOF帧编号。主机模式下，主机发送的最后一个SOF帧编号。
0x04c	SIE_CTRL	SIE控制寄存器
0x050	SIE_STATUS	SIE状态寄存器
0x054	INT_EP_CTRL	中断端点控制寄存器
0x058	BUFF_STATUS	缓冲区状态寄存器。此位被设置表示该端点的缓冲区已完成（前提是已启用缓冲区中断）。可能会同时完成两个缓冲区，因此清除缓冲区状态位后，该位可能在下一个时钟周期立即重新被置位。
0x05c	BUFF_CPU_SHOULD_HANDLE	应处理哪一个双缓冲区。仅在每个缓冲区产生中断时有效（即非每两个缓冲区产生一次中断）。对主机中断端点轮询无效，因为它们仅为单缓冲。
0x060	EP_ABORT	仅设备端：可设置为忽略该端点的缓冲区控制寄存器，以便撤销缓冲区。在此位被清除之前，每次访问该端点均会发送NAK。当可安全修改缓冲区控制寄存器时，EP_ABORT_DONE寄存器中的相应位将被置位。
0x064	EP_ABORT_DONE	仅设备端：与EP_ABORT配合使用。端点空闲时设置，以告知程序员可安全修改缓冲区控制寄存器。
0x068	EP_STALL_ARM	设备：此位必须与缓冲区控制寄存器中的STALL位同时设置，以便在EP0上发送STALL信号。设备控制器在接收到SETUP包时会清除这些位，因为USB规范要求接收到SETUP包时必须清除STALL状态。
0x06c	NAK_POLL	由主机控制器使用。设置设备回复NAK时重试前的等待时间，单位为微秒。
0x070	EP_STATUS_STALL_NAK	设备：当IRQ_ON_NAK或IRQ_ON_STALL位被设置时，该位也被置位。对于EP0，该信号源自SIE_CTRL。对于所有其他端点，该信号来源于端点控制寄存器。
0x074	USB_MUXING	USB控制器的连接位置。默认应为to_phy。
0x078	USB_PWR	当VBUS信号未接入GPIO时，对电源信号进行覆盖。先设置覆盖值，再启用覆盖，切换至覆盖值。

Offset	Name	Info
0x07c	USBPHY_DIRECT	This register allows for direct control of the USB phy. Use in conjunction with usbphy_direct_override register to enable each override bit.
0x080	USBPHY_DIRECT_OVERRIDE	Override enable for each control in usbphy_direct
0x084	USBPHY_TRIM	Used to adjust trim values of USB phy pull down resistors.
0x088	LINESTATE_TUNING	Used for debug only.
0x08c	INTR	Raw Interrupts
0x090	INTE	Interrupt Enable
0x094	INTF	Interrupt Force
0x098	INTS	Interrupt status after masking & forcing
0x100	SOF_TIMESTAMP_RAW	Device only. Raw value of free-running PHY clock counter @48MHz. Used to calculate time between SOF events.
0x104	SOF_TIMESTAMP_LAST	Device only. Value of free-running PHY clock counter @48MHz when last SOF event occurred.
0x108	SM_STATE	
0x10c	EP_TX_ERROR	TX error count for each endpoint. Write to each field to reset the counter to 0.
0x110	EP_RX_ERROR	RX error count for each endpoint. Write to each field to reset the counter to 0.
0x114	DEV_SM_WATCHDOG	Watchdog that forces the device state machine to idle and raises an interrupt if the device stays in a state that isn't idle for the configured limit. The counter is reset on every state transition. Set limit while enable is low and then set the enable.

## USB: ADDR\_ENDP Register

Offset: 0x000

### Description

Device address and endpoint control

Table 1196.  
ADDR\_ENDP Register

Bits	Description	Type	Reset
31:20	Reserved.	-	-
19:16	<b>ENDPOINT:</b> Device endpoint to send data to. Only valid for HOST mode.	RW	0x0
15:7	Reserved.	-	-
6:0	<b>ADDRESS:</b> In device mode, the address that the device should respond to. Set in response to a SET_ADDR setup packet from the host. In host mode set to the address of the device to communicate with.	RW	0x00

## USB: ADDR\_ENDP1, ADDR\_ENDP2, ..., ADDR\_ENDP14, ADDR\_ENDP15 Registers

Offsets: 0x004, 0x008, ..., 0x038, 0x03c

### Description

Interrupt endpoint N. Only valid for HOST mode.

偏移量	名称	说明
0x07c	<a href="#">USBPHY_DIRECT</a>	此寄存器允许对USB物理层直接控制。需与usbphy_direct_override寄存器配合使用以启用相应覆盖位。
0x080	<a href="#">USBPHY_DIRECT_OVERRIDE</a>	usbphy_direct 中各控制项的覆盖使能
0x084	<a href="#">USBPHY_TRIM</a>	用于调整 USB 物理层下拉电阻的微调值。
0x088	<a href="#">LINESTATE_TUNING</a>	仅供调试使用。
0x08c	<a href="#">中断</a>	原始中断
0x090	<a href="#">INTE</a>	中断使能
0x094	<a href="#">INTF</a>	中断触发
0x098	<a href="#">INTS</a>	掩码与强制后的中断状态
0x100	<a href="#">SOF_TIMESTAMP_RAW</a>	仅限设备模式。48MHz 下自由运行物理层时钟计数器的原始值。用于计算 SOF 事件间时间。
0x104	<a href="#">SOF_TIMESTAMP_LAST</a>	仅限设备模式。上次 SOF 事件发生时 48MHz 自由运行物理层时钟计数器的值。
0x108	<a href="#">SM_STATE</a>	
0x10c	<a href="#">EP_TX_ERROR</a>	每端点的发送错误计数。向各字段写入以将计数器清零。
0x110	<a href="#">EP_RX_ERROR</a>	每端点的接收错误计数。向各字段写入以将计数器清零。
0x114	<a href="#">DEV_SM_WATCHDOG</a>	看门狗：若设备长时间处于非空闲状态，强制状态机置于空闲并触发中断。计数器在每次状态转换时复位。  先在 enable 低电平时设置限制值，再设使能。

## USB: SIE\_STATUS寄存器

偏移量: 0x050

### 描述

SIE状态寄存器

表1202。  
SIE\_STATUS寄存器

位	描述	类型	复位
31	<b>DATA_SEQ_ERROR</b> : 数据序列错误。  设备在以下情况下可能触发序列错误：  * 收到SETUP包后紧跟DATA1包 (数据阶段应始终为DATA0) * 主机收到的OUT包数据PID与从DPSRAM读取的缓冲区控制寄存器中的数据PID不匹配  主机在以下情况下可能触发数据序列错误：  * 设备发送的IN包数据PID错误	WC	0x0
30	<b>ACK_REC</b> : 已接收ACK。由主机和设备共同引发。	WC	0x0
29	<b>STALL_REC</b> : 主机: 接收到STALL信号	WC	0x0
28	<b>NAK_REC</b> : 主机: 接收到NAK信号	WC	0x0
27	<b>RX_TIMEOUT</b> : 若在USB规范规定的最大时间内未收到ACK，则主机和设备均会引发接收超时 (RX timeout)。	WC	0x0
26	<b>RX_OVERFLOW</b> : 若串行接收引擎接收数据过快，则会引发接收溢出。	WC	0x0
25	<b>BIT_STUFF_ERROR</b> : 位填充错误。由串行接收引擎检测并引发。	WC	0x0
24	<b>CRC_ERROR</b> : CRC错误。由串行接收引擎检测并引发。	WC	0x0
23	<b>ENDPOINT_ERROR</b> : 端点发生错误。请读取ep_rx_error和ep_tx_error寄存器以确定具体的错误端点。	WC	0x0
22:20	保留。	-	-
19	<b>BUS_RESET</b> : 设备: 接收到总线复位信号	WC	0x0

Bits	Description	Type	Reset
18	<b>TRANS_COMPLETE:</b> Transaction complete.  Raised by device if:  * An IN or OUT packet is sent with the <b>LAST_BUFF</b> bit set in the buffer control register  Raised by host if:  * A setup packet is sent when no data in or data out transaction follows * An IN packet is received and the <b>LAST_BUFF</b> bit is set in the buffer control register * An IN packet is received with zero length * An OUT packet is sent and the <b>LAST_BUFF</b> bit is set	WC	0x0
17	<b>SETUP_REC:</b> Device: Setup packet received	WC	0x0
16	<b>CONNECTED:</b> Device: connected	RO	0x0
15:13	Reserved.	-	-
12	<b>RX_SHORT_PACKET:</b> Device or Host has received a short packet. This is when the data received is less than configured in the buffer control register. Device: If using double buffered mode on device the buffer select will not be toggled after writing status back to the buffer control register. This is to prevent any further transactions on that endpoint until the user has reset the buffer control registers. Host: the current transfer will be stopped early.	WC	0x0
11	<b>RESUME:</b> Host: Device has initiated a remote resume. Device: host has initiated a resume.	WC	0x0
10	<b>VBUS_OVER_CURR:</b> VBUS over current detected	RO	0x0
9:8	<b>SPEED:</b> Host: device speed. Disconnected = 00, LS = 01, FS = 10	RO	0x0
7:5	Reserved.	-	-
4	<b>SUSPENDED:</b> Bus in suspended state. Valid for device and host. Host and device will go into suspend if neither Keep Alive / SOF frames are enabled.	RO	0x0
3:2	<b>LINE_STATE:</b> USB bus line state	RO	0x0
1	Reserved.	-	-
0	<b>VBUS_DETECTED:</b> Device: VBUS Detected	RO	0x0

## USB: NAK\_POLL Register

Offset: 0x06c

### Description

Used by the host controller. Sets the wait time in microseconds before trying again if the device replies with a NAK.

Table 1209.  
NAK\_POLL Register

Bits	Description	Type	Reset
31:28	<b>RETRY_COUNT_HI</b> : Bits 9:6 of nak_retry count	RO	0x0
27	<b>EPX_STOPPED_ON_NAK</b> : EPX polling has stopped because a nak was received	WC	0x0
26	<b>STOP_EPX_ON_NAK</b> : Stop polling epx when a nak is received	RW	0x0
25:16	<b>DELAY_FS</b> : NAK polling interval for a full speed device	RW	0x010
15:10	<b>RETRY_COUNT_LO</b> : Bits 5:0 of nak_retry_count	RO	0x00
9:0	<b>DELAY_LS</b> : NAK polling interval for a low speed device	RW	0x010

## USB: EP\_STATUS\_STALL\_NAK Register

Offset: 0x070

### Description

Device: bits are set when the **IRQ\_ON\_NAK** or **IRQ\_ON\_STALL** bits are set. For EP0 this comes from **SIE\_CTRL**. For all other endpoints it comes from the endpoint control register.

Table 1210.  
EP\_STATUS\_STALL\_N  
AK Register

Bits	Description	Type	Reset
31	<b>EP15_OUT</b>	WC	0x0
30	<b>EP15_IN</b>	WC	0x0

位	描述	类型	复位
5	<b>EP2_OUT</b>	WC	0x0
4	<b>EP2_IN</b>	WC	0x0
3	<b>EP1_OUT</b>	WC	0x0
2	<b>EP1_IN</b>	WC	0x0
1	<b>EP0_OUT</b>	WC	0x0
0	<b>EP0_IN</b>	WC	0x0

## USB: EP\_STALL\_ARM 寄存器

偏移: 0x068

### 描述

设备：此位必须与缓冲区控制寄存器中的 **STALL** 位同时设置，方可向 EP0 上发送 STALL。

设备控制器在收到 SETUP 包时会清除这些位，因 USB 规范要求收到 SETUP 包时必须清除 STALL 状态。

表1208。  
EP\_STALL\_ARM 寄存器

位	描述	类型	复位
31:2	保留。	-	-
1	<b>EP0_OUT</b>	读写	0x0
0	<b>EP0_IN</b>	读写	0x0

## USB: NAK\_POLL 寄存器

偏移: 0x06C

### 描述

由主机控制器使用。设置设备回复 NAK 时重试前的等待时间，单位为微秒。

表1209。  
NAK\_POLL 寄存器

位	描述	类型	复位
31:28	<b>RETRY_COUNT_HI</b> : nak_retry 计数的第9至第6位	只读	0x0
27	<b>EPX_STOPPED_ON_NAK</b> : EPX 因接收到 nak 而停止轮询	WC	0x0
26	<b>STOP_EPX_ON_NAK</b> : 收到 NAK 时停止轮询 epx	读写	0x0
25:16	<b>DELAY_FS</b> : 全速设备的 NAK 轮询间隔	读写	0x010
15:10	<b>RETRY_COUNT_LO</b> : nak_retry_count 的第5至0位	只读	0x00
9:0	<b>DELAY_LS</b> : 低速设备的 NAK 轮询间隔	读写	0x010

## USB: EP\_STATUS\_STALL\_NAK 寄存器

偏移: 0x070

### 描述

设备：当 **IRQ\_ON\_NAK** 或 **IRQ\_ON\_STALL** 位被设置时，该位也被置位。对于 EP0，该信号源自 **SIE\_CTRL**。对于所有其他端点，该信号来源于端点控制寄存器。

表1210。

## USB: USB\_MUXING寄存器

偏移: 0x074

### 描述

USB控制器的连接位置。默认应设置为to\_phy。

Table 1211.  
USB\_MUXING Register

Bits	Description	Type	Reset
31	<b>SWAP_DPDM:</b> Swap the USB PHY DP and DM pins and all related controls and flip receive differential data. Can be used to switch USB DP/DP on the PCB. This is done at a low level so overrides all other controls.	RW	0x0
30:5	Reserved.	-	-
4	<b>USBPHY_AS_GPIO:</b> Use the usb DP and DM pins as GPIO pins instead of connecting them to the USB controller.	RW	0x0
3	<b>SOFTCON</b>	RW	0x0
2	<b>TO_DIGITAL_PAD</b>	RW	0x0
1	<b>TO_EXTPHY</b>	RW	0x0
0	<b>TO_PHY</b>	RW	0x1

## USB: USB\_PWR Register

Offset: 0x078

### Description

Overrides for the power signals in the event that the VBUS signals are not hooked up to GPIO. Set the value of the override and then the override enable to switch over to the override value.

Table 1212. USB\_PWR Register

Bits	Description	Type	Reset
31:6	Reserved.	-	-
5	<b>OVERRCURR_DETECT_EN</b>	RW	0x0
4	<b>OVERRCURR_DETECT</b>	RW	0x0
3	<b>VBUS_DETECT_OVERRIDE_EN</b>	RW	0x0
2	<b>VBUS_DETECT</b>	RW	0x0
1	<b>VBUS_EN_OVERRIDE_EN</b>	RW	0x0
0	<b>VBUS_EN</b>	RW	0x0

## USB: USBPHY\_DIRECT Register

Offset: 0x07c

### Description

This register allows for direct control of the USB phy. Use in conjunction with usbphy\_direct\_override register to enable each override bit.

Table 1213.  
USBPHY\_DIRECT Register

Bits	Description	Type	Reset
31:26	Reserved.	-	-
25	<b>RX_DM_OVERRIDE:</b> Override rx_dm value into controller	RW	0x0
24	<b>RX_DP_OVERRIDE:</b> Override rx_dp value into controller	RW	0x0
23	<b>RX_DD_OVERRIDE:</b> Override rx_dd value into controller	RW	0x0
22	<b>DM_OVV:</b> DM over voltage	RO	0x0
21	<b>DP_OVV:</b> DP over voltage	RO	0x0
20	<b>DM_OVCN:</b> DM overcurrent	RO	0x0

表1211。  
USB\_MUXING寄存器

位	描述	类型	复位
31	<b>SWAP_DPDM</b> : 交换USB PHY的DP和DM引脚及所有相关控制，并翻转接收的差分信号。可用于切换PCB上的USB DP/DM。 此操作在底层完成，覆盖所有其他控制。	读写	0x0
30:5	保留。	-	-
4	<b>USBPHY_AS_GPIO</b> : 将USB DP和DM引脚用作GPIO，而非连接到USB控制器。	读写	0x0
3	<b>SOFTCON</b>	读写	0x0
2	<b>TO_DIGITAL_PAD</b>	读写	0x0
1	<b>TO_EXTPHY</b>	读写	0x0
0	<b>TO_PHY</b>	读写	0x1

## USB: USB\_PWR 寄存器

偏移量: 0x078

### 说明

当VBUS信号未接入GPIO时，对电源信号进行覆盖。先设置覆盖值，再启用覆盖，切换至覆盖值。

表1212. USB\_PWR  
寄存器

## USB: USBPHY\_TRIM 寄存器

偏移: 0x084

### 描述

用于调整 USB 物理层下拉电阻的微调值。

表 1215。  
USBPHY\_TRIM  
寄存器

位	描述	类型	复位
31:13	保留。	-	-
12:8	<b>DM_PULLDN_TRIM:</b> 驱动至 USB PHY 的值 DM 下拉电阻微调控制 实验数据表明复位值有效，但该寄存器允许根据需要进行调整	读写	0x1f
7:5	保留。	-	-
4:0	<b>DP_PULLDN_TRIM:</b> 驱动至 USB PHY 的值 DP 下拉电阻微调控制 实验数据表明复位值有效，但该寄存器允许根据需要进行调整	读写	0x1f

## USB: LINESTATE\_TUNING 寄存器

偏移: 0x088

### 描述

仅供调试使用。

Table 1216.  
LINESTATE\_TUNING  
Register

Bits	Description	Type	Reset
31:12	Reserved.	-	-
11:8	<b>SPARE_FIX</b>	RW	0x0
7	<b>DEV_LS_WAKE_FIX</b> : Device - exit suspend on any non-idle signalling, not qualified with a 1ms timer	RW	0x1
6	<b>DEV_RX_ERR QUIESCE</b> : Device - suppress repeated errors until the device FSM is next in the process of decoding an inbound packet.	RW	0x1
5	<b>SIE_RX_CHATTER_SEO_FIX</b> : RX - when recovering from line chatter or bitstuff errors, treat SEO as the end of chatter as well as 8 consecutive idle bits.	RW	0x1
4	<b>SIE_RX_BITSTUFF_FIX</b> : RX - when a bitstuff error is signalled by rx_dasm, unconditionally terminate RX decode to avoid a hang during certain packet phases.	RW	0x1
3	<b>DEV_BUFF_CONTROL_DOUBLE_READ_FIX</b> : Device - the controller FSM performs two reads of the buffer status memory address to avoid sampling metastable data. An enabled buffer is only used if both reads match.	RW	0x1
2	<b>MULTI_HUB_FIX</b> : Host - increase inter-packet and turnaround timeouts to accommodate worst-case hub delays.	RW	0x0
1	<b>LINESTATE_DELAY</b> : Device/Host - add an extra 1-bit debounce of linestate sampling.	RW	0x0
0	<b>RCV_DELAY</b> : Device - register the received data to account for hub bit dribble before EOP. Only affects certain hubs.	RW	0x0

## USB: INTR Register

Offset: 0x08c

### Description

Raw Interrupts

Table 1217. INTR  
Register

Bits	Description	Type	Reset
31:24	Reserved.	-	-
23	<b>EPX_STOPPED_ON_NAK</b> : Source: NAK_POLL.EPX_STOPPED_ON_NAK	RO	0x0

6	<b>DEV_RX_ERR QUIESCE</b> : 设备 - 抑制重复错误，直到设备状态机下一次进入解码入站数据包的阶段。	读写	0x1
5	<b>SIE_RX_CHATTER_SEO_FIX</b> : 接收 - 从线路抖动或比特填充错误恢复时，将SEO视为抖动结束标志，同时视为8个连续空闲位	读写	0x1
4	<b>SIE_RX_BITSTUFF_FIX</b> : 接收 - 当rx_dasm报告比特填充错误时，无条件终止接收解码，以避免在特定数据包阶段出现挂起。	读写	0x1
3	<b>DEV_BUFF_CONTROL_DOUBLE_READ_FIX</b> : 设备 - 控制器状态机对缓冲区状态存储地址执行两次读取，以避免采样亚稳态数据。仅当两次读取结果一致时，启用的缓冲区方可使用。	读写	0x1
2	<b>MULTI_HUB_FIX</b> : 主机 - 增加数据包间隔和切换超时时间，以适应最坏情况下集线器的延迟。	读写	0x0
1	<b>LINESTATE_DELAY</b> : 设备/主机 - 对线路状态采样增加额外的1位硬件消抖。	读写	0x0
0	<b>RCV_DELAY</b> : 设备 - 注册接收数据以补偿集线器结束标志(EOP)前的位漂移。仅影响特定集线器。	读写	0x0

## 12.8. System timers

### 12.8.1. Overview

The system timer peripheral on RP2350 provides a microsecond timebase for the system, and generates interrupts based on this timebase. RP2350 has two instances of the system timer: **TIMER0** and **TIMER1**. This allows for two separately controlled timers, each in a different security domain. It supports the following features:

- A single 64-bit counter, incrementing once per microsecond
  - Read from a pair of latching registers for race-free reads over a 32-bit bus
- Four alarms that match on the lower 32 bits of the counter and generate IRQ on match

The timer uses a one microsecond reference generated by the tick generators (see [Section 8.5](#)), and derived from the reference clock ([Figure 33](#)), which itself is usually connected directly to the crystal oscillator ([Section 8.2](#)).

The 64-bit counter effectively cannot overflow (thousands of years at 1 MHz), so the system timer is completely monotonic in practice.

#### 12.8.1.1. Changes from RP2040

- RP2350 now has two timer instances: **TIMER0** and **TIMER1**
- On RP2350, the tick source for each timer comes from the system-level tick generators (see [Section 8.5](#))
- RP2350 added two new registers: **LOCKED** is used to disable write access to the timer, and **SOURCE** allows the timer to

## 12.8. 系统定时器

### 12.8.1. 概述

RP2350 的系统定时器外设为系统提供微秒时间基准，并基于该时间基准产生中断。RP2350 具有两个系统定时器实例：**TIMER0** 和 **TIMER1**。这允许两个定时器分别独立控制，且各位于不同的安全域中。支持以下功能：

- 单个 64 位计数器，每微秒递增一次
  - 通过一对锁存寄存器读取，实现 32 位总线上的无竞争读取
- 四个报警器，匹配计数器低 32 位时生成中断请求

该定时器使用由滴答发生器（参见第 8.5 节）产生的单微秒参考信号，参考信号源自参考时钟（图 33），通常直接连接至晶体振荡器（第 8.2 节）。

64 位计数器实际上无法溢出（在 1 MHz 频率下可持续数千年），因此系统定时器在实际应用中具备完全的单调性。

#### 12.8.1.1. RP2040 的变更

- RP2350 现有两个定时器实例：**TIMER0** 和 **TIMER1**
- 在 RP2350 中，每个定时器的节拍源来自系统级节拍发生器（见第 8.5 节）
- RP2350 新增两个寄存器：**LOCKED** 用于禁止写入定时器，**SOURCE** 允许定时器

count system clock cycles rather than a 1 µs tick

### 12.8.1.2. Other timer resources on RP2350

The system timer provides a global timebase for software. RP2350 has a number of other programmable counter resources which can provide regular interrupts, or trigger DMA transfers.

- The PWM ([Section 12.5](#)) contains 12× 16-bit programmable counters. These counters:
  - run at up to system speed
  - can generate interrupts to either of two system IRQ lines
  - can be continuously reprogrammed via the DMA
  - can trigger DMA transfers to other peripherals
- 12× PIO state machines ([Chapter 11](#)) can count 32-bit values at system speed, and generate interrupts.
- The DMA ([Section 12.6](#)) has four internal pacing timers which trigger transfers at regular intervals.
- Each Cortex-M33 core ([Section 3.7](#)) has a standard 24-bit SysTick timer, counting either the microsecond tick ([Section 8.5](#)) or the system clock.
- SIO has a standard 64-bit RISC-V platform timer ([Section 3.1.8](#)). Arm and RISC-V software can use this timer.
- The Power Manager ([Chapter 6](#)) incorporates a 64-bit timer (AON Timer) which nominally counts milliseconds (see [Section 12.10](#)). This is the only timer that runs when the chip is in its lowest power state, with all switchable power domains powered down. It is used to schedule power-ups.

### 12.8.2. Counter

The timer has a 64-bit counter, but RP2350 only has a 32-bit data bus. This means that the `TIME` value is accessed through a pair of registers. These are:

- `TIMEHW` and `TIMELW` to write the time
- `TIMEHR` and `TIMELR` to read the time

To use these pairs, access the lower register, `L`, followed by the higher register, `H`. In the read case, reading the `L` register latches the value in the `H` register to provide an accurate time. To read the raw time without any latching, use `TIMERAWH` and `TIMERAWL`.

#### CAUTION

Don't write to the `TIMEHW` and `TIMELW` registers to force a new time value if other software may be using the timer. The SDK uses the time value for timeouts, elapsed time, and more, and expects the value to increase monotonically.

### 12.8.3. Alarms

The timer has 4 alarms, and outputs a separate interrupt for each alarm. The alarms match on the lower 32 bits of the 64-bit counter, which means they can be fired at a maximum of  $2^{32}$  microseconds into the future. This is equivalent to:

- $2^{32} \div 10^6$ : ~4295 seconds
- $4295 \div 60$ : ~72 minutes

计数系统时钟周期，而非 $1\mu\text{s}$ 节拍

### 12.8.1.2. RP2350上的其他定时器资源

系统定时器为软件提供全局时间基准。RP2350具备多种其他可编程计数资源，可实现定期中断或触发DMA传输。

- PWM（第12.5节）包含12个16位可编程计数器。这些计数器：
  - 以最高系统速度运行
  - 能够向两个系统IRQ线路中的任意一条生成中断
  - 可通过DMA持续重新编程
  - 能够触发对其他外设的DMA传输
- 12个PIO状态机（第11章）能够以系统速度计数32位值，并生成中断。
- DMA（第12.6节）设有四个内部节奏计时器，能够在固定时间间隔触发传输。
- 每个Cortex-M33内核（第3.7节）均配备标准的24位SysTick计时器，可计数微秒时钟滴答（第8.5节）或系统时钟。
- SIO配备标准的64位RISC-V平台计时器（第3.1.8节），Arm和RISC-V软件均可使用该计时器。
- 电源管理器（第6章）包含64位计时器（AON Timer），名义上计数毫秒（参见第12.10节）。当芯片处于最低功耗状态且所有可切换电源域均关闭时，该计时器为唯一运行计时器。该功能用于计划开机时间。

### 12.8.2. 计数器

计时器配备64位计数器，但RP2350仅具备32位数据总线。这意味着 `TIME` 值通过一对寄存器访问。该寄存器对如下：

- `TIMEHW` 和 `TIMELW` 用于写入时间
- `TIMEHR` 和 `TIMELR` 用于读取时间

使用这些寄存器对时，应先访问低位寄存器 `L`，随后访问高位寄存器 `H`。在读取时，读取 `L` 寄存器会锁存 `H` 寄存器中的值，从而保证时间的准确性。若需读取未锁存的原始时间，请使用 `TIMERAWH` 与 `TIMERAWL`。

#### 警告

如其他软件可能在使用计时器，请勿向 `TIMEHW` 和 `TIMELW` 寄存器写入，避免强制设置新的时间值。SDK利用时间值进行超时、计时等功能，要求该值单调递增。

### 12.8.3. 警报

计时器配备4个警报，且每个警报均输出单独中断信号。报警通过匹配64位计数器的低32位实现，这意味着报警最多可以在未来 $2^{32}$ 微秒内触发。相当于：

- $2^{32} \div 10^6$ : 约4295秒
- $4295 \div 60$ : 约72分钟

**NOTE**

This timer supports alarm intervals on the order of one microsecond to one hour. For a longer alarm, see [Section 12.10](#).

To enable an alarm:

1. Enable the interrupt at the timer with a write to the appropriate alarm bit in `INTE` (e.g. `(1 << 0)` for `ALARM0`).
2. Enable the appropriate timer interrupt at the processor (see [Section 3.2](#)).
3. Write the time you would like the interrupt to fire to `ALARM0` (i.e. the current value in `TIMERAWL` plus your desired alarm time in microseconds). Writing the time to the `ALARM` register sets the `ARMED` bit as a side effect.

Once the alarm has fired, the `ARMED` bit clears to `0`. To clear the latched interrupt, write a `1` to the appropriate bit in `INTR`.

## 12.8.4. Programmer's model

**NOTE**

The timer's tick (see [Section 8.5](#)) must be running for the timer to start counting. The SDK starts this tick as part of the platform initialisation code.

### 12.8.4.1. Reading the time

**NOTE**

Time here refers to the number of microseconds since the timer was started, not a clock. For a clock, see [Section 12.10](#).

To read the 64-bit time, read `TIMELR` followed by `TIMEHR`. Reading `TIMELR` latches (stops) the value in `TIMEHR` until `TIMEHR` is read. Because RP2350 has 2 cores, it is unsafe to do this if the second core executes code that can also access the timer, or if the timer is read concurrently in an IRQ handler and in thread mode. If one core reads `TIMELR` followed by another core reading `TIMELR`, the value in `TIMEHR` isn't necessarily accurate. The example below shows the simplest form of getting the 64-bit time:

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/timer/timer\\_lowlevel/timer\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/timer/timer_lowlevel/timer_lowlevel.c) Lines 15 - 23

```

15 // Simplest form of getting 64 bit time from the timer.
16 // It isn't safe when called from 2 cores because of the latching
17 // so isn't implemented this way in the sdk
18 static uint64_t get_time(void) {
19 // Reading low latches the high value
20 uint32_t lo = timer_hw->timelr;
21 uint32_t hi = timer_hw->timehr;
22 return ((uint64_t) hi << 32u) | lo;
23 }
```

The SDK provides a `time_us_64` function that uses a more thorough method to get the 64-bit time, which makes use of the `TIMERAWH` and `TIMERAWL` registers. The `RAW` registers don't latch, making `time_us_64` safe to call from multiple cores at once.

**注意**

该计时器支持从一微妙到一小时的报警间隔。如需更长时间的报警，请参见第12.10节。

启用报警步骤如下：

1. 通过向INT0寄存器中相应的报警位写入值（例如`(1 << 0)`对应 ALARM0）以启用计时器中断。
2. 在处理器端启用相应的计时器中断（详见第3.2节）。
3. 向 ALARM0 写入期望的中断触发时间（即当前 TIMERAWL 值加上期望的报警时间，单位为微妙）。向 ALARM 寄存器写入时间后，作为副作用会设置 ARMED位。

当报警触发后，ARMED位将清零为 0。要清除锁存中断，请向 INTR寄存器中的相应位写入 1。

## 12.8.4. 程序员模型

**注意**

计时器的节拍（参见第8.5节）必须在运行中，计时器才能开始计数。SDK在平台初始化代码中启动此节拍。

### 12.8.4.1 读取时间

**注意**

此处的时间指自计时器启动以来经过的微妙数，而非时钟时间。有关时钟功能，请参见第12.10节。

要读取64位时间，先读取 TIMELR，再读取 TIMEHR。读取 TIMELR会锁存（停止） TIMEHR的值，直到读取 TIMEHR为止。由于RP2350具有两个核心，若第二核心执行的代码也访问计时器，或计时器在中断处理程序与线程模式下并发读取，则此操作不安全。如果一个核心读取 TIMELR，紧接着另一个核心读取 TIMEHR， TIMEHR中的值不一定准确。以下示例展示了获取64位时间的最简形式：

Pico示例：[https://github.com/raspberrypi/pico-examples/blob/master/timer/timer\\_lowlevel/timer\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/timer/timer_lowlevel/timer_lowlevel.c) 第15至23行

```

15 // 从定时器获得64位时间的最简形式。
16 // 由于锁存机制，双核心调用时不安全
17 // 因此SDK中未采用此实现方式
18 static uint64_t get_time(void) {
19 // 读取低位会锁存高位值
20 uint32_t lo = timer_hw->timelr;
21 uint32_t hi = timer_hw->timehr;
22 return ((uint64_t) hi << 32u) | lo;
23 }
```

该SDK提供了一个 time\_us\_64函数，采用更为彻底的方法获取64位时间，利用了 TIMERAWH和 TIMERAWL寄存器。由于 RAW寄存器不具备锁存功能， time\_us\_64函数可以安全地被多个核心同时调用。

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_timer/timer.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_timer/timer.c) Lines 57 - 73

```

57 uint64_t timer_time_us_64(timer_hw_t *timer) {
58 // Need to make sure that the upper 32 bits of the timer
59 // don't change, so read that first
60 uint32_t hi = timer->timerawh;
61 uint32_t lo;
62 do {
63 // Read the lower 32 bits
64 lo = timer->timerawl;
65 // Now read the upper 32 bits again and
66 // check that it hasn't incremented. If it has loop around
67 // and read the lower 32 bits again to get an accurate value
68 uint32_t next_hi = timer->timerawh;
69 if (hi == next_hi) break;
70 hi = next_hi;
71 } while (true);
72 return ((uint64_t) hi << 32u) | lo;
73 }
```

#### 12.8.4.2. Set an alarm

The standalone timer example, `timer_lowlevel`, demonstrates how to set an alarm at a hardware level without the additional abstraction over the timer provided by SDK. To use these abstractions, see [Section 12.8.4.4](#).

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/timer/timer\\_lowlevel/timer\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/timer/timer_lowlevel/timer_lowlevel.c) Lines 27 - 74

```

27 // Use alarm 0
28 #define ALARM_NUM 0
29 #define ALARM_IRQ timer.hardware_alarm_get_irq_num(timer_hw, ALARM_NUM)
30
31 // Alarm interrupt handler
32 static volatile bool alarm_fired;
33
34 static void alarm_irq(void) {
35 // Clear the alarm irq
36 hw_clear_bits(&timer_hw->intr, 1u << ALARM_NUM);
37
38 // Assume alarm 0 has fired
39 printf("Alarm IRQ fired\n");
40 alarm_fired = true;
41 }
42
43 static void alarm_in_us(uint32_t delay_us) {
44 // Enable the interrupt for our alarm (the timer outputs 4 alarm irqs)
45 hw_set_bits(&timer_hw->inte, 1u << ALARM_NUM);
46 // Set irq handler for alarm irq
47 irq_set_exclusive_handler(ALARM_IRQ, alarm_irq);
48 // Enable the alarm irq
49 irq_set_enabled(ALARM_IRQ, true);
50 // Enable interrupt in block and at processor
51
52 // Alarm is only 32 bits so if trying to delay more
53 // than that need to be careful and keep track of the upper
54 // bits
55 uint64_t target = timer_hw->timerawl + delay_us;
56
57 // Write the lower 32 bits of the target time to the alarm which
58 // will arm it
59 timer_hw->alarm[ALARM_NUM] = (uint32_t) target;
```

SDK链接: [https://github.com/raspberrypi/pico-sdk/blob/master/src/p2\\_common/hardware\\_timer/timer.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/p2_common/hardware_timer/timer.c) 第57至73行

```

57 uint64_t timer_time_us_64(timer_hw_t *timer) {
58 // 需要确保计时器的高32位
59 // 不发生变化，因此先读取高位
60 uint32_t hi = timer->timerawh;
61 uint32_t lo;
62 do {
63 // 读取低32位
64 lo = timer->timerawl;
65 // 现在再次读取高32位,
66 // 并检查其是否未递增。如若递增，则循环重新读取
67 // 再读一次低32位，以获得准确数值
68 uint32_t next_hi = timer->timerawh;
69 if (hi == next_hi) break;
70 hi = next_hi;
71 } while (true);
72 return ((uint64_t) hi << 32u) | lo;
73 }
```

#### 12.8.4.2. 设置闹钟

独立定时器示例`timer_lowlevel`演示了如何在硬件层面设置闹钟，而不使用SDK提供的定时器抽象。要使用这些抽象，请参见第12.8.4.4节。

Pico示例: [https://github.com/raspberrypi/pico-examples/blob/master/timer/timer\\_lowlevel/timer\\_lowlevel.c](https://github.com/raspberrypi/pico-examples/blob/master/timer/timer_lowlevel/timer_lowlevel.c) 第27至74行

```

27 // 使用闹钟0
28 #define ALARM_NUM 0
29 #define ALARM_IRQ timer_hardware_alarm_get_irq_num(timer_hw, ALARM_NUM)
30
31 // 闹钟中断处理函数
32 static volatile bool alarm_fired;
33
34 static void alarm_irq(void) {
35 // 清除闹钟中断请求
36 hw_clear_bits(&timer_hw->intr, 1u << ALARM_NUM);
37
38 // 假设闹钟0已触发
39 printf("闹钟中断请求已触发\n");
40 alarm_fired = true;
41 }
42
43 static void alarm_in_us(uint32_t delay_us) {
44 // 使能我们的闹钟中断（定时器会输出4个闹钟中断）
45 hw_set_bits(&timer_hw->inte, 1u << ALARM_NUM);
46 // 设置闹钟中断对应的中断处理函数
47 irq_set_exclusive_handler(ALARM_IRQ, alarm_irq);
48 // 使能闹钟中断
49 irq_set_enabled(ALARM_IRQ, true);
50 // 在模块和处理器级别使能中断
51
52 // 闹钟计数器仅为32位，若延迟时间超过此值
53 // 需谨慎处理并记录高位部分
54 // 位
55 uint64_t target = timer_hw->timerawl + delay_us;
56
57 // 将目标时间的低32位写入闹钟寄存器，
58 // 以激活闹钟
59 timer_hw->alarm[ALARM_NUM] = (uint32_t) target;
```

```

60 }
61
62 int main() {
63 stdio_init_all();
64 printf("Timer lowlevel!\n");
65
66 // Set alarm every 2 seconds
67 while (1) {
68 alarm_fired = false;
69 alarm_in_us(1000000 * 2);
70 // Wait for alarm to fire
71 while (!alarm_fired);
72 }
73 }
```

### 12.8.4.3. Busy wait

If you don't want to use an alarm to wait for a period of time, use a while loop instead. The SDK provides various `busy_wait_` functions to do this:

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_timer/timer.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_timer/timer.c) Lines 77 - 122

```

77 void timer_busy_wait_us_32(timer_hw_t *timer, uint32_t delay_us) {
78 if (0 <= (int32_t)delay_us) {
79 // we only allow 31 bits, otherwise we could have a race in the loop below with
80 // values very close to 2^32
81 uint32_t start = timer->timerawl;
82 while (timer->timerawl - start < delay_us) {
83 tight_loop_contents();
84 }
85 } else {
86 busy_wait_us(delay_us);
87 }
88 }
89
90 void timer_busy_wait_us(timer_hw_t *timer, uint64_t delay_us) {
91 uint64_t base = timer_time_us_64(timer);
92 uint64_t target = base + delay_us;
93 if (target < base) {
94 target = (uint64_t)-1;
95 }
96 absolute_time_t t;
97 update_us_since_boot(&t, target);
98 timer_busy_wait_until(timer, t);
99 }
100
101 void timer_busy_wait_ms(timer_hw_t *timer, uint32_t delay_ms)
102 {
103 if (delay_ms <= 0xffffffff / 1000) {
104 timer_busy_wait_us_32(timer, delay_ms * 1000);
105 } else {
106 timer_busy_wait_us(timer, delay_ms * 1000ull);
107 }
108 }
109
110 void timer_busy_wait_until(timer_hw_t *timer, absolute_time_t t) {
111 uint64_t target = to_us_since_boot(t);
112 uint32_t hi_target = (uint32_t)(target >> 32u);
113 uint32_t hi = timer->timerawh;
114 while (hi < hi_target) {
```

```

60 }
61
62 int main() {
63 stdio_init_all();
64 printf("Timer lowlevel!\n");
65
66 // 每2秒设置一次闹钟
67 while (1) {
68 alarm_fired = false;
69 alarm_in_us(1000000 * 2);
70 // 等待闹钟触发
71 while (!alarm_fired);
72 }
73 }
```

#### 12.8.4.3. 忙等待

如果不使用闹钟等待某段时间，可改用while循环。SDK 提供了多种 `busy_wait_` 函数以实现此功能：

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_timer/timer.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_timer/timer.c) 第77至122行

```

77 void timer_busy_wait_us_32(timer_hw_t *timer, uint32_t delay_us) {
78 if (0 <= (int32_t)delay_us) {
79 // 我们仅允许31位，否则下面的循环中可能会出现竞态条件
80 // 该值极其接近2^32
81 uint32_t start = timer->timerawl;
82 while (timer->timerawl - start < delay_us) {
83 tight_loop_contents();
84 }
85 } else {
86 busy_wait_us(delay_us);
87 }
88 }
89
90 void timer_busy_wait_us(timer_hw_t *timer, uint64_t delay_us) {
91 uint64_t base = timer_time_us_64(timer);
92 uint64_t target = base + delay_us;
93 if (target < base) {
94 target = (uint64_t)-1;
95 }
96 absolute_time_t t;
97 update_us_since_boot(&t, target);
98 timer_busy_wait_until(timer, t);
99 }
100
101 void timer_busy_wait_ms(timer_hw_t *timer, uint32_t delay_ms)
102 {
103 if (delay_ms <= 0xffffffff / 1000) {
104 timer_busy_wait_us_32(timer, delay_ms * 1000);
105 } else {
106 timer_busy_wait_us(timer, delay_ms * 1000ull);
107 }
108 }
109
110 void timer_busy_wait_until(timer_hw_t *timer, absolute_time_t t) {
111 uint64_t target = to_us_since_boot(t);
112 uint32_t hi_target = (uint32_t)(target >> 32u);
113 uint32_t hi = timer->timerawh;
114 while (hi < hi_target) {
```

```

115 hi = timer->timerawh;
116 tight_loop_contents();
117 }
118 while (hi == hi_target && timer->timerawl < (uint32_t) target) {
119 hi = timer->timerawh;
120 tight_loop_contents();
121 }
122 }
```

#### 12.8.4.4. Complete example using SDK

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/timer/hello\\_timer/hello\\_timer.c](https://github.com/raspberrypi/pico-examples/blob/master/timer/hello_timer/hello_timer.c) Lines 11 - 57

```

11 volatile bool timer_fired = false;
12
13 int64_t alarm_callback(alarm_id_t id, __unused void *user_data) {
14 printf("Timer %d fired!\n", (int) id);
15 timer_fired = true;
16 // Can return a value here in us to fire in the future
17 return 0;
18 }
19
20 bool repeating_timer_callback(__unused struct repeating_timer *t) {
21 printf("Repeat at %lld\n", time_us_64());
22 return true;
23 }
24
25 int main() {
26 stdio_init_all();
27 printf("Hello Timer!\n");
28
29 // Call alarm_callback in 2 seconds
30 add_alarm_in_ms(2000, alarm_callback, NULL, false);
31
32 // Wait for alarm callback to set timer_fired
33 while (!timer_fired) {
34 tight_loop_contents();
35 }
36
37 // Create a repeating timer that calls repeating_timer_callback.
38 // If the delay is > 0 then this is the delay between the previous callback ending and the
39 // next starting.
40 // If the delay is negative (see below) then the next call to the callback will be exactly
41 // 500ms after the
42 // start of the call to the last callback
43 struct repeating_timer timer;
44 add_repeating_timer_ms(500, repeating_timer_callback, NULL, &timer);
45 sleep_ms(3000);
46 bool cancelled = cancel_repeating_timer(&timer);
47 printf("cancelled... %d\n", cancelled);
48 sleep_ms(2000);
49
50 // Negative delay so means we will call repeating_timer_callback, and call it again
51 // 500ms later regardless of how long the callback took to execute
52 add_repeating_timer_ms(-500, repeating_timer_callback, NULL, &timer);
53 sleep_ms(3000);
54 cancelled = cancel_repeating_timer(&timer);
55 printf("cancelled... %d\n", cancelled);
56 sleep_ms(2000);
57 printf("Done\n");
```

```

115 hi = timer->timerawh;
116 tight_loop_contents();
117 }
118 while (hi == hi_target && timer->timerawl < (uint32_t) target) {
119 hi = timer->timerawh;
120 tight_loop_contents();
121 }
122 }
```

#### 12.8.4.4. 使用 SDK 的完整示例

Pico 示例：[https://github.com/raspberrypi/pico-examples/blob/master/timer/hello\\_timer/hello\\_timer.c](https://github.com/raspberrypi/pico-examples/blob/master/timer/hello_timer/hello_timer.c) 第 11-57 行

```

11 volatile bool timer_fired = false;
12
13 int64_t alarm_callback(alarm_id_t id, __unused void *user_data) {
14 printf("定时器%d触发! \n", (int) id);
15 timer_fired = true;
16 // 此处可返回以微秒为单位的值，用于将来触发
17 return 0;
18 }
19
20 bool repeating_timer_callback(__unused struct repeating_timer *t) {
21 printf("重复触发时间%lld\n", time_us_64());
22 return true;
23 }
24
25 int main() {
26 stdio_init_all();
27 printf("你好，定时器! \n");
28
29 // 2 秒后调用 alarm_callback
30 add_alarm_in_ms(2000, alarm_callback, NULL, false);
31
32 // 等待 alarm_callback 设置 timer_fired
33 while (!timer_fired) {
34 tight_loop_contents();
35 }
36
37 // 创建一个调用 repeating_timer_callback 的重复定时器。
38 // 如果延迟 > 0，则该延迟为上一次回调结束与下一次回调开始之间的间隔。
39
40 // 上一次回调调用开始后的500毫秒
41 struct repeating_timer timer;
42 add_repeating_timer_ms(500, repeating_timer_callback, NULL, &timer);
43 sleep_ms(3000);
44 bool cancelled = cancel_repeating_timer(&timer);
45 printf("cancelled... %d\n", cancelled);
46 sleep_ms(2000);
47
48 // 负延迟表示我们将调用 repeating_timer_callback，并在
49 // 500毫秒后再次调用，无论回调运行耗时多久
50 add_repeating_timer_ms(-500, repeating_timer_callback, NULL, &timer);
51 sleep_ms(3000);
52 cancelled = cancel_repeating_timer(&timer);
53 printf("cancelled... %d\n", cancelled);
54 sleep_ms(2000);
55 printf("Done\n");
```

```

56 return 0;
57 }

```

## 12.8.5. List of registers

The `TIMER0` and `TIMER1` registers start at base addresses of `0x400b0000` and `0x400b8000` respectively (defined as `TIMER0_BASE` and `TIMER1_BASE` in SDK).

*Table 1227. List of TIMER registers*

Offset	Name	Info
0x00	<code>TIMEHW</code>	Write to bits 63:32 of time always write timelw before timehw
0x04	<code>TIMEHW</code>	Write to bits 31:0 of time writes do not get copied to time until timehw is written
0x08	<code>TIMEHR</code>	Read from bits 63:32 of time always read timelr before timehr
0x0c	<code>TIMELR</code>	Read from bits 31:0 of time
0x10	<code>ALARM0</code>	Arm alarm 0, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM0 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x14	<code>ALARM1</code>	Arm alarm 1, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM1 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x18	<code>ALARM2</code>	Arm alarm 2, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM2 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x1c	<code>ALARM3</code>	Arm alarm 3, and configure the time it will fire. Once armed, the alarm fires when <code>TIMER_ALARM3 == TIMELR</code> . The alarm will disarm itself once it fires, and can be disarmed early using the ARMED status register.
0x20	<code>ARMED</code>	Indicates the armed/disarmed status of each alarm. A write to the corresponding ALARMx register arms the alarm. Alarms automatically disarm upon firing, but writing ones here will disarm immediately without waiting to fire.
0x24	<code>TIMERAWH</code>	Raw read from bits 63:32 of time (no side effects)
0x28	<code>TIMERAWL</code>	Raw read from bits 31:0 of time (no side effects)
0x2c	<code>DBGPAUSE</code>	Set bits high to enable pause when the corresponding debug ports are active
0x30	<code>PAUSE</code>	Set high to pause the timer
0x34	<code>LOCKED</code>	Set locked bit to disable write access to timer Once set, cannot be cleared (without a reset)

```

56 return 0;
57 }

```

## 12.8.5. 寄存器列表

TIMER0和TIMER1寄存器的基地址分别为0x400b0000和0x400b8000（SDK中定义为TIMER0\_BASE和TIMER1\_BASE）。

表 1227.  
TIMER 寄存器列表

偏移量	名称	说明
0x00	TIMEHW	写入 time 寄存器的第 63:32 位 必须始终先写入 timelw，然后再写入 timehw
0x04	TIMELW	写入 time 寄存器的第 31:0 位 写入操作在写入 timehw 之前不会反映到 time
0x08	TIMEHR	读取 time 寄存器的第 63:32 位 必须始终先读取 timelr，然后再读取 timehr
0x0c	TIMELR	读取 time 寄存器的第 31:0 位
0x10	ALARM0	启动报警 0 并配置其触发时间。 报警启动后，当 TIMER_ALARM0 等于 TIMELR 时触发。 报警触发后将自动解除启动，也可通过 ARMED 状态寄存器提前解除。
0x14	ALARM1	启动报警 1 并配置其触发时间。 一旦启动，当 TIMER_ALARM1 等于 TIMELR 时，警报触发。 报警触发后将自动解除启动，也可通过 ARMED 状态寄存器提前解除。
0x18	ALARM2	启动警报 2，并配置其触发时间。 一旦启动，当 TIMER_ALARM2 等于 TIMELR 时，警报触发。警报触发后自动解除，也可通过 ARMED 状态寄存器提前解除。
0x1c	ALARM3	启动警报 3，并配置其触发时间。 一旦启动，当 TIMER_ALARM3 等于 TIMELR 时，警报触发。 报警触发后将自动解除启动，也可通过 ARMED 状态寄存器提前解除。
0x20	ARMED	指示每个警报的启动或解除状态。 写入对应的 ALARMx 寄存器以启动警报。 警报触发后自动解除，但写入 1 可立即解除，无需等待触发。
0x24	TIMERAWH	直接读取时间的第 63 至 32 位（无副作用）
0x28	TIMERAWL	直接读取时间的第 31 至 0 位（无副作用）
0x2c	DBGPAUSE	将位设置为高电平以启用对应调试端口激活时的暂停功能
0x30	暂停	置高电平以暂停计时器
0x34	已锁定	设置锁定位以禁用对计时器的写访问 设置后不可清除（除非复位）

Offset	Name	Info
0x38	SOURCE	Selects the source for the timer. Defaults to the normal tick configured in the ticks block (typically configured to 1 microsecond). Writing to 1 will ignore the tick and count clk_sys cycles instead.
0x3c	INTR	Raw Interrupts
0x40	INTE	Interrupt Enable
0x44	INTF	Interrupt Force
0x48	INTS	Interrupt status after masking & forcing

## TIMER: TIMEHW Register

Offset: 0x00

Table 1228. TIMEHW Register

Bits	Description	Type	Reset
31:0	Write to bits 63:32 of time always write timelw before timehw	WF	0x00000000

## TIMER: TIMELW Register

Offset: 0x04

Table 1229. TIMELW Register

Bits	Description	Type	Reset

## 12.9. Watchdog

### 12.9.1. Overview

The watchdog is a countdown timer which can be configured to reset selected components when it reaches zero. In normal operation it is periodically loaded with a non-zero value to prevent the reset occurring. If the chip locks up or software gets stuck in a loop, the reset allows recovery.

The watchdog is reset by any chip-level reset (see [Section 7.3](#)). The sources of the chip-level reset are:

- Power-On Reset (POR)
- Brown-out Detection (BOD)
- External Reset (from the RUN pin)
- Debugger Reset Request
- Rescue Debug Port Request
- Watchdog - a chip-level reset triggered by the Watchdog will reset the Watchdog
- SWCORE powerdown
- Glitch Detector
- Debugger HZD Reset Request

These are described in [Section 7.3.3](#).

### 12.9.2. Changes from RP2040

On RP2040, the watchdog contained a tick generator used to generate a 1µs tick for the watchdog. This was also distributed to the system timer. On RP2350, the watchdog instead takes a tick input from the system-level ticks block. See [Section 8.5](#).

As on RP2040 the watchdog can trigger a PSM (Power-on State Machine) sequence to reset system components or it can be used to reset selected subsystem components. On RP2350, the watchdog can also trigger a chip level reset.

### 12.9.3. Watchdog counter

The watchdog counter is loaded by the [LOAD](#) register. The current value can be seen in [CTRL.TIME](#).

偏移: 0x48

## 12.9. 看门狗

### 12.9.1. 概述

看门狗是一种倒计时定时器，当计数归零时可配置为重置选定组件。在正常运行时，它会周期性地载入一个非零值以防止复位发生。如果芯片锁死或软件陷入循环，复位功能将允许系统恢复。

看门狗可被任何芯片级复位（参见第7.3节）重置。芯片级复位的来源如下：

- 上电复位 (POR)
- 欠压检测 (BOD)
- 外部复位 (来自RUN引脚)
- 调试器复位请求
- 救援调试端口请求
- 看门狗——由看门狗触发的芯片级复位将重置看门狗
- SWCORE掉电
- 瞬态故障检测器
- 调试器HWD复位请求

详见第7.3.3节。

### 12.9.2. 与RP2040的差异

在RP2040中，看门狗内含一个用于生成1μs计时的滴答发生器。该信号也分发至系统定时器。在RP2350中，看门狗改为接受来自系统级滴答模块的滴答输入。

请参阅第8.5节。

在RP2040上，看门狗可以触发PSM（上电状态机）序列以重置系统组件，或用于重置选定的子系统组件。在RP2350上，看门狗还可触发芯片级复位。

### 12.9.3. 看门狗计数器

看门狗计数器通过LOAD寄存器加载。当前值可在CTRL.TIME寄存器中查看。

## 12.9.4. Control watchdog reset levels

To control the level of reset triggered by a watchdog event, use the registers outside the watchdog register block:

- **POWMAN\_WATCHDOG** allows the watchdog to trigger chip level resets
- **PSM\_WDSEL** allows the watchdog to trigger system resets by running a full or partial PSM sequence (Power-on State Machine)
- **RESETS\_WDSEL** allows the watchdog to trigger subsystem resets

These are described in the Resets section, see [Chapter 7](#).

## 12.9.5. Scratch registers

The watchdog contains eight 32-bit scratch registers that can store information between soft resets of the chip. The scratch registers reset when:

- the watchdog is used to trigger a chip level reset
- a **rst\_n\_run** event occurs, triggered by toggling the RUN pin or cycling the digital core supply (DVDD)

The bootrom checks the watchdog scratch registers for a magic number on boot. You can use this to soft reset the chip into user-specified code. See [Section 5.2.4](#) for more information.

### **NOTE**

Additional general-purpose scratch registers are available in POWMAN **SCRATCH0** through **SCRATCH7**. These registers also survive power cycling the switched core domain.

## 12.9.6. Programmer's model

The SDK provides a **hardware\_watchdog** driver to control the watchdog.

### 12.9.6.1. Enabling the watchdog

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_watchdog/watchdog.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_watchdog/watchdog.c) Lines 47 - 76

```

47 // Helper function used by both watchdog_enable and watchdog_reboot
48 void _watchdog_enable(uint32_t delay_ms, bool pause_on_debug) {
49 valid_params_if(HARDWARE_WATCHDOG, delay_ms <= WATCHDOG_LOAD_BITS / (1000 *
50 WATCHDOG_XFACTOR));
51 hw_clear_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_ENABLE_BITS);
52 // Reset everything apart from ROSC and XOSC
53 hw_set_bits(&psm_hw->wdsel, PSM_WDSEL_BITS & ~(PSM_WDSEL_ROSC_BITS |
54 PSM_WDSEL_XOSC_BITS));
55 uint32_t dbg_bits = WATCHDOG_CTRL_PAUSE_DBG0_BITS |
56 WATCHDOG_CTRL_PAUSE_DBG1_BITS |
57 WATCHDOG_CTRL_PAUSE_JTAG_BITS;
58
59 if (pause_on_debug) {
60 hw_set_bits(&watchdog_hw->ctrl, dbg_bits);
61 } else {
62 hw_clear_bits(&watchdog_hw->ctrl, dbg_bits);
63 }
64 }
```

## 12.9.4. 控制看门狗复位级别

要控制由看门狗事件触发的复位级别，请使用看门狗寄存器块外的寄存器：

- `POWMAN_WATCHDOG` 允许看门狗触发芯片级复位。
- `PSM_WDSEL` 允许看门狗通过执行完整或部分PSM序列（上电状态机）触发系统复位。
- `RESETS_WDSEL` 允许看门狗触发子系统复位。

详见复位章节，第7章。

## 12.9.5. 暂存寄存器

看门狗包含八个32位临时寄存器，可在芯片软复位期间保存信息。临时寄存器将在以下情况下复位：

- 看门狗用于触发芯片级复位。
- a `rst_n_run` 事件发生，触发条件为切换RUN引脚或循环数字核心电源（DVDD）

启动只读存储器在引导时检查看门狗擦写寄存器中的魔术数字。您可以利用此功能将芯片软复位至用户指定的代码。更多信息详见第5.2.4节。

### 注意

POWMAN SCRATCH0至SCRATCH7提供额外的通用擦写寄存器。这些寄存器在切换核心域电源时数值依然保持。

## 12.9.6. 程序员模型

SDK提供硬件看门狗驱动程序以控制看门狗。

### 12.9.6.1. 启用看门狗

SDK地址：[https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_watchdog/watchdog.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_watchdog/watchdog.c) 行47至76

```

47 // 此辅助函数由watchdog_enable和watchdog_reboot共同调用
48 void _watchdog_enable(uint32_t delay_ms, bool pause_on_debug) {
49 valid_params_if(HARDWARE_WATCHDOG, delay_ms <= WATCHDOG_LOAD_BITS / (1000 *
50 WATCHDOG_XFACTOR));
51
52 // 重置除ROSC和XOSC之外的所有模块
53 hw_set_bits(&psm_hw->wdsel, PSM_WDSEL_BITS & ~(PSM_WDSEL_ROSC_BITS |
54 PSM_WDSEL_XOSC_BITS));
55
55 uint32_t dbg_bits = WATCHDOG_CTRL_PAUSE_DBG0_BITS |
56 WATCHDOG_CTRL_PAUSE_DBG1_BITS |
57 WATCHDOG_CTRL_PAUSE_JTAG_BITS;
58
59 if (pause_on_debug) {
60 hw_set_bits(&watchdog_hw->ctrl, dbg_bits);
61 } else {
62 hw_clear_bits(&watchdog_hw->ctrl, dbg_bits);
63 }
64 }
```

```

65 if (!delay_ms) {
66 hw_set_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_TRIGGER_BITS);
67 } else {
68 load_value = delay_ms * (1000 * WATCHDOG_XFACTOR);
69 if (load_value > WATCHDOG_LOAD_BITS)
70 load_value = WATCHDOG_LOAD_BITS;
71
72 watchdog_update();
73
74 hw_set_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_ENABLE_BITS);
75 }
76 }
```

### 12.9.6.2. Updating the watchdog counter

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/p2\\_common/hardware\\_watchdog/watchdog.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/p2_common/hardware_watchdog/watchdog.c) Lines 24 - 28

```

24 static uint32_t load_value;
25
26 void watchdog_update(void) {
27 watchdog_hw->load = load_value;
28 }
```

### 12.9.6.3. Usage

The Pico Examples repository provides a `hello_watchdog` example that uses the `hardware_watchdog` to demonstrate use of the watchdog.

Pico Examples: [https://github.com/raspberrypi/pico-examples/blob/master/watchdog/hello\\_watchdog/hello\\_watchdog.c](https://github.com/raspberrypi/pico-examples/blob/master/watchdog/hello_watchdog/hello_watchdog.c) Lines 11 - 33

```

11 int main() {
12 stdio_init_all();
13
14 if (watchdog_enable_caused_reboot()) {
15 printf("Rebooted by Watchdog!\n");
16 return 0;
17 } else {
18 printf("Clean boot\n");
19 }
20
21 // Enable the watchdog, requiring the watchdog to be updated every 100ms or the chip will
22 // reboot
23 // second arg is pause on debug which means the watchdog will pause when stepping through
24 // code
25 watchdog_enable(100, 1);
26
27 for (uint i = 0; i < 5; i++) {
28 printf("Updating watchdog %d\n", i);
29 watchdog_update();
30 }
31
32 // Wait in an infinite loop and don't update the watchdog so it reboots us
33 printf("Waiting to be rebooted by watchdog\n");
34 while(1);
35 }
```

```

65 if (!delay_ms) {
66 hw_set_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_TRIGGER_BITS);
67 } else {
68 load_value = delay_ms * (1000 * WATCHDOG_XFACTOR);
69 if (load_value > WATCHDOG_LOAD_BITS)
70 load_value = WATCHDOG_LOAD_BITS;
71
72 watchdog_update();
73
74 hw_set_bits(&watchdog_hw->ctrl, WATCHDOG_CTRL_ENABLE_BITS);
75 }
76 }
```

### 12.9.6.2. 更新看门狗计数器

SDK: [https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2\\_common/hardware\\_watchdog/watchdog.c](https://github.com/raspberrypi/pico-sdk/blob/master/src/rp2_common/hardware_watchdog/watchdog.c) 第24至28行

```

24 static uint32_t load_value;
25
26 void watchdog_update(void) {
27 watchdog_hw->load = load_value;
28 }
```

### 12.9.6.3. 使用说明

Pico 示例仓库提供了一个[hello\\_watchdogexample](#), 使用[hardware\\_watchdog](#)演示看门狗的功能。

Pico 示例: [https://github.com/raspberrypi/pico-examples/blob/master/watchdog/hello\\_watchdog/hello\\_watchdog.c](https://github.com/raspberrypi/pico-examples/blob/master/watchdog/hello_watchdog/hello_watchdog.c) 第11至33行

```

11 int main() {
12 stdio_init_all();
13
14 if (watchdog_enable_caused_reboot()) {
15 printf("由看门狗重启! \n");
16 return 0;
17 } else {
18 printf("正常启动\n");
19 }
20
21 // 启用看门狗, 必须每100ms更新一次看门狗, 否则芯片将会重启
22 // 第二个参数表示调试时暂停, 即单步调试时看门狗将暂停
23 watchdog_enable(100, 1);
24
25 for (uint i = 0; i < 5; i++) {
26 printf("正在更新看门狗 %d\n", i);
27 watchdog_update();
28 }
29
30 // 进入无限循环不更新看门狗, 导致设备重启
31 printf("等待被看门狗重启\n");
32 while(1);
33 }
```

## 12.9.7. List of registers

The watchdog registers start at a base address of **0x400d8000** (defined as **WATCHDOG\_BASE** in SDK).

Table 1247. List of WATCHDOG registers

Offset	Name	Info
0x00	CTRL	Watchdog control The rst_wdsel register determines which subsystems are reset when the watchdog is triggered. The watchdog can be triggered in software.
0x04	LOAD	Load the watchdog timer. The maximum setting is 0xffffffff which corresponds to approximately 16 seconds.
0x08	REASON	Logs the reason for the last reset. Both bits are zero for the case of a hardware reset.  Additionally, as of RP2350, a debugger warm reset of either core (SYSRESETREQ or hartreset) will also clear the watchdog reason register, so that software loaded under the debugger following a watchdog timeout will not continue to see the timeout condition.
0x0c	SCRATCH0	Scratch register. Information persists through soft reset of the chip.
0x10	SCRATCH1	Scratch register. Information persists through soft reset of the chip.
0x14	SCRATCH2	Scratch register. Information persists through soft reset of the chip.
0x18	SCRATCH3	Scratch register. Information persists through soft reset of the chip.
0x1c	SCRATCH4	Scratch register. Information persists through soft reset of the chip.
0x20	SCRATCH5	Scratch register. Information persists through soft reset of the chip.
0x24	SCRATCH6	Scratch register. Information persists through soft reset of the chip.
0x28	SCRATCH7	Scratch register. Information persists through soft reset of the chip.

### WATCHDOG: CTRL Register

Offset: 0x00

#### Description

Watchdog control

The rst\_wdsel register determines which subsystems are reset when the watchdog is triggered.

The watchdog can be triggered in software.

Table 1248. CTRL Register

Bits	Description	Type	Reset
31	<b>TRIGGER:</b> Trigger a watchdog reset	SC	0x0
30	<b>ENABLE:</b> When not enabled the watchdog timer is paused	RW	0x0
29:27	Reserved.	-	-
26	<b>PAUSE_DBG1:</b> Pause the watchdog timer when processor 1 is in debug mode	RW	0x1

## 12.9.7. 寄存器列表

看门狗寄存器的基地址为 **0x400d8000** (在SDK中定义为 WATCHDOG\_BASE)。

表1247。看门狗寄存器列表

偏移量	名称	说明
0x00	CTRL	看门狗控制 rst_wdsel寄存器决定当看门狗触发时哪些子系统将被复位。 看门狗可通过软件触发。
0x04	LOAD	加载看门狗定时器。最大设置值为0xffffffff，约等于16秒。
0x08	REASON	记录上次复位的原因。在硬件复位情况下，两位均为零。  此外，自RP2350起，任一核心的调试器热复位（SYSRESETREQ或hartreset）亦会清除看门狗原因寄存器，以致调试器下加载的软件在看门狗超时后不会持续检测到超时状态。
0x0c	SCRATCH0	临时寄存器。信息在芯片软复位后依然保持。
0x10	SCRATCH1	临时寄存器。信息在芯片软复位后依然保持。
0x14	SCRATCH2	临时寄存器。信息在芯片软复位后依然保持。
0x18	SCRATCH3	临时寄存器。信息在芯片软复位后依然保持。
0x1c	SCRATCH4	临时寄存器。信息在芯片软复位后依然保持。
0x20	SCRATCH5	临时寄存器。信息在芯片软复位后依然保持。
0x24	SCRATCH6	临时寄存器。信息在芯片软复位后依然保持。
0x28	SCRATCH7	临时寄存器。信息在芯片软复位后依然保持。

### WATCHDOG: CTRL寄存器

偏移: 0x00

#### 描述

看门狗控制

## 12.10. Always-on timer

### 12.10.1. Overview

The always-on timer (AON Timer) is the only timer that operates in all power modes. It can be used as a real-time counter or an interval timer and incorporates an alarm which can be used to trigger a power-up event or an interrupt. It incorporates a 64-bit counter intended to count 1ms ticks, but the tick generator can be configured to run faster or slower if required. Note that the AON Timer tick generator is independent of all other tick generators on the chip.

The default tick source is the 32kHz on-chip low-power oscillator (LPOSC), see [Section 8.4](#). The LPOSC frequency is not precise and may vary with voltage and temperature. When the chip core is powered, the tick source can be switched to the on-chip crystal oscillator (XOSC) for greater precision. If greater precision is also required when the chip core is

## 12.10. 常时开启定时器

### 12.10.1. 概述

始终开启定时器（AON定时器）是唯一在所有电源模式下持续运行的定时器。它可用作实时计数器或间隔定时器，并内置报警器，可用于触发加电事件或中断。它集成了一个64位计数器，设计用于计数1ms滴答，但滴答发生器可根据需要配置为更快或更慢运行。请注意，AON定时器的滴答发生器独立于芯片上所有其他滴答发生器。

默认滴答源为32kHz片上低功耗振荡器（LPOSOC），详见第8.4节。LPOSOC频率不精确，且可能因电压和温度变化而波动。当芯片核心供电时，滴答源可切换至片上晶体振荡器（XOSC），以获得更高精度。如果在芯片核心

unpowered, then a 32kHz clock or a 1ms tick can be supplied from an external source. Alternatively, the AON Timer can be synchronised to an external 1Hz source.

The AON Timer is integrated with the power manager (POWMAN) and shares the POWMAN register block. Writes are limited to 16 bits because a key (`0x5afe`) is required in the top 16 bits to prevent erroneous writes from locking up the chip. Most AON Timer registers can be enabled for write by Non-secure software, unlike other POWMAN registers. However, the registers used to select an external clock, select an external tick source, and enable power-up on alarm can only be written by Secure software.

### 12.10.2. Changes from RP2040

The RP2040 Real Time Clock (RTC) is not used in RP2350. Instead, RP2350 has a timer in the Always-On power domain which is used for scheduling power-up events and can also be used as a real-time counter. The AON Timer works differently from the RP2040 RTC. It counts milliseconds to 64 bits and this value can be used to calculate the date and time in software if required.

### 12.10.3. Accessing the AON Timer

To start and stop the AON Timer, write to `TIMER.RUN`.

To read the current 64-bit AON Timer value, use the following  $2 \times 32$ -bit read-only registers:

- `READ_TIME_UPPER`
- `READ_TIME_LOWER`

Because the AON Timer can increment during a read, use the following procedure to protect against erroneous reads:

1. Read `READ_TIME_UPPER`
2. Read `READ_TIME_LOWER`
3. Read `READ_TIME_UPPER`
4. If the `READ_TIME_UPPER` value changes between steps 1 and 3, repeat the whole procedure

When used as a real time clock, the 64-bit time value is set using  $4 \times 16$ -bit registers. These registers can only be written when the AON Timer is stopped by writing a 0 to `TIMER.RUN`:

- `SET_TIME_63TO48`
- `SET_TIME_47TO32`
- `SET_TIME_31TO16`
- `SET_TIME_15TO0`

These registers cannot be used to read the time value.

When used as an interval timer, write a 1 to `TIMER.CLEAR` to clear the timer value. It is not necessary to stop the AON Timer to do this. The `TIMER.CLEAR` register is self-clearing: it returns to 0 when the operation completes. This allows easy implementation of an alarm that wakes the chip or generates an interrupt at regular intervals.

### 12.10.4. Using the alarm

To set the alarm time, use the following  $4 \times 16$ -bit registers:

- `ALARM_TIME_63TO48`
- `ALARM_TIME_47TO32`

断电时也需更高精度，则可由外部来源提供32kHz时钟或1ms滴答。或者，AON定时器可与外部1Hz信号同步。

AON定时器集成于电源管理器（POWMAN）中，且共享POWMAN寄存器块。写入操作限制为16位，因顶部16位须包含密钥（[0x5afe](#)），以防止错误写入导致芯片锁死。与其他POWMAN寄存器不同，大多数AON定时器寄存器允许非安全软件写入。

但选择外部时钟、外部计数源及使能报警开机的寄存器，仅允许安全软件写入。

### 12.10.2. 与RP2040的差异

RP2040的实时时钟（RTC）未在RP2350中使用。RP2350在始终开启的电源域内设有定时器，用于调度开机事件，也可用作实时间计数器。AON定时器的工作机制不同于RP2040的RTC。它以64位计数毫秒数，必要时该值可用于软件中计算日期和时间。

### 12.10.3. 访问AON定时器

要启动和停止AON定时器，请写入TIMER.RUN。

要读取当前的64位AON定时器值，请使用以下两个32位只读寄存器：

- [READ\\_TIME\\_UPPER](#)
- [READ\\_TIME\\_LOWER](#)

由于AON定时器在读取时可能递增，请按照以下步骤防止读取错误：

1. 读取READ\_TIME\_UPPER
2. 读取READ\_TIME\_LOWER
3. 再次读取READ\_TIME\_UPPER
4. 若步骤1与步骤3中READ\_TIME\_UPPER的值不同，请重复上述过程。

作为实时时钟使用时，64位时间值通过4个16位寄存器设置。只有在通过写入0到TIMER.RUN停止AON定时器后，这些寄存器才能写入：

- [SET\\_TIME\\_63TO48](#)
- [SET\\_TIME\\_47TO32](#)
- [SET\\_TIME\\_31TO16](#)
- [SET\\_TIME\\_15TO0](#)

这些寄存器不用于读取时间值。

作为间隔定时器使用时，写入1到TIMER.CLEAR以清除定时器值。执行此操作时，无需停止AON定时器。TIMER.CLEAR寄存器为自清零寄存器：操作完成后其值自动恢复为0。该机制使得能够轻松实现周期性唤醒芯片或产生中断的报警功能。

### 12.10.4. 使用警报

设置报警时间时，请使用以下四个16位寄存器：

- [ALARM\\_TIME\\_63TO48](#)
- [ALARM\\_TIME\\_47TO32](#)

- [ALARM\\_TIME\\_31TO16](#)
- [ALARM\\_TIME\\_15TO0](#)

To avoid false alarms, disable the alarm before setting the alarm time.

To enable the alarm, use [TIMER.ALARM\\_ENAB](#).

When the alarm fires, the AON Timer sets the alarm status flag [TIMER.ALARM](#).

To clear the alarm status flag, write a 1 to the alarm status flag.

To configure the alarm to trigger a power-up, set [TIMER.PWRUP\\_ON\\_ALARM](#). This feature is not available to Non-secure code.

The alarm can be configured to trigger an interrupt. The interrupt is handled in the standard way using the following register fields:

- [INTR.TIMER](#) - raw interrupt
- [INTE.TIMER](#) - interrupt enable
- [INTF.TIMER](#) - force interrupt
- [INTS.TIMER](#) - interrupt status

## 12.10.5. Selecting the AON Timer tick source

The AON Timer indicates the current configuration with read-only flags. [Table 1252](#) provides a list of sources supported by the 1kHz AON Timer tick.

*Table 1252. AON Timer tick generators*

Tick source	Read-only flag
LPOSC clock division	<a href="#">TIMER.USING_LPOSC</a>
XOSC clock division	<a href="#">TIMER.USING_XOSC</a>
external 1kHz tick	<a href="#">TIMER.USING_GPIO_1KHZ</a>

### **i** NOTE

The LPOSC clock can be substituted by an external 32kHz clock.

### 12.10.5.1. Using LPOSC as the AON Timer tick source

LPOSC is the default source and can be used in all power modes. It nominally runs at 32.768kHz and can only be tuned to 1% accuracy. The AON Timer derives the 1ms tick from the LPOSC using a 6.16 bit fractional divider whose divisor is initialised to 32.768. The divisor can be modified to achieve greater accuracy. Because the LPOSC frequency varies with supply voltage and temperature, accuracy is limited unless supply voltage and temperature are stable. To modify the divisor, write to the following registers:

- [LPOSC\\_FREQ\\_KHZ\\_INT](#) (default value: 32)
- [LPOSC\\_FREQ\\_KHZ\\_FRAC](#) (default value: 0.768)

These registers should only be written when [TIMER.RUN](#) = 0 or [TIMER.USING\\_LPOSC](#) = 0.

If the tick source is not LPOSC, you can switch it back to LPOSC by writing a 1 to [TIMER.USE\\_LPOSC](#). It is not necessary to stop the AON Timer to do this. The newly selected tick will be synchronised to the current tick, so the operation may take up to 1 tick cycle (1ms in normal operation). When the operation is complete, [TIMER.USE\\_LPOSC](#) will self-clear and [TIMER.USING\\_LPOSC](#) will be set. Due to sampling, a small error of up to 2 periods of the newly selected clock will be subtracted from the time. When switching to LPOSC at 32kHz, an error of up to 62µs will be subtracted.

- [ALARM\\_TIME\\_31TO16](#)
- [ALARM\\_TIME\\_15TO0](#)

为避免误报警，请在设置报警时间前禁用报警功能。

启用报警功能，请设置 `TIMER.ALARM_ENAB`。

报警触发时，AON定时器会将报警状态标志 `TIMER.ALARM` 置位。

清除报警状态标志，请向该标志写入 1。

若要配置报警触发开机，请设置 `TIMER.PWRUP_ON_ALARM`。该功能对非安全代码不可用。

报警可配置为触发中断。中断通过以下寄存器字段以标准方式处理：

- [INTR.TIMER — 原始中断](#)
- [INTE.TIMER — 中断使能](#)
- [INTF.TIMER — 强制中断](#)
- [INTS.TIMER — 中断状态](#)

### 12.10.5. 选择AON定时器的计时源

AON定时器使用只读标志指示当前配置状态。表1252列出了1kHz AON定时器滴答支持的信号源。

表1252。AON  
定时器计时发生器

计时源	只读标志
LPOSC时钟分频	<code>TIMER.USING_LPOSC</code>
XOSC时钟分频	<code>TIMER.USING_XOSC</code>
外部1kHz计时信号	<code>TIMER.USING_GPIO_1KHZ</code>

**i 注意**

LPOSC时钟可由外部32kHz时钟替代。

#### 12.10.5.1 使用LPOSC作为AON定时器计时源

LPOSC为默认计时源，可在所有电源模式下使用。其标称频率为32.768kHz，调节精度仅达1%。AON定时器通过一款6.1位分数分频器（初值为32.768）从LPOSC导出1ms计时，分频值可调整以提升精度。由于LPOSC频率受供电电压和温度影响，除非这些条件稳定，否则其精度受限。若要修改除数，请向以下寄存器写入数据：

- [LPOSC\\_FREQ\\_KHZ\\_INT](#)（默认值：32）
- [LPOSC\\_FREQ\\_KHZ\\_FRAC](#)（默认值：0.768）

仅当 `TIMER.RUN = 0` 或 `TIMER.USING_LPOSC = 0` 时，方可向这些寄存器写入。

若时基源非 LPOSC，您可通过向 `TIMER.USE_LPOSC` 写入1切换回 LPOSC，且无需停止 AON 定时器。新选定的时基会与当前时基同步，故操作最多可能持续一个时基周期（正常运行时为1毫秒）。操作完成后，`TIMER.USE_LPOSC` 将自动清零，且 `TIMER.USING_LPOSC` 将被置位。由于采样，时间中将扣除最多两个新选时钟周期的微小误差。切换至32kHz LPOSC 时，最多扣除62微秒误差。

### 12.10.5.2. Using an external clock in place of LPOSC

If LPOSC isn't sufficiently accurate, an external 32.768kHz clock can be used. This will be multiplexed onto the internal low-power clock and will therefore drive all components that are driven by that clock, including the power sequencer components. The external clock can be used in all power modes. When an external clock is in use, you can stop the LPOSC (see [Section 8.4](#)).

To select an external 32kHz clock:

1. Configure the GPIO source as described in [Section 12.10.7](#).
2. Switch to the external LPOSC by setting `EXT_TIME_REF.DRIVE_LPCK`. This register should only be written when `TIMER.RUN = 0` and the power sequencer is inactive. You can only write to this register from Secure code.

The external 32kHz clock replaces the clock from LPOSC. Therefore the same registers are used for AON Timer configuration (see [Section 12.10.5.1](#)):

- `TIMER.USE_LPOSC`
- `TIMER.USING_LPOSC`
- `LPOSC_FREQ_KHZ_INT`
- `LPOSC_FREQ_KHZ_FRAC`

### 12.10.5.3. Using the XOSC as the AON Timer tick source

The XOSC clock is provided via the reference clock (`clk_ref`). The user must ensure the reference clock is being driven from the XOSC before selecting it as the source of the AON Timer tick. This is the normal configuration following boot. To check, look for `CLK_REF_SELECTED = 0x4`. The reference clock may be a divided version of the XOSC. The divisor defaults to 1 and can be read from `CLK_REF_DIV.INT`. If the chip is operated with a faster XOSC, the clock sent to the AON Timer must not exceed 29MHz.

The AON Timer derives the 1ms tick from the XOSC using a 16.16 bit fractional divider whose divisor is initialised to 12000.0. This assumes a 12MHz crystal is used and the reference clock divisor is 1. If that is not the case, the divisor in the AON Timer can be modified by writing to the following registers:

- `XOSC_FREQ_KHZ_INT` (default value: 12000)
- `XOSC_FREQ_KHZ_FRAC` (default value: 0)

These registers should only be written when `TIMER.RUN = 0` or `TIMER.USING_XOSC = 0`.

To select the XOSC as the AON Timer tick source, write a 1 to `TIMER.USE_XOSC`. It is not necessary to stop the AON Timer to do this. The newly selected tick will be synchronised to the current tick, so the operation may take up to 1 tick cycle (1ms in normal operation). When the operation is complete `TIMER.USE_XOSC` will self-clear and `TIMER.USING_XOSC` will be set. Due to sampling, a small error of up to 2 periods of the newly selected clock will be subtracted from the time. When switching to XOSC at 12MHz an error of up to 167ns will be subtracted.

When the chip core is powered down the XOSC will stop. If `TIMER.USING_XOSC` is set, the power-down sequencer automatically reverts to `TIMER.USING_LPOSC` before the XOSC stops.

### 12.10.5.4. Using an external 1ms tick source

To select an external 1ms tick source, configure the GPIO source as described in [Section 12.10.7](#). Then, write a 1 to `TIMER.USE_GPIO_1KHZ`. It is not necessary to stop the AON Timer to do this, however the newly selected tick will not be synchronised to the current tick, so the operation will advance the time by up to 1ms. If using an external 1ms tick it is recommended to set the time after selecting the source. When the operation is complete `TIMER.USE_GPIO_1KHZ` will self-clear and `TIMER.USING_GPIO_1KHZ` will be set.

The tick is triggered from the falling edge of the selected GPIO. For correct sampling, the GPIO pulse width and interval must both be greater than the period of LPOSC (>31us). This limits the maximum frequency of the external tick to

### 12.10.5.2 使用外部时钟替代低功耗振荡器 (LPOSC)

若LPOSC精度不足，可使用外部32.768kHz时钟。该时钟将复用至内部低功耗时钟，因此驱动所有由该时钟驱动的组件，包括电源时序器组件。外部时钟适用于所有电源模式。使用外部时钟时，可停止LPOSC（详见第8.4节）。

选择外部32kHz时钟的步骤如下：

1. 按照第12.10.7节配置GPIO源。
2. 通过设置EXT\_TIME\_REF.DRIVE\_LPCK切换至外部LPOSC。该寄存器仅在TIMER.RUN = 0且电源时序器处于非活动状态时写入。该寄存器仅允许安全代码写入。

外部32kHz时钟替代LPOSC时钟，因此AON定时器配置使用相同寄存器（详见第12.10.5.1节）：

- [TIMER.USE\\_LPOSC](#)
- [TIMER.USING\\_LPOSC](#)
- [LPOSC\\_FREQ\\_KHZ\\_INT](#)
- [LPOSC\\_FREQ\\_KHZ\\_FRAC](#)

### 12.10.5.3. 使用XOSC作为AON定时器的时钟源

XOSC时钟通过参考时钟（[clk\\_ref](#)）提供。用户必须确保参考时钟已由XOSC驱动，方可将其选作AON定时器时钟源。此为启动后的正常配置。

检查时，请确认CLK\_REF\_SELECTED = [0x4](#)。参考时钟可能是XOSC的分频版本。分频系数默认为1，可从CLK\_REF\_DIV.INT读取。若芯片使用更高速的XOSC，送入AON定时器的时钟频率不得超过29MHz。

AON定时器通过16.16位分数分频器，从XOSC导出1毫秒节拍，分频系数初始化为12000.0。此设定假设使用12MHz晶振，且参考时钟分频系数为1。如果情况并非如此，则可通过向以下寄存器写入数据来修改AON计时器的除数：

- [XOSC\\_FREQ\\_KHZ\\_INT](#)（默认值：12000）
- [XOSC\\_FREQ\\_KHZ\\_FRAC](#)（默认值：0）

仅当 TIMER.RUN = 0 或 TIMER.USING\_XOSC = 0 时，方可向这些寄存器写入数据。

要选择XOSC作为AON计时器的时钟源，请向TIMER.USE\_XOSC写入1。无需停止AON计时器即可完成此操作。新选定的时基会与当前时基同步，故操作最多可能持续一个时基周期（正常运行时为1毫秒）。操作完成后，[TIMER.USE\\_XOSC](#)会自动清零，且[TIMER.USING\\_XOSC](#)会被设置。由于采样原因，时间上会扣除新时钟周期最多两个周期的小误差。切换至12MHz XOSC时，最多会扣除167ns的误差。

当芯片核心断电时，XOSC将停止运行。如果TIMER.USING\_XOSC被设置，则断电序列器会在XOSC停止之前自动恢复至TIMER.USING\_LPOSC。

### 12.10.5.4. 使用外部1毫秒计时源

要选择外部1毫秒计时源，请按照第12.10.7节的说明配置GPIO源。然后，将1写入TIMER.USE\_GPIO\_1KHZ。无须停止AON定时器，但新选择的计时信号不会与当前计时同步，因此该操作会使时间向前推进最多1毫秒。使用外部1毫秒计时源时，建议在选择计时源后设置时间。操作完成后，TIMER.USE\_GPIO\_1KHZ将自动清零，同时TIMER.USING\_GPIO\_1KHZ将被设置。

计时信号由所选GPIO的下降沿触发。为确保正确采样，GPIO脉冲宽度和间隔均须大于LPOSC的周期（>31微秒）。此限制了外部时钟的最大频率为

16kHz.

The external 1ms tick can be used in all power modes.

### 12.10.6. Synchronising the AON timer to an external 1Hz clock

In applications that use GPS, a 1s tick may be available. This can be used to synchronise the AON Timer and thus compensate for inaccuracy in the LPOSC frequency. It can be used with any tick source, but there is little to be gained if the selected source is already reasonably accurate.

If the LPOSC is fast, the ms counter pauses at a 1 second step until the 1s tick is received. If the LPOSC is slow, the 1s tick causes the ms counter to run very quickly until reaching the 1 second step. This ensures that all ms values are counted, ensuring that any alarm set to ms precision will fire. A more sophisticated synchronisation method can be implemented in software.

To use the hardware synchronisation feature, configure the GPIO source as described in [Section 12.10.7](#). Then, enable the feature by writing a 1 to `TIMER.USE_GPIO_1HZ`. This can be set at any time, it is not necessary to stop the AON Timer. When the operation is complete `TIMER.USE_GPIO_1HZ` will self-clear and `TIMER.USING_GPIO_1HZ` will be set.

The tick is triggered from the falling edge of the selected GPIO. For correct sampling, the GPIO pulse width and interval must be greater than the period of LPOSC (>31us).

The external 1s tick can be used in all power modes.

### 12.10.7. Using an external clock or tick from GPIO

The following features use a GPIO as a clock or a tick:

- external 32kHz clock source
- external 1kHz tick
- external 1Hz tick

Only 4 GPIOs are available for these features. You can only select one, because they share the same GPIO selection logic. The set of 4 GPIOs differs between package types. The selection is controlled by a 2-bit register field.

The AON Timer uses the following GPIOs:

- `EXT_TIME_REF.SOURCE_SEL = 0` → GPIO12
- `EXT_TIME_REF.SOURCE_SEL = 1` → GPIO20
- `EXT_TIME_REF.SOURCE_SEL = 2` → GPIO14
- `EXT_TIME_REF.SOURCE_SEL = 3` → GPIO22

### 12.10.8. Using a tick faster than 1ms

The tick rate can be increased by scaling the value written to the LPOSC and XOSC frequency registers. For example, if the frequency value is divided by 4 then the AON Timer will tick 4 times per ms. The minimum value that can be written to the frequency registers is 2.0, therefore the maximum upscaling using this method with LPOSC is 16, giving a time resolution of 1/16th of 1 ms (= 62.5us).

As described previously, the external tick is limited to 16kHz, so the maximum upscaling using this method is also 16. This gives a time resolution of 1/16th of 1 ms (62.5μs).

These limitations can be overcome either by using a faster external clock (see [Section 12.10.5.2](#)) or keeping the chip core powered so the AON Timer is always running from the XOSC. If a faster external clock is used then the power sequencer timings will also need to be adjusted.

16kHz。

外部1毫秒计时脉冲可在所有功率模式下使用。

### 12.10.6. 将AON定时器同步至外部1Hz时钟

在使用GPS的应用中，可能提供1秒计时脉冲。该脉冲可用于同步始终通电计时器（AON Timer），从而补偿低功耗振荡器（LPOSC）频率的不准确性。此脉冲可与任何计时脉冲源配合使用，但若所选源已经较为准确，则几乎无明显益处。

若LPOSC频率偏快，毫秒计数器将在达到1秒刻度前暂停，直至收到1秒脉冲。若LPOSC频率偏慢，1秒脉冲将使毫秒计数器加速运行，直至达到1秒刻度。此设计确保所有毫秒数计数完整，保证任何基于毫秒精度设置的警报均能准确触发。更高级的同步方法可通过软件实现。

欲启用硬件同步功能，请按照第12.10.7节配置GPIO信号源，然后向TIMER.USE\_GPIO\_1HZ寄存器写入1以启用。该操作可在任意时点执行，无需停止始终通电计时器。操作完成后，TIMER.USE\_GPIO\_1HZ寄存器自动清零，且TIMER.USING\_GPIO\_1HZ寄存器将被置位。

滴答信号由所选GPIO的下降沿触发。为确保采样正确，GPIO脉冲宽度和间隔必须大于LPOSC的周期（>31微秒）。

外部1秒滴答信号可在所有电源模式下使用。

### 12.10.7. 使用GPIO的外部时钟或滴答信号

以下功能使用GPIO作为时钟或滴答信号：

- 外部32kHz时钟源
- 外部1kHz计时信号
- 外部1Hz滴答信号

仅有4个GPIO可用于这些功能。由于它们共享相同的GPIO选择逻辑，因此只能选择其中之一。4个GPIO的集合因封装类型而异。选择由一个2位寄存器字段控制。

AON定时器使用以下GPIO：

- `EXT_TIME_REF_SOURCE_SEL = 0` → GPIO12
- `EXT_TIME_REF_SOURCE_SEL = 1` → GPIO20
- `EXT_TIME_REF_SOURCE_SEL = 2` → GPIO14
- `EXT_TIME_REF_SOURCE_SEL = 3` → GPIO22

### 12.10.8. 使用快于1毫秒的滴答信号

通过调整写入LPOSC和XOSC频率寄存器的值，可增加滴答频率。例如，若频率值除以4，则AON定时器每毫秒会滴答4次。频率寄存器允许的最小写入值为2.0，因此使用LPOSC通过此方法的最大倍增因子为16，时间分辨率达到1/16毫秒（即62.5μs）。

如前所述，外部时钟频率限制为16kHz，因此此方法的最大倍增因子同样为16。这意味着时间分辨率为1/16毫秒（62.5μs）。

上述限制可通过使用更高速的外部时钟（详见第12.10.5.2节）或保持芯片核心供电，使AON定时器持续从XOSC运行来突破。如选用更高速外部时钟，则需相应调整电源序列器的时序。

For example, suppose 1μsec timer precision is required. The user could supply an external 2-25MHz clock in place of the LPOSC and program both the LPOSC and XOSC frequency registers in MHz units rather than kHz. The maximum frequency of the external clock is 29MHz.

### 12.10.9. List of registers

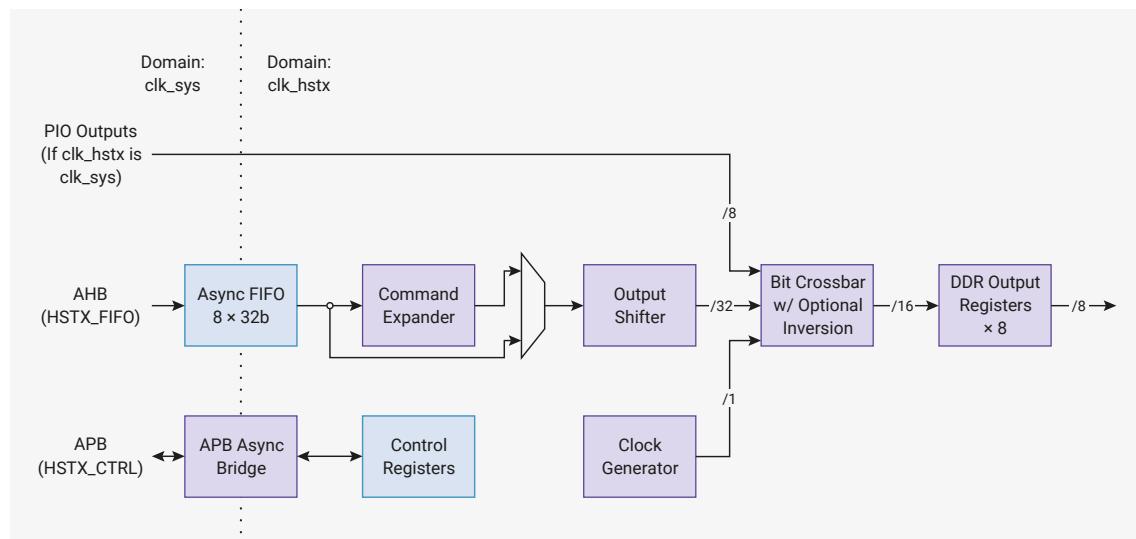

The AON Timer shares a register address space with the power management subsystems in the always-on domain. The address space is referred to as **POWMAN** elsewhere in this document and a complete list of **POWMAN** registers is provided in [Section 6.4](#). The registers associated with the AON Timer are:

- [SET\\_TIME\\_63TO48](#)
- [SET\\_TIME\\_47TO32](#)
- [SET\\_TIME\\_31TO16](#)
- [SET\\_TIME\\_15T00](#)
- [READ\\_TIME\\_UPPER](#)
- [READ\\_TIME\\_LOWER](#)
- [ALARM\\_TIME\\_63TO48](#)
- [ALARM\\_TIME\\_47TO32](#)
- [ALARM\\_TIME\\_31TO16](#)
- [ALARM\\_TIME\\_15T00](#)
- [TIMER](#)

## 12.11. HSTX

The high-speed serial transmit (HSTX) streams data from the system clock domain to up to 8 GPIOs at a rate independent of the system clock. On RP2350, GPIOs 12 through 19 are HSTX-capable. HSTX is output-only.

*Figure 126. A 32-bit-wide asynchronous FIFO provides high-bandwidth access from the system DMA. The command expander manipulates the datastream, and the output shift register portions the 32-bit data over successive HSTX clock cycles, swizzled by the bit crossbar. Outputs are double-data-rate: two bits per pin per cycle.*

HSTX drives data through GPIOs using DDR output registers to transfer up to two bits per clock cycle per pin. The HSTX balances all delays to GPIO outputs within 300 picoseconds, minimising common-mode components when using neighbouring GPIOs as a pseudo-differential driver. This also helps maintain destination setup and hold time when a clock is driven alongside the output data.

The maximum frequency for the HSTX clock is 150 MHz, the same as the system clock. With DDR output operation, this

例如，假设需要1微秒的定时器精度。用户可提供外部2-25MHz时钟替代LPOSC，并以MHz单位编程LPOSC和XOSC频率寄存器，而非kHz。外部时钟最大频率为29MHz。

### 12.10.9. 寄存器列表

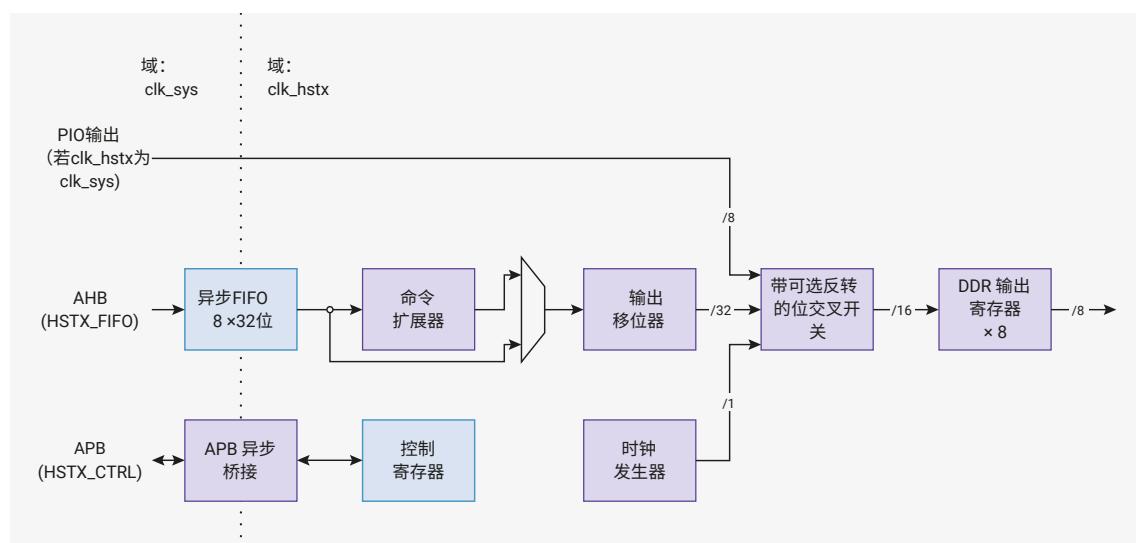

AON定时器与常电域中的电源管理子系统共享寄存器地址空间。该地址空间在本文档其他部分称为 **POWMAN**，第6.4节提供了 **POWMAN寄存器完整列表**。**AON定时器相关寄存器**如下：

- [SET\\_TIME\\_63T048](#)
- [SET\\_TIME\\_47T032](#)
- [SET\\_TIME\\_31T016](#)
- [SET\\_TIME\\_15T00](#)
- [READ\\_TIME\\_UPPER](#)
- [READ\\_TIME\\_LOWER](#)
- [ALARM\\_TIME\\_63T048](#)
- [ALARM\\_TIME\\_47T032](#)
- [ALARM\\_TIME\\_31T016](#)
- [ALARM\\_TIME\\_15T00](#)
- [定时器](#)

### 12.11. HSTX

高速串行传输（HSTX）将数据从系统时钟域传输至最多8个GPIO，传输速率独立于系统时钟。在RP2350上，GPIO12至GPIO19支持HSTX，且HSTX仅支持输出。

图126。一个32位宽的异步FIFO提供来自系统DMA的高带宽访问。  
命令扩展器操纵数据流，输出移位寄存器将在连续的HSTX时钟周期内分段传输32位数据，位交叉开关对数据位进行重排。  
输出采用双数据率：每个引脚每个时钟周期传输两位数据

HSTX通过GPIO使用DDR输出寄存器驱动数据，每个引脚每个时钟周期传输最多两位数据。HSTX将所有GPIO输出的延迟控制在300皮秒内，最大程度减少使用相邻GPIO作为伪差分驱动时的共模成分。这也有助于在时钟与输出数据同时驱动时，维持目的端的建立和保持时间。

HSTX时钟的最大频率为150 MHz，与系统时钟相同。在DDR输出操作模式下，此

is a maximum data rate of 300 Mb/s per pin. There are no limits on the frequency ratio of the system and HSTX clocks, however each clock must be individually fast enough to maintain your required throughput. Very low system clock frequencies coupled with very high HSTX frequencies might encounter system DMA bandwidth limitations, since the DMA is capped at one HSTX FIFO write per system clock cycle.

### 12.11.1. Data FIFO

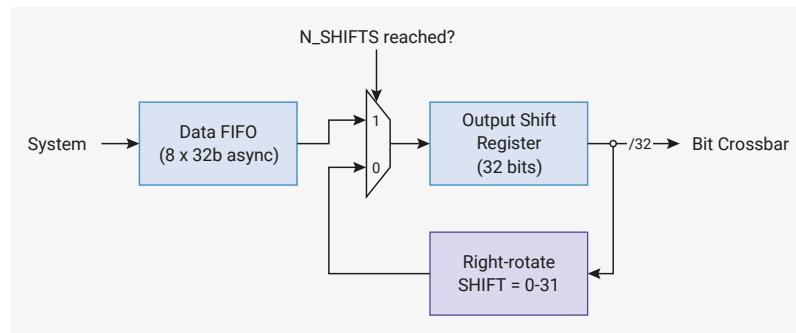

An 8-entry, 32-bit-wide FIFO buffers data between the system clock domain (`clk_sys`) and the HSTX clock domain (`clk_hstx`). This is accessed through the AHB **FASTPERI** arbiter, providing single-cycle write access from the DMA. The FIFO status is also available through this same bus interface, for faster polled processor IO; see [Section 12.11.8](#).

The FIFO is accessed through a bus interface separate from the control registers ([Section 12.11.7](#)), which take multiple cycles to access due to the asynchronous bus crossing. This design avoids incurring bus stalls on the system DMA or the **FASTPERI** arbiter when accessing the FIFO.

The HSTX side also pops 32 bits at a time from the FIFO. The word data stream from the FIFO is optionally manipulated by the command expander ([Section 12.11.5](#)) before being passed to the output shift register.

### 12.11.2. Output shift register

*Figure 127. Every cycle, the output shift register either refills 32 bits from the FIFO or recirculates data through a right-rotate function. The rotate can be used to perform left or right shifts, and to repeat data.*

The HSTX's internal data paths are 32 bits wide, but the output is narrower: no more than 16 bits can be output per HSTX cycle (8 GPIOs  $\times$  DDR). The output shift register adapts these mismatched data widths. The output shift register is a 32-bit shift register, which always refills 32 bits at a time, either from the command expander output or directly from the data FIFO.

The source of data for the output shift register is configured by the `CSR.EXPAND_EN` field:

- when set, the command expander interposes the FIFO and the output shift register
- when clear, the command expander is bypassed, popping the FIFO directly into the shift register

Whenever `CSR.EN` is low, the shift register is flushed to empty. Once HSTX has been configured, and `EN` is set high, the shift register is ready to accept data, and will pop data as soon as it becomes available.

After popping the first data word, the shift register will now shift every *HSTX clock cycle* until it becomes empty. The shift behaviour is configured by:

- `CSR.N_SHIFTS`, which determines how many times to shift before the register is considered empty
- `CSR.SHIFT`, which is a *right-rotate* applied to the shift register every cycle

`CSR.N_SHIFTS` and `CSR.SHIFT` must only be changed when `CSR.EN` is low. It is safe to change these fields in the same register write that sets `EN` from low to high.

`SHIFT  $\times$  N_SHIFTS` is not necessarily less than or equal to 32. For example, a `SHIFT` of 31 might be used to shift the register *left* by one bit per cycle, since right-rotate is a modular operation, and -1 is equal to 31 under a modulus of 32.

When the shift register is about to become empty, it will immediately refill with fresh data from the command expander or FIFO if data is available. When data is available, the shift register is never empty for any cycle. If data is not available,

每个引脚的最大数据速率为300 Mb/s。系统时钟与HSTX时钟之间的频率比无固定限制，但各时钟必须单独足够快以保证所需的吞吐量。极低的系统时钟频率配合极高的HSTX频率可能导致系统DMA带宽受限，因为DMA在每个系统时钟周期内最多允许一次HSTX FIFO写入。

### 12.11.1. 数据FIFO

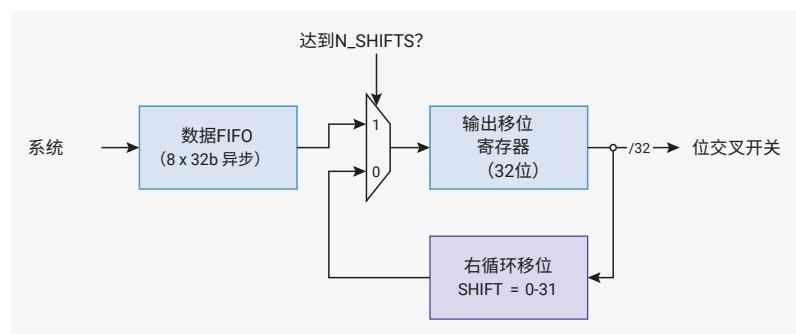

一个8级、32位宽的FIFO在系统时钟域（`clk_sys`）与HSTX时钟域（`clk_hstx`）之间缓冲数据。该FIFO通过AHB **FASTPERI**仲裁器访问，DMA可实现单周期写入。FIFO状态同样通过该总线接口提供，以支持更快速的处理器轮询IO；详见第12.11.8节。

FIFO通过与控制寄存器（第12.11.7节）不同的总线接口访问，控制寄存器因异步总线跨域访问需多个周期。该设计避免在访问FIFO时对系统DMA或 **FASTPERI**仲裁器产生总线阻塞。

HSTX端同样一次从FIFO弹出32位。FIFO中的字数据流在传递到输出移位寄存器之前，可由命令扩展器（第12.11.5节）选择性地处理。

### 12.11.2. 输出移位寄存器

图127。每个周期，输出移位寄存器要么从FIFO重新填充32位数据，要么通过右循环功能对数据进行循环。该循环功能可用于执行左移或右移位操作，以及数据重复。

HSTX的内部数据路径宽度为32位，但输出宽度较窄：每个HSTX周期输出不超过16位（8个GPIO × DDR）。输出移位寄存器用于调整这些不匹配的数据宽度。输出移位寄存器为32位宽的移位寄存器，始终一次性补充32位数据，数据来源为命令扩展器输出或直接来自数据FIFO。

输出移位寄存器的数据来源由CSR.EXPAND\_EN字段配置：

- 设置时，命令扩展器介于FIFO与输出移位寄存器之间
- 清除时，跳过命令扩展器，直接从FIFO弹出数据进入移位寄存器

每当CSR.EN为低电平时，移位寄存器将被清空。一旦配置HSTX且 EN置为高电平，移位寄存器即准备好接收数据，并将在数据可用时立即弹出。

弹出第一个数据字后，移位寄存器将在每个HSTX时钟周期执行一次移位，直至寄存器为空。移位行为由以下项配置：

- CSR.N\_SHIFTS，确定在寄存器被视为空之前应移位的次数
- CSR.SHIFT，定义每个时钟周期对移位寄存器执行的右旋转转移位

仅当CSR.EN处于低电平时，CSR.N\_SHIFTS和CSR.SHIFT方可更改。在与将EN从低电平置为高电平的寄存器写操作中同时更改这些字段是安全的。

`SHIFT × N_SHIFTS`不一定小于或等于32。例如，`SHIFT`值为31可用于每周期将寄存器左移一位；由于右旋转为模运算，在模32下，-1等价于31。

当移位寄存器即将空时，若命令扩展器或FIFO中有数据可用，将立即重新填充新数据。只要有数据可用，移位寄存器在任何周期内均不会为空。若无数据可用，

the shift register becomes empty and stops shifting until more data is provided. Once data is provided, the shift register refills and begins shifting once again.

### 12.11.3. Bit crossbar

The bit crossbar controls which bits of the output shift register appear on which GPIOs during the first and second half of each HSTX clock cycle. There is a configuration register for each pin, **BIT0** through **BIT7**:

- **BITx.SEL\_P** selects which shift register bit (0 through 31) is output for the first half of each HSTX clock cycle
- **BITx.SEL\_N** selects which shift register bit (0 through 31) is output for the second half of each clock cycle
- **BITx.INV** inverts the output (logical NOT)
- **BITx.CLK** indicates that this pin should be connected to the clock generator ([Section 12.11.4](#)) rather than the output shift register

To disable DDR behaviour set **SEL\_N** equal to **SEL\_P**. To implement a differential output, configure two pins identically except for the **INV** bit, which should be set for one pin and clear for the other.

#### 12.11.3.1. Examples: one pin

Together with the **SHIFT** and **N\_SHIFTS** controls for the shift register, the pin configuration determines the data layout passed through the HSTX. Since not all of us are accustomed to thinking in four dimensions, it's worth going through some examples with a single pin:

- **N\_SHIFTS = 32, SHIFT = 1, SEL\_P = 0, SEL\_N = 0:**
  - Shift out one bit per HSTX clock cycle, LSB-first.
  - Each cycle, the shift register advances to the right by one, and the least-significant bit at that time is presented to the pin for both halves of the cycle, since **SEL\_P** and **SEL\_N** both select the same bit.
- **N\_SHIFTS = 32, SHIFT = 31, SEL\_P = 31, SEL\_N = 31:**
  - Shift out one bit per HSTX clock cycle, MSB-first.
  - Each cycle, the shift register advances to the left by one (or rather, wraps around the right-hand edge of the register and ends up one bit left of where it started), and the most-significant bit at that time is presented to the pin.
- **N\_SHIFTS = 16, SHIFT = 2, SEL\_P = 0, SEL\_N = 1:**
  - Shift out two bits per HSTX clock cycle, LSB-first.
  - Each cycle, the shift register advances to the right by two. The least-significant bit is presented to the pin for the first half of that cycle, and the neighbouring bit is presented for the second half.
- **N\_SHIFTS = 16, SHIFT = 30, SEL\_P = 31, SEL\_N = 30:**
  - Shift out two bits per HSTX clock cycle, MSB-first.
  - Each cycle, the shift register advances to the left by two. The most-significant bit is presented to the pin for the first half of that cycle, and the neighbouring bit is presented for the latter half.
- **N\_SHIFTS = 8, SHIFT = 4, SEL\_P = 0, SEL\_N = 0:**
  - Shift out the least-significant bit in each group of 4 bits, over the course of 8 clock cycles.
  - Each cycle, the shift register advances by to the right by four. The least-significant bit of the shift register is presented to the pin. The bit indices presented to the pin are therefore 0, 4, 8, 12, 16, 20, 24, and 28.
- **N\_SHIFTS = 32, SHIFT = 4, SEL\_P = 0, SEL\_N = 0:**
  - Shift out the least-significant bit in each group of 4 bits, over the course of 8 clock cycles.
  - Each cycle, the shift register advances by to the right by four. The least-significant bit of the shift register is presented to the pin. The bit indices presented to the pin are therefore 0, 4, 8, 12, 16, 20, 24, and 28.

移位寄存器将变为空并停止移位，直至提供新数据。一旦提供数据，移位寄存器将重新填充并恢复移位。

### 12.11.3. 位交叉开关

位交叉开关控制输出移位寄存器的位于每个HSTX时钟周期上半周期和下半周期分别映射至相应GPIO。每个引脚均设有一个配置寄存器，位于 BIT0 至 BIT7：

- **BITx.SEL\_P** 选择移位寄存器的哪一位（0 至 31）在每个 HSTX 时钟周期的前半周期输出
- **BITx.SEL\_N** 选择移位寄存器的哪一位（0 至 31）在每个时钟周期的后半周期输出
- **BITx.INV** 对输出取反（逻辑非）
- **BITx.CLK** 指示该引脚应连接至时钟发生器（第 12.11.4 节），而非移位寄存器输出端

欲禁止 DDR 行为，请将 **SEL\_N** 设置为与 **SEL\_P** 相同。为实现差分输出，应将两个引脚配置相同，唯独 **INV** 位，一引脚设置为 1，另一引脚清零。

#### 12.11.3.1 示例：单个引脚

结合对移位寄存器的 **SHIFT** 和 **N\_SHIFTS** 控制，引脚配置决定经 HSTX 传输的数据布局。鉴于我们未必习惯于四维思考，现通过单引脚示例加以说明：

- **N\_SHIFTS = 32, SHIFT = 1, SEL\_P = 0, SEL\_N = 0:**
  - 每个HSTX时钟周期输出一位，最低有效位优先。
  - 每个周期中，移位寄存器向右移动一位，且该时刻的最低有效位在周期的两个半周期内均输出至引脚，因为 **SEL\_P** 和 **SEL\_N** 均选择相同的位。
- **N\_SHIFTS = 32, SHIFT = 31, SEL\_P = 31, SEL\_N = 31:**
  - 每个HSTX时钟周期输出一位，最高有效位优先。
  - 每个周期中，移位寄存器向左移动一位（或绕过寄存器的右端，最终处于起始位置左侧一位），此时的最高有效位输出至引脚。
- **N\_SHIFTS = 16, SHIFT = 2, SEL\_P = 0, SEL\_N = 1:**
  - 每个 HSTX 时钟周期移出两个比特，最低有效位优先。
  - 每个周期内，移位寄存器向右移动两个比特。该周期前半部分，最低有效位输出至引脚；后半部分输出相邻比特。
- **N\_SHIFTS = 16, SHIFT = 30, SEL\_P = 31, SEL\_N = 30:**
  - 每个 HSTX 时钟周期移出两个比特，最高有效位优先。
  - 每个周期内，移位寄存器向左移动两个比特。该周期前半部分，最高有效位输出至引脚；后半部分输出相邻比特。
- **N\_SHIFTS = 8, SHIFT = 4, SEL\_P = 0, SEL\_N = 0:**
  - 在8个时钟周期内，每组4位中的最低有效位依次移出。
  - 每个周期，移位寄存器向右移动四位。移位寄存器的最低有效位被输出到引脚。因此，输出到引脚的位索引分别为0、4、8、12、16、20、24和28。
- **N\_SHIFTS = 32, SHIFT = 4, SEL\_P = 0, SEL\_N = 0:**

- Same as the previous, but repeats the 8-cycle pattern four times before refreshing the shift register.
- Rotating by 32 restores the original value that was popped into the shift register from the FIFO or command expander.

### 12.11.3.2. Examples: multiple pins

The separation of shift register and bit crossbar allows both zipped and unzipped multi-bit records, once multiple pins are involved. For example, compare these two configurations:

- `N_SHIFTS = 8, SHIFT = 4, BIT0.SEL_P = 0, BIT0.SEL_N = 2, BIT1.SEL_P = 1, BIT1.SEL_N = 3:`
  - Each 32-bit word consists of 16 bit-pairs, and a new bit-pair is presented to `BIT0` and `BIT1` twice per cycle.
  - The shift register advances by 4 every cycle, introducing two new bit-pairs to the rightmost four bits of the shift register
- `N_SHIFTS = 8, SHIFT = 2, BIT0.SEL_P = 0, BIT0.SEL_N = 1, BIT1.SEL_P = 16, BIT1.SEL_N = 17:`
  - Each 32-bit word consists of a pair of 16-bit values, each of which is shifted to one pin out of `BIT0` and `BIT1` at a rate of two bits per cycle.
  - The shift register advances by two every cycle, introducing a new bit-pair to bits 1:0 for the `BIT0` pin, and also introducing a new bit-pair to bits 17:16 for the `BIT1` pin.

Depending on software needs, it might be preferable to pack together all of the bits output on the same cycle (zipped records), or all of the bits that go through the same pin (unzipped records), so HSTX supports both.

As a final, concrete example, take TMDS (used in DVI): here each 32-bit word contains  $3 \times 10$ -bit TMDS symbols, each of which is serialised to a differential pair over the course of 10 TMDS bit times. For performance, it's preferable to make each HSTX clock period equal to two TMDS bit periods, by leveraging the DDR capability. A possible configuration would therefore be:

- `CSR: N_SHIFTS = 5, SHIFT = 2`
- `BIT0: SEL_P = 0, SEL_N = 1, INV = 0`
- `BIT1: SEL_P = 0, SEL_N = 1, INV = 1`
- `BIT2: SEL_P = 10, SEL_N = 11, INV = 0`
- `BIT3: SEL_P = 10, SEL_N = 11, INV = 1`
- `BIT4: SEL_P = 20, SEL_N = 21, INV = 0`
- `BIT5: SEL_P = 20, SEL_N = 21, INV = 1`

The missing piece for TMDS is the clock, which has a period of 10 TMDS bit periods, or 5 HSTX clock periods when shifting two bits per cycle per pin. HSTX has a special-purpose clock generator so that pseudo-clock bits do not have to be packed into the FIFO data stream. The clock generator is covered in the next section.

### 12.11.4. Clock generator

The clock generator is a counter that provides a periodic signal over the course of `n` HSTX clock cycles, configured by `CSR.CLKDIV`. The clock period is always an integer number of HSTX clock cycles, in the range 1 to 16 inclusive. The clock generator supports both odd and even periods, using the DDR outputs to support mid-HSTX-cycle output transitions. There is only a single clock generator – to emulate multiple clocks, pack pseudo-clock bits into FIFO data.

The clock generator increments on cycles where the output shift register is shifted. Generally, the clock period will be a divisor of `CSR.N_SHIFTS` so that clock and data maintain a consistent alignment. In the TMDS example in the previous section, a `CLKDIV` of 5 would be suitable, so that the clock repeats every time the shift register refreshes. This matches the requirement for a TMDS clock period of 10 bit periods, since two bits are transferred every cycle.

The clock generator output is connected to any pin whose `BITx.CLK` bit is set (e.g. `BIT0.CLK`). To produce differential

- 与前述相同，但在刷新移位寄存器之前，将8周期模式重复四次。
- 旋转32位将恢复从FIFO或命令扩展器弹入移位寄存器的原始值。

### 12.11.3.2 示例：多引脚

移位寄存器与位交叉开关的分离允许在涉及多个引脚时，既支持压缩也支持未压缩的多位记录。例如，比较以下两种配置：

- N\_SHIFTS = 8, SHIFT = 4, BIT0.SEL\_P = 0, BIT0.SEL\_N = 2, BIT1.SEL\_P = 1, BIT1.SEL\_N = 3:**
  - 每个32位字由16对位组成，每个时钟周期向 **BIT0** 和 **BIT1** 提供两个新的位对。
  - 移位寄存器每周期移动4位，在移位寄存器最右侧的四个位引入两个新的位对。
- N\_SHIFTS = 8, SHIFT = 2, BIT0.SEL\_P = 0, BIT0.SEL\_N = 1, BIT1.SEL\_P = 16, BIT1.SEL\_N = 17:**
  - 每个32位字由一对16位值组成，每个值以每周期两位的速率移向 **BIT0** 和 **BIT1** 的对应引脚。
  - 移位寄存器每个周期前进两个位置，为位1:0的 **BIT0** 引脚引入一对新比特，同时为位17:16的 **BIT1** 引脚引入另一对新比特。

根据软件需求，可能更适合将同一周期输出的所有位打包在一起（压缩记录），或将所有经过同一引脚的位分开（非压缩记录），因此HSTX支持这两种方式。

作为最终且具体的示例，考虑TMDS（用于DVI）：每个32位字包含3个10位TMDS符号，每个符号在10个TMDS比特周期内串行传输至一对差分信号线上。为提高性能，最好利用DDR功能，使每个HSTX时钟周期等于两个TMDS比特周期。因此，可能的配置如下：

- CSR: N\_SHIFTS = 5, SHIFT = 2**
- BIT0: SEL\_P = 0, SEL\_N = 1, INV = 0**
- BIT1: SEL\_P = 0, SEL\_N = 1, INV = 1**
- BIT2: SEL\_P = 10, SEL\_N = 11, INV = 0**
- BIT3: SEL\_P = 10, SEL\_N = 11, INV = 1**
- BIT4: SEL\_P = 20, SEL\_N = 21, INV = 0**
- BIT5: SEL\_P = 20, SEL\_N = 21, INV = 1**

TMDS缺失的部分是时钟，其周期为10个TMDS位周期，或当每个引脚每周期移位两个位时为5个HSTX时钟周期。HSTX配备专用时钟发生器，因而无需将伪时钟位打包进 FIFO数据流。时钟发生器将在下一节详细介绍。

### 12.11.4. 时钟发生器

时钟发生器是一个计数器，在 **n** 个HSTX时钟周期内提供周期性信号，其配置由 **CSR.CLKDIV** 决定。时钟周期始终为1至16之间的整数个HSTX时钟周期。时钟发生器支持奇数和偶数周期，利用 **DDR** 输出以支持HSTX时钟周期中间的输出跳变。仅有单一时钟发生器——若需模拟多个时钟，应将伪时钟位打包到FIFO数据中。

时钟发生器在输出移位寄存器移位的周期内递增。通常，时钟周期应为 **CSR.N\_SHIFTS** 的因数，以确保时钟与数据维持一致的对齐。在前述TMDS示例中，设置 **CLKDIV** 为5适宜，使时钟在移位寄存器刷新时重复。此设置满足TMDS时钟周期为10位周期的要求，因每周期传输两个比特。

时钟发生器输出连接至任一其 **BITx.CLK** 位被置位的引脚（例如 **BIT0.CLK**）。要生成差分

clock outputs, connect the clock to two pins, and invert one of them.

The `CSR.CLKPHASE` field defines the initial phase (count) of the clock generator, configured in units of one half HSTX clock cycle. The clock generator resets whenever `CSR.EN` is low and holds at this initial phase. Once `CSR.EN` is set and the output shift register begins to shift, the clock generator advances.

Clock generator output whilst `CSR.EN` is low is determined by the relation of clock period and initial clock phase: if the initial clock phase is less than one half clock period, then the output is initially low. Otherwise, it is initially high. The clock generator can be thought of as being low for the first half of each generation period, and high for the second half.

The maximum `CSR.CLKPHASE` is only 15 *half* HSTX clock cycles. The maximum `CSR.CLKDIV` is 16 *full* HSTX clock cycles: initial phases of greater than or equal to 180 degrees with the maximum clock period require the inversion of the clock using the bit crossbar inversion controls.

Only change `CSR.CLKPHASE` and `CSR.CLKDIV` when `CSR.EN` is low. It is safe to modify them in the same register write that sets `EN` from low to high.

#### 12.11.4.1. Example: centre-aligned clock

When transmitting source-synchronous data, the data sink (the receiver) must not see data transitions too late before or too soon after the active edges of the clock. Violating these setup and hold constraints can lead to undefined operation of the external data sink.

Since the HSTX output delays are all mutually balanced, you can meet these constraints by placing clock transitions halfway between data transitions, known as centre-aligned clocking.

Since this positions the clock with a temporal resolution of one half of a bit time, the maximum data rate is one bit per HSTX clock cycle per pin. Because the clock already uses DDR, you cannot use DDR to increase the data rate. Therefore for all `BIT0` through `BIT7`, `BITx.SEL_N` is equal to `BITx.SEL_P`.

For single-data-rate data, with an active rising edge, use the following clock generator settings:

- `CSR.CLKDIV` = 1 (1 HSTX clock period)
- `CSR.CLKPHASE` = 1 (1/2 HSTX clock period)

The clock is delayed by half an HSTX cycle, to offset it from the launch of the first data.

For single-data-rate data, with an active *falling* edge, use the following clock generator settings:

- `CSR.CLKDIV` = 1 (1 HSTX clock period)
- `CSR.CLKPHASE` = 2 (1 HSTX clock period)

Alternatively, you could use the same settings as an active-rising edge clock, with the clock output inverted via the bit crossbar configuration.

For double-data-rate data, with active rising and active falling edges, use the following clock generator settings:

- `CSR.CLKDIV` = 2 (2 HSTX clock period)
- `CSR.CLKPHASE` = 1 (1/2 HSTX clock period)

In all three cases, the data rate is the same, at 1 bit per HSTX clock cycle, per pin.

#### 12.11.5. Command expander

时钟输出，请将时钟信号连接至两个引脚，并使其中一个引脚的信号反相。

CSR.CLKPHASE 字段定义时钟发生器的初始相位（计数），单位为半个 HSTX 时钟周期。当 CSR.EN 处于低电平时，时钟发生器复位并保持在该初始相位。一旦 CSR.EN 被置位且输出移位寄存器开始移位，时钟发生器开始计数。

在 CSR.EN 为低电平时，时钟发生器输出由时钟周期与初始时钟相位的关系决定：若初始时钟相位小于半个时钟周期，输出初始为低电平；否则，输出初始为高电平。时钟发生器可视为在每个生成周期的前半周期输出低电平，后半周期输出高电平。

CSR.CLKPHASE 最大值仅为 15 半个 HSTX 时钟周期。最大 CSR.CLKDIV 为 16 完整 HSTX 时钟周期：当初始相位大于或等于 180 度且时钟周期为最大时，须使用位交叉反转控制以反转时钟信号。

仅当 CSR.EN 处于低电平时，方可更改 CSR.CLKPHASE 和 CSR.CLKDIV。可在设置 EN 从低电平到高电平的同一次寄存器写入操作中安全修改它们。

#### 12.11.4.1 示例：居中对齐时钟

在传输源同步数据时，数据接收端（接收器）不得在时钟的有效沿之前过早，或在有效沿之后过早检测到数据跳变。违反这些建立时间和保持时间约束可能导致外部数据接收端的操作异常或不确定。

由于所有 HSTX 输出延迟相互平衡，您可通过将时钟跳变定位于数据跳变之间的中点，即使用居中对齐时钟方式，来满足这些时序约束。

由于时钟的位置具有半个比特时间的时间分辨率，最大数据速率为每针脚每个 HSTX 时钟周期一个比特。鉴于时钟已采用 DDR，不能通过 DDR 进一步提高数据速率。因此，对于所有 BIT0 到 BIT7，`BITx.SEL_N` 等于 `BITx.SEL_P`。

对于单数据速率数据，在上升沿有效时，请使用以下时钟发生器设置：

- `CSR.CLKDIV = 1` (1 个 HSTX 时钟周期)
- `CSR.CLKPHASE = 1` (1/2 个 HSTX 时钟周期)

时钟延迟半个 HSTX 周期，以使其与第一个数据的触发时间错开。

对于单数据速率数据，在下降沿有效时，请使用以下时钟发生器设置：

- `CSR.CLKDIV = 1` (1 个 HSTX 时钟周期)
- `CSR.CLKPHASE = 2` (1 个 HSTX 时钟周期)

或者，您可以使用与上升沿有效时钟相同的设置，通过位交叉开关配置反转时钟输出。

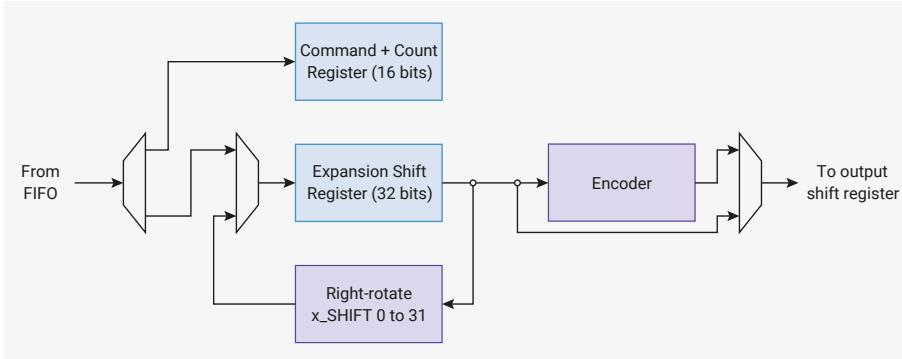

对于双数据速率数据，在上升沿和下降沿均有效时，请使用以下时钟发生器设置：

- `CSR.CLKDIV = 2` (2 个 HSTX 时钟周期)
- `CSR.CLKPHASE = 1` (1/2 个 HSTX 时钟周期)

在所有三种情况下，数据速率均相同，为每个引脚每个 HSTX 时钟周期 1 位。

#### 12.11.5. 命令扩展器

Figure 128. A mixture of commands and data are popped from the FIFO. Data can be repeated or shifted through the expansion shift register, and optionally passed through an encoder before passing on to the output shift register.

The command expander can be inserted inline between the data FIFO and the output shift register to manipulate the stream of data words. In general, the output stream is larger than the input stream, hence the name expander. The commander expander is enabled by setting `CSR.EXPAND_EN`. Only modify this field when `CSR.EN` is low. It is safe to modify this field in the same register write that sets `EN` from low to high. When the command expander is disabled, data passes directly from the data FIFO to the output shift register without being modified by the expander.

When the command expander is enabled, the data FIFO carries a mixture of data and commands for the expander. Each command consists of a 4-bit opcode and a 12-bit length, packed in the 16 LSBs of a data FIFO word, with the opcode in bits 15 through 12, and the length in bits 11 through 0. The available commands are:

- `0x0`: RAW
- `0x1`: RAW\_REPEAT
- `0x2`: TMDS
- `0x3`: TMDS\_REPEAT
- `0xf`: NOP

When the HSTX is first enabled, if the command expander is enabled, it expects the first word in the data FIFO to be a command. If this command is not a `NOP`, it will be followed by some amount of data, then another command. Operation continues in this manner, with runs of data interspersed with commands. A command always acts as a prefix to the data that follows it in the FIFO.

The count field determines the number of words output by this command to the output shift register downstream, from 1 to 4095. A count of 0 is reserved to mean "infinite". The number of words that this command reads from the data FIFO in order to produce the specified quantity of downstream data depends on the command and the `EXPAND_SHIFT.ENC_N_SHIFTS` and `EXPAND_SHIFT.RAW_N_SHIFTS` register fields.

The expansion shift register always pops from the FIFO once at the beginning of the command. After this point, commands bearing the `x_REPEAT` suffix continue to circulate the same contents through the shift register, rotating right by `EXPAND_SHIFT.ENC_SHIFT` or `EXPAND_SHIFT.RAW_SHIFT` each time the output shift register pulls new data from the command expander. Use a shift of 0 to repeat identical data without shifting. This is useful, for example, for transmitting runs of the same TMDS control symbol during horizontal blanking periods in DVI.

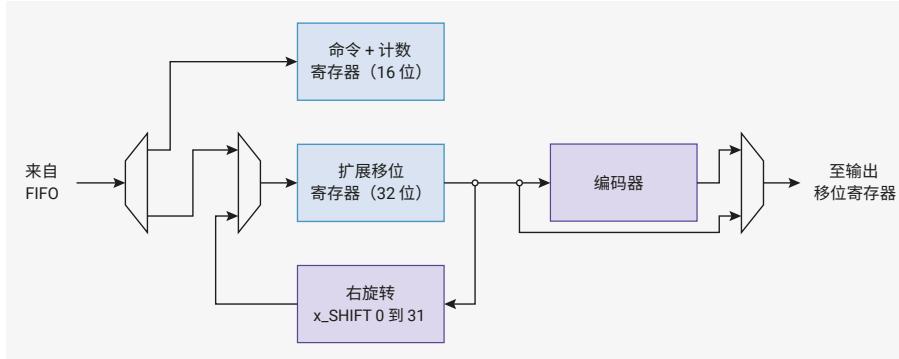

RP2350 only implements a TMDS encoder, reserving the remaining opcode space for additional encoders in the future. `RAW` and `RAW_REPEAT` commands bypass the encoder. `TMDS` and `TMDS_REPEAT` commands are TMDS-encoded before being passed to the output shift register. `NOP` commands have no data, therefore whether they bypass the encoder or not is a philosophical question beyond the scope of this datasheet.

The `EXPAND_SHIFT` register has two copies for each of its fields. Fields prefixed with `RAW_` are used for `RAW` and `RAW_REPEAT` commands. All other commands use fields prefixed with `ENC_`, which pass through the encoder. For example, in DVI, TMDS control symbols using `RAW_REPEAT` commands may be unshifted. Pixel data using TMDS commands may be shifted out one pixel at a time, so it is useful to have banked shift controls.

The `EXPAND_SHIFT.ENC_N_SHIFTS` and `EXPAND_SHIFT.RAW_N_SHIFTS` fields control how often the expansion shift register is refilled for encoded and raw commands respectively. `x_REPEAT` commands ignore these fields since they never refill from the FIFO, and function similarly to the `CSR.N_SHIFTS` field that controls the output shift register.

The command expander can only pop from the data FIFO once per cycle, so heavy use of commands (particularly `NOP`

图 128。从 FIFO 弹出的是命令和数据的混合体。数据可在通过扩展移位寄存器时重复或移位，且可选择经过编码器后传递至输出移位寄存器。

命令扩展器可在线插入于数据 FIFO 与输出移位寄存器之间，以操作数据字流。一般情况下，输出流比输入流更大，因此称为扩展器。通过设置 CSR.EXPAND\_EN 启用命令扩展器。仅当 CSR.EN 为低时方可修改此字段。与同时将 EN 从低置高的寄存器写操作中修改该字段是安全的。当命令扩展器被禁用时，数据直接从数据 FIFO 传送至输出移位寄存器，且不会被扩展器修改。

当命令扩展器启用时，数据 FIFO 包含扩展器使用的混合数据与命令。每条命令由 4 位操作码和 12 位长度组成，封装于数据 FIFO 字的 16 位最低有效位中，操作码位于第 15 至 12 位，长度位于第 11 至 0 位。可用命令如下：

- 0x0: RAW
- 0x1: RAW\_REPEAT
- 0x2: TMDS
- 0x3: TMDS\_REPEAT
- 0xf: NOP

当 HSTX 首次启用且命令扩展器开启时，它期望数据 FIFO 中的第一个字为命令。若该命令非 NOP，则后续会跟随一定数量的数据，然后是下一条命令。操作以此种方式继续，数据块与命令交替出现。命令始终作为紧随其后的 FIFO 中数据的前缀。

计数字段确定该命令向下游输出移位寄存器输出的数据字数，范围为 1 至 4095。计数值 0 被保留用以表示“无限”。该命令为产生指定数量的下游数据，从数据 FIFO 读取的字数依赖于命令及 EXPAND\_SHIFT.ENC\_N\_SHIFTS 和 EXPAND\_SHIFT.RAW\_N\_SHIFTS 寄存器字段。

扩展移位寄存器在命令开始时始终从 FIFO 弹出一次。此后，带有 x\_REPEAT 后缀的命令持续通过移位寄存器循环相同内容，每当输出移位寄存器从命令扩展器读取新数据时，按 EXPAND\_SHIFT.ENC\_SHIFT 或 EXPAND\_SHIFT.RAW\_SHIFT 向右旋转。使用移位值 0 以无移位方式重复相同数据。例如，在 DVI 的水平消隐期间传输连续相同的 TMDS 控制符号时，此功能非常有用。

RP2350 仅实现了 TMDS 编码器，保留剩余的操作码空间以便将来添加更多编码器。

RAW 和 RAW\_REPEAT 命令绕过编码器。TMDS 和 TMDS\_REPEAT 命令在传递给输出移位寄存器之前先进行 TMDS 编码。NOP 命令不包含数据，因此其是否绕过编码器属于超出本数据手册范围的哲学性问题。

EXPAND\_SHIFT 寄存器中每个字段均有两个副本。带有 RAW\_ 前缀的字段用于 RAW 和 RAW\_REPEAT 命令。所有其他命令使用带有 ENC\_ 前缀的字段，这些字段通过编码器传递。例如，在 DVI 中，使用 RAW\_REPEAT 命令的 TMDS 控制符号可能不会被移位。使用 TMDS 命令的像素数据可能一次移出一个像素，因此具有分组移位控制非常实用。

EXPAND\_SHIFT.ENC\_N\_SHIFTS 和 EXPAND\_SHIFT.RAW\_N\_SHIFTS 字段分别控制编码命令和原始命令的扩展移位寄存器的重填频率。x\_REPEAT 命令忽略这些字段，因为它们从不从 FIFO 重填，且功能类似于控制输出移位寄存器的 CSR.N\_SHIFTS 字段。

命令扩展器每个周期仅能从数据 FIFO 弹出一次，因此频繁使用命令（特别是 NOP）

commands) can impact HSTX throughput. For use cases that output from the HSTX on every cycle, configure the output shift register with [CSR.N\\_SHIFTS > 1](#). This is required because the command expander cannot output data on the cycle where it pops a command from the FIFO, so the expansion shift register is empty for at least one cycle.

### 12.11.6. PIO-to-HSTX coupled mode

HSTX can connect up to 8 PIO pin outputs to the bit crossbar. Only use the bit crossbar when [clk\\_hstx](#) connects directly to [clk\\_sys](#) ([CLK\\_HSTX\\_CTRL.AUXSRC](#) must select [clk\\_sys](#)).

**NOTE**

Running the two clocks at the same frequency is not sufficient. You must select [clk\\_sys](#) directly.

To enable coupled mode, set [CSR.COUPLED\\_MODE](#). The [COUPLED\\_SEL](#) field in the same register selects the PIO instance, 0 through 2, to couple to HSTX. When coupled mode is enabled, IO outputs 12 through 19 inclusive on the selected PIO instance appear at bit crossbar [PSEL\\_N](#) and [PSEL\\_P](#) indices 31:24, replacing the most significant 8 bits of the output shift register from the point of view of the bit crossbar.

This mode allows PIO programs to make use of the HSTX's DDR outputs. You can use this mode to drive a clock at the full system clock rate or to position clock transitions relative to data transitions with half-system-clock-cycle resolution.

The PIO outputs used for couple mode are always bits 19 through 12 of the pin outputs driven from that GPIO, independent of [GPIOBASE](#). When [GPIOBASE](#) is 0, the PIO outputs used for coupled mode are those that would normally appear on the [HSTX](#) pins. When [GPIOBASE](#) is 16, this uses the PIO outputs that would appear on GPIOs 28 through 35.

The operation of PIO is not affected in any way by coupled mode being enabled.

Outputs presented through the HSTX coupled mode interface have one additional system clock cycle of delay compared to those presented directly from PIO to the pads.

### 12.11.7. List of control registers

The control registers start at a base address of [0x400c0000](#) (defined as [HSTX\\_CTRL\\_BASE](#) in the SDK). They are accessed through an asynchronous bus crossing, so each bus access takes several cycles, the exact figure depending on the ratio of [clk\\_sys](#) and [clk\\_hstx](#).

Table 1253. List of HSTX\_CTRL registers

Offset	Name	Info
0x00	<a href="#">CSR</a>	
0x04	<a href="#">BIT0</a>	Data control register for output bit 0
0x08	<a href="#">BIT1</a>	Data control register for output bit 1
0x0c	<a href="#">BIT2</a>	Data control register for output bit 2
0x10	<a href="#">BIT3</a>	Data control register for output bit 3
0x14	<a href="#">BIT4</a>	Data control register for output bit 4
0x18	<a href="#">BIT5</a>	Data control register for output bit 5
0x1c	<a href="#">BIT6</a>	Data control register for output bit 6
0x20	<a href="#">BIT7</a>	Data control register for output bit 7
0x24	<a href="#">EXPAND_SHIFT</a>	Configure the optional shifter inside the command expander
0x28	<a href="#">EXPAND_TMDS</a>	Configure the optional TMDS encoder inside the command expander

命令) 会影响 HSTX 的吞吐量。对于在每个周期均从 HSTX 输出的用例，需将输出移位寄存器配置为 CSR.N\_SHIFTS > 1。原因在于命令扩展器无法在弹出命令的周期输出数据，导致扩展移位寄存器至少空闲一个周期。

### 12.11.6. PIO与HSTX耦合模式

HSTX 最多可连接 8 个 PIO 引脚输出至位交叉开关。仅当 `clk_hstx`直接连接至 `clk_sys`时才使用位交叉开关 (CLK\_HSTX\_CTRL.AUXSRC 必须选择 `clk_sys`)。

#### 注意

仅使两个时钟以相同频率运行是不够的。您必须直接选择 `clk_sys`。

要启用耦合模式，请设置 CSR.COUPLLED\_MODE。同一寄存器中的COUPLED\_SEL字段选择要与 HSTX 耦合的 PIO 实例（编号 0至2）。启用耦合模式时，所选 PIO 实例中编号12至19的 IO 输出将在位交叉开关 PSEL\_N和 PSEL\_P索引31:24处出现，从位交叉开关的视角替代输出移位寄存器的最高有效8位。

该模式允许 PIO 程序利用 HSTX 的 DDR 输出。您可以使用此模式以完整系统时钟速率驱动时钟，或以半系统时钟周期分辨率定位时钟转换相对于数据转换的位置。

用于耦合模式的 PIO 输出始终是对应 GPIO 驱动的引脚输出中的第19位至第12位，且独立于 GPIOBASE。当 `GPIOBASE`为0时，用于耦合模式的 PIO 输出即是通常出现在 `HSTX`引脚上的输出。当 `GPIOBASE`为16时，该设置使用的PIO输出对应GPIO 28至35。

启用耦合模式不会以任何方式影响PIO的操作。

通过HSTX耦合模式接口输出相较于直接由PIO输出到引脚存在一个额外的系统时钟周期延迟。

### 12.11.7. 控制寄存器列表

控制寄存器起始于基地址 `0x400c0000` (在SDK中定义为HSTX\_CTRL\_BASE)。它们通过异步总线交叉访问，因此每次总线访问耗时多个时钟周期，具体时长取决于 `clk_sys`与 `clk_hstx`的比例。

表 1253。HSTX\_CTRL 寄存器列表

偏移量	名称	说明
0x00	CSR

## HSTX\_CTRL: CSR Register

Offset: 0x00

Table 1254. CSR Register

Bits	Description	Type	Reset
31:28	<p><b>CLKDIV:</b> Clock period of the generated clock, measured in HSTX clock cycles. Can be odd or even. The generated clock advances only on cycles where the shift register shifts.</p> <p>For example, a clkdiv of 5 would generate a complete output clock period for every 5 HSTX clocks (or every 10 half-clocks).</p> <p>A CLKDIV value of 0 is mapped to a period of 16 HSTX clock cycles.</p>	RW	0x1
27:24	<p><b>CLKPHASE:</b> Set the initial phase of the generated clock.</p> <p>A CLKPHASE of 0 means the clock is initially low, and the first rising edge occurs after one half period of the generated clock (i.e. CLKDIV/2 cycles of clk_hstx). Incrementing CLKPHASE by 1 will advance the initial clock phase by one half clk_hstx period. For example, if CLKDIV=2 and CLKPHASE=1:</p> <ul style="list-style-type: none"> <li>* The clock will be initially low</li> <li>* The first rising edge will be 0.5 clk_hstx cycles after asserting first data</li> <li>* The first falling edge will be 1.5 clk_hstx cycles after asserting first data</li> </ul> <p>This configuration would be suitable for serialising at a bit rate of clk_hstx with a centre-aligned DDR clock.</p> <p>When the HSTX is halted by clearing CSR_EN, the clock generator will return to its initial phase as configured by the CLKPHASE field.</p> <p>Note CLKPHASE must be strictly less than double the value of CLKDIV (one full period), else its operation is undefined.</p>	RW	0x0
23:21	Reserved.	-	-
20:16	<p><b>N_SHIFTS:</b> Number of times to shift the shift register before refilling it from the FIFO. (A count of how many times it has been shifted, <b>not</b> the total shift distance.)</p> <p>A register value of 0 means shift 32 times.</p>	RW	0x05
15:13	Reserved.	-	-
12:8	<p><b>SHIFT:</b> How many bits to right-rotate the shift register by each cycle.</p> <p>The use of a rotate rather than a shift allows left shifts to be emulated, by subtracting the left-shift amount from 32. It also allows data to be repeated, when the product of SHIFT and N_SHIFTS is greater than 32.</p>	RW	0x06
7	Reserved.	-	-
6:5	<b>COUPLED_SEL:</b> Select which PIO to use for coupled mode operation.	RW	0x0

## HSTX\_CTRL: CSR寄存器

偏移: 0x00

表1254. CSR  
寄存器

位	描述	类型	复位
31:28	<p><b>CLKDIV:</b> 生成时钟的周期，单位为HSTX时钟周期。 可以为奇数或偶数。生成的时钟仅在移位寄存器移位的周期内前进。</p> <p>例如，clkdiv为5时，每5个HSTX时钟周期（或每10个半时钟周期）生成一个完整的输出时钟周期。</p> <p>CLKDIV值为0时，映射为16个HSTX时钟周期的周期。</p>	读写	0x1
27:24	<p><b>CLKPHASE:</b> 设置生成时钟的初始相位。</p> <p>CLKPHASE为0表示时钟初始为低电平，第一个上升沿发生在生成时钟半周期之后（即clk_hstx的CLKDIV/2个周期）。CLKPHASE每增加1，将使初始时钟相位提前半个clk_hstx周期。例如，当CLKDIV=2且CLKPHASE=1时：</p> <ul style="list-style-type: none"> <li>* 时钟初始为低电平</li> <li>* 第一个上升沿将在首次数据激活后0.5个clk_hstx周期出现</li> <li>* 第一个下降沿将在首次数据激活后1.5个clk_hstx周期出现</li> </ul> <p>此配置适合以clk_hstx比特率串行化，并采用中心对齐DDR时钟。</p> <p>当通过清除CSR_EN停止HSTX时，时钟发生器将恢复到由CLKPHASE字段配置的初始相位。</p> <p>注意：CLKPHASE必须严格小于CLKDIV的两倍（即一个完整周期），否则其操作行为未定义。</p>	读写	0x0
23:21	保留。	-	-
20:16	<p><b>N_SHIFTS:</b> 在从FIFO重新填充移位寄存器之前移位的次数。（计数的是移位的次数，不是总移位距离。）</p> <p>寄存器值为0表示移位32次。</p>	读写	0x05
15:13	保留。	-	-
12:8	<p><b>SHIFT:</b> 每个周期对移位寄存器右旋转的位数。</p> <p>使用旋转而非移位可通过从32中减去左移位量来模拟左移。当SHIFT与N_SHIFTS的乘积大于32时，该机制还允许数据重复。</p>	读写	0x06
7	保留。	-	-
6:5	<b>COUPLED_SEL:</b> 选择用于耦合模式操作的PIO端口。	读写	0x0

Bits	Description	Type	Reset
4	<p><b>COUPLED_MODE:</b> Enable the PIO-to-HSTX 1:1 connection. The HSTX must be clocked <b>directly</b> from the system clock (not just from some other clock source of the same frequency) for this synchronous interface to function correctly.</p> <p>When COUPLED_MODE is set, BITx_SEL_P and SEL_N indices 24 through 31 will select bits from the 8-bit PIO-to-HSTX path, rather than shifter bits. Indices of 0 through 23 will still index the shift register as normal.</p> <p>The PIO outputs connected to the PIO-to-HSTX bus are those same outputs that would appear on the HSTX-capable pins if those pins' FUNCSELs were set to PIO instead of HSTX.</p> <p>For example, if HSTX is on GPIOs 12 through 19, then PIO outputs 12 through 19 are connected to the HSTX when coupled mode is engaged.</p>	RW	0x0
3:2	Reserved.	-	-
1	<p><b>EXPAND_EN:</b> Enable the command expander. When 0, raw FIFO data is passed directly to the output shift register. When 1, the command expander can perform simple operations such as run length decoding on data between the FIFO and the shift register.</p> <p>Do not change CXPD_EN whilst EN is set. It's safe to set CXPD_EN simultaneously with setting EN.</p>	RW	0x0
0	<p><b>EN:</b> When EN is 1, the HSTX will shift out data as it appears in the FIFO. As long as there is data, the HSTX shift register will shift once per clock cycle, and the frequency of popping from the FIFO is determined by the ratio of SHIFT and SHIFT_THRESH.</p> <p>When EN is 0, the FIFO is not popped. The shift counter and clock generator are also reset to their initial state for as long as EN is low. Note the initial phase of the clock generator can be configured by the CLKPHASE field.</p> <p>Once the HSTX is enabled again, and data is pushed to the FIFO, the generated clock's first rising edge will be one half-period after the first data is launched.</p>	RW	0x0

## 12.12. TRNG

### 12.12.1. Overview

RP2350 contains an Arm IP-based True Random Number Generator block. It supports the following features:

- Compliance with FIPS Publication 140-2, BSI AIS-31, and NIST SP 800-90B
- Produces approximately 7.5 kb/s of entropy when the core runs at 150 MHz

On request, the TRNG block generates a block of 192 entropy bits generated by automatically processing a series of periodic samples from the TRNG block's internal Ring Oscillator (ROSC).

位	描述	类型	复位
7:5	<b>L0_NBITS</b> : 通道0 TMDS编码器的有效数据位数，从旋转数据的第7位起算。字段值 0 → 7 对应编码长度为 1 → 8 位。	读写	0x0

## 12.12. TRNG

### 12.12.1. 概述

RP2350包含基于Arm IP的真正随机数生成模块。支持以下功能：

- 符合FIPS Publication 140-2、BSI AIS-31及NIST SP 800-90B标准
- 当核心运行于150 MHz时，产生约7.5 kb/s的熵

应请求，TRNG模块生成一块192位的熵数据，通过自动处理来自TRNG模块内部环形振荡器（ROSC）的一系列周期性采样产生。

The TRNG block's ROSC is a free-running oscillator with no direct connection to the system clocks on RP2350. As a result, the ROSC generally runs asynchronously to the system clocks.

After a sufficient number of samples have been collected, the TRNG block completes the generation process and presents the random number in the [EHR\\_DATA\[x\]](#) result registers.

For more information, see [ARM IP - True Random Number Generator](#)

## 12.12.2. Configuration

The TRNG block contains three different built-in entropy checking mechanisms: At reset, these are all enabled by default and hence do not require explicit enabling.

You can configure the TRNG block in the following ways:

- Configure the frequency of the ROSC by selecting one of four ROSC **chain lengths**, see [TRNG\\_CONFIG](#).
- Configure the ROSC sampling period in terms of system clock ticks, see [SAMPLE\\_CNT1](#).

Because the system clock generally runs much faster than the ROSC, the sampling period is expected to be at least a few tens of system clock ticks.

Because the characteristics of the TRNG ROSC and system clock frequency will differ for each implementation of the TRNG IP block, Arm details a TRNG characterisation procedure to determine the most appropriate ROSC chain length and sampling frequency settings on each SoC design. For details about that characterisation procedure, see [ARM TrustZone True Number Generator](#).

Software drivers for the RP2350 TRNG block do not utilise the standard approach (see [Section 12.12.4](#)). As a result, software does not configure the ROSC length and sample count settings provided by the Arm characterisation procedure.

When configuring the TRNG block, consider the following principles:

- As average generation time increases, result quality increases and failed entropy checks decrease.
- A low sample count decreases average generation time, but increases the chance of NIST test-failing results and failed entropy checks.

For acceptable results with an average generation time of about 2 milliseconds, use ROSC chain length settings of 0 or 1 and sample count settings of 20-25.

Larger sample count settings (e.g. 100) provide proportionately slower average generation times. These settings significantly reduce, but do not eliminate NIST test failures and entropy check failures. Results occasionally take an especially long time to generate.

## 12.12.3. Operation

To initiate TRNG generation, set the [RND\\_SRC\\_EN](#) bit in [RND\\_SOURCE\\_ENABLE](#). The TRNG will run until:

- It has successfully completed the generation of a random number.
- One, or more, of the internal entropy checking mechanisms indicates a failed run.

In either case, you can read the resultant status from [RNG\\_ISR](#).

To generate TRNG block interrupts, set bits in [RNG\\_IMR](#). Use [RNG\\_ICR](#) to clear active interrupt status bits.

The [EHR\\_DATA\[x\]](#) registers read 0 until successful generation has occurred, so the CPU cannot read random number results during generation,

After successful generation, read the last result register, [EHR\\_DATA\[5\]](#) to clear all of the result registers. If the result fails an entropy check, no results are presented and the [EHR\\_DATA\[x\]](#) registers all read as 0.

After TRNG generation and when not in use, the [RND\\_SRC\\_EN](#) bit should be cleared.

TRNG模块内的ROSC为自由振荡器，且与RP2350系统时钟无直接连接，因此ROSC通常异步于系统时钟运行。

采集足够数量的样本后，TRNG模块完成生成过程，并将随机数输出至EHR\_DATA[x]结果寄存器。

更多详情，请参见ARM IP - 真随机数生成器

### 12.12.2. 配置

TRNG模块包含三种内置熵检测机制：复位时默认全部启用，无需显式激活。

您可以通过以下方式配置TRNG模块：

- 通过选择四种ROSC链长之一，配置ROSC的频率，详见TRNG\_CONFIG。
- 根据系统时钟周期配置ROSC采样周期，详见SAMPLE\_CNT1。

由于系统时钟通常远快于ROSC，采样周期预计至少为数十个系统时钟周期。

鉴于TRNG ROSC特性及系统时钟频率因每个TRNG IP模块的实现而异，Arm制定了TRNG特征化程序，以确定每个SoC设计中最合适的ROSC链长度与采样频率设置。有关该特征化程序的详细信息，请参见ARM TrustZone真随机数生成器。

RP2350 TRNG模块的软件驱动不采用标准方案（参见第12.12.4节），因此软件不会配置Arm特征化程序所提供的ROSC长度及采样计数设置。

配置TRNG模块时，请遵循以下原则：

- 随着平均生成时间的增加，结果质量提升，熵校验失败次数减少。
- 较低的采样计数虽能降低平均生成时间，但会增加NIST测试失败和熵校验失败的概率。

为了获得约2毫秒平均生成时间的可接受结果，请将ROSC链长度设置为0或1，样本计数设置为20至25。

较大的样本计数设置（例如100）将导致平均生成时间相应增加。这些设置虽能显著减少NIST测试失败及熵检测失败的发生，但无法完全消除。生成结果有时可能耗费异常长的时间。

### 12.12.3. 操作

要启动TRNG生成，请在RND\_SOURCE\_ENABLE寄存器中设置 RND\_SRC\_EN位。TRNG将持续运行，直到：

- 成功完成一次随机数生成。
- 一个或多个内部熵检测机制指示运行失败。

无论哪种情况，您均可从RNG\_ISR寄存器读取结果状态。

要生成TRNG块中断，请设置RNG\_IMR寄存器中的相关位。使用RNG\_ICR清除活动中断状态位。

在成功生成之前，EHR\_DATA[x]寄存器读取值为0，因此CPU在生成期间无法读取随机数结果，

生成成功后，读取最后的结果寄存器EHR\_DATA[5]以清除所有结果寄存器。如果结果未通过熵检查，则不会提供任何结果，且EHR\_DATA[x]寄存器均读取为0。

TRNG生成后且不使用时，应清除 RND\_SRC\_EN位。

## 12.12.4. Caveats

The generation of random numbers by the TRNG block is not a deterministic process.

Although the modal and mean average times required to generate random numbers are quite similar, the generation process can occasionally take *much* longer to complete: in excess of 100 times the average. Any run resulting in a failed entropy check discards the result, requiring another generation process.

You can accommodate these unpredictable generation times in your system design. For example, you might generate a small pool of random numbers, initiating subsequent generation whenever space becomes available in the pool.

In the interests of simplicity and timing predictability, alternative approaches were adopted for the RP2350 bootrom and the SDK TRNG block drivers. The methodologies used can be found via the links below. However, nothing in the TRNG block in RP2350 precludes using the block as specified in Arm documentation.

### 12.12.4.1. Bootrom

The bootrom streams raw TRNG ROSC samples (the TRNG random source) directly into the hardware SHA-256 accelerator. It bypasses all internal checking and conditioning in the TRNG. SHA-256 is a robust hash function which avoids the pitfalls of some of the conditioning logic in the TRNG, most notably the von Neumann decorrelator.

The bootrom has some hard constraints which guide its implementation choices, most notably: *the bootrom must boot*. It cannot afford to poll the TRNG for an indeterminate amount of time to wait for a random number to appear. Complex error handling is also undesirable.

A link to the bootrom source can be found in [Chapter 5](#). Consult the source code for the exact implementation of the per-boot random number generation, in `varm_boot_path.c`.

The A2 bootrom TRNG code is written in assembly due to various implementation constraints, and may not be that illuminating. The following is excerpted from the A1 bootrom source, lightly edited for readability:

```
// Boot RNG is derived by streaming a large number of TRNG ROSC samples
// into the SHA-256. BOOT_TRNG_SAMPLE_BLOCKS is the number of SHA-256
// blocks to hash, each containing 384 samples from the TRNG ROSC:
const int BOOT_TRNG_SAMPLE_BLOCKS = 25;

// Fixed delay is required after TRNG soft reset
trng_hw->trng_sw_reset = -1u;
(void)trng_hw->trng_sw_reset;
(void)trng_hw->trng_sw_reset;
// Initialise SHA internal state by writing START bit
sha256_hw->csr = SHA256_CSR_RESET | SHA256_CSR_START_BITS;

// Sample one ROSC bit into EHR every cycle, subject to CPU keeping up. More
// temporal resolution to measure ROSC phase noise is better, if we use a
// high quality hash function instead of naive VN decorrelation. (Also more
// metastability events, which are a secondary noise source)
trng_hw->sample_cnt1 = 0;
// Disable checks and bypass decorrelators, to stream raw TRNG ROSC samples:
trng_hw->trng_debug_control = -1u;
// Start ROSC if it is not already started
trng_hw->rnd_source_enable = -1u;
// Clear all interrupts (including EHR_VLD) -- we will check this
// later, after seeding RCP.
trng_hw->rng_icr = -1u;

// Each half-block (192 samples) takes approx 235 cycles, so 470 cycles/block:
for (int half_blocks = 0; half_blocks < 2 * BOOT_TRNG_SAMPLE_BLOCKS; ++half_blocks) {

 // Wait for 192 ROSC samples to fill EHR, this should take constant time:
 while (trng_hw->trng_busy)
```

## 12.12.4. 注意事项

TRNG模块生成随机数的过程非确定性。

尽管生成随机数所需的众数和平均时间非常接近，生成过程有时却会大幅延长：超过平均时间100倍以上。任何未通过熵检查的运行结果均被丢弃，需重新进行生成。

您应在系统设计中考虑这些不可预测的生成时间。例如，您可以预生成一小批随机数池，在池中有空间时启动后续生成。

为简化设计并提升时序可预测性，RP2350 bootrom及SDK TRNG模块驱动采用了替代方案。所采用的方法论可通过以下链接获取。然而，RP2350中的TRNG模块并不排除按照Arm文档规范使用该模块。

### 12.12.4.1. Bootrom

bootrom将原始的TRNG ROSC样本（即TRNG随机源）直接输入到硬件SHA-256加速器。它绕过了TRNG中的所有内部检测和调节。SHA-256是一种强健的哈希函数，能够避免TRNG部分调节逻辑的缺陷，尤其是冯·诺依曼去相关器。

bootrom具有若干严格约束以指导其实现选择，最显著的是：bootrom必须能够成功启动。它无法承受轮询TRNG以等待随机数出现的不确定时长。复杂的错误处理同样不可取。

第5章中提供了bootrom源码链接。请参考源代码以了解每次启动随机数生成的具体实现，位于[varm\\_boot\\_path.c](#)。

由于多种实现限制，A2 bootrom 的 TRNG 代码采用汇编语言编写，可能不够直观。以下摘录自 A1 bootrom 源代码，经过轻微编辑以提升可读性：

```
// 引导随机数生成器 (RNG) 通过对大量 TRNG ROSC 样本进行流式处理而得到
// 并送入 SHA-256。BOOT_TRNG_SAMPLE_BLOCKS 表示要哈希的 SHA-256 块数，

const int BOOT_TRNG_SAMPLE_BLOCKS = 25;

// TRNG 软复位后需固定延迟 trng_hw->trng_sw_reset = -
1u;
(void)trng_hw->trng_sw_reset;
(void)trng_hw->trng_sw_reset;
// 通过写入 START 位初始化 SHA 内部状态
sha256_hw->csr = SHA256_CSR_RESET | SHA256_CSR_START_BITS;

// 每周期将一个 ROSC 位采样到 EHR，前提是 CPU 能跟上。（还有更多的//亚稳态事件，它们是次要的噪声源）

trng_hw->sample_cnt1 = 0;
// 禁用检查并绕过去相关器，以流式传输原始TRNG ROSC样本：
trng_hw->trng_debug_control = -1u;
// 如果ROSC尚未启动，则启动ROSC
trng_hw->rnd_source_enable = -1u;
// 清除所有中断（包括EHR_VLD）——稍后在为RCP加种子时会检查此项。

trng_hw->rng_icr = -1u;

// 每个半块 (192个样本) 大约需要235个周期，因此每块约470个周期：
for (int half_blocks = 0; half_blocks < 2 * BOOT_TRNG_SAMPLE_BLOCKS; ++half_blocks) {

 // 等待192个ROSC样本填满EHR，该过程应持续固定时间：
 while (trng_hw->trng_busy)
```

```

;

// Copy 6 EHR words to SHA-256, plus garbage (RND_SOURCE_ENABLE and
// SAMPLE_CNT1) which pads us out to half of a SHA-256 block. This means
// we can avoid checking SHA-256 ready whilst reading EHR, so we restart
// sampling sooner. (SHA-256 becomes non-ready for 57 cycles after each
// 16 words written.)
io_ro_32 *src = &trng_hw->ehr_data[0];
io_wo_32 *dst = &sha256_hw->wdata;
for (int i = 0; i < 8; ++i) {
 *dst = src[i];
}

// TRNG is now sampling again, having started after we read the last EHR
// word. Grab some in-progress SHA bits and use them to modulate the
// chain length, to reduce chance of injection locking:
trng_hw->trng_config = sha256_hw->sum[0];
}

// Wait for SHA result -- if skipped we get the previous block's digest. Note
// this never becomes true if we wrote a number of words % 16 != 0.
while (!(sha256_hw->csr & SHA256_CSR_SUM_VLD_BITS))
;

// The per-boot random will change on every core 0 reset (except debugger
// skipping ROM). If this is a problem then the user can sample the
// per-boot random into a preserved variable in main SRAM.
for (int i = 0; i < 4; ++i) {
 bootram->always.boot_random.e[i] = sha256_hw->sum[4 + i];
}

trng_hw->trng_config = 0;
// Stop ROSC as it's a waste of power
trng_hw->rnd_source_enable = 0;

```

The boottrom resets the SHA-256 and TRNG via RESETS immediately before the above code runs. This code typically runs with `clk_sys` running from the system ROSC, at its initial boot frequency of approximately 12 MHz. The 256-bit result is available in the `SUM0` through `SUM7` registers after the code completes.

This code does not represent best programming practice: for example it writes ones into reserved bits in the `TRNG_DEBUG_CONTROL` register. It was written with close reference to the hardware implementation. The above code listing serves only to document the *method* the boottrom uses to generate random numbers at boot time, for the once-per-boot random number available via the `get_sys_info()` ROM API as well as for initialising the RCP salt registers ([Section 3.6.3.1](#)).

#### 12.12.4.2. SDK

The `pico_rand` library uses the TRNG as one of its entropy sources. It streams raw ROSC samples from the TRNG ROSC in a similar manner to the boottrom. It uses the `xoroshiro128**` and `splitmix64()` PRNG functions to condition the output.

#### 12.12.5. List of registers

The TRNG control registers start at a base address of `0x400f0000` (defined as `TRNG_BASE` in the SDK).

Table 1261. List of TRNG registers

Offset	Name	Info
0x100	RNG_IMR	Interrupt masking.

```

;

// 将6个EHR字复制至SHA-256，外加垃圾数据（RND_SOURCE_ENABLE和// SAMPLE_C
NT1），用于填充至SHA-256块的一半。这意味着//我们可以在读取EHR时避免检查SHA-256是
否就绪，从而更早重新开始采样。（每写入16个字后，SHA-256会非就绪状态持续57个时钟周期
。）

io_ro_32 *src = &trng_hw->ehr_data[0];
io_wo_32 *dst = &sha256_hw->wdata;
for (int i = 0; i < 8; ++i) {
 *dst = src[i];
}

// TRNG已重新启动采样，因我们刚读取完最后一个EHR字。提取部分SHA正在进行的位数，用
以调节链长，以降低注入锁定的可能性：

trng_hw->trng_config = sha256_hw->sum[0];
}

// 等待SHA结果——若跳过此步，将获上一区块的摘要。注意//若写入字数%m 16 ≠ 0，此条件将永远
不成立。
while (!(sha256_hw->csr & SHA256_CSR_SUM_VLD_BITS))
;

// 每次核心0重置时，每次启动的随机数都会发生变化（调试器例外，跳过只读存储器）。若此
为问题，用户可将该启动随机数采样保存于主SRAM中的持久变量。

for (int i = 0; i < 4; ++i) {
 bootrom->always.boot_random.e[i] = sha256_hw->sum[4 + i];
}

trng_hw->trng_config = 0;
// 停止ROSC以节省功耗
trng_hw->rnd_source_enable = 0;

```

bootrom 在上述代码执行前，通过复位（RESETS）立即重置了 SHA-256 和真随机数生成器（TRNG）。该代码通常在系统ROSC以约12 MHz初始启动频率运行时执行。代码完成后，256位结果可在 SUM0 至 SUM7 寄存器中读取。

该代码并非最佳编程实践：例如，它向 TRNG\_DEBUG\_CONTROL 寄存器的保留位写入了全1。其编写过程紧密参照硬件实现。上述代码仅用于记录bootrom在启动时生成随机数的方法，此随机数通过[get\\_sys\\_info\(\)](#)只读存储器 API 获取，每次启动可用一次，同时用于初始化 RCP 盐寄存器（第 3.6.3.1 节）。

#### 12.12.4.2. SDK

该 [pico\\_rand](#) 库以 TRNG 作为其熵源之一。其以类似 bootrom 的方式，从 TRNG ROSC 流式传输原始 ROSC 采样。它应用 [xoroshiro128\\*\\*](#) 和 [splitmix64\(\)](#) 伪随机数生成函数对输出进行调节。

#### 12.12.5. 寄存器列表

TRNG 控制寄存器地址为 [0x400f0000](#)（SDK 中定义为 TRNG\_BASE）。

表1261：TRNG寄  
存器列表

偏移量	名称	说明
0x100	RNG_IMR	中断屏蔽。

Offset	Name	Info
0x104	RNG_ISR	RNG status register. If corresponding RNG_IMR bit is unmasked, an interrupt will be generated.
0x108	RNG_ICR	Interrupt/status bit clear Register.

## 12.13. SHA-256 accelerator

RP2350 is equipped with an implementation of the SHA-256 hash algorithm, as defined in the FIPS 180-4 standard available from NIST publications. A hash algorithm digests an arbitrary-length stream of data, known as the **message**, and produces a fixed-size result, known as a **hash**. In the case of SHA-256, the result is always 256 bits in size. Hash algorithms are designed such that:

- Given the hash, it is impossible (or implausibly computationally hard) to recover the original message.
- Small changes to the original message result, on average, in large changes to the hash.
- Given a message with a particular hash, it is impossible (or implausibly computationally hard) to generate a different message with the same hash.

These properties make hash algorithms useful for checking the integrity of data, in the face of both accidental bit flips and deliberate tampering.

To compute a SHA-256 with the RP2350 SHA-256 accelerator:

- Initialise the algorithm state by writing a 1 to **CSR.START**.
- Write the message to the **WDATA** register, polling **CSR.WDATA\_RDY** in between writes.

## 12.13. SHA-256 加速器

RP2350 采用了 SHA-256 哈希算法的实现，该算法依据 NIST 发布的 FIPS 180-4 标准定义。哈希算法对任意长度的数据流，即“消息”，进行摘要计算，生成固定长度的结果，即“哈希值”。在SHA-256中，结果始终为256位。哈希算法设计具有以下特性：

- 已知哈希值时，不可能（或计算上极为困难）恢复原始消息。
- 对原始消息的细微更改通常会导致哈希值发生显著变化。
- 已知某消息及其哈希值时，不可能（或计算上极为困难）生成具有相同哈希值的不同消息。

这些特性使哈希算法在防止意外位翻转和恶意篡改时，用于验证数据完整性。

使用RP2350 SHA-256加速器计算SHA-256时，应执行以下步骤：

1. 向CSR.START寄存器写入1以初始化算法状态。
2. 将消息写入WDATA寄存器，写入期间轮询CSR.WDATA\_RDY状态。

3. Write additional trailer and padding data to [WDATA](#), as described in [Section 12.13.1](#) below.
4. Poll [CSR.SUM\\_VLD](#) to wait for the last block to be digested.
5. Read the 256-bit result from the 8 read-only result registers starting at [SUM0](#).

### 12.13.1. Message padding

Pad message content according to the standard SHA-256 method as described in the [FIPS 180-4 Secure Hash Standard](#): append the message with single bit [1](#), then a number of [0](#) bits, then a 64-bit count of the number of message bits. So for a message [M](#) with length [L](#) bits the padded message should be:

1. message [M](#)
2. [1](#)
3. [k](#) zero bits, where [k](#) is the smallest non-negative solution to the equation:  $L + 1 + k = 448 \text{ mod } 512$
4. a 64-bit block indicating [L](#) (the length of the message) in binary

For example, the 8 bit ASCII message [abc](#) has a length of 24 bits. This is padded with [1](#), then  $448 - (24 + 1) = 423$  [0](#) bits, and then the message length as a 64-bit value as follows:

```
01100001 01100010 01100011 1 00000000 000...0 00000000 000...0 00011000
|-----message-----| 1 |--423 0 bits--| |----64 bit len----|
```

### 12.13.2. Throughput

SHA-256 processes data one 512-bit block at a time. This requires 16 32-bit writes, 32 16-bit writes, or 64 8-bit writes to the [WDATA](#) register. An APB register write costs 4 cycles, so it takes at least 64 system clock cycles to write a data block.

Once a full block is transferred, the SHA core takes a further 57 cycles to complete the block digest. [CSR.WDATA\\_RDY](#) goes low, and you must not write to [WDATA](#) during this time.

The maximum throughput is therefore one block per 121 system clock cycles, or 0.53 bytes per cycle. At a 150 MHz system clock this is 79.3 MB/s. This throughput is achieved when you use 32-bit transfers from the DMA. Using narrower transfers result in lower throughput, as does polling the [CSR.WDATA\\_RDY](#) flag when transferring data from the processor.

### 12.13.3. Data size and endianness

Data is sent in message blocks of 512 bits, padded as described in [Section 12.13.1](#). The SHA-256 accelerator updates its 256-bit output state for each input block. The SHA-256 algorithm is defined in terms of big-endian message words, but this accelerator provides a byte swap function via [CSR.BSWAP](#) to support little-endian data. [BSWAP](#) is set by default. For more information, see the register descriptions.

[WDATA](#) supports 8-bit, 16-bit and 32-bit writes. The bus interface accumulates 8 and 16-bit writes in a 32-bit shift register before passing them into the SHA-256 algorithm core. This means you must take care when mixing writes of different sizes, because taking the shift register level from less than to greater than 32 bits in a single write will silently drop data. You can avoid this issue by not mixing [WDATA](#) write sizes within a single SHA-256 message block (64 bytes).

### 12.13.4. DMA DREQ interface

The block can request the DMA controller to send entire blocks of data at once. Configure transfer size using

3. 根据第12.13.1节的描述，向WDATA寄存器写入额外的尾部和填充数据。
4. 轮询CSR.SUM\_VLD寄存器，等待最后一个数据块被处理完成。
5. 从起始于 SUM0 的 8 个只读结果寄存器中读取 256 位结果。

### 12.13.1. 消息填充

根据 FIPS 180-4 《安全哈希标准》中描述的标准 SHA-256 方法对消息内容进行填充：在消息后附加单个比特 **1**，随后是若干个 **0** 比特，然后附加表示消息比特数的 64 位计数。因此，对于长度为 L 比特的消息 M，填充后的消息应为：

1. 消息 **M**
2. **1**
3. **k** 个零比特，其中 **k** 为满足以下方程的最小非负整数解： $L + 1 + k = 448 \bmod 512$
4. 一个 64 位区块，表示消息长度 **L**（二进制格式）

例如，8 位 ASCII 消息 **abc** 的长度为 24 比特。其填充方式为：先附加 **1** 比特，再附加  $448 - (24 + 1) = 423$  个 **0** 比特，最后附加表示消息长度的 64 位值，如下所示：

```
01100001 01100010 01100011 1 00000000 000...0 00000000 000...0 00011000
|-----消息-----| 1 |--423 0 bits--| |----64 bit len----|
```

### 12.13.2. 吞吐量

SHA-256 每次处理一个 512 位的数据块。这需要向 WDATA 寄存器写入 16 次 32 位数据、32 次 16 位数据或 64 次 8 位数据。一次 APB 寄存器写入耗费 4 个周期，因此写入一个数据块至少需要 64 个系统时钟周期。

数据块传输完成后，SHA 核心还需 57 个周期以完成该数据块的摘要计算。当 CSR.WDATA\_RDY 变为低电平时，期间不得向 WDATA 寄存器写入数据。

因此最大吞吐量为每 121 个系统时钟周期处理一个数据块，或每个周期 0.53 字节。在 150 MHz 系统时钟下，该吞吐量为 79.3 MB/s。此吞吐量通过使用 DMA 进行 32 位传输实现。使用较窄的数据传输宽度或在处理器传输数据时轮询 CSR.WDATA\_RDY 标志，均会降低吞吐量。

### 12.13.3. 数据大小与字节序

数据以 512 位的消息块形式发送，填充方式详见第 12.13.1 节。SHA-256 加速器针对每个输入块更新其 256 位输出状态。SHA-256 算法以大端消息字定义，但该加速器通过 CSR.BSWAP 提供字节交换功能，以支持小端数据。**BSWAP** 默认开启。

欲了解更多信息，请参见寄存器描述。

**WDATA** 支持 8 位、16 位及 32 位写入。总线接口在将数据传输至 SHA-256 算法核心之前，会将 8 位和 16 位写入累积于 32 位移位寄存器中。因此，在混合不同大小的写入时必须谨慎，单次写入若导致移位寄存器位宽从低于 32 位提升至高于 32 位，将无声丢弃数据。为避免此问题，建议在单个 SHA-256 消息块（64 字节）中不要混用 **WDATA** 写入大小。

### 12.13.4. DMA DREQ 接口

该块可请求 DMA 控制器一次传送完整数据块。通过以下方式配置传输大小

`CSR.DMA_SIZE` so that the DMA controller requests the correct number of transfers.

The DREQ always requests one full SHA block of data at a time. Do not start a DMA on a non-block boundary.

### 12.13.5. List of registers

The SHA-256 registers start at a base address of `0x400f8000` (defined as `SHA256_BASE` in SDK).

Table 1280. List of SHA256 registers

Offset	Name	Info
0x00	<code>CSR</code>	Control and status register
0x04	<code>WDATA</code>	Write data register
0x08	<code>SUM0</code>	256-bit checksum result. Contents are undefined when <code>CSR_SUM_VLD</code> is 0.

## 12.14. QSPI memory interface (QMI)

### 12.14.1. Overview

The QSPI memory interface (QMI) provides read/write memory-mapped access to two external QSPI memory devices. RP2350 has a single QMI instance, embedded in the XIP subsystem ([Section 4.4](#)), which replaces the SSI interface present on RP2040. The QMI supports serial-SPI, dual-SPI, and quad-SPI transfers, with two chip selects and shared clock/data signals.

## 12.14. QSPI 存储接口（QMI）

### 12.14.1. 概述

QSPI 存储器接口（QMI）提供对两个外部 QSPI 存储设备的读/写内存映射访问。

RP2350 具有单一的 QMI 实例，嵌入于 XIP 子系统（第 4.4 节），替代了 RP2040 上的 SSI 接口。QMI 支持串行 SPI、双 SPI 和四 SPI 传输，配备两个片选信号及共享的时钟/数据信号。

Figure 129. QMI block diagram: AHB accesses are address-translated, broken down into the necessary QSPI transfer phases such as command, address and data, and interfaced to the external QSPI signals via the serialiser/deserialiser. There is a chip select per device, and shared clock/data signals. Separately, the direct mode interface can be used to issue raw SPI commands through a pair of FIFOs, which can be used to program and configure the external QSPI devices.

Each chip select corresponds to a 16 MB AHB address window, so a maximum of 32 MB of external memory is supported. Chip select 0, which has a dedicated external pin, is mapped to addresses starting from `0x10000000`, and chip select 1, which is available as an alternate GPIO function, starts from `0x11000000`. This mapping is mirrored in the uncached and uncached + untranslated XIP address windows described in [Section 4.4](#).

All timing and SPI command format parameters are configured per chip select, with the correct configuration used automatically based on address decode. For example, `M0_TIMING` configures timing parameters for accesses to chip select 0, and `M1_TIMING` is an identical register for chip select 1.

The serial clock (`SCK`) is any integer division of the system clock in the range 1 to 256. The divisors can be adjusted at any time. Input sample timing can be adjusted in half-system-clock-cycle increments, to compensate for clock-to-data delay at high `SCK` frequencies. Double transfer rate mode (DTR) is implemented by halving the `SCK` frequency whilst maintaining the data transfer rate, which is capped at 4 bits per system clock cycle.

The number of `SCK` cycles issued for each access depends on the access size, which varies between one byte and one cache line. For example, an uncached one-byte read by a processor will fetch exactly one byte of data over the QSPI bus, to avoid wasting time fetching unwanted data. Cache misses are always issued as 64-bit QSPI transfers.

Optionally, the QMI can automatically chain sequentially addressed AHB accesses into a single, long QSPI transfer. This avoids issuing redundant commands and addresses on the QSPI bus, and is particularly beneficial for cold code paths and for streaming in flash data using the XIP streaming hardware ([Section 4.4.3](#)). For PSRAM compatibility, chains can be broken when they exceed a maximum chip select time (`M0_TIMING.MAX_SELECT`) or when they cross certain power-of-two address boundaries (`M0_TIMING.PAGEBREAK`). [Section 12.14.2.1](#) goes into more detail on these features.

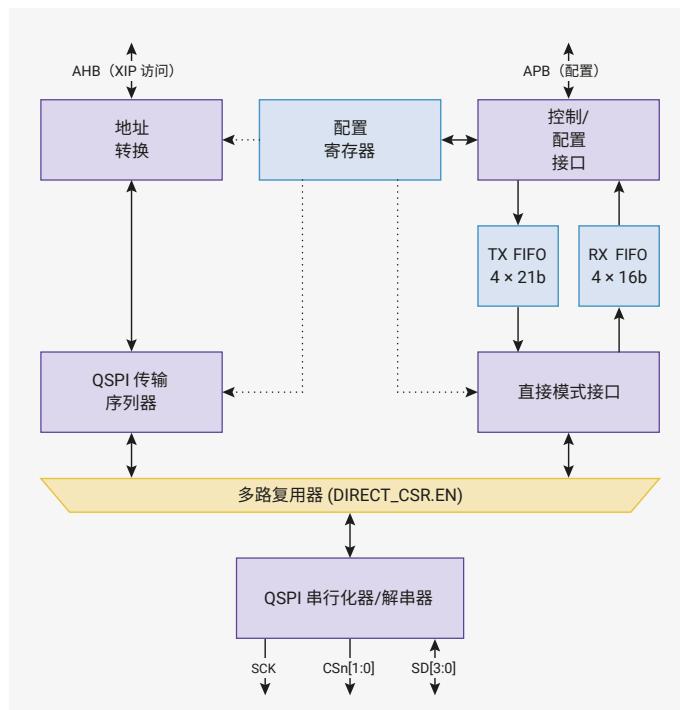

The QMI can map addresses with its built-in address translation hardware: each chip select is partitioned into 4 × 4 MB windows, whose physical base address and aperture size are configured in units of 4 kB (one flash sector). This enables the runtime addresses of flash programs to be independent of where they are stored: for example, a flash-resident bootloader at flash storage address 0 could select one of multiple flash-resident program images, all of them linked to run at address `0x10000000`, and these can be executed in place with no position-independent code required. Address translation is described fully in [Section 12.14.4](#).

Finally, the direct-mode interface is included for cases where software needs to communicate directly with the external QSPI devices, for example to access status registers. This interface also supports serial, dual, and quad interface widths as described in [Section 12.14.5](#).

图129。QMI框图：

AHB访问经过地址转换，拆分为必要的QSPI传输阶段，如命令、地址和数据，通过串行/反串行器与外部QSPI信号接口。

每个设备均设有芯片选择信号，时钟和数据信号为共享信号。此外，直接模式接口可通过一对FIFO发送原始SPI命令，用于编程和配置外部QSPI设备。

每个芯片选择对应16 MB的AHB地址窗口，因此最多支持32 MB外部存储器。芯片选择0拥有专用的外部引脚，其地址映射从 **0x1** 开始**0000000**，芯片选择1作为备用GPIO功能提供，其地址映射从 **0x1100000** 开始。该映射反映于第4.4节所述的无缓存及无缓存加未转换的XIP地址窗口中。

所有时序和SPI命令格式参数均针对每个芯片选择信号配置，且根据地址译码自动采用正确的配置。例如，M0\_TIMING配置芯片选择0的时序参数，M1\_TIMING为芯片选择1对应的同类寄存器。

串行时钟 (**SCK**) 是系统时钟的任意整数分频，分频范围为1至256。分频系数可随时调整。输入采样时序可按半个系统时钟周期增量调整，以补偿高 **SCK** 频率下的时钟至数据延迟。双倍传输速率模式 (DTR) 通过将 **SCK** 频率减半实现，同时保持数据传输速率，且速率最高为每个系统时钟周期4位。

每次访问发出的 **SCK** 周期数取决于访问大小，范围从一个字节至一个缓存行。例如，处理器对未缓存的单字节读取操作将在QSPI总线上精确获取一个字节的数据，以避免浪费时间读取不需要的数据。Cache misses 始终以64位QSPI传输方式发出。

QMI可选择性地自动将连续地址的AHB访问链式合并为单一的长QSPI传输。这避免在QSPI总线上发出冗余命令及地址，特别有利于冷代码路径和通过XIP流式硬件（第4.4.3节）流式传输闪存数据。为兼容PSRAM，当链路超过最大片选时间（M0\_TIMING.MAX\_SELECT）或跨越特定的2的幂次地址边界（M0\_TIMING.PAGEBREAK）时，链路可被中断。[第12.14.2.1节](#)对此功能进行了详细说明。

QMI可通过其内置地址转换硬件映射地址：每个片选划分为4个4 MB窗口，其物理基址和孔径大小均以4 KB（一个闪存扇区）为单位配置。这使得闪存程序的运行时地址独立于其存储位置：例如，驻留于闪存存储地址0处的启动加载程序可选择多个闪存驻留程序映像中的一个，这些映像均被链接为在地址 **0x1** 上运行。**0000000** 这些指令可以直接在原地执行，无需使用位置无关代码。地址转换详见第12.14.4节。

最后，直接模式接口包含于内，适用于软件需要与外部QSPI设备直接通信的场景，例如访问状态寄存器。该接口同样支持串行、双线和四线接口宽度，具体详见第12.14.5节。

## 12.14.2. QSPI transfers

A QSPI bus connects one host, such as QMI, to multiple devices, such as a serial NOR flash. It consists of:

- One chip select line per device (**CSn**)
- One shared clock line (**SCK**)
- Up to four shared data lines (**SD0** through **SD3**)

No single specification defines the format of QSPI commands. However, certain de facto command sets exist on most QSPI flash/SRAM/PSRAM devices. QMI supports the most common variations of these commands.

QMI is primarily a memory interface, not a general-purpose QSPI peripheral. Although the direct-mode interface (Section 12.14.5) allows arbitrary QSPI accesses by passing raw data through the FIFOs, QMI is optimised for preformatted read/write transfers in response to AHB read/write bus accesses.

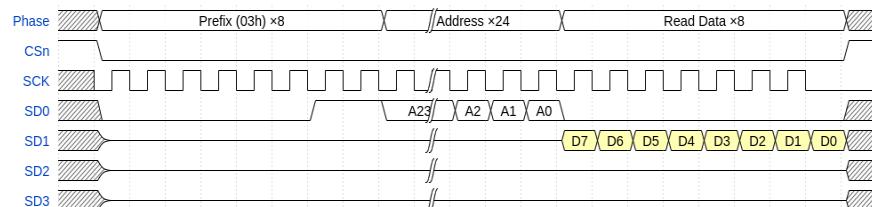

All QSPI read/write accesses performed by the QMI use the following five phases:

1. **Prefix:** An optional, constant 8-bit value that indicates the SPI command being performed (referred to as the **command prefix** or **instruction prefix** in SPI device datasheets)
2. **Address:** A 24-bit byte address that specifies the SPI memory location being read/written, corresponding to the lower 24 bits of the AHB address
3. **Suffix:** An optional, constant 8-bit value which follows the address in certain access modes
4. **Dummy:** 0-value (SPI) or high-impedance (dual/quad-SPI) cycles which precede the data, to provide the SPI device adequate time to access the first address
5. **Data:** Transfers memory contents to/from the SPI device at sequential byte addresses from the initial address indicated in the address phase

The chip select for the addressed device is asserted before the prefix phase, and de-asserted at the end of the data phase.

Each phase has a length in bits and interface width (single/dual/quad) configured using **M0\_RFMT/M1\_RFMT** (for reads) and **M0\_WFMT/M1\_WFMT** for writes. The **M0/M1** versions of each register configure accesses to memory windows 0 and 1 (the two chip selects) respectively. This allows you to address two different QSPI devices with different command formats transparently.

*Figure 130. An example serial read. After an 8-bit prefix, the host sends 24 address bits, and the device replies with data starting from the next cycle.*

**Figure 130** illustrates the **03h** serial read command. This section refers to a handful of common QSPI read/write commands used by QSPI flash/SRAM/PSRAM devices; refer to a QSPI device datasheet for command details. For example, the [W25Q16JV datasheet available from Winbond](#) provides descriptions of all of the read commands mentioned in this section.

Applying the five-phase structure introduced previously, the **03h** QSPI transaction breaks down as follows:

1. 8-bit prefix, at serial width (prefix = **0x03**)
2. 24-bit address, at serial width
3. No suffix (length 0)
4. No dummy bits (length 0)
5. Data bits, at serial width

The number of address bits is fixed at 24 for all QMI accesses. The number of data bits depends on the size of the transfer: this diagram shows 8 bits being transferred, which corresponds to an uncached byte read from the processor.

## 12.14.2. QSPI 传输

QSPI总线将一个主机（如QMI）连接至多个设备，如串行NOR闪存，包含以下部分：

- 每个设备各一条芯片选择线（**CSn**）
- 一条共享时钟线（**SCK**）
- 最多四条共享数据线（**SD0**至**SD3**）

目前暂无单一规范定义QSPI命令格式。然而，大多数QSPI闪存/SRAM/PSRAM设备采用某些事实标准的命令集。QMI支持这些命令的多数常见变体。

QMI主要作为内存接口，而非通用QSPI外设。尽管直接模式接口（第12.14.5节）允许通过FIFO传递原始数据实现任意QSPI访问，QMI更为优化用于响应AHB读写总线访问的预格式化读写传输。

所有由QMI执行的QSPI读写访问均包含以下五个阶段：

1. 前缀：一个可选的、固定的8位值，用于指示正在执行的SPI命令（在SPI设备数据手册中称为命令前缀或指令前缀）
2. 地址：一个24位字节地址，指定被读写的SPI存储位置，且对应AHB地址的低24位
3. 后缀：一个可选的、固定的8位值，在某些访问模式中紧随地址之后
4. 虚拟：取值为0（SPI）或高阻抗状态（双线/四线SPI）的时钟周期，位于数据信号之前，为SPI设备提供访问起始地址的充分时间
5. 数据：从地址阶段指示的起始地址开始，按顺序字节地址传输内存内容至/自SPI设备

在前缀阶段之前，所选设备的片选信号被置位；在数据阶段结束时，片选信号被复位。

每个阶段包含以位为单位的长度和接口宽度（单/双/四线），通过M0\_RFMT/M1\_RFMT（用于读取）及M0\_WFMT/M1\_WFMT（用于写入）进行配置。每个寄存器的 M0/M1 版本分别用于配置对存储窗口0和1（即两个片选）的访问。该设计允许您透明地使用不同命令格式寻址两个不同的QSPI设备。

图130。一个示例串行读取流程。在8位前缀后，主机发送24位地址，设备自下一个时钟周期开始返回数据。

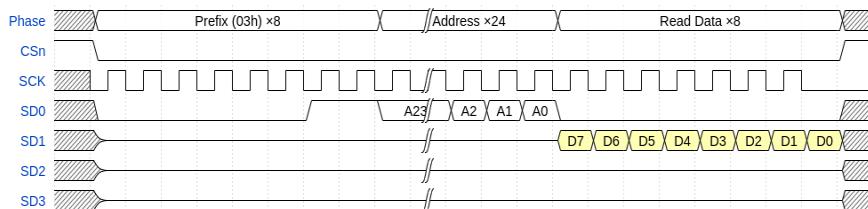

图130展示了 03h 串行读取命令。本节涉及一些QSPI闪存/SRAM/PSRAM设备常用的QSPI读写命令；具体命令详情请参阅对应的QSPI设备数据手册。例如，Winbond发布的W25Q16JV数据手册包含本节所述全部读取命令的说明。

应用前述提出的五阶段结构，03h QSPI 事务分解如下：

1. 8位前缀，串行宽度下（前缀= 0x03）
2. 24位地址，串行宽度下
3. 无后缀（长度为0）
4. 无虚拟位（长度为0）
5. 数据位，串行宽度下

所有QMI访问的地址位数固定为24位。数据位数取决于传输大小：本图示显示传输8位数据，代表处理器读取的未缓存字节。

The **M0\_RFMT/M1\_RFMT** registers configure all other parameters used for the data phase, such as serial interface width.

The four data lines **SD3** through **SD0** make up the QSPI bus. At serial width, the host drives data out on **SD0**, and the device responds with data travelling in the opposite direction on **SD1**. **SD3** and **SD2** are undriven during serial-SPI and dual-SPI width parts of a transfer, and are usually pulled high. The shaded background behind the **D7** through **D0** data bits indicates that the transfer direction is device-to-host. Higher interface widths use the **SDx** lines bidirectionally.

Figure 131. The **0Bh** read command adds 8 dummy cycles between address and data, to permit higher bus frequencies.

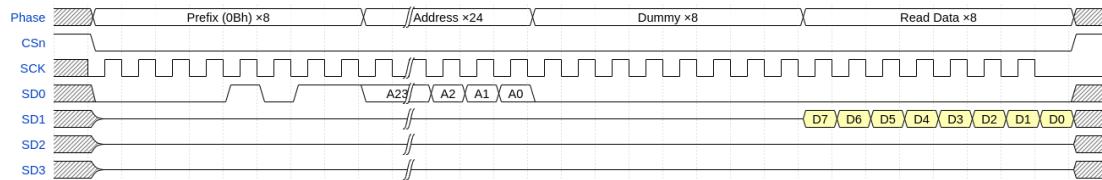

Figure 131 shows the **0Bh** serial read command, a common variation on the **03h**. **0Bh** adds dummy cycles between the address and data phases, which helps hide the initial access latency of the storage array inside of the QSPI device. This allows higher operating frequencies.

Applying the five-phase structure introduced previously, the **0Bh** QSPI transaction breaks down as follows:

1. 8-bit prefix, at serial width (prefix = **0x0b**)
2. 24-bit address, at serial width
3. No suffix (length 0)
4. Eight dummy bits, at serial width
5. Data bits, at serial width

At serial width, the QMI continues to drive the **SD0** line low throughout the dummy phase, as this line is unidirectional at this width. At dual-SPI and quad-SPI width, **SD0** is tristated during the dummy phase along with **SD1** through **SD3**.

QMI idles its clock low between transfers, expecting data to be captured on the leading edge of each clock pulse (i.e. the rising edge). In legacy Motorola SPI terms, the clock polarity is 0 and the clock phase is 0. Other clock polarities and phases are not supported. To ensure data is stable across the rising edge, new data is launched on each *falling* edge.

When transfer chaining is disabled (Section 12.14.2.1), QMI takes advantage of this clock behaviour by suppressing the final clock pulse on reads. This saves energy by avoiding unnecessary **SCK** transitions, and by not inadvertently requesting the data that immediately follows the requested data. QMI still leaves one full **SCK** period where the last data is valid, and still captures at the point the **SCK** rising edge would be launched (Section 12.14.3), but the actual **SCK** clock pulse is suppressed.

Figure 132. An **EBh** quad I/O read command. The command prefix is serial, but address and data are 4 bits per cycle.

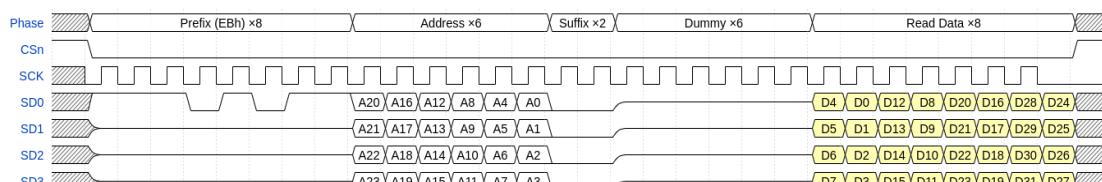

Figure 132 shows a quad-width read transfer. In this example, the command prefix is still transferred at serial width, but the full quad-width is used thereafter, as the prefix identifies the width of the access.

Applying the five-phase structure introduced previously, the QSPI transaction breaks down as follows:

1. 8-bit prefix, at serial width (prefix = **0xeb**)
2. 24-bit address, at quad width
3. 8-bit suffix, at quad width (suffix = **0x00**)
4. 24 dummy bits, at quad width
5. Data bits, at quad width

The suffix is an extension of the command prefix, placed after the address bits to avoid extending the initial access

M0\_RFMT/M1\_RFMT寄存器配置数据阶段使用的所有其他参数，例如串行接口宽度。

QSPI总线由四条数据线 SD3至 SD0组成。在串行宽度下，主机通过 SD0线输出数据，设备则通过相反方向的 SD1线返回数据。在序列 SPI和双 SPI宽度的传输阶段，SD3和 SD2处于未驱动状态，通常被上拉。数据位 D7至 D0后的阴影背景表示传输方向为设备到主机。更高的接口宽度使用 SDx线路进行双向通信。

图131。0Bh读取命令在地址与数据之间加入了8个空周期，以支持更高的总线频率。

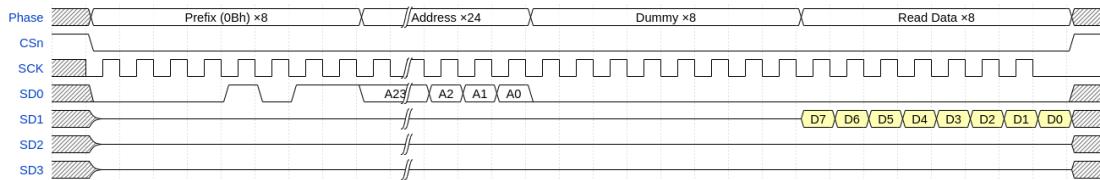

图131显示了0Bh串行读取命令，这是03h的一种常见变体。0Bh命令在地址与数据阶段之间插入空周期，有助于掩盖QSPI设备内存阵列的初始访问延迟。这使得更高的工作频率成为可能。

根据之前介绍的五阶段结构，0Bh QSPI 事务具体分解如下：

1. 8位前缀，串行宽度（前缀 = 0x0b）
2. 24位地址，串行宽度下
3. 无后缀（长度为0）
4. 八位虚拟位，按串行宽度处理
5. 数据位，串行宽度下

在串行宽度下，QMI在虚拟阶段持续将 SD0线拉低，因该线在此宽度下为单向。在双SPI和四SPI宽度下，SD0在虚拟阶段与SD1至 SD3一起进入三态状态。

QMI在传输间隙保持时钟线为低电平，预期数据在每个时钟脉冲的上升沿被采集。按照传统摩托罗拉SPI术语，时钟极性为0，时钟相位为0。不支持其他时钟极性和相位设置。为确保数据在上升沿稳定，新数据在每个下降沿发出。

当禁用传输链（参见第12.14.2.1节）时，QMI利用此时钟特性，在读取过程中抑制最后的时钟脉冲。此举通过避免不必要的SCK切换，并避免无意中请求紧随所请求数据之后的数据，从而节省能量。QMI仍保留一个完整的SCK周期，在该周期内最后一个数据有效，并且仍在 SCK上升沿即将触发的时点捕获数据（参见第12.14.3节），但实际的SCK时钟脉冲被抑制。

图132。一条EBh四路I/O读命令。命令前缀为串行传输，但地址和数据每周期为4位。

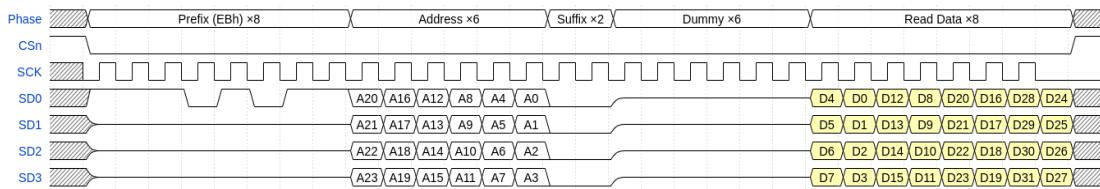

图132显示了四宽度读取传输。在本例中，命令前缀仍以串行宽度传输，但随后采用完整四宽度，因为前缀用于标识访问宽度。

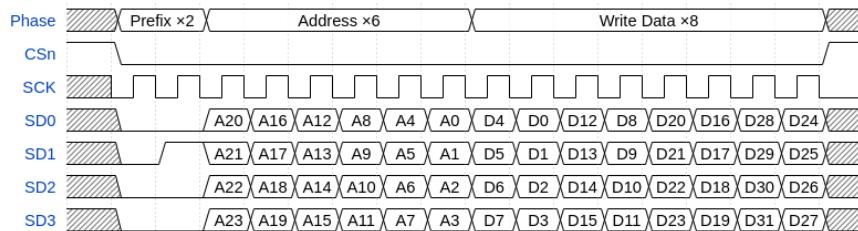

应用先前介绍的五阶段结构，QSPI事务拆分如下：

1. 8位前缀，串行宽度（前缀 = 0xeb）
2. 24位地址，四宽度
3. 8位后缀，四宽度（后缀 = 0x00）
4. 24位虚拟位，四宽度
5. 数据位，四倍宽度

后缀是命令前缀的扩展，置于地址位之后，以避免扩展初始访问。

latency. The bit patterns used for prefixes and suffixes are configured using the [M0\\_RCMD/M1\\_RCMD](#) registers (for reads) and [M0\\_WCMD/M1\\_WCMD](#) registers (for writes). One common use of the suffix on EBh quad I/O read commands is to enter a so-called continuous read mode, where the prefix of the next command is skipped (assumed to be the same as the current command) to reduce the number of cycles required for the next read access.

Figure 133. An 02h write transfer, shown with the device in QPI mode (4 bits per cycle for all transfers)

[Figure 133](#) shows a write command at quad width. In this example, the command prefix is also issued in quad mode, which is common for QSPI RAM. Since read and write commands mix freely, dropping the prefix (like flash continuous read mode) is less useful, so QSPI RAM devices often support a **QPI mode** that also issues command prefixes in quad width to reduce per-access cost.

Applying the five-phase structure introduced previously, the QSPI transaction breaks down as follows:

1. 8-bit prefix, at quad width (prefix = `0x02`)
2. 24-bit address, at quad width
3. No suffix (0 bits)
4. No dummy bits
5. Data bits, at quad width

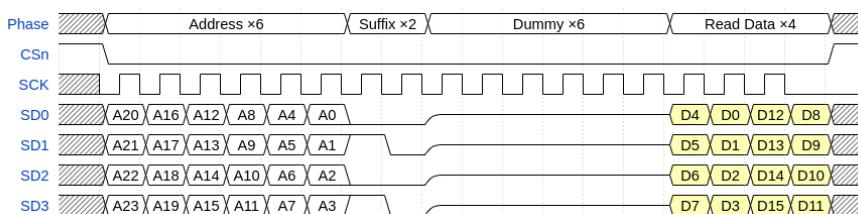

It is worth noting the bit and byte order in this diagram. SPI is conventionally MSB-first within each byte. When multiple bits transfer each cycle (using the `SD0`, `SD1`, `SD2` and `SD3` data lines in parallel), higher-numbered data lines carry more-significant bits. The first cycle of the data transfer in [Figure 133](#) transfers the four most-significant bits of the first byte of data. The most-significant bit (bit 7) transfers on `SD3`, and the least-significant of these bits (bit 4) transfers on `SD0`.

Since RP2350 is a little-endian system, higher byte addresses correspond to higher numerical significance. Figure [Figure 133](#) shows the transfer of a 32-bit value spanning four consecutive byte addresses, starting at the initial address transmitted by the host during the address phase. The first two cycles of the data phase transfer the first byte, containing the 8 least-significant bits of the 32-bit value. The last two cycles of the data phase transfer the last byte, containing the 8 most-significant bits of the 32-bit value (bits 31 through 24, inclusive).

#### 12.14.2.1. Transfer chaining

Referring back to [Figure 132](#), which shows a 32-bit QSPI read with an EBh serial prefix, it's evident that more time is spent issuing the prefix and address (14 cycles) and waiting for the initial read latency (an additional 8 cycles), than actually transferring the data (8 cycles). This overhead leaves only a small fraction of the theoretical maximum QSPI throughput available for transferring data from flash, which limits the performance of direct code execution.

Figure 134. An EBh read, without the command prefix. The suffix is used to indicate the lack of prefix on the next command.

[Figure 134](#) shows how this can be improved by **continuous read mode**, which uses a suffix (here `0xa0`) to indicate the lack of command prefix on the next command. This example only transfers 16 bits of data (e.g. an uncached halfword read by the processor). Suffixes are effectively free to transfer, because they are transferred during the latency wait period between the address being issued and the first data returned from the QSPI device's internal storage. However, this still leaves the majority of the QSPI bus cycles spent issuing addresses and waiting, not transferring data.

延迟。用于前缀和后缀的位模式通过M0\_RCMD/M1\_RCMD寄存器（用于读取）和M0\_WCMD/M1\_WCMD寄存器（用于写入）进行配置。EBh四倍I/O读取命令中后缀的一个常见用途是进入所谓的连续读取模式，其中跳过下一条命令的前缀（假定与当前命令相同），以减少下一次读取访问所需的周期数。

图133展示了四倍宽度的写命令。在此示例中，命令前缀也以四倍模式发出，这在QSPI RAM中较为常见。由于读写命令可自由混合，丢弃前缀（如闪存连续读取模式）实用性较低，因此QSPI RAM设备通常支持一个QPI模式，在该模式下命令前缀同样以四倍宽度发出，以降低每次访问的开销。

应用先前介绍的五阶段结构，QSPI事务拆分如下：

1. 8位前缀，四倍宽度 (prefix = **0x02**)
2. 24位地址，四宽度
3. 无后缀 (0位)
4. 无虚位
5. 数据位，四倍宽度

需要注意图中展示的位序和字节序。SPI通常在每个字节内采用最高有效位优先传输。当每个周期传输多个位（使用 SD0、SD1、SD2 和 SD3 数据线并行时），编号较高的数据线传输更高位的比特。图133中数据传输的第一个周期传输了第一个字节的四个最高有效位。最高有效位（第7位）在 SD3 上传输，而这些位中最低有效的（第4位）在 SD0 上传输。

由于RP2350采用小端模式，更高字节地址对应更高数值权重。图133展示了从主机在地址阶段发送的初始地址开始，跨越四个连续字节地址的32位值传输。数据阶段的前两个周期传输第一个字节，该字节包含32位值的最低8位。数据阶段的最后两个周期传输最后一个字节，该字节包含32位值的最高8位（包括第31位至第24位）。

#### 12.14.2.1. 传输链

参考图132，该图显示带有EBh串行前缀的32位QSPI读取，可见发出前缀和地址（14个周期）及等待初始读取延迟（额外8个周期）所花费的时间，超过了实际传输数据（8个周期）的时间。该开销仅留极少部分理论最大QSPI吞吐量用于从闪存传输数据，从而限制了直接代码执行的性能。

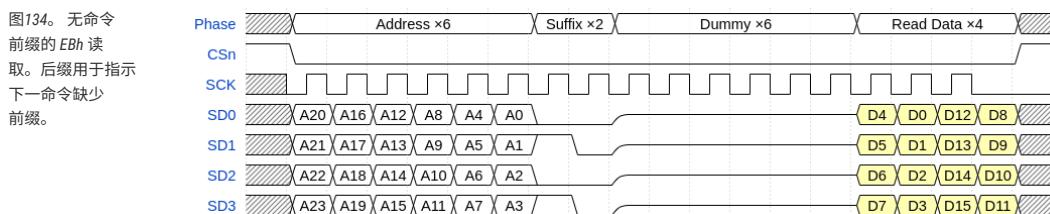

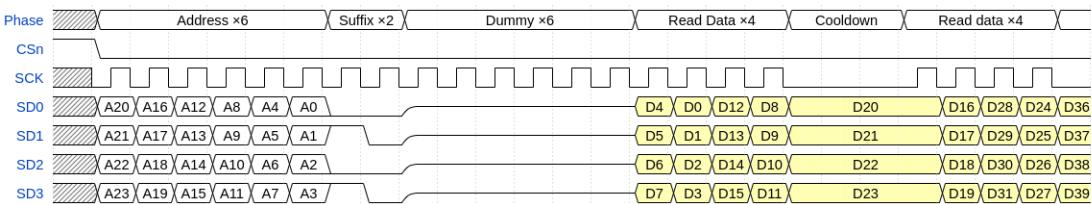

图134展示了如何通过连续读取模式来改进此过程，该模式使用后缀（此处为 **0xa0**）表示下一条命令缺少命令前缀。此示例仅传输16位数据（例如处理器执行的未缓存半字读取）。后缀的传输实际上是免费的，因为它们在从地址发出至QSPI设备内部存储返回首批数据的延迟等待期间传输。然而，这仍导致QSPI总线的大多数周期用于发出地址和等待，而非传输数据。

Consequently, QSPI memory's random-access performance is much lower than its sequential-access performance.

Figure 135. An EB<sub>h</sub> read, with a subsequent sequential read chained onto the next transfer

QMI's transfer chaining feature exploits the difference between sequential and non-sequential access speed. Figure 135 shows two sequentially-addressed halfword reads (i.e. the address of the second transfer is two plus the address of the first transfer), with M0\_TIMING.COOLDOWN/M1\_TIMING.COOLDOWN set to a non-zero value.

In Figure 134, QMI suppressed the last clock pulse and immediately released the chip select after the last data transferred. When transfer chaining is enabled, as in Figure 135, QMI does *not* suppress the last clock pulse, instead keeping the chip select asserted. It remains in this state for a certain amount of time, configured by the COOLDOWN register field, waiting for another transfer. QMI then executes the next transfer by appending more clocks to the current transfer. The chip select remains asserted throughout instead of releasing and reasserting between commands. To benefit from transfer chaining, the next transfer must meet the following criteria:

- same direction as the previous transfer (read/write)
- address sequential to the previous transfer (equal to previous address plus previous size)
- address in the same window as the previous transfer (same chip select)
- previous transfer did not reach a page break boundary (configured by M0\_TIMING.PAGEBREAK/ M1\_TIMING.PAGEBREAK)

This considerably improves throughput for long uncached linear transfers such as using the XIP stream peripheral (Section 4.4.3) or executing cold code sequences which tend to miss the cache many times sequentially.

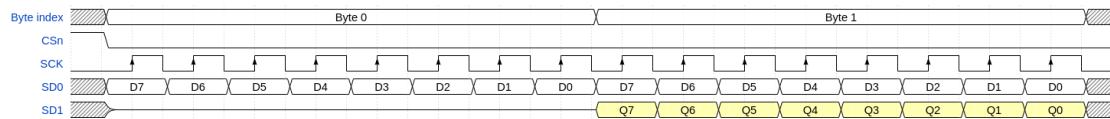

This can continue for arbitrarily many transfers. It is possible to read the entire contents of a typical flash device using transfer chaining from a single address.

Note that the transfer chaining feature can slightly degrade random access performance. If the next transfer is non-sequential, the chip select must be de-asserted, possibly dwell high for some minimum period (depending on timing requirements of the QSPI device), and then be reasserted to issue the new address. If transfer chaining were not used, the chip select would have de-asserted immediately following the end of the previous transfer, avoiding some of this delay. This can be mitigated by tuning the COOLDOWN timer register parameter to avoid leaving the chip select asserted for excessively long periods, since sequential transfers are usually tightly grouped in time.

### 12.14.3. Timing

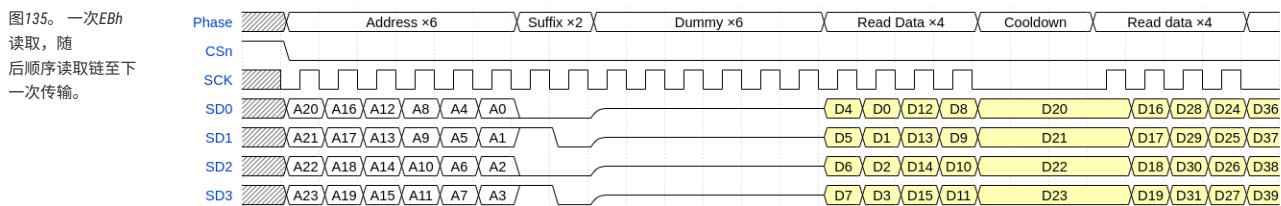

QMI operates in SPI mode 0, capturing data on each rising edge of SCK. New data is asserted on each subsequent falling edge. The first output data launches simultaneously with the assertion of the chip select, as illustrated by Figure 136.

Figure 136. A bidirectional SPI transfer, as used by QMI.

QMI timing is relative to the system clock. As this is generally quite fast relative to external signals, the M0\_TIMING.CLKDIV/M1\_TIMING.CLKDIV field can uniformly slow SCK and data lines by an integer factor.

因此，QSPI存储的随机访问性能远低于其顺序访问性能。

QMI的传输链功能利用了顺序访问与非顺序访问速度的差异。图135展示了两个顺序地址的半字读取（即第二次传输地址为第一次传输地址加二），且M0\_TIMING.COOLDOWN/M1\_TIMING.COOLDOWN设置为非零值。

在图134中，QMI抑制了最后一个时钟脉冲，并在最后一笔数据传输后立即释放芯片选择信号。当启用传输链式处理时，如图135所示，QMI不会抑制最后一个时钟脉冲，而是保持芯片选择信号保持有效。芯片选择信号将保持该状态一段时间，由COOLDOWN寄存器字段配置，等待下一次传输。随后，QMI通过向当前传输附加更多时钟来执行下一笔传输。

芯片选择信号在整个过程中均保持有效，而非在命令之间释放再重新拉低。要利用传输链式处理，下一笔传输必须满足以下条件：

- 传输方向与上一笔相同（读/写）
- 地址连续于上一笔传输（等于前一个地址加上前一次传输的大小）
- 地址位于与上一笔传输相同的窗口内（相同芯片选择信号）
- 上一笔传输未到达页边界中断（由M0\_TIMING.PAGEBREAK或M1\_TIMING.PAGEBREAK配置）

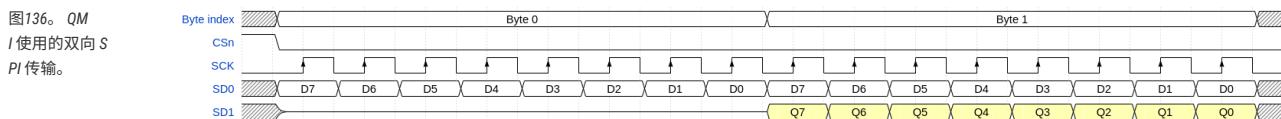

这显著提升了长时间未缓存的线性传输吞吐量，例如使用XIP流外设（第4.4.3节）或执行冷代码序列，而这些序列通常会连续多次未命中缓存。

该过程可持续进行任意次数的传输。通过单地址传输链，能够读取典型闪存设备的完整内容。

请注意，传输链功能可能会略微降低随机访问性能。若下一次传输非连续，则必须释放片选信号，并可能需在片选信号保持高电平的一定最短时间内停留（视QSPI设备的时序要求而定），然后重新断言片选以发出新地址。若不使用传输链，片选信号将在前一次传输结束后立即释放，以避免部分延时。可通过调整COOLDOWN定时器寄存器参数予以缓解，以避免片选信号长时间保持断言状态，因连续传输通常时间间隔较短。

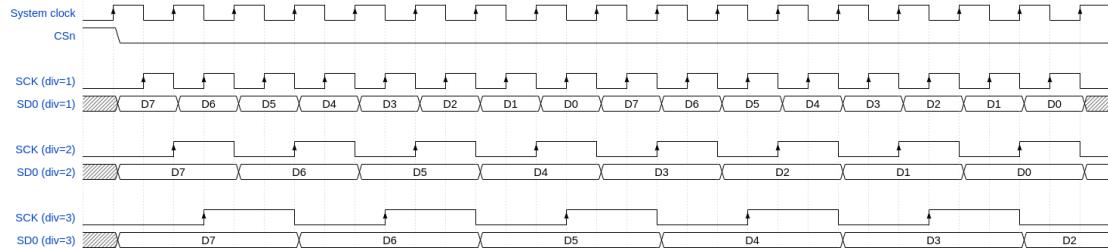

### 12.14.3. 时序

QMI运行于SPI模式0，在每个SCK上升沿捕获数据。新数据在每个随后的下降沿被断言。如图136所示，第一个输出数据与片选信号的断言同时启动。

QMI的时序以系统时钟为参考。由于系统时钟相对于外部信号通常较快，M0\_TIMING.CLKDIV/M1\_TIMING.CLKDIV字段可将SCK和数据信号统一按整数倍数减速。

Figure 137. The CLKDIV controls set the number of system clock cycles per SCK cycle, for each memory window.

QMI uses DDR input/output registers to enable a resolution of one half system clock cycle for output signal generation and input sampling. This allows QMI to support odd clock divisors, including divide-by-one (`SCK` frequency equal to system clock frequency).

#### **i NOTE**

In practice, the maximum `SCK` frequency is constrained by the limits of the attached QSPI device, the signal integrity afforded by the PCB layout, and IO delays in the pads. See [Section 12.14.3.4](#).

### 12.14.3.1. Input sampling and RXDELAY

QMI samples input data on the rising edge of `SCK` ([Section 12.14.3](#)). To introduce additional delay to the input delay register (helpful when the round trip delay is longer than half an `SCK` cycle), use `M0_TIMING.RXDELAY/M1_TIMING.RXDELAY`. `RXDELAY` counts delay in half system clock cycles, instead of `SCK` cycles.

### 12.14.3.2. Chip select timing

To save power, chip select is de-asserted after a transaction completes. To leave chip select asserted after a transaction, use `M0_TIMING.COOLDOWN/M1_TIMING.COOLDOWN`. This can reduce latency and increase bus throughput.

Chip select can be asserted one system clock cycle early via `M0_TIMING.SELECT_SETUP/M1_TIMING.SELECT_SETUP`. Some flash devices require this setting at very high `SCK` frequencies. Without this setting, QMI asserts chip select one half `SCK` period before the first rising edge of `SCK`. This is simultaneous with the assertion of the first data on `SDO`.

Chip select hold time can also be extended by up to 3 additional system clock cycles via `M0_TIMING.SELECT_HOLD/M1_TIMING.SELECT_HOLD`.

To enforce a maximum amount of time that chip select can remain asserted, use `M0_TIMING.MAX_SELECT/M1_TIMING.MAX_SELECT`. This is useful for PSRAM devices, which must issue internal DRAM refresh cycles when deselected.

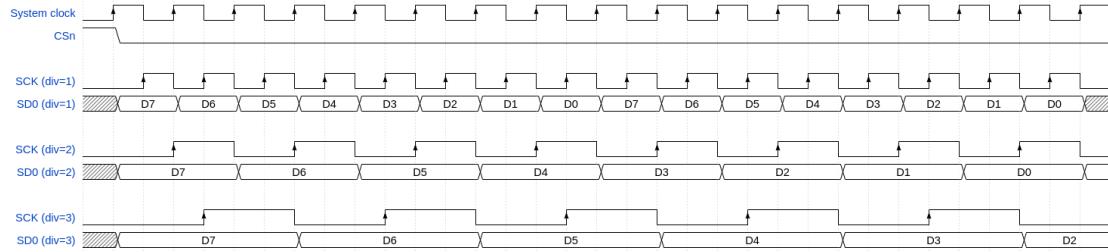

To enforce a minimum amount of time that chip select can remain de-asserted, use `M0_TIMING.MIN_DESELECT/M1_TIMING.MIN_DESELECT`.

### 12.14.3.3. Double transfer rate (DTR)

Some QSPI memory devices transfer data on both edges of `SCK`. This feature, known as **double transfer rate** (DTR), allows a lower `SCK` frequency for a given data transfer rate, reducing EM emissions and the energy cost of toggling the external clock. To enable DTR mode (per-window and per-direction), set the `M0_RFMT.DTR/M1_RFMT.DTR` flag (for reads) or `M0_WFMT.DTR/M1_WFMT.DTR` (for writes).

QMI implements DTR by halving the clock frequency whilst maintaining the data rate. To achieve this, QMI *inverts* alternate single transfer rate `SCK` clock periods, transforming a low-high-low-high sequence into a low-high-high-low sequence. When DTR is disabled, the QMI launches data on `SCK` falling edges and captures on rising edges. When DTR is enabled, the QMI launches data at the point half-way in between two `SCK` edges, and captures on each edge, as shown in [Figure 138](#).

图137。 CLKD  
IV 控制设置每个  
内存窗口中每个 SC  
K 周期所对应的系  
统时钟周期  
数。

QMI 采用 DDR 输入/输出寄存器，实现输出信号生成与输入采样的半系统时钟周期分辨率。此设计使 QMI 支持奇数分频，包括除以一（即 SCK 频率等同于系统时钟频率）。

### ① 注意

在实际应用中，最大 SCK 频率受限于连接的 QSPI 设备性能、PCB 布局的信号完整性以及焊盘中的 IO 延迟。详见第 12.14.3.4 节。

#### 12.14.3.1 输入采样与 RXDELAY

QMI 于 SCK 上升沿采样输入数据（参见第 12.14.3 节）。当往返延迟超过半个 SCK 周期时，为增加输入延迟寄存器的延迟，可使用 M0\_TIMING.RXDELAY / M1\_TIMING.RXDELAY。RXDELAY 的延迟以半个系统时钟周期为单位，而非 SCK 周期。

#### 12.14.3.2 片选时序

为节约能耗，事务完成后片选信号会被取消断言。若需在事务完成后保持片选信号断言状态，请使用 M0\_TIMING.COOLDOWN / M1\_TIMING.COOLDOWN。此操作可降低延迟并提升总线吞吐量。

芯片选择信号可通过 M0\_TIMING.SELECT\_SETUP/M1\_TIMING.SELECT\_SETUP 提前一个系统时钟周期断言。某些闪存设备在非常高的 SCK 频率下需要此项设置。若未设置此项，QMI 会在第一个 SCK 上升沿之前提前半个 SCK 周期断言芯片选择信号。此操作与第一笔数据在 SDx 上的断言同时发生。

芯片选择保持时间也可通过 M0\_TIMING.SELECT\_HOLD/M1\_TIMING.SELECT\_HOLD 额外延长最多 3 个系统时钟周期。

为强制芯片选择信号保持断言的最长时间，应使用 M0\_TIMING.MAX\_SELECT/M1\_TIMING.MAX\_SELECT。此设置对 PSRAM 设备尤为重要，因为其在取消选择时必须执行内部 DRAM 刷新周期。

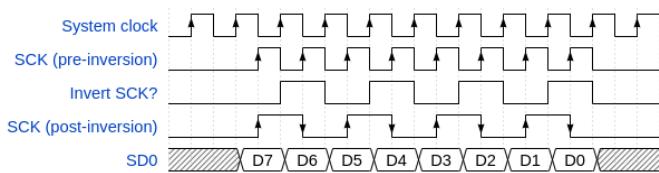

为强制芯片选择信号保持非断言的最短时间，应使用 M0\_TIMING.MIN\_DESELECT/M1\_TIMING.MIN\_DESELECT。

#### 12.14.3.3. 双倍传输速率 (DTR)

某些 QSPI 存储器设备在 SCK 的双边沿传输数据。该功能称为 **double transfer rate** (DTR)，在特定数据传输速率下允许降低 SCK 频率，从而减少电磁辐射和切换外部时钟的能耗。要启用 DTR 模式（针对窗口和方向），请设置 M0\_RFMT.DTR/M1\_RFMT.DTR 标志（读取）或 M0\_WFMT.DTR/M1\_WFMT.DTR 标志（写入）。

QMI 通过将时钟频率减半，同时保持数据速率，实现 DTR。为实现此目的，QMI 反转交替的单传输速率 SCK 时钟周期，将低-高-低-高序列转换为低-高-高-低序列。当禁用 DTR 时，QMI 于 SCK 下降沿发送数据，并于上升沿采样。启用 DTR 时，QMI 在两 SCK 边沿之间的中点发送数据，并在每个边沿采样，如图 138 所示。

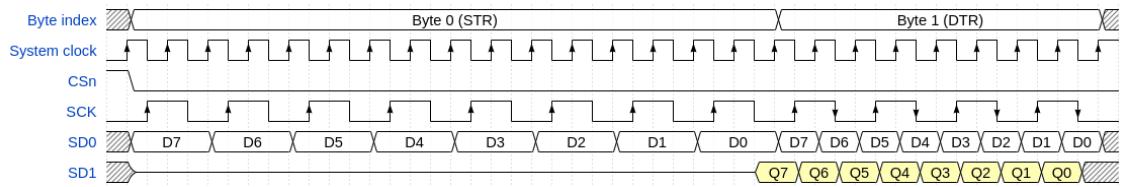

Figure 138. DTR is implemented by halving the SCK frequency whilst maintaining data rate.

Enabling DTR mode does not change the data timing, only the SCK timing. Data is launched at the point where a SCK negative edge would be, had the clock rate not been halved.

When DTR is enabled, the prefix and dummy phase of a transfer remain single transfer rate. In these phases, data bits are doubled to match the half-rate SCK, so that new data is ready in time for each rising edge only. Figure 139 shows the first byte (the command prefix) at single transfer rate and the second byte (address and data) at double transfer rate.

Figure 139. Parts of DTR-enabled transfers are still single transfer rate: effectively each data bit is sent twice.

The arrows on the SCK line in Figure 139 show the active edges of SCK (where data is captured). The single transfer rate portion of the access expects data capture on the rising edge. The double transfer rate portion of the access expects data capture on both edges.

Data travelling from device to host is likewise launched on both edges of SCK. Each time the QMI launches a new clock edge, there is some delay as transitions propagate through the RP2350 pad output delay, QSPI device SCK-to-SD<sub>x</sub> delay, and back in through the RP2350 SD<sub>x</sub> pad input delays. QMI captures data simultaneously with the launch of the next SCK edge, plus any delay configured by M0\_TIMING.RXDELAY/M1\_TIMING.RXDELAY. The round-trip delay from SCK output back to SD<sub>x</sub> input provides the SD<sub>x</sub> input hold time. If the input setup time is not sufficient, you can increase RXDELAY. For more information, see the specific QSPI device datasheet, as well as Section 12.14.3.4.

#### 12.14.3.4. AC timing parameters

The QMI interface is timed using the internal system clock. Skew between different QMI pins for inputs or outputs is kept to a minimum. Any additional setup or hold time is supported by using additional clock cycle delays as mentioned in other sections. Skew values vary depending on whether we consider just the dedicated QSPI pins (QSPI\_SS, QSPI\_SD[3:0], QSPI\_SCLK) or include the Bank 0 GPIO XIP special functions (for the additional QMI chip select). Different package options have different skew timing, shown below.

Table 1291. QMI Timing skew

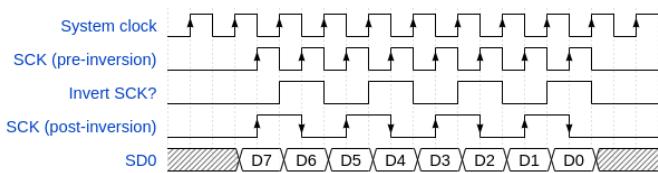

Interface	Typical Skew (ps)	Max Skew (ps)
QSPI input	15	25
QSPI output	100	180
Bank 0 GPIO (QFN-60) output	1080	1725
Bank 0 GPIO (QFN-80) output	1280	2100

It is also useful to know the delay from internal register running on system clock to output pin, and similarly the delay from input pin to the sampling register running on system clock. Table 1292 provides worst case process, voltage, and temperature timings for inputs and outputs on QSPI, and outputs on GPIO. Note that this delay varies based on the VDDIO voltage level as shown in the table.

Table 1292. QMI Timing delay

Path	Max delay (ns) VDDIO=3.3V	Max delay (ns) VDDIO=1.8V
QSPI input to system clock	1.5	1.2
system clock to QSPI output	2.5	3.6

图138。 DTR通过将SCK频率减半，同时保持数据传输速率不变来实现。

启用DTR模式不会改变数据时序，仅修正 SCK的时序。数据在本应出现 SCK负边沿的位置被传输，假设时钟频率未减半。

启用DTR时，传输的前缀和虚拟阶段仍保持单倍传输速率。在这些阶段，数据位被加倍以匹配减半的 SCK频率，确保每个上升沿都有新数据准备就绪。图139显示第一个字节（命令前缀）为单倍传输速率，第二个字节（地址和数据）为双倍传输速率。

图139。部分启用DTR的传输仍然采用单倍传输速率：实际上每个数据位被发送两次。

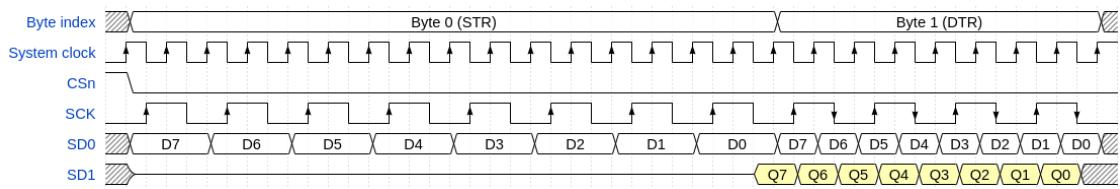

图139中 SCK线上的箭头表示 SCK的有效边沿（数据采样点）。访问的单传输速率部分预期在上升沿捕获数据。访问的双传输速率部分预期在两个沿上捕获数据。

从设备到主机传输的数据同样在 SCK的两个沿上启动。每当QMI启动新的时钟沿时，信号传递过程中存在延迟，包括RP2350引脚输出延迟、QSPI设备 SCK至SDx的延迟，以及返回RP2350 SDx引脚输入的延迟。QMI在启动下一SCK沿时同时捕获数据，加上由M0\_TIMING.RXDELAY/M1\_TIMING.RXDELAY配置的延迟。由 SCK输出返回 SDx输入的往返延迟提供了 SDx输入保持时间。如果输入建立时间不足，可以增加 RXDELAY。更多信息请参阅特定QSPI设备的数据手册及第12.14.3.4节。

#### 12.14.3.4. AC 时序参数

QMI 接口采用内部系统时钟进行时序控制。不同 QMI 引脚的输入或输出时钟偏斜保持在最小范围内。如其他章节所述，通过使用额外的时钟周期延迟支持任何额外的建立时间或保持时间。时钟偏斜值取决于仅考虑专用 QSPI 引脚 (QSPI\_SS、QSPI\_SD[3:0]、QSPI\_SCLK) 还是包括 Bank 0 GPIO XIP 特殊功能 (用于额外的 QMI 片选)。不同封装选项的时钟偏斜时序不同，如下所示。

表 1291. QMI 时序偏斜

接口	典型偏斜 (ps)	最大偏斜 (ps)
QSPI 输入	15	25
QSPI 输出	100	180
Bank 0 GPIO (QFN-60) 输出	1080	1725
Bank 0 GPIO (QFN-80) 输出	1280	2100

了解从运行于系统时钟的内部寄存器到输出引脚的延迟，以及从输入引脚到运行于系统时钟的采样寄存器的延迟，亦十分重要。表1292列出了QSPI输入和输出以及GPIO输出在工艺、电压和温度最坏情况下的时序。请注意，该延迟会根据表中显示的 VDDIO电压等级而变化。

表 1292. QMI 时序延迟

路径	最大延迟 (纳秒) VDDIO=3.3V	最大延迟 (纳秒) VDDIO=1.8V
QSPI输入到系统时钟	1.5	1.2
系统时钟到QSPI输出	2.5	3.6

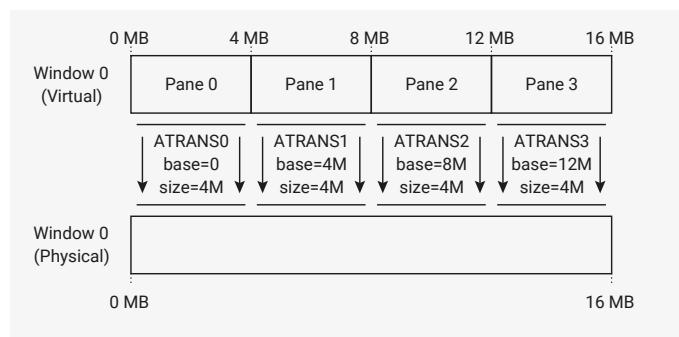

Path	Max delay (ns) VDDIO=3.3V	Max delay (ns) VDDIO=1.8V
system clock to GPIO (QFN-60) output	3.5	4.9
system clock to GPIO (QFN-80) output	4.1	5.4

#### 12.14.4. Address translation

QMI applies a configurable mapping from the *virtual* address requested by the processor or DMA to the *physical* address transmitted to the external QSPI device. This is performed separately for each of the 16 MB chip select windows. You cannot map contents between devices.

Each window is divided into four *panes*, each independently mapped onto the physical address space for that window. The default configuration applied on QMI reset, as shown in Figure 140, is a 1:1 identity mapping between virtual and physical addresses. In this state the address mapping has no effect, and the entire 16 MB address space of the external QSPI device is mapped directly into the system address space.

Figure 140. By default, each window is set up to map the full 16 MB virtual address space directly 1:1 with the 16 MB physical address space.

Each pane corresponds to the one of the four `ATRANSx` registers for that window: `ATRANS0` through `ATRANS3` for window 0, and `ATRANS4` through `ATRANS7` for window 1.

The virtual base address of each pane is fixed and assigned in 4 MB increments. There are two configurable parameters for the mapping of that pane into physical address space:

- **BASE**: defines the physical address corresponding to offset 0 in the virtual address pane. Configured in units of 4 kB (one flash sector), ranging from 0 to (16 MB minus 4 kB).
- **SIZE**: defines the amount of address space mapped by this pane. Configured in units of 4 kB (one flash sector) ranging from 0 to 4 MB.

The mapping grows from the start of the pane. A **SIZE** of 1 MB maps the first 1 MB of that pane's virtual address range to downstream memory, and the remainder is unmapped. A **SIZE** of 0 means that no address within this virtual address pane is accessible. Accesses beyond the currently configured **SIZE** return a bus error, and do not pass through to the downstream QSPI bus. As a result, they have no effect on the external memory device.

Figure 141. The **BASE** of a pane defines where its physical mapping begins. The **SIZE** defines how far it extends. A **SIZE** of 0 means no addresses are mapped through that pane.

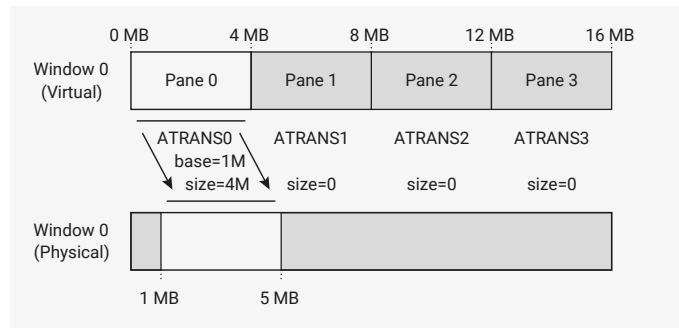

Figure 141 shows an example mapping, where the first 4 MB of virtual address space for chip select 0 (virtual address offsets `0x000000` through `0x3fffff` inclusive) map to a 4 MB physical address window starting at a 1 MB offset (physical address offsets `0x100000` through `0x4fffff` inclusive). This mapping could be used for flash that contains a 1 MB

路径	最大延迟 (纳秒) VDDIO=3.3V	最大延迟 (纳秒) VDDIO=1.8V
系统时钟到GPIO (QFN-60) 输出	3.5	4.9
系统时钟到GPIO (QFN-80) 输出	4.1	5.4

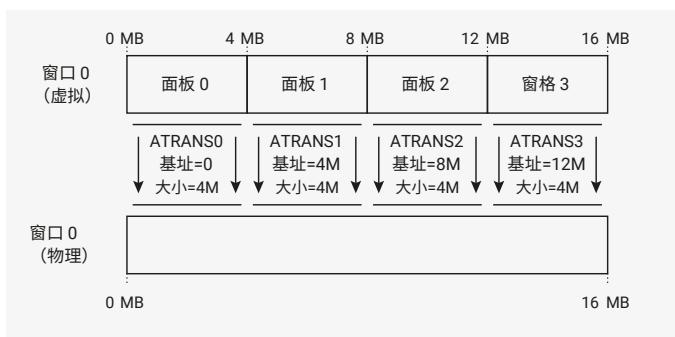

#### 12.14.4. 地址转换

QMI针对处理器或DMA请求的虚拟地址应用了可配置映射，转换为传输到外部QSPI设备的物理地址。此操作针对每个16 MB芯片选择窗口单独执行。禁止在不同设备之间映射内容。

每个窗口划分为四个窗格，每个窗格独立映射到该窗口对应的物理地址空间。

如图140所示，QMI复位时的默认配置为虚拟地址与物理地址之间的1:1同一映射。在该状态下，地址映射无效，外部QSP I设备的整个16 MB地址空间被直接映射到系统地址空间。

图140。默认情况下，每个窗口均设置为将完整的16 MB虚拟地址空间直接1:1映射到16 MB物理地址空间。

每个窗格对应该窗口的四个ATRANSx寄存器之一：窗口0的ATRANS0至ATRANS3，窗口1的ATRANS4至ATRANS7。

每个窗格的虚拟基址固定，以4 MB为单位递增分配。映射该窗格到物理地址空间有两个可配置参数：

- **BASE**：定义虚拟地址窗格中偏移地址0对应的物理地址。以4 kB（一个闪存扇区）为单位配置，范围从0至（16 MB减4 kB）。
- **SIZE**：定义该窗格所映射的地址空间大小。以4 kB（一个闪存扇区）为单位配置，范围从0至4 MB。

映射从窗格的起始位置开始。一个SIZE为1 MB，将该窗格虚拟地址范围的前1 MB映射到下游内存，其余部分未映射。一个SIZE为0表示该虚拟地址窗格内没有地址可被访问。访问超出当前配置的SIZE将返回总线错误，且不会传递至下游QSPI总线。因此，这些访问不会对外部存储设备产生任何影响。

图141。窗格的BASE定义其物理映射的起始位置。SIZE定义映射的延伸范围。SIZE为0表示该窗格未映射任何地址。

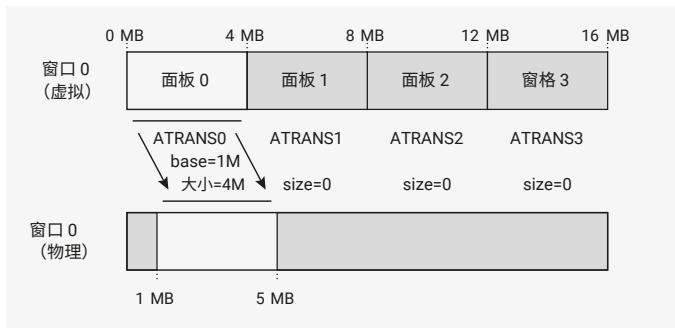

图141显示了一个示例映射，其中芯片选择0的虚拟地址空间前4 MB（虚拟地址偏移 0x000000 至 0xffffffff 包含）映射到起始于1 MB偏移的4 MB物理地址窗口（物理地址偏移 0x100000 至 0x4fffffff 包含）。此映射可用于包含1 MB

bootloader application followed by a 4 MB user application. Ideally, the user application should not be aware of the flash layout defined by the bootloader; that way, the same application can run under different bootloader implementations. The virtual-to-physical mapping solves this problem by making the storage location of the user application (starting at 1 MB) independent of the address it appears at in the system address space (starting at 0 MB).

#### 12.14.4.1. Bootrom support for address translation

The bootrom can automatically configure address translation at boot time, so that a binary stored at some arbitrary location in physical flash storage can appear at a runtime flash address of 0.

This is done automatically when the booted image is inside of a flash partition (Section 5.1.2), and can be adjusted manually based on a rolling window delta specified in the `IMAGE_DEF` of the launched executable (Section 5.1.4).

The bootrom source code and bootrom documentation often refers to the QMI `ATRANS` mapping as "rolling windows", due to the modulo address wrapping on 16 MB boundaries – see Section 5.1.19.

#### 12.14.4.2. Translation and the XIP cache

The QMI address translation is performed downstream of the system XIP cache (Section 4.4.1). Therefore, the XIP cache is a *virtual* cache with respect to this translation, because the address translation performed inside QMI is opaque to the XIP cache.

Consequently, changes to the QMI address translation necessitate a flush of the XIP cache. From the cache's point of view, the translation change has moved QMI memory contents around in the cache's downstream address space in a way that is incoherent with the cache contents, so a flush is required to restore coherence. At a minimum, any virtual address whose `ATRANSx` register (`ATRANS0` through `ATRANS7`) has been modified, and which may be allocated in the cache in either the clean or the dirty state, must be flushed. It may be simplest to flush the entire cache.

QMI's address mapping creates another hazard: the same physical address may map to multiple virtual addresses, and therefore may be allocated multiple times in the XIP cache. When you write to a physical address through a cached virtual address alias, the XIP cache does not propagate the change to other aliases. To avoid this issue, do not allow multiple aliases of the same writable physical address at the same instant. Aliasing read-only memory is usually safe. Aliases that exist at different points in time (for example, across an RTOS context switch boundary) can be kept coherent with appropriate cleaning and flushing when the translation is changed.

### 12.14.5. Direct mode

In direct mode, the AHB XIP address window is disconnected from the QSPI bus, and the bus is controlled through a TX/RX FIFO pair, similar to a normal SPI peripheral. In this state, the XIP window becomes inaccessible. Attempting to access it generates a bus fault. This mode is used for low-level access to the QSPI bus, for example when issuing flash erase/programming commands, or when accessing QSPI device status registers.

All direct-mode operation is controlled through `DIRECT_CSR`, with data being exchanged through `DIRECT_TX` and `DIRECT_RX`. To enable direct mode, first set `DIRECT_CSR.EN`, and then poll for `DIRECT_CSR.BUSY` to go low to ensure that any in-progress XIP transfer at the point direct mode was enabled has completed.

Direct mode has its own clock divisor and RX sampling delay, configured by `DIRECT_CSR.CLKDIV` and `DIRECT_CSR.RXDELAY`. These are separate from the per-window settings configured in `M0_TIMING/M1_TIMING`, because serial commands used for control purposes may have different frequency limits than data accesses used for execute-in-place.

For each push to `DIRECT_TX`, QMI will issue 8 or 16 bits of FIFO data to the QSPI bus. Optionally, the same number of bits are simultaneously sampled and returned in `DIRECT_RX`. The clock is initially low, and data is always captured on the rising edge of `SCK`, transitioning on the subsequent falling edge.

After pushing to `DIRECT_TX`, `DIRECT_CSR.BUSY` will go high, and remain high until all direct-mode activity has completed. This works even if no RX data is returned, so is more reliable than polling the RX FIFO status. The `BUSY` flag

引导加载程序应用程序，随后是4 MB用户应用程序的闪存。理想情况下，用户应用程序不应了解由引导加载程序定义的闪存布局；如此，相同的应用程序可在不同引导加载程序实现下运行。

虚拟地址到物理地址的映射通过使用户应用程序的存储位置（从1 MB开始）与其在系统地址空间中出现的地址（从0 MB开始）相互独立，解决了该问题。

#### 12.14.4.1 Bootrom对地址转换的支持

Bootrom能在启动时自动配置地址转换，使存储在物理闪存任意位置的二进制文件，在运行时表现为起始于0地址的闪存地址。

当启动映像位于闪存分区（第5.1.2节）时，该过程自动完成；且可依据启动可执行文件的 `IMAGE_DEF` 中指定的滚动窗口偏移量进行手动调整（第5.1.4节）。

引导只读存储器源代码及其文档通常将QMI `ATRANS` 映射称为“滚动窗口”，这是由于16 MB边界上的模地址回绕——详见第5.1.19节。

#### 12.14.4.2. 翻译与XIP缓存

QMI地址翻译在系统XIP缓存（第4.4.1节）之后进行。因此，对于该翻译而言，XIP缓存是一个虚拟缓存，因为QMI内部执行的地址翻译对XIP缓存是透明的。

因此，对QMI地址翻译的更改须刷新XIP缓存。从缓存视角来看，翻译更改导致QMI内存内容在缓存的下游地址空间内以与缓存内容不一致的方式移动，故须刷新以恢复一致性。至少，任何其 `ATRANSx` 寄存器（`ATRANS0`至`ATRANS7`）被修改，且可能以干净或脏状态缓存的虚拟地址，必须刷新。最简单的方法可能是清空整个缓存。

QMI 的地址映射引发另一种风险：同一物理地址可能映射至多个虚拟地址，因而可能在 XIP 缓存中被多次分配。当通过缓存的虚拟地址别名写入物理地址时，XIP 缓存不会将改动传播至其他别名。为避免此类问题，请勿在同一时间允许同一可写物理地址存在多个别名。对只读存储器进行别名映射通常是安全的。

存在于不同时点的别名（例如跨越 RTOS 上下文切换边界时）可通过在地址映射变更时进行适当清理与刷新以保持一致性。

#### 12.14.5. 直接模式

在直接模式下，AHB XIP 地址窗口与 QSPI 总线断开连接，且总线通过 TX/RX FIFO 对进行控制，类似于普通 SPI 外设。在此状态下，XIP 窗口不可访问。尝试访问该窗口将导致总线故障。该模式用于对 QSPI 总线的底层访问，例如发出闪存擦除/编程命令，或访问 QSPI 设备状态寄存器时。

**所有直接模式操作均通过 `DIRECT_CSR` 控制，数据通过 `DIRECT_TX` 和 `DIRECT_RX` 进行交换。启用直接模式时，须先设置 `DIRECT_CSR.EN`，然后轮询 `DIRECT_CSR.BUSY` 至低电平，以确保在启用直接模式时任何正在进行的 XIP 传输已完成。**

直接模式拥有独立的时钟分频器和RX采样延迟，分别由 `DIRECT_CSR.CLKDIV` 和 `DIRECT_CSR.RXDELAY` 配置。此设置独立于 `M0_TIMING/M1_TIMING` 中配置的每窗口参数，原因在于用于控制的串行命令的频率限制可能与用于执行就地访问的数据访问频率不同。

每次向 `DIRECT_TX` 推送数据时，QMI 将向 QSPI 总线发送 8 位或 16 位 FIFO 数据。可选地，同等位数的数据会同步采样并返回至 `DIRECT_RX`。时钟初始为低电平，数据始终在 `SCK` 上升沿被采集，并在随后的下降沿完成转换。

将数据推送至 `DIRECT_TX` 后，`DIRECT_CSR.BUSY` 将变为高电平，并保持高电平，直到所有直接模式操作完成。即使未返回任何 RX 数据，该方法依然有效，因此比轮询 RX FIFO 状态更可靠。`BUSY` 标志

stays high for half an [SCK](#) period after the transfer finishes, to ensure safe chip select timing when this is used to drive the chip selects – see [Section 12.14.5.2](#).

QMI will never push to a full RX FIFO, or drop data as a result of the FIFO being full – instead, the interface is paused until the system pops [DIRECT\\_RX](#). This avoids a common trap of RX data being lost when the processor is heavily interrupted during direct-mode operation, but software must take care not to poll for [DIRECT\\_CSR.BUSY](#) low without also checking the RX FIFO, as this can cause a deadlock when the FIFO fills.

### 12.14.5.1. Controls in DIRECT\_TX

The TX FIFO carries control information as well as data, with data in the 16 LSBs, and control information in the immediately more-significant bits:

- [DIRECT\\_TX.NOPUSH](#) inhibits the [DIRECT\\_RX](#) push which would match this TX data. This avoids creating garbage when pushing control/address information at the start of a transfer.
- [DIRECT\\_TX.DWIDTH](#) is the data width of this FIFO record. 0 means the 8 LSBs contain data, and 1 means the 16 LSBs contain data. This also determines the amount of data returned in the matching [DIRECT\\_RX](#) entry.
- [DIRECT\\_TX.IWIDTH](#) is the interface width (single/dual/quad) used to clock out this FIFO record. The corresponding RX data is sampled at the same width.
- [DIRECT\\_TX.OE](#) controls the pad direction for bidirectional transfers. It is ignored for serial [IWIDTH](#), since [SD0](#) is always an output and [SD1](#) always an input. At dual/quad width, it must be set in order to enable the output drivers for the duration of this FIFO record. The TX data is don't-care when [IWIDTH](#) is dual/quad and [OE](#) is not set.

The default when all control bits are zero is an 8-bit serial transfer, with 8 bits of sampled data returned. Therefore, you can ignore the control bits and treat this as a plain 8-bit data FIFO.

### 12.14.5.2. Chip select control

There are two options for driving the chip selects, both via [DIRECT\\_CSR](#):

- [DIRECT\\_CSR ASSERT\\_CS0N](#) and [DIRECT\\_CSR ASSERT\\_CS1N](#) will *immediately* drive the corresponding chip select low when set
- [DIRECT\\_CSR AUTO\\_CS0N](#) and [DIRECT\\_CSR AUTO\\_CS1N](#) configure the corresponding chip select to be set low whenever the interface is busy, i.e. when the [DIRECT\\_CSR.BUSY](#) flag is high due to a previous [DIRECT\\_TX](#) push

#### **! IMPORTANT**

The [ASSERT\\_CSxN](#) fields assert the chip select *unconditionally*, including when [DIRECT\\_CSR.EN](#) is clear. Software must take care not to set these fields when XIP transfers may be active.

## 12.14.6. List of registers

The QMI control registers start at address [0x400d0000](#), defined as [XIP\\_QMI\\_BASE](#) in the SDK.

Table 1293. List of QMI registers

Offset	Name	Info
0x00	<a href="#">DIRECT_CSR</a>	Control and status for direct serial mode  Direct serial mode allows the processor to send and receive raw serial frames, for programming, configuration and control of the external memory devices. Only SPI mode 0 (CPOL=0 CPHA=0) is supported.
0x04	<a href="#">DIRECT_TX</a>	Transmit FIFO for direct mode

传输完成后，BUSY标志保持高电平，持续半个SCK周期，以确保当其用于驱动片选信号时的安全时序——详见第 12.14.5.2 节。

QMI 不会向满的 RX FIFO 推送数据，也不会因 FIFO 满而丢弃数据——接口将暂停，直到系统弹出 DIRECT\_RX。这避免了处理器在直接模式操作中频繁中断时导致 RX 数据丢失的常见问题，但软件必须注意，无论何时轮询 DIRECT\_CSR.BUSY 变为低电平，都应同时检查 RX FIFO，否则 FIFO 满时可能会导致死锁。

### 12.14.5.1. DIRECT\_TX 中的控制

TX FIFO 承载控制信息及数据，数据位于最低 16 位，控制信息位于紧挨其上的更高位：

- DIRECT\_TX.NOPUSH 抑制匹配该 TX 数据的 DIRECT\_RX 推送。此操作避免在传输起始阶段推送控制或地址信息时产生无效数据。
- DIRECT\_TX.DWIDTH 表示该 FIFO 记录的数据宽度。数值 0 表示最低有效的 8 位包含数据，数值 1 表示最低有效的 16 位包含数据。该参数亦决定匹配的 DIRECT\_RX 条目所返回的数据量。
- DIRECT\_TX.IWIDTH 为用于时钟输出该 FIFO 记录的接口宽度（单路/双路/四路）。对应的 RX 数据以相同宽度进行采样。
- DIRECT\_TX.OE 控制双向传输中引脚的方向。对于串行 IWIDTH，该设置被忽略，因为 SD0 始终为输出，而 SD1 始终为输入。在双路或四路宽度模式下，必须设置该位以启用本 FIFO 记录持续期间的输出驱动。当 IWIDTH 为双路或四路且 OE 未设置时，TX 数据处于无关状态。

当所有控制位均为零时，默认进行8位串行传输，返回采样的8位数据。因此，您可以忽略控制位，将其视为纯粹的8位数据FIFO。

### 12.14.5.2. 芯片选择控制

通过DIRECT\_CSR，有两种芯片选择驱动方式：

- 设置DIRECT\_CSR ASSERT\_CS0N 和 DIRECT\_CSR ASSERT\_CS1N 时，将立即驱动对应的芯片选择信号拉低。
- DIRECT\_CSR.AUTO\_CS0N 和 DIRECT\_CSR.AUTO\_CS1N 配置对应的芯片选择信号在接口忙碌时（即因先前 DIRECT\_TX 推送导致 DIRECT\_CSR.BUSY 标志为高电平时）被拉低。

#### 重要

ASSERT\_CSxN 字段会无条件断言芯片选择信号，包括在 DIRECT\_CSR.EN 清除时。软件必须避免在可能存在 XIP 传输的情况下设置这些字段。

### 12.14.6. 寄存器列表

QMI 控制寄存器起始地址为 0x400d0000，在 SDK 中定义为 XIP\_QMI\_BASE。

表1293。QMI 寄存器列表

偏移量	名称	说明
0x00	DIRECT_CSR	直接串行模式的控制与状态 直接串行模式允许处理器发送和接收原始串行帧，用于外部存储器设备的编程、配置及控制。仅支持 SPI 模式 0 (CPOL=0, CPH A=0)。
0x04	DIRECT_TX	直接模式的发送 FIFO

Offset	Name	Info
0x08	DIRECT_RX	Receive FIFO for direct mode
0x0c	M0_TIMING	Timing configuration register for memory address window 0.
0x10	M0_RFMT	Read transfer format configuration for memory address window 0.
0x14	M0_RCMD	Command constants used for reads from memory address window 0.
0x18	M0_WFMT	Write transfer format configuration for memory address window 0.
0x1c	M0_WCMD	Command constants used for writes to memory address window 0.
0x20	M1_TIMING	Timing configuration register for memory address window 1.
0x24	M1_RFMT	Read transfer format configuration for memory address window 1.
0x28	M1_RCMD	Command constants used for reads from memory address window 1.
0x2c	M1_WFMT	Write transfer format configuration for memory address window 1.
0x30	M1_WCMD	Command constants used for writes to memory address window 1.
0x34	ATRANS0	Configure address translation for XIP virtual addresses 0x000000 through 0x3fffff (a 4 MiB window starting at +0 MiB).
0x38	ATRANS1	Configure address translation for XIP virtual addresses 0x400000 through 0x7fffff (a 4 MiB window starting at +4 MiB).
0x3c	ATRANS2	Configure address translation for XIP virtual addresses 0x800000 through 0xbfffff (a 4 MiB window starting at +8 MiB).
0x40	ATRANS3	Configure address translation for XIP virtual addresses 0xc00000 through 0xfffffff (a 4 MiB window starting at +12 MiB).
0x44	ATRANS4	Configure address translation for XIP virtual addresses 0x1000000 through 0x13fffff (a 4 MiB window starting at +16 MiB).
0x48	ATRANS5	Configure address translation for XIP virtual addresses 0x1400000 through 0x17fffff (a 4 MiB window starting at +20 MiB).
0x4c	ATRANS6	Configure address translation for XIP virtual addresses 0x1800000 through 0x1bfffff (a 4 MiB window starting at +24 MiB).
0x50	ATRANS7	Configure address translation for XIP virtual addresses 0x1c00000 through 0x1fffff (a 4 MiB window starting at +28 MiB).

## QMI: DIRECT\_CSR Register

Offset: 0x00

偏移量	名称	说明
0x08	DIRECT_RX	直接模式的接收FIFO
0x0c	M0_TIMING	内存地址窗口0的时序配置寄存器
0x10	M0_RFMT	内存地址窗口的读取传输格式配置0.
0x14	M0_RCMD	用于从内存地址读取的命令常量窗口0
0x18	M0_WFMT	内存地址窗口0的写入传输格式配置
0x1c	M0_WCMD	用于写入内存地址窗口的命令常量0.
0x20	M1_TIMING	内存地址窗口1的时序配置寄存器
0x24	M1_RFMT	内存地址窗口的读取传输格式配置1.
0x28	M1_RCMD	用于从内存地址读取的命令常量窗口1
0x2c	M1_WFMT	内存地址窗口1的写传输格式配置
0x30	M1_WCMD	用于写入内存地址窗口的命令常量1.
0x34	ATRANS0	配置XIP虚拟地址的地址转换 0x000000至0x3FFFF (起始于+0 MiB的4 MiB窗口)
0x38	ATRANS1	配置XIP虚拟地址的地址转换 0x400000至0x7FFFF (起始于+4 MiB的4 MiB窗口)
0x3c	ATRANS2	配置XIP虚拟地址的地址转换 0x800000 到 0xbffff (从 +8 MiB 起始的 4 MiB 窗口)。
0x40	ATRANS3	配置XIP虚拟地址的地址转换 0xc00000 到 0xfffffff (从 +12 MiB 起始的 4 MiB 窗口)。
0x44	ATRANS4	配置XIP虚拟地址的地址转换 0x1000000 到 0x13ffff (从 +16 MiB 起始的 4 MiB 窗口)。
0x48	ATRANS5	配置XIP虚拟地址的地址转换 0x1400000 到 0x17ffff (从 +20 MiB 起始的 4 MiB 窗口)。
0x4c	ATRANS6	配置XIP虚拟地址的地址转换 0x1800000 到 0x1bffff (从 +24 MiB 起始的 4 MiB 窗口)。
0x50	ATRANS7	配置XIP虚拟地址的地址转换 0x1c00000 到 0x1fffff (从 +28 MiB 起始的 4 MiB 窗口)。

## QMI: DIRECT\_CSR 寄存器

偏移: 0x00

**Description**

Control and status for direct serial mode

Direct serial mode allows the processor to send and receive raw serial frames, for programming, configuration and control of the external memory devices. Only SPI mode 0 (CPOL=0 CPHA=0) is supported.

*Table 1294.  
DIRECT\_CSR Register*

Bits	Description	Type	Reset
31:30	<b>RXDELAY:</b> Delay the read data sample timing, in units of one half of a system clock cycle. (Not necessarily half of an SCK cycle.)	RW	0x0
29:22	<b>CLKDIV:</b> Clock divisor for direct serial mode. Divisors of 1..255 are encoded directly, and the maximum divisor of 256 is encoded by a value of CLKDIV=0.  The clock divisor can be changed on-the-fly by software, without halting or otherwise coordinating with the serial interface. The serial interface will sample the latest clock divisor each time it begins the transmission of a new byte.	RW	0x06
21	Reserved.	-	-
20:18	<b>RXLEVEL:</b> Current level of DIRECT_RX FIFO	RO	0x0
17	<b>RXFULL:</b> When 1, the DIRECT_RX FIFO is currently full. The serial interface will be stalled until data is popped; the interface will not begin a new serial frame when the DIRECT_TX FIFO is empty or the DIRECT_RX FIFO is full.	RO	0x0
16	<b>RXEMPTY:</b> When 1, the DIRECT_RX FIFO is currently empty. If the processor attempts to read more data, the FIFO state is not affected, but the value returned to the processor is undefined.	RO	0x0
15	Reserved.	-	-
14:12	<b>TXLEVEL:</b> Current level of DIRECT_TX FIFO	RO	0x0
11	<b>TXEMPTY:</b> When 1, the DIRECT_TX FIFO is currently empty. Unless the processor pushes more data, transmission will stop and BUSY will go low once the current 8-bit serial frame completes.	RO	0x0
10	<b>TXFULL:</b> When 1, the DIRECT_TX FIFO is currently full. If the processor tries to write more data, that data will be ignored.	RO	0x0
9:8	Reserved.	-	-
7	<b>AUTO_CS1N:</b> When 1, automatically assert the CS1n chip select line whenever the BUSY flag is set.	RW	0x0
6	<b>AUTO_CS0N:</b> When 1, automatically assert the CS0n chip select line whenever the BUSY flag is set.	RW	0x0
5:4	Reserved.	-	-
3	<b>ASSERT_CS1N:</b> When 1, assert (i.e. drive low) the CS1n chip select line.  Note that this applies even when DIRECT_CSR_EN is 0.	RW	0x0
2	<b>ASSERT_CS0N:</b> When 1, assert (i.e. drive low) the CS0n chip select line.  Note that this applies even when DIRECT_CSR_EN is 0.	RW	0x0

**描述**

直接串行模式的控制与状态

直接串行模式允许处理器发送和接收原始串行帧，用于外部存储器设备的编程、配置及控制。仅支持SPI模式0（CPOL=0，CPHA=0）。

表 1294。  
DIRECT\_CSR 寄存器

位	描述	类型	复位
31:30	<b>RXDELAY:</b> 以系统时钟周期一半为单位，延迟读取数据采样时序。（不一定 是SCK周期的一半。）	读写	0x0
29:22	<b>CLKDIV:</b> 直接串行模式的时钟分频系数。除数1至255直接编码，最大除数256用CLKDIV=0表示。  时钟分频系数可由软件动态修改，无需停止或协调串行接口。串行接口在开始传输新字节时采样最新时钟分频值。	读写	0x06
21	保留。	-	-
20:18	<b>RXLEVEL:</b> 当前DIRECT_RX FIFO的级别。	只读	0x0
17	<b>RXFULL:</b> 当值为1时，DIRECT_RX FIFO已满。串行接口将暂停，直到数据被弹出；当DIRECT_TX FIFO为空或DIRECT_RX FIFO满时，接口不会开始新的串行帧。	只读	0x0
16	<b>RXEMPTY:</b> 当值为1时，DIRECT_RX FIFO为空。若处理器尝试读取更多数据，FIFO状态保持不变，但返回值为未定义。	只读	0x0
15	保留。	-	-
14:12	<b>TXLEVEL:</b> DIRECT_TX FIFO 当前级别	只读	0x0
11	<b>TXEMPTY:</b> 当为1时，DIRECT_TX FIFO 当前为空。除非处理器继续推送数据，否则传输将在当前8位串行帧结束后停止，且BUSY信号将置低。	只读	0x0
10	<b>TXFULL:</b> 当为1时，DIRECT_TX FIFO 当前已满。如果处理器尝试写入更多数据，该数据将被忽略。	只读	0x0
9:8	保留。	-	-
7	<b>AUTO_CS1N:</b> 当为1时，每当BUSY标志被置位时，自动断言CS1n芯片选择线。	读写	0x0
6	<b>AUTO_CS0N:</b> 当为1时，每当BUSY标志被置位时，自动断言CS0n芯片选择线。	读写	0x0
5:4	保留。	-	-
3	<b>ASSERT_CS1N:</b> 当为1时，断言（即拉低）CS1n芯片选择线。  请注意，此规则即使在DIRECT_CSR_EN为0时亦适用。	读写	0x0
2	<b>ASSERT_CS0N:</b> 当为1时，断言（即拉低）CS0n芯片选择线。  请注意，此规则即使在DIRECT_CSR_EN为0时亦适用。	读写	0x0

Bits	Description	Type	Reset
1	<p><b>BUSY:</b> Direct mode busy flag. If 1, data is currently being shifted in/out (or would be if the interface were not stalled on the RX FIFO), and the chip select must not yet be deasserted.</p> <p>The busy flag will also be set to 1 if a memory-mapped transfer is still in progress when direct mode is enabled. Direct mode blocks new memory-mapped transfers, but can't halt a transfer that is already in progress. If there is a chance that memory-mapped transfers may be in progress, the busy flag should be polled for 0 before asserting the chip select.</p> <p>(In practice you will usually discover this timing condition through other means, because any subsequent memory-mapped transfers when direct mode is enabled will return bus errors, which are difficult to ignore.)</p>	RO	0x0
0	<p><b>EN:</b> Enable direct mode.</p> <p>In direct mode, software controls the chip select lines, and can perform direct SPI transfers by pushing data to the DIRECT_TX FIFO, and popping the same amount of data from the DIRECT_RX FIFO.</p> <p>Memory-mapped accesses will generate bus errors when direct serial mode is enabled.</p>	RW	0x0

## QMI: DIRECT\_TX Register

Offset: 0x04

### Description

Transmit FIFO for direct mode

Table 1295.  
DIRECT\_TX Register

Bits	Description	Type	Reset
31:21	Reserved.	-	-
20	<p><b>NOPUSH:</b> Inhibit the RX FIFO push that would correspond to this TX FIFO entry.</p> <p>Useful to avoid garbage appearing in the RX FIFO when pushing the command at the beginning of a SPI transfer.</p>	WF	0x0
19	<p><b>OE:</b> Output enable (active-high). For single width (SPI), this field is ignored, and SD0 is always set to output, with SD1 always set to input.</p> <p>For dual and quad width (DSPI/QSPI), this sets whether the relevant SDx pads are set to output whilst transferring this FIFO record. In this case the command/address should have OE set, and the data transfer should have OE set or clear depending on the direction of the transfer.</p>	WF	0x0
18	<b>DWIDTH:</b> Data width. If 0, hardware will transmit the 8 LSBs of the DIRECT_TX DATA field, and return an 8-bit value in the 8 LSBs of DIRECT_RX. If 1, the full 16-bit width is used. 8-bit and 16-bit transfers can be mixed freely.	WF	0x0
17:16	<b>IWIDTH:</b> Configure whether this FIFO record is transferred with single/dual/quad interface width (0/1/2). Different widths can be mixed freely.	WF	0x0
	Enumerated values:		
	0x0 → S: Single width		

位	描述	类型	复位
1	<p><b>BUSY:</b> 直接模式忙标志。若为1，则表示数据当前正在移入或移出（或者若接口未因RX FIFO阻塞则会进行移入/移出），芯片选择信号不得取消断言。</p> <p>若启用直接模式且内存映射传输仍在进行，忙标志亦将被置为1。直接模式阻止新的内存映射传输，但无法中止已在进行的传输。若可能存在内存映射传输正在进行，应在断言芯片选择信号前轮询忙标志至0。</p> <p>（实际上，您通常会通过其他手段发现该时序条件，因为启用直接模式后任何后续的内存映射传输都会返回总线错误，而此类错误难以忽视。）</p>	只读	0x0
0	<p><b>EN:</b> 使能直接模式。</p> <p>在直接模式下，软件控制芯片选择线，可通过向DIRECT_TX FIFO推送数据，并从DIRECT_RX FIFO弹出等量数据来执行直接SPI传输。</p> <p>启用直接串行模式时，内存映射访问将引发总线错误。</p>	读写	0x0

	0x2 → Q: Quad width		
15:0	<b>DATA:</b> Data pushed here will be clocked out falling edges of SCK (or before the very first rising edge of SCK, if this is the first pulse). For each byte clocked out, the interface will simultaneously sample one byte, on rising edges of SCK, and push this to the DIRECT_RX FIFO.  For 16-bit data, the least-significant byte is transmitted first.	WF	0x0000

## QMI: DIRECT\_RX Register

Offset: 0x08

### Description

Receive FIFO for direct mode

Table 1296.  
DIRECT\_RX Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	With each byte clocked out on the serial interface, one byte will simultaneously be clocked in, and will appear in this FIFO. The serial interface will stall when this FIFO is full, to avoid dropping data.  When 16-bit data is pushed into the TX FIFO, the corresponding RX FIFO push will also contain 16 bits of data. The least-significant byte is the first one received.	RF	0x0000

## QMI: M0\_TIMING, M1\_TIMING Registers

Offsets: 0x0c, 0x20

### Description

Timing configuration register for memory address window 0/1.

Table 1297.  
M0\_TIMING,  
M1\_TIMING Registers

Bits	Description	Type	Reset
31:30	<b>COOLDOWN:</b> Chip select cooldown period. When a memory transfer finishes, the chip select remains asserted for 64 x COOLDOWN system clock cycles, plus half an SCK clock period (rounded up for odd SCK divisors). After this cooldown expires, the chip select is always deasserted to save power.  If the next memory access arrives within the cooldown period, the QMI may be able to append more SCK cycles to the currently ongoing SPI transfer, rather than starting a new transfer. This reduces access latency and increases bus throughput.  Specifically, the next access must be in the same direction (read/write), access the same memory window (chip select 0/1), and follow sequentially the address of the last transfer. If any of these are false, the new access will first deassert the chip select, then begin a new transfer.  If COOLDOWN is 0, the address alignment configured by PAGEBREAK has been reached, or the total chip select assertion limit MAX_SELECT has been reached, the cooldown period is skipped, and the chip select will always be deasserted one half SCK period after the transfer finishes.	RW	0x1

## QMI：M0\_TIMING, M1\_TIMING 寄存器

偏移量：0x0c, 0x20

### 描述

内存地址窗口 0/1 的时序配置寄存器。

表 1297。  
M0\_TIMING,  
M1\_TIMING 寄存器

位	描述	类型	复位
31:30	<p>冷却周期：芯片选择冷却时长。内存传输完成后，芯片选择保持断言状态，持续 <math>64 \times</math> 冷却周期的系统时钟周期，加半个 SCK 时钟周期（奇数 SCK 除数时向上取整）。冷却周期结束后，芯片选择将始终撤销，以节省功耗。</p> <p>若下一次内存访问在冷却周期内到达，QMI 可能在当前进行的 SPI 传输中追加更多 SCK 周期，而非开启新传输。此举可降低访问延迟并提升总线吞吐量。</p> <p>具体要求下一次访问需保持相同方向（读/写）、访问相同内存窗口（片选 0/1），且地址需紧接上一次传输的顺序。若任一条件不满足，新访问将先解除片选信号，然后启动新传输。</p> <p>若 COOLDOWN 为 0，或已达到 PAGEBREAK 配置的地址对齐，或已达到片选最大断言限制 MAX_SELECT，则跳过冷却期，片选信号将在传输结束后一半 SCK 周期内始终解除断言。</p>	读写	0x1

Bits	Description	Type	Reset
29:28	<p><b>PAGEBREAK:</b> When page break is enabled, chip select will automatically deassert when crossing certain power-of-2-aligned address boundaries. The next access will always begin a new read/write SPI burst, even if the address of the next access follows in sequence with the last access before the page boundary.</p> <p>Some flash and PSRAM devices forbid crossing page boundaries with a single read/write transfer, or restrict the operating frequency for transfers that do cross page a boundary. This option allows the QMI to safely support those devices.</p> <p>This field has no effect when COOLDOWN is disabled.</p>	RW	0x0
	Enumerated values:		
	0x0 → NONE: No page boundary is enforced		
	0x1 → 256: Break bursts crossing a 256-byte page boundary		
	0x2 → 1024: Break bursts crossing a 1024-byte quad-page boundary		
	0x3 → 4096: Break bursts crossing a 4096-byte sector boundary		
27:26	Reserved.	-	-
25	<p><b>SELECT_SETUP:</b> Add up to one additional system clock cycle of setup between chip select assertion and the first rising edge of SCK.</p> <p>The default setup time is one half SCK period, which is usually sufficient except for very high SCK frequencies with some flash devices.</p>	RW	0x0
24:23	<p><b>SELECT_HOLD:</b> Add up to three additional system clock cycles of active hold between the last falling edge of SCK and the deassertion of this window's chip select.</p> <p>The default hold time is one system clock cycle. Note that flash datasheets usually give chip select active hold time from the last <b>rising</b> edge of SCK, and so even zero hold from the last falling edge would be safe.</p> <p>Note that this is a minimum hold time guaranteed by the QMI: the actual chip select active hold may be slightly longer for read transfers with low clock divisors and/or high sample delays. Specifically, if the point two cycles after the last RX data sample is later than the last SCK falling edge, then the hold time is measured from <b>this</b> point.</p> <p>Note also that, in case the final SCK pulse is masked to save energy (true for non-DTR reads when COOLDOWN is disabled or PAGE_BREAK is reached), all of QMI's timing logic behaves as though the clock pulse were still present. The SELECT_HOLD time is applied from the point where the last SCK falling edge would be if the clock pulse were not masked.</p>	RW	0x0

位	描述	类型	复位
29:28	<p><b>PAGEBREAK:</b> 启用分页断点后，跨越特定2的幂对齐地址边界时，片选信号将自动解除断言。即使下一次访问地址在分页边界前与上次访问地址连续，下一次访问也将始终启动新的读/写SPI突发传输。</p> <p>部分闪存与PSRAM设备禁止单次读/写传输跨越分页边界，或对跨页传输的工作频率加以限制。此选项允许QMI安全地支持这些设备。</p> <p>当禁用COOLDOWN时，此字段无效。</p>	读写	0x0
	枚举值：		
	0x0 → NONE：不强制页面边界		
	0x1 → 256：在跨越256字节页面边界时终止突发		
	0x2 → 1024：在跨越1024字节四页边界时终止突发		
	0x3 → 4096：在跨越4096字节扇区边界时终止突发		
27:26	保留。	-	-
25	<p><b>SELECT_SETUP:</b> 在芯片选择信号断言与SCK第一个上升沿之间增加最多一个系统时钟周期的设置时间。</p> <p>默认设置时间为半个SCK周期，通常足够。 但对于某些高速SCK频率下的闪存设备例外。</p>	读写	0x0
24:23	<p><b>SELECT_HOLD:</b> 在SCK最后一个下降沿与该窗口芯片选择信号取消断言之间，增加最多三个系统时钟周期的保持时间。</p> <p>默认保持时间为一个系统时钟周期。请注意，闪存数据手册通常规定芯片选择有效保持时间从SCK最后一个上升沿开始计时，因此即便从最后一个下降沿计算零保持时间，也属安全。</p> <p>请注意，此为QMI保证的最小保持时间：对于低时钟分频和/或高采样延迟的读取传输，芯片选择激活保持时间可能会稍长。具体而言，若最后一个R X数据采样后两个周期的时间点晚于最后一个SCK下降沿，则保持时间应从该时间点开始计算。</p> <p>还应注意，若为节能掩盖了最终的SCK脉冲（当禁用COOLDOWN或达到PAGE_BREAK时，非DTR读取有效），QMI所有定时逻辑均视时钟脉冲依然存在。SELECT_HOLD时间自假定时钟脉冲未被掩盖时最后一个SCK下降沿出现的时间点起算。</p>	读写	0x0

Bits	Description	Type	Reset
22:17	<p><b>MAX_SELECT:</b> Enforce a maximum assertion duration for this window's chip select, in units of 64 system clock cycles. If 0, the QMI is permitted to keep the chip select asserted indefinitely when servicing sequential memory accesses (see COOLDOWN).</p> <p>This feature is required to meet timing constraints of PSRAM devices, which specify a maximum chip select assertion so they can perform DRAM refresh cycles. See also MIN_DESELECT, which can enforce a minimum deselect time.</p> <p>If a memory access is in progress at the time MAX_SELECT is reached, the QMI will wait for the access to complete before deasserting the chip select. This additional time must be accounted for to calculate a safe MAX_SELECT value. In the worst case, this may be a fully-formed serial transfer, including command prefix and address, with a data payload as large as one cache line.</p>	RW	0x00
16:12	<p><b>MIN_DESELECT:</b> After this window's chip select is deasserted, it remains deasserted for half an SCK cycle (rounded up to an integer number of system clock cycles), plus MIN_DESELECT additional system clock cycles, before the QMI reasserts either chip select pin.</p> <p>Nonzero values may be required for PSRAM devices which enforce a longer minimum CS deselect time, so that they can perform internal DRAM refresh cycles whilst deselected.</p>	RW	0x00
11	Reserved.	-	-
10:8	<p><b>RXDELAY:</b> Delay the read data sample timing, in units of one half of a system clock cycle. (Not necessarily half of an SCK cycle.) An RXDELAY of 0 means the sample is captured at the SDI input registers simultaneously with the rising edge of SCK launched from the SCK output register.</p> <p>At higher SCK frequencies, RXDELAY may need to be increased to account for the round trip delay of the pads, and the clock-to-Q delay of the QSPI memory device.</p>	RW	0x0
7:0	<p><b>CLKDIV:</b> Clock divisor. Odd and even divisors are supported. Defines the SCK clock period in units of 1 system clock cycle. Divisors 1..255 are encoded directly, and a divisor of 256 is encoded with a value of CLKDIV=0.</p> <p>The clock divisor can be changed on-the-fly, even when the QMI is currently accessing memory in this address window. All other parameters must only be changed when the QMI is idle.</p> <p>If software is increasing CLKDIV in anticipation of an increase in the system clock frequency, a dummy access to either memory window (and appropriate processor barriers/fences) must be inserted after the Mx_TIMING write to ensure the SCK divisor change is in effect <i>before</i> the system clock is changed.</p>	RW	0x04

## QMI: M0\_RFMT, M1\_RFMT Registers

Offsets: 0x10, 0x24

### Description

Read transfer format configuration for memory address window 0/1.

Configure the bus width of each transfer phase individually, and configure the length or presence of the command prefix, command suffix and dummy/turnaround transfer phases. Only 24-bit addresses are supported.

位	描述	类型	复位
22:17	<p><b>MAX_SELECT:</b> 以64个系统时钟周期为单位，强制执行该窗口芯片选择的最大断言持续时间。若设为0，QMI在处理连续内存访问时（详见COOLDOWN）允许芯片选择无限期保持断言状态。</p> <p>此特性旨在满足PSRAM设备的定时约束，该设备规定最大芯片选择断言时间以便完成DRAM刷新周期。另请参见MIN_DESELECT，该参数可用以强制执行最小取消选择时间。</p> <p>若在达到MAX_SELECT时内存访问仍在进行，QMI将等待该访问完成后再取消芯片选择信号。</p> <p>计算安全的MAX_SELECT值时，必须考虑此额外时间。在最坏情况下，该过程可能为完整的串行传输，包括命令前缀和地址，数据负载最大可达一个缓存行。</p>	读写	0x00
16:12	<p><b>MIN_DESELECT:</b> 在本时间窗口芯片选择信号被取消后，芯片选择保持取消状态半个SCK周期（向上取整至系统时钟整数周期数），再加上MIN_DESELECT个系统时钟周期，QMI才会重新断言任一芯片选择引脚。</p> <p>对于需要较长最小CS取消选择时间以在取消选择期间执行内部DRAM刷新周期的PSRAM设备，可能需设置非零值。</p>	读写	0x00
11	保留。	-	-
10:8	<p><b>RXDELAY:</b> 以系统时钟周期一半为单位，延迟读取数据采样时序。（不必然为半个SCK周期。）当RXDELAY为0时，样本在SCK输出寄存器发出的SCK上升沿同时被采集至SDI输入寄存器。</p> <p>在较高的SCK频率下，可能需要增加RXDELAY以补偿焊盘的往返时延及QSPI存储器设备的时钟至Q延迟。</p>	读写	0x0
7:0	<p><b>CLKDIV:</b> 时钟分频系数。支持奇数和偶数分频系数。以1个系统时钟周期为单位定义SCK时钟周期。分频系数1至255直接编码，分频系数256则用CLKDIV=0编码。</p> <p>时钟分频系数可动态调整，即使QMI当前正在访问该地址窗口内的存储器。所有其他参数仅可在QMI空闲时更改。</p> <p>若软件为配合系统时钟频率提升而增加CLKDIV，必须在Mx_TIMING寄存器写入后，插入对任一存储窗口的虚拟访问及相应的处理器屏障/栅栏操作，以确保SCK分频变更在系统时钟切换之前生效。</p>	读写	0x04

## QMI：M0\_RFMT，M1\_RFMT 寄存器

偏移量：0x10, 0x24

### 描述

读取内存地址窗口0/1的传输格式配置。

分别配置每个传输阶段的总线宽度，并配置命令前缀、命令后缀及虚拟/转换传输阶段的长度或是否存在。仅支持24位地址。

The reset value of the Mx\_RFMT register is configured to support a basic 03h serial read transfer with no additional configuration.

*Table 1298.  
M0\_RFMT, M1\_RFMT  
Registers*

Bits	Description	Type	Reset
31:29	Reserved.	-	-
28	<b>DTR:</b> Enable double transfer rate (DTR) for read commands: address, suffix and read data phases are active on both edges of SCK. SDO data is launched centre-aligned on each SCK edge, and SDI data is captured on the SCK edge that follows its launch.  DTR is implemented by halving the clock rate; SCK has a period of 2 x CLK_DIV throughout the transfer. The prefix and dummy phases are still single transfer rate.  If the suffix is quad-width, it must be 0 or 8 bits in length, to ensure an even number of SCK edges.	RW	0x0
27:19	Reserved.	-	-

## QMI: M0\_WCMD, M1\_WCMD Registers

Offsets: 0x1c, 0x30

### Description

Command constants used for writes to memory address window 0/1.

The reset value of the Mx\_WCMD register is configured to support a basic 02h serial write transfer with no additional configuration.

Table 1301.  
M0\_WCMD,  
M1\_WCMD Registers

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:8	<b>SUFFIX:</b> The command suffix bits following the address, if Mx_WFMT_SUFFIX_LEN is nonzero.	RW	0xa0
7:0	<b>PREFIX:</b> The command prefix bits to prepend on each new transfer, if Mx_WFMT_PREFIX_LEN is nonzero.	RW	0x02

## QMI: ATRANS0, ATRANS4 Registers

Offsets: 0x34, 0x44

### Description

Configure address translation for a 4 MiB window of XIP virtual addresses starting at  $n \times 4$  MiB.

Address translation allows a program image to be executed in place at multiple physical flash addresses (for example, a double-buffered flash image for over-the-air updates), without the overhead of position-independent code.

At reset, the address translation registers are initialised to an identity mapping, so that they can be ignored if address translation is not required.

Note that the XIP cache is fully virtually addressed, so a cache flush is required after changing the address translation.

Table 1302. ATRANS0,  
ATRANS4 Registers

Bits	Description	Type	Reset
31:27	Reserved.	-	-
26:16	<b>SIZE:</b> Translation aperture size for this virtual address range, in units of 4 kiB (one flash sector).  Bits 21:12 of the virtual address are compared to SIZE. Offsets greater than SIZE return a bus error, and do not cause a QSPI access.	RW	0x400
15:12	Reserved.	-	-
11:0	<b>BASE:</b> Physical address base for this virtual address range, in units of 4 kiB (one flash sector).  Taking a 24-bit virtual address, firstly bits 23:22 (the two MSBs) are masked to zero, and then BASE is added to bits 23:12 (the upper 12 bits) to form the physical address. Translation wraps on a 16 MiB boundary.	RW	0x000

15:8	后缀：当Mx_WFMT_SUFFIX_LEN非零时，位于地址后的命令后缀位。	读写	0xa0
7:0	前缀：当Mx_WFMT_PREFIX_LEN非零时，每次新传输前必须添加的命令前缀位。	读写	0x02

## QMI：ATRANS0，ATRANS4寄存器

偏移：0x34, 0x44

### 描述

配置从 $n \times 4$  MiB起始的XIP虚拟地址的4 MiB窗口的地址转换。

地址转换允许程序镜像在多个物理闪存地址处原位执行（例如，用于无线升级的双缓冲闪存镜像），从而免去位置无关代码的开销。

复位时，地址转换寄存器初始化为恒等映射，因此若不需要地址转换，则可忽略。

注意，XIP缓存完全采用虚拟寻址，因此更改地址转换后必须刷新缓存。

## 12.15. System Control Registers

These registers are not associated with any particular peripheral. They control, or provide information about, system-level hardware such as the bus fabric. This is also where chip identification information such as the JEDEC IDCODE is provided in a software-accessible manner.

### 12.15.1. SYSINFO

#### 12.15.1.1. Overview

The sysinfo block contains system information. The first register contains the Chip ID, which allows the programmer to know which version of the chip software is running on. The second register indicates which package configuration is

## 12.15. 系统控制寄存器

这些寄存器不与任何特定外设关联。其用于控制系统级硬件或提供相关信息，例如总线结构。此处亦以软件可访问的方式提供芯片识别信息，如JEDEC IDCODE。

### 12.15.1. SYSINFO

#### 12.15.1.1. 概述

sysinfo块包含系统信息。第一个寄存器包含芯片ID，允许程序员识别芯片软件的运行版本。第二个寄存器指示所使用的

used (QFN-60 or QFN-80). The third register will always read as 1.

### 12.15.1.2. List of registers

The sysinfo registers start at a base address of `0x40000000` (defined as `SYSINFO_BASE` in SDK).

*Table 1306. List of SYSINFO registers*

Offset	Name	Info
0x00	<a href="#">CHIP_ID</a>	JEDEC JEP-106 compliant chip identifier.
0x04	<a href="#">PACKAGE_SEL</a>	Package selection indicator, 0 = QFN80, 1 = QFN60
0x08	<a href="#">PLATFORM</a>	Platform register. Allows software to know what environment it is running in during pre-production development. Post-production, the PLATFORM is always ASIC, non-SIM.
0x14	<a href="#">GITREF_RP2350</a>	Git hash of the chip source. Used to identify chip version.

## SYSINFO: CHIP\_ID Register

**Offset:** 0x00

### Description

JEDEC JEP-106 compliant chip identifier.

*Table 1307. CHIP\_ID Register*

Bits	Description	Type	Reset
31:28	<b>REVISION</b>	RO	-
27:12	<b>PART</b>	RO	-

## 12.15.2. SYSCFG

### 12.15.2.1. Overview

The system config block controls miscellaneous chip settings, including:

- Check debug halt status of both cores
- Processor GPIO input synchroniser control (set to 1 to allow input synchroniser bypassing to reduce latency for synchronous clocks)
- SWD interface control from inside the chip (allows one core to debug another, which may make debug connectivity easier)
- State-retaining memory power down (SRAM periphery can be powered down when not in use to save a small amount of power)
  - when powered down in this way, power is still applied to the SRAM storage array; use the Power Manager (Chapter 6) to completely remove power
- Additional controls found in the [AUXCTRL](#) register

### 12.15.2.2. Changes from RP2040

- Moved the NMI mask to per-core registers in the EPPB ([Section 3.7.5.1](#)). The new registers reset on a processor warm reset, which avoids issues with NMIs asserting during the bootrom early boot process.
- Expanded [MEMPOWERDOWN](#) to cover new memory banks
- Removed controls from [DBGFORCE](#) to account for the new single-DP debug topology

### 12.15.2.3. List of registers

The system config registers start at a base address of [0x40008000](#) (defined as [SYSCFG\\_BASE](#) in SDK).

## 12.15.2. SYSCFG

### 12.15.2.1. 概述

系统配置块控制杂项芯片设置，包括：

- 检查两个核心的调试停止状态
- 处理器 GPIO 输入同步器控制（设置为 1以允许输入同步器绕过，从而减少同步时钟延迟）
- 芯片内部的 SWD 接口控制（允许一个核心调试另一个核心，可能使调试连接更便捷）
- 状态保持内存断电（SRAM 外围设备在不使用时可断电以节省少量功耗）
  - 以此方式断电时，仍会向 SRAM 存储阵列供电；使用电源管理器（第6章）可完全切断电源
- AUXCTRL 寄存器中的其他控制

### 12.15.2.2. 相较于 RP2040 的变更

- 已将 NMI 掩码移动至 EPPB 中的每核寄存器（见第3.7.5.1节）。新寄存器在处理器热重置时复位，从而避免了启动只读存储器早期启动过程中 NMI 触发的问题。
- 扩展MEMPOWERDOWN以涵盖新的内存块
- 从DBGFORCE中移除控制项以适应新的单DP调试拓扑结构

### 12.15.2.3. 寄存器列表

系统配置寄存器起始基地址为 **0x40008000**（在SDK中定义为SYSCFG\_BASE）。

表1311。SYSCFG  
寄存器列表

偏移量	名称	说明
0x00	PROC_CONFIG	处理器配置

Offset	Name	Info
0x04	PROC_IN_SYNC_BYPASS	For each bit, if 1, bypass the input synchronizer between that GPIO and the GPIO input register in the SIO. The input synchronizers should generally be unbypassed, to avoid injecting metastabilities into processors. If you're feeling brave, you can bypass to save two cycles of input latency. This register applies to GPIO 0...31.
0x08	PROC_IN_SYNC_BYPASS_HI	For each bit, if 1, bypass the input synchronizer between that GPIO and the GPIO input register in the SIO. The input synchronizers should generally be unbypassed, to avoid injecting metastabilities into processors. If you're feeling brave, you can bypass to save two cycles of input latency. This register applies to GPIO 32...47. USB GPIO 56..57 QSPI GPIO 58..63
0x0c	DBGFORCE	Directly control the chip SWD debug port

## SYSCFG: PROC\_CONFIG Register

Offset: 0x00

### Description

Configuration for processors

Table 1312.  
PROC\_CONFIG  
Register

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>PROC1_HALTED:</b> Indication that proc1 has halted	RO	0x0
0	<b>PROC0_HALTED:</b> Indication that proc0 has halted	RO	0x0

## SYSCFG: PROC\_IN\_SYNC\_BYPASS Register

Offset: 0x04

### Description

For each bit, if 1, bypass the input synchronizer between that GPIO and the GPIO input register in the SIO. The input synchronizers should generally be unbypassed, to avoid injecting metastabilities into processors.  
If you're feeling brave, you can bypass to save two cycles of input latency. This register applies to GPIO 0...31.

偏移量	名称	说明
0x04	PROC_IN_SYNC_BYPASS	对于每一位，若为1，则绕过该GPIO与SIO中GPIO输入寄存器之间的输入同步器。 输入同步器通常不应被绕过，以避免向处理器引入亚稳态。 一般建议不绕过输入同步器，以防止向处理器注入亚稳态。 如有胆识，可绕过该同步器以节省两周期的输入延迟。 延迟。该寄存器适用于GPIO 0至31。
0x08	PROC_IN_SYNC_BYPASS_HI	对于每一位，若为1，则绕过该GPIO与SIO中GPIO输入寄存器之间的输入同步器。 输入同步器通常不应被绕过，以避免向处理器引入亚稳态。 一般建议不绕过输入同步器，以防止向处理器注入亚稳态。 如有胆识，可绕过该同步器以节省两周期的输入延迟。 延迟。该寄存器适用于GPIO 32至47及USB GPIO 56至57。 QSPI GPIO 58至63
0x0c	DBGFORCE	直接控制芯片的SWD调试端口
0x10	MEMPOWERDOWN	控制存储器的电源降压（PD）引脚。 置高电平可使存储器进入低功耗状态。在此状态下，存储器内容将被保留，但无法访问。 请谨慎使用。
0x14	AUXCTRL	辅助系统控制寄存器

Offset: 0x14

### Description

Auxiliary system control register

Table 1317. AUXCTRL Register

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	* Bits 7:3: Reserved  * Bit 2: Set to mask OTP power analogue power supply detection from resetting OTP controller and PSM  * Bit 1: When clear, the LPOSC output is XORed into the TRNG ROSC output as an additional, uncorrelated entropy source. When set, this behaviour is disabled.  * Bit 0: Force POWMAN clock to switch to LPOSC, by asserting its WDRESET input. This must be set before initiating a watchdog reset of the RSM from a stage that includes CLOCKS, if POWMAN is running from clk_ref at the point that the watchdog reset takes place. Otherwise, the short pulse generated on clk_ref by the reset of the CLOCKS block may affect POWMAN register state.	RW	0x00

## 12.15.3. TBMAN

TBMAN refers to the testbench manager, used during chip development simulations to verify the design. During these simulations TBMAN allows software running on RP2350 to control the testbench and simulation environment. On the real chip, it has no effect other than providing a single **PLATFORM** register that indicates that this is the real chip. This **PLATFORM** functionality is duplicated in the sysinfo (Section 12.15.1) registers.

### 说明

辅助系统控制寄存器

表 1317。AUXCTRL 寄存器

位	描述	类型	复位
31:8	保留。	-	-
7:0	* 位 7:3：保留 * 位 2：设置以屏蔽 OTP 电源模拟电源检测，防止 OTP 控制器与 PSM 被重置。 * 位 1：清除时，LPOSC 输出将被异或加入 TRNG ROSC 输出，作为额外的非相关熵源。设置后，该行为将被禁用。 * 位 0：通过断言其 WDRESET 输入，强制 POWMAN 时钟切换至 LPOSC。在启动包含 CLOCKS 阶段的 RSM 看门狗复位之前，且当看门狗复位发生时 POWMAN 正从 clk_ref 运行，必须设置此项。否则，CLOCKS 模块复位时在 clk_ref 上产生的短脉冲可能会影响 POWMAN 寄存器状态。	读写	0x00

### 12.15.3. TBMAN

TBMAN 指测试平台管理器，在芯片开发仿真过程中用于验证设计。在这些仿真中，TBMAN 允许运行于 RP2350 上的软件控制测试平台及仿真环境。在实际芯片中，其唯一作用是提供一个 PLATFORM 寄存器，用以标示这是实际芯片。该 PLATFORM 功能在 sysinfo（第12.15.1节）寄存器中亦有重复实现。

### 12.15.3.1. List of registers

The TBMAN registers start at a base address of `0x40160000` (defined as `TBMAN_BASE` in SDK).

*Table 1318. List of TBMAN registers*

Offset	Name	Info
0x0	PLATFORM	Indicates the type of platform in use

## TBMAN: PLATFORM Register

**Offset:** 0x0

0	<b>ASIC</b> : Indicates the platform is an ASIC	RO	0x1

## 12.15.4. BUSCTRL

This block provides basic controls and monitoring for the system bus fabric.

### 12.15.4.1. Bus priority

RP2350 implements a dynamic bus priority scheme described in [Section 2.1.1](#). The `BUS_PRIORITY` register implements the priority controls for this scheme.

### 12.15.4.2. Performance counters

There are four 24-bit counters, each of which can subscribe to a single performance event from the system bus fabric. Counters saturate at a value of all-ones: the counter stops incrementing when it reaches its maximum value, rather than wrapping to zero.

The performance counters are initially disabled: you must write 1 to `PERFCTR_EN` before the counters begin to increment. Write any value to a counter to clear the counter to zero in before running a profiled section of code, and enable the counters immediately before entering the profiled section. Disable the counters again immediately upon leaving the profiled section. The counters do not support arbitrary writes: they only count up from zero.

Write to a performance event selector register `PERFSEL0` through `PERFSEL3` to select the performance event which increments the corresponding counter, `PERFCTR0` through `PERFCTR3`.

For each of the seventeen downstream bus ports on the main system AHB5 crossbar shown in [Figure 5](#), there are four types of event which the performance counters detect. These events do not distinguish reads from writes, but they do distinguish different types of bus stall, which can be helpful when diagnosing performance issues. The types of event are:

#### Access

Increment when any access completes on this downstream port.

#### Contested access

Increment when any access completes on this downstream port which previously stalled due to the port being

### 12.15.3.1. 寄存器列表

TBMAN 寄存器起始地址为 `0x40160000` (SDK 中定义为 TBMAN\_BASE)。

0	<b>ASIC</b> ：表示该平台为专用集成电路	只读	0x1

## 12.15.4. BUSCTRL

本模块提供系统总线结构的基础控制与监控功能。

### 12.15.4.1. 总线优先级

RP2350实现了第2.1.1节所述的动态总线优先级方案。BUS\_PRIORITY寄存器执行该方案的优先级控制。

### 12.15.4.2. 性能计数器

共有四个24位计数器，每个计数器可订阅系统总线结构中的单一性能事件。

计数器在全1值时达到饱和：计数器达到最大值后停止递增，且不回绕至零。

性能计数器初始处于禁用状态：必须向PERFCTR\_EN写入 `1`，计数器方可开始递增。在运行受分析代码段之前，写入任意值以将计数器清零，并在进入该代码段前立即启用计数器。在离开受分析代码段时，立即再次禁用计数器。计数器不支持任意写入：仅能从零开始递增。

向性能事件选择寄存器PERFSEL0至PERFSEL3写入数据，以选择使对应计数器PERFCTR0至PERFCTR3递增的性能事件。

对于主系统AHB5交叉开关图5所示的十七个下游总线端口，每个端口的性能计数器可检测四种事件类型。这些事件不区分读写操作，但能区分不同类型的总线阻塞，有助于性能问题的诊断。事件类型包括：

#### 访问权限

任何访问在该下游端口完成时递增计数。

#### 争用访问

任何先前因端口被

occupied by another access. For example, if two managers access an initially idle port simultaneously, one will complete before the other. The access that completes first is said to not be contested, and does not increment this counter. The access that completes second (which was initially deferred due to the access from the other manager) is contested, and increments this counter when it completes.

#### Upstream-stalled cycle

Increment once per cycle while any manager experiences a stall on this port. This may be either due to arbitration with another manager (a contested access) or due to a stall on the downstream bus port, such as access to a slow peripheral. This is measured at the port, before leaving the main AHB5 crossbar.

#### Downstream-stalled cycle

Increment once per cycle while this port itself experiences a stall on the downstream bus. This indicates the peripheral or memory device itself being slow to respond, such as an XIP cache miss.

The first two event types listed above are the same as RP2040. The latter two are new for RP2350.

### 12.15.4.3. List of registers

The Bus Fabric registers start at a base address of **0x40068000** (defined as **BUSCTRL\_BASE** in SDK).

Table 1320. List of BUSCTRL registers

Offset	Name	Info
0x00	<a href="#">BUS_PRIORITY</a>	Set the priority of each master for bus arbitration.
0x04	<a href="#">BUS_PRIORITY_ACK</a>	Bus priority acknowledge
0x08	<a href="#">PERFCTR_EN</a>	Enable the performance counters. If 0, the performance counters do not increment. This can be used to precisely start/stop event sampling around the profiled section of code.  The performance counters are initially disabled, to save energy.
0x0c	<a href="#">PERFCTR0</a>	Bus fabric performance counter 0
0x10	<a href="#">PERFSEL0</a>	Bus fabric performance event select for PERFCTR0
0x14	<a href="#">PERFCTR1</a>	Bus fabric performance counter 1
0x18	<a href="#">PERFSEL1</a>	Bus fabric performance event select for PERFCTR1
0x1c	<a href="#">PERFCTR2</a>	Bus fabric performance counter 2
0x20	<a href="#">PERFSEL2</a>	Bus fabric performance event select for PERFCTR2
0x24	<a href="#">PERFCTR3</a>	Bus fabric performance counter 3
0x28	<a href="#">PERFSEL3</a>	Bus fabric performance event select for PERFCTR3

## BUSCTRL: BUS\_PRIORITY Register

**Offset:** 0x00

#### Description

Set the priority of each master for bus arbitration.

Table 1321.  
BUS\_PRIORITY  
Register

Bits	Description	Type	Reset
31:13	Reserved.	-	-
12	<b>DMA_W:</b> 0 - low priority, 1 - high priority	RW	0x0
11:9	Reserved.	-	-
8	<b>DMA_R:</b> 0 - low priority, 1 - high priority	RW	0x0

另一访问占用而阻塞的访问在该下游端口完成时递增计数。例如，如果两个管理器同时访问一个初始空闲的端口，其中一个访问将先完成。先完成的访问称为无竞争访问，不会增加此计数器。第二个完成的访问（因另一个管理器的访问最初被延迟）被视为有竞争访问，并在完成时增加此计数器。

#### 上游阻塞周期

只要任何管理器在该端口发生阻塞，每个周期递增一次。这可能是由于与其他管理器的仲裁（即有竞争访问）或下游总线端口的阻塞，例如访问慢速外设。此统计测量位置为端口处，在离开主AHB5交叉开关之前。

#### 下游阻塞周期

只要该端口自身在下游总线上发生阻塞，每个周期递增一次。这表明外设或存储设备响应缓慢，如XIP缓存未命中。

上述前两种事件类型与RP2040相同，后两种则为RP2350新增。

#### 12.15.4.3. 寄存器列表

总线结构寄存器起始基址为 [0x40068000](#)（在SDK中定义为BUSCTRL\_BASE）。

表1320。BUSCTRL寄存器列表

偏移量	名称	说明

# Chapter 13. OTP

RP2350 provides 8 kB of one-time programmable storage (OTP), which holds:

- Preprogrammed per-device information, such as unique device identifier and oscillator trim values
- Security configuration such as debug disable and secure boot enable
- Public key fingerprints for secure boot
- Symmetric keys for decryption of flash contents into SRAM
- Configuration for the USB bootloader, such as customising VID/PID and descriptors
- Bootable software images, for low-cost flashless applications or custom bootloaders
- Any other user-defined data, such as per-device personalisation values

For the full listing of predefined OTP contents, see [Section 13.10](#).

OTP is physically an array of 4096 rows of 24 bits each. You can directly access these 24-bit values, but there is also hardware support for storing 16 bits of data in each row, with 6 bits of Hamming ECC protection and 2 bits of bit polarity reversal protection, yielding an ECC data capacity of 8192 bytes.

On a blank device, the OTP contents is all zeroes, except for some basic device information pre-programmed during manufacturing test. Each bit can be *irreversibly* programmed from zero to one. To program the OTP contents:

- Directly access the registers using the SBPI bridge
- Call the bootrom `otp_access` API ([Section 5.4.8.21](#))
- Use the PICOBLOCK interface of the USB bootloader ([Section 5.6](#))

RP2350 enforces page-based permissions on OTP to partition Secure from Non-secure data and to ensure that contents that should not change *do not* change. The OTP address space is logically partitioned into 64 pages, each 64 rows in size, for a total of 128 bytes of ECC data per page. Pages initially have full read-write permissions, but can be restricted to read-only or inaccessible for each of Secure, Non-secure and bootloader access.

The page permissions themselves are stored in OTP. Locking pages in this way is an irreversible operation, referred to as *hard locking*. The hardware also supports *soft locking*, where a page's permissions are further restricted by writing to the relevant register in `SW_LOCK0` through `SW_LOCK63`; this restriction remains in effect until the next OTP reset. Resetting the OTP block also resets the processors, so soft locking can be used to restrict the availability of sensitive content like decryption keys to early boot stages.

OTP access keys ([Section 13.5.2](#)) provide an additional layer of protection. A fixed challenge is written to a write-only OTP area. Pages registered to that key require the key to be entered to a write-only register in order to open read or write access. This supports configuration data that can be accessed or edited by the board manufacturer, but not by general firmware running on the device.

## 13.1. OTP address map

The OTP hardware resides in a 128 kB region starting at `0x40120000` (OTP\_BASE in the SDK). Bit 16 of the address is used to select either the OTP control registers, in the lower 64 kB, or one of the OTP read data aliases, in the upper 64 kB of this space.

The OTP control registers ([Section 13.9](#)) are aliased at 4 kB intervals to implement the usual set, clear, and XOR atomic write aliases described in [Section 2.1.3](#).

The read data region starting at `0x40130000` divides further into four aliases:

- `0x40130000, OTP_DATA_BASE`: ECC read alias. A 32-bit read returns the ECC-corrected data for two neighbouring rows, or all-ones on permission failure. Only the first 8 kB is populated.

# 第13章 一次性可编程存储器 (OTP)

RP2350 提供8 kB的一次性可编程存储 (OTP) , 其内容包括:

- 预编程的每个设备信息, 例如唯一设备标识符和振荡器校准值
- 安全配置, 如禁用调试功能和启用安全启动
- 用于安全启动的公钥指纹
- 用于将闪存内容解密到SRAM的对称密钥
- USB引导加载程序的配置, 例如自定义VID/PID及描述符
- 可启动的软件镜像, 适用于低成本无闪存应用或自定义引导加载程序
- 任何其他用户定义的数据, 如每个设备的个性化参数

有关预定义OTP内容的完整列表, 请参见第13.10节。

OTP物理上由4096行24位组成的阵列构成。您可以直接访问这些24位数值, 但硬件同时支持在每行存储16位数据, 配备6位海明码ECC保护和2位比特极性反转保护, 从而实现8192字节的ECC数据容量。

在一台空白设备上, OTP内容全部为零, 除了一些在制造测试期间预先编程的基本设备信息。每个位均可不可逆地由零编程为一。编程OTP内容的步骤如下:

- 通过SBPI桥接器直接访问寄存器
- 调用bootrom的 `otp_access` API (第5.4.8.21节)
- 使用USB引导加载程序的PICOBLOCK接口 (第5.6节)

RP2350针对OTP实施基于页面的权限控制, 以划分安全区与非安全区数据, 并确保不应更改的内容不会被更改。OTP地址空间逻辑上划分为64页, 每页64行大小, 每页包含128字节的ECC数据。各页面初始具备完全读写权限, 但可针对安全区、非安全区及引导加载程序访问分别限制为只读或不可访问。

页面权限信息本身存储于OTP中。以此方式锁定页面是一种不可逆操作, 称为硬锁定。硬件还支持软锁定, 即通过向SW\_LOCK0至SW\_LOCK63中的相应寄存器写入值, 进一步限制页面权限; 此限制将持续有效, 直至下一次OTP重置。

重置OTP块同时也会重置处理器, 因此软锁定可用于限制敏感内容 (例如解密密钥) 仅在早期引导阶段可用。

OTP访问密钥 (第13.5.2节) 提供了额外的安全保护层。一个固定挑战值被写入只写OTP区域。注册到该密钥的页面必须将密钥输入到只写寄存器, 方可开启读写访问权限。该机制支持配置数据, 允许板载制造商访问或编辑, 但禁止设备上运行的一般固件访问。

## 13.1. OTP 地址映射

OTP硬件位于起始地址 `0x40120000` (SDK中的OTP\_BASE) 起始的128 kB区域。地址第 16位用于选择该区域内的OTP控制寄存器 (低64 kB) 或OTP读取数据别名 (高64 kB) 。

OTP 控制寄存器 (第13.9节) 以4 kB间隔进行别名映射, 以实现第2.1.3节中描述的常规置位、清除及异或 (XOR) 原子写入别名。

从 `0x40130000` 开始的读取数据区域进一步划分为四个别名:

- `0x40130000`, `OTP_DATA_BASE`: ECC读取别名。进行32位读取时, 将返回两个相邻行经ECC校正的数据, 权限不符时返回全1。仅填充了首8 kB。

- **0x40138000, OTP\_DATA\_GUARDED\_BASE:** ECC guarded read alias. Successful reads return the same data as **OTP\_DATA\_BASE**. Only the first 8 kB is populated.
- **0x40134000, OTP\_DATA\_RAW\_BASE:** raw read alias. A 32-bit read directly returns the 24-bit contents of a single row, with zeroes in the eight MSBs, or returns all-ones on permission failure.
- **0x4013c000, OTP\_DATA\_RAW\_GUARDED\_BASE:** raw, guarded read alias. Successful reads return the same data as **OTP\_DATA\_RAW\_BASE**.

Bit 14 of the address selects ECC (0) vs raw (1). Bit 15 of the address selects unguarded (0) vs guarded (1) access. Guarded reads return the same data as unguarded reads, but perform additional hardware consistency checks and return bus faults on permission failure. For more information, see [Section 13.1.1](#).

#### **! IMPORTANT**

The read data regions starting at **0x40130000** are accessible only when **USR.DCTRL** is set, otherwise all reads return a bus error response. This bit is clear when the OTP is being programmed via the SBPI bridge.

Writing to the read data aliases is not a valid operation, and will always return a bus fault. The OTP is programmed by the SBPI bridge, which is used internally by the bootrom **otp\_access** API, [Section 5.4.8.21](#).

### 13.1.1. Guarded reads

Reads through the guarded aliases differ from unguarded reads in the following ways:

- Permission failures return bus faults rather than a bit pattern of all-ones.
- Uncorrectable ECC errors return a bus fault if detected.
- Guarded reads perform an additional hardware consistency check to detect power transients. If this check fails, the read returns a bus fault.

These checks help to make the OTP fail-safe in contexts where deliberate fault injection is a possibility. For example, the RP2350 bootrom uses guarded reads to check boot configuration flags.

The data returned from a successful guarded read is the same as the data returned by a successful read from the corresponding unguarded alias.

#### **! IMPORTANT**

Users relying on OTP data in a Secure context should always perform guarded reads, and it is strongly recommended to use ECC. For rows where ECC is not possible, software should take care to ensure the consistency of data across multiple overlapping reads.

## 13.2. Background: OTP IP details

The RP2350 OTP subsystem uses the Synopsys NVM OTP IP, which comes in 3 parts:

- Integrated Power Supply (IPS), including:
  - Charge Pump (for programming)
  - Regulator (for reading)
- OTP Macro (SHF, Fuse)
  - 4096 × 24 (8 kB with ECC, 16-bit ECC write granularity)
- Access port (AP), providing:

- **0x40138000, OTP\_DATA\_GUARDED\_BASE**: ECC受保护读取别名。成功读取时返回与 **OTP\_DATA\_BASE** 相同的数据。仅填充了首 8 kB。
- **0x40134000, OTP\_DATA\_RAW\_BASE**: 原始读取别名。进行 32 位读取时，直接返回单行的 24 位内容，最高 8 位为零；权限不符时返回全 1。
- **0x4013c000,OTP\_DATA\_RAW\_GUARDED\_BASE**: 原始的，受保护读取别名。成功读取返回与 **OTP\_DATA\_RAW\_BASE** 相同的数据。

地址的第 14 位选择 ECC (0) 或原始数据 (1)。地址的第 15 位选择非保护访问 (0) 或保护访问 (1)。受保护读取返回与非保护读取相同的数据，但会执行额外的硬件一致性检查，并在权限失败时返回总线故障。更多信息，请参见第 13.1.1 节。

#### **!** 重要

起始地址为 **0x40130000** 的读取数据区域仅在 USR.DCTRL 设置时可访问，否则所有读取操作均返回总线错误。当通过 SBPI 桥对 OTP 编程时，该位被清除。

写入读取数据别名不是有效操作，且始终返回总线故障。OTP 由 SBPI 桥编程，该桥由 bootrom 内部使用的 **otp\_access** 接口控制，详见第 5.4.8.21 节。

### 13.1.1. 保护读取

受保护别名的读取与非受保护读取在以下方面存在差异：

- 权限失败时返回总线故障，而非全为 1 的位模式。
- 检测到不可纠正的 ECC 错误时，将返回总线故障。
- 受保护读取会执行额外的硬件一致性检查以检测电源瞬态。若该检查失败，读取操作将返回总线故障。

这些检查有助于在存在故意故障注入可能性的环境中，使 OTP 实现容错安全。例如，RP2350 BootROM 使用受保护读取检查启动配置标志。

成功的受保护读取返回的数据，与相应非受保护别名的成功读取返回的数据相同。

#### **!** 重要

在安全环境中依赖 OTP 数据的用户应始终执行受保护读取，且强烈建议使用 ECC。对于无法使用 ECC 的行，软件应确保多次重叠读取的数据一致性。

## 13.2. 背景：OTP IP 细节

RP2350 OTP 子系统采用 Synopsys NVM OTP IP，该 IP 包括三部分：

- 集成电源供应 (IPS)，包括：
  - 电荷泵（用于编程）
  - 稳压器（用于读取）
- OTP 宏单元 (SHF, 保险丝)
  - 4096×24 (8 kB, 含 ECC, 16 位 ECC 写入粒度)
- 访问端口 (AP)，提供：

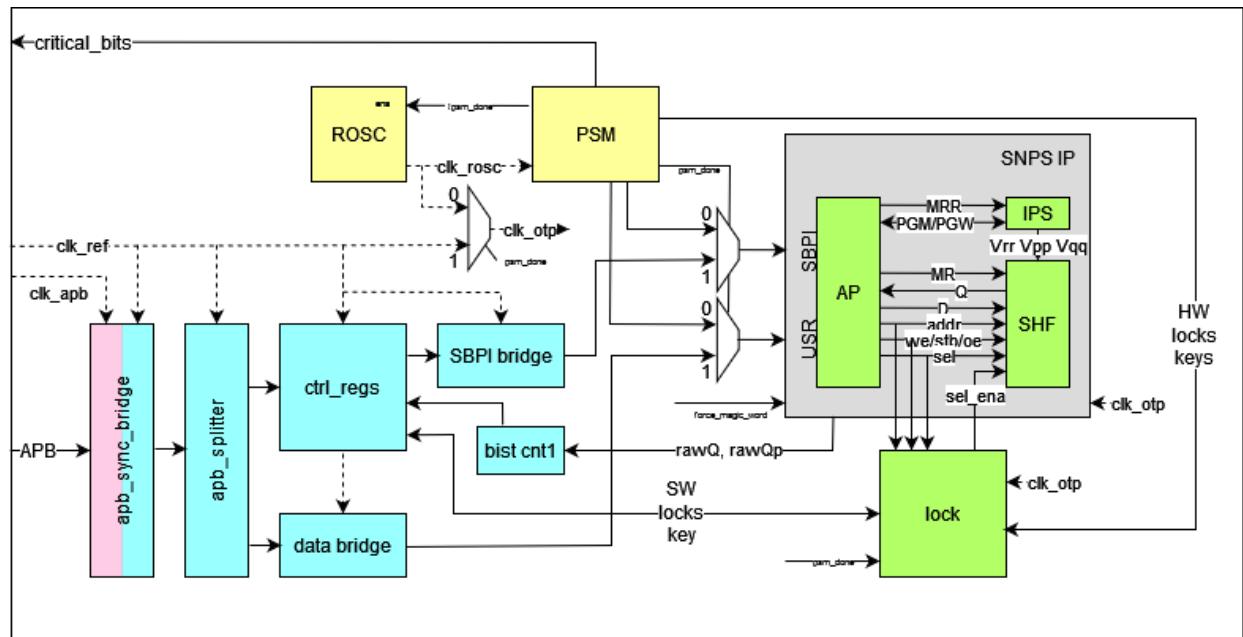

- Basic read access
  - Programming access
  - ECC and bit redundancy
  - BOOT function, which polls for stable OTP power supply at start-of-day

### 13.3. Background: OTP hardware architecture

This diagram shows the integration of the three Synopsys IP components, and the Raspberry Pi hardware added to make this all function in the context of RP2350's system and security architecture. More specifically:

- APB interface(s) to connect to the SoC
  - Internal ring oscillator with clock edge randomisation
  - Power-up state machine, running off the ring oscillator
  - Lock shim, sitting between the SNPS RTL and the memory core (fuse)

*Figure 142. OTP architecture*

The OTP subsystem clock is initially provided by the OTP boot oscillator (Section 13.3.3) during hardware startup, but switches to `clk_ref` before any software runs on the processors. The frequency of `clk_ref` must not exceed 25 MHz when accessing the OTP.

### 13.3.1. Lock shim

The lock shim is inserted between the Synopsys AP block and the SHF block, and is used to enforce read/write page locks, based on:

- The OTP address presented on the AP → SHF bus
  - The read/write strobe on the AP → SHF bus
  - The security attribute of the upstream bus access which caused this SHF access (assumed to be Secure if SBPI is currently enabled via USR.DCTRL)

Because the Synopsys AP performs both reads and writes in the course of programming an OTP row, it is impossible to disable reads to an address without also disabling writes. Three lock states are supported:

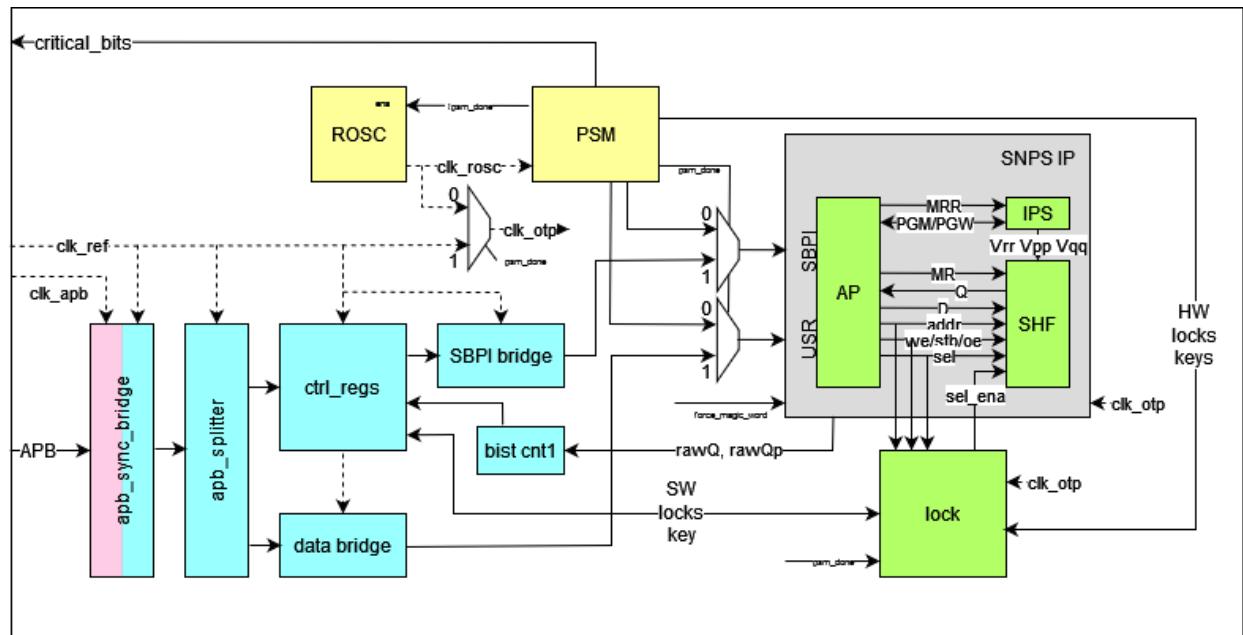

- 基本读取访问
- 编程访问
- ECC 及位冗余
- BOOT 功能，在系统启动时轮询稳定的 OTP 电源

### 13.3. 背景：OTP 硬件架构

本图展示了三个 Synopsys IP 组件的集成情况，以及为使其在 RP2350 系统和安全架构上下文中正常运行而添加的 Raspberry Pi 硬件。具体包括：

- 用于连接 SoC 的 APB 接口
- 内部环形振荡器，带时钟边沿随机化
- 启动状态机，基于环形振荡器运行
- 锁定衬套，位于 SNPS RTL 与存储核心（保险丝）之间

图 142. OTP 架构

OTP 子系统时钟在硬件启动期间最初由 OTP 启动振荡器（第 13.3.3 节）提供，但在处理器运行任何软件之前切换至 `clk_rf`。访问OTP时，`clk_ref`的频率不得超过25 MHz。

#### 13.3.1. 锁存衬垫

锁定衬垫插入于Synopsys AP模块与SHF模块之间，用于基于以下条件强制执行读写页锁定：

- AP → SHF 总线上呈现的OTP地址
- AP → SHF 总线上的读写选通信号
- 导致该SHF访问的上游总线访问的安全属性（如当前通过USR.DCTRL启用SBPI，则视为安全访问）

鉴于Synopsys AP在编程OTP行时既执行读操作又执行写操作，故无法禁用对某地址的读取而不同禁用写入。支持三种锁定状态：

- Read/Write
- Read-only
- Inaccessible

The full locking scheme is described in in [Section 13.5](#), but to summarise:

- The lock state of each OTP page is read from OTP at boot time.
- There is a separate copy of the lock state for Secure/Non-secure accesses. The lock shim applies the Secure read permissions to Secure reads, and the Non-secure read permissions to Non-secure reads. There is no such rule for writes, because Non-secure code is not capable of accessing the programming hardware.
- The lock encoding in OTP storage is such that a page can always be locked down to a less permissive state (in the order RW → RO → Inaccessible) but can never return to a more permissive state.
- Software can advance the state of each individual lock at runtime without programming OTP, and this lasts until the OTP PSM is re-run.
- Software locks also obey the lock progression order (RW → RO → Inaccessible) and can not be regressed.

The full locking scheme is described in in [Section 13.5](#).

### 13.3.2. External interfaces

The OTP integration has one upstream APB interface, which splits internally onto two separate interfaces. This guarantees the hardware only serves a single upstream APB access at a time, with a single PPROT security level.

The first APB interface is the *data* interface (or data bridge) (OTPD). It has the following characteristics:

- Read-only
- Connects to the Synopsys device access port (DAP)
- Data interface reads always return 32 or 24 bits of valid data
- The data interface address is rounded down to a multiple of 32 bits, so that narrow reads return the correct byte lanes
- There is an 8 kB window which supports 32-bit ECC reads
  - Each upstream bus read is split into two OTP accesses, each of which returns 16 bits of error-corrected data from the OTP
- There is an 8 kB window which supports guarded 32-bit ECC reads, and returns a bus error if the guarding read fails.
  - Functions the same as the ECC read window, but reads the Synopsys boot word before accessing the OTP array, and return a bus error if the first read does not match the expected constant
  - Used to increase confidence in software OTP reads in the bootrom
- There is a 16 kB window which supports 24-bit raw reads
  - Each access returns a single raw 24-bit OTP row, bypassing error correction
  - Software must provide its own redundancy (e.g. triple majority vote)
  - Allows bit-mutable data structures, such as boot flags, or thermometer counters

The second APB interface is the *command* interface. This provides two main functions:

- Provides a bridge to the SBPI interface (Synopsys proprietary Serial and Byte-Parallel Interface bus)
  - SBPI connects to the Programmable Master Controller (PMC), with access to the DAP, DATAPATH, charge pump (IPS), and fuse memory (SHF)

- 读/写
- 只读
- 不可访问

完整的锁定方案详述于第13.5节，简述如下：

- 每个OTP页的锁定状态在启动时从OTP中读取。
- 针对安全/非安全访问分别保存独立的锁定状态副本。锁片对安全读取应用安全读取权限，对非安全读取应用非安全读取权限。写入操作无此规则，因非安全代码无法访问编程硬件。
- OTP存储中的锁定编码保证页面只能锁定至更严格状态（顺序为RW → RO → 不可访问），且绝不允许回退至较宽松状态。
- 软件可在运行时提升各单独锁状态，且无需重新编程OTP，该状态持续至OTP PSM重新执行。
- 软件锁同样遵循锁定进阶顺序（RW → RO → 不可访问），且不可回退。

完整锁定方案详见第13.5节。

### 13.3.2. 外部接口

OTP集成含一上游APB接口，内部划分为两个独立接口。此设计确保硬件任一时刻仅处理单一上游APB访问，且采用单一PPROT安全级别。

第一个APB接口是数据接口（或数据桥）（OTPD）。其具有以下特性：

- 只读
- 连接至Synopsys设备访问端口（DAP）
- 数据接口读取始终返回32位或24位有效数据
- 数据接口地址向下取整至32位的倍数，以确保窄宽读取返回正确的字节通道
- 具有一个8 kB的窗口，支持32位ECC读取
  - 每个上游总线读取操作拆分为两次OTP访问，每次返回16位经过纠错的数据
- 具有一个8 kB的窗口，支持保护式32位ECC读取，保护读取失败时返回总线错误
  - 其功能与ECC读取窗口相同，但在访问OTP阵列前读取Synopsys启动字，首次读取若不符预期常量则返回总线错误
  - 用于提升bootrom中软件OTP读取的可靠性
- 有一个16 kB窗口，支持24位原始读取
  - 每次访问返回单个24位原始OTP行，绕过错误校正
  - 软件必须自行提供冗余（例如三重多数投票）
  - 支持位可变数据结构，如启动标志或温度计计数器；第二个APB接口为命令接口
- 提供以下两项主要功能：
  - 作为SBPI接口（Synopsys专有串行及字节并行接口总线）的桥接
    - SBPI连接至可编程主控制器（PMC），可访问DAP、DATAPATH、充电泵（IPS）及熔丝存储器（SHF）

- Allows arbitrary OTP operations, including programming
- Only accessible to Secure reads and writes
- Provides control registers for Raspberry Pi hardware
  - Registers have different accessibility according to Secure/Non-secure and read/write
  - Software lock registers are always readable by both security domains

Hardware configuration data read from OTP during the power-up sequence drives system-level control signals, e.g. disabling CoreSight APs. This is described in more detail in ([Section 13.3.4](#)).

A single system-level interrupt output (IRQ) generates interrupts for the following sources:

- Secure read failed due to locks
- Non-secure read failed due to locks
- Write failed due to locks
- SBPI FLAG, used by the PMC to signal completion
- Data port access when DCTRL is set error
  - `USR.DCTRL` tells the SNPS AP whether the SBPI bridge or data bridge can access the memory array; this help debugging SW if a data access is attempted whilst the DAP is inaccessible

Any failed access also returns a bus fault (`PSLVERR`). To determine whether an OTP address is accessible, query the lock tables.

Non-secure code cannot access the interrupt status registers.

### 13.3.3. OTP boot oscillator

The OTP startup sequence ([Section 13.3.4](#)) runs from a local ring oscillator, dedicated to the OTP subsystem. This is separate from the system ring oscillator (the ROSC) which provides the system clock to run the processors during boot.

- The OTP boot oscillator is the only clock used by the OTP power-up state machine
- The OTP boot oscillator dynamically randomises its own frequency controls, to deliberately add jitter to the clock
- The OTP boot oscillator stops when the PSM completes, and does not start again until the OTP resets
- The OTP clock automatically switches to `clk_ref` when the OTP boot oscillator stops

The boot oscillator has a nominal frequency of 12MHz. It provides the clock for reading out hardware configuration from OTP, including the critical flags ([Section 13.4](#)) which configure hardware security features such as debug disable and the glitch detectors.

Keeping this oscillator local to the OTP hardware subsystem reduces the power signature of the clock itself, due to the lower switched clock capacitance. Along with the random jitter of the frequency controls, this helps frustrate attempts to recover OTP access keys and debug keys via power signature analysis attacks, or to disable security features by timing fault injection against the OTP clock.

Only the OTP boot oscillator enables the ROSC frequency randomisation feature by default: for later operations using the system ROSC ([Section 8.3](#)), you must explicitly enable this feature on that oscillator, by programming the ROSC control registers. The crystal oscillator (XOSC) does not support frequency randomisation.

### 13.3.4. Power-up state machine

The OTP is the second item in the switched core domain's Power-On State Machine ([Section 7.4](#)), after the processor cold reset. OTP does not release its `rst_done`, or enable any debug interface (including the factory test JTAG described in [Section 10.10](#)), until the OTP PSM reads out OTP-resident hardware configuration. The `rst_done` output to the system

- 允许执行任意OTP操作，包括编程
- 仅安全域可读写访问
- 提供Raspberry Pi硬件的控制寄存器
  - 寄存器根据安全/非安全及读/写权限不同，具备不同的访问权限
  - 软件锁寄存器始终对两个安全域可读

加电序列期间，从OTP读取的硬件配置信息驱动系统级控制信号，例如禁用CoreSight APs。详见第13.3.4节。

单一系统级中断输出（IRQ）为下列源产生中断：

- 因锁定导致安全读取失败
- 因锁定导致非安全读取失败
- 因锁定导致写入失败
- SBPI 标志，由 PMC 用于指示完成状态
- 当 DCTRL 设置时，数据端口访问错误
  - **USR.DCTRL**指示 SNPS AP 是否允许 SBPI 桥或数据桥访问存储器阵列；当 DAP 无法访问时，若尝试数据访问，此功能有助于调试软件

任何访问失败同时返回总线错误（**PSLVERR**）。要确定 OTP 地址是否可访问，请查询锁定表。

非安全代码无权访问中断状态寄存器。

### 13.3.3. OTP 启动振荡器

OTP 启动序列（第 13.3.4 节）由专用于 OTP 子系统的本地环形振荡器驱动。该振荡器独立于系统环形振荡器（ROSC），后者为处理器启动时提供系统时钟。

- OTP 引导振荡器是 OTP 上电状态机唯一使用的时钟。
- OTP 启动振荡器动态随机调整其自身的频率控制，以故意向时钟添加抖动。
- OTP 启动振荡器在 PSM 完成时停止，并且在 OTP 复位之前不会重新启动。
- 当 OTP 启动振荡器停止时，OTP 时钟会自动切换至 **clk\_ref**。

启动振荡器的额定频率为 12MHz。它为从 OTP 读取硬件配置提供时钟，包括配置硬件安全功能（如调试禁用和故障检测器）的关键标志（第 13.4 节）。

将该振荡器保持在 OTP 硬件子系统本地，因降低了开关时钟电容，从而减小了时钟本身的功率特征。结合频率控制的随机抖动，此举有助于防止通过功率特征分析攻击恢复 OTP 访问密钥和调试密钥，或通过对 OTP 时钟实施时序故障注入以禁用安全功能。

仅 OTP 启动振荡器默认启用 ROSC 频率随机化功能：对于后续使用系统 ROSC（第 8.3 节）的操作，必须通过编程 ROSC 控制寄存器显式启用该振荡器的此功能。晶体振荡器（XOSC）不支持频率随机化。

### 13.3.4. 上电状态机

OTP 是交换核心域电源开启状态机（第 7.4 节）中的第二项，位于处理器冷复位之后。OTP 在读取 OTP 中驻留的硬件配置之前，不释放其 **rst\_done** 信号，也不启用任何调试接口（包括第 10.10 节所述的工厂测试 JTAG）。向系统输出的 **rst\_done** 信号

PSM holds the rest of the system in reset until the OTP PSM completes, so that no software runs until the OTP's contents are known.

The OTP boot sequence runs from a local ring oscillator. This oscillator is dedicated to the OTP subsystem, and is separate from the main system ROSC used by the processors at boot. The sequence is:

1. First, the PSM runs the Synopsys boot instruction. This has the following steps:
  - a. Wait for the power supply to return a 'good' value.
  - b. Read consistency check location until hardware sees the correct value for 16 successive reads. Consistency checks use predefined words stored in mask ROM cells with similar analogue properties to OTP cells.
2. Read critical flags (non-ECC): each critical bit is redundant across 8 OTP rows, with three-of-eight vote for each flag.
3. Read hardware access keys via ECC read interface.
4. Read valid bits for hardware access keys, including the debug keys ([Section 3.5.9.2](#))
5. Initialise page lock registers from the lock page via raw read interface.
6. Assert `rst_done` signal to the system power-on state machine
7. The system reset sequence continues, starting with the system ROSC

RP2350 A3 adds correctness checks and robustness to the PSM. For more information about these additions, see [RP2350-E16](#).

## 13.4. Critical flags

Critical flags enable hardware security features which are fundamental to RP2350's secure boot implementation. The OTP power-up state machine reads critical flags very early in the system reset sequence, before any code runs on the processors.

Most critical flags are in the main Boot Configuration page, page 1. These are listed under **CRIT1** in the OTP data listing. The exceptions are the Arm/RISC-V disable flags, which are in the Chip Info page, page 0. This page is made read-only during factory programming, so users can not write to the **CRIT0** flags.

Critical flags define **0** as the unprogrammed value, and **1** as the programmed value. On a blank device, all of the **CRIT1** flags are **0**. The reset value specified below is the value assigned to the internal logic net between the OTP reset being applied and the OTP PSM completing. For example, the reset value of **1** for the debug disable flags implies that debug is not accessible whilst the OTP PSM is running, but may be available afterward, depending on the value read from OTP storage.

- **ARM\_DISABLE** (reset: **0**): Force the **ARCHSEL** register to RISC-V, at higher priority than RISC-V disable flag, secure boot enable flag, or default boot architecture flag.
- **RISCV\_DISABLE** (reset: **0**): Force the **ARCHSEL** register to Arm, at higher priority than the default boot architecture flag.
- **SECURE\_BOOT\_ENABLE** (reset: **1**): Enable boot signature checking in bootrom, disable factory JTAG, and force the **ARCHSEL** register to Arm, at higher priority than the default boot architecture flag.
- **SECURE\_DEBUG\_DISABLE** (reset: **1**): Disable factory JTAG, block Secure accesses from Mem-APs, and block halt requests to Secure processors.
  - Prevents secure AP accesses by masking their `ap_secure_en` signals.
  - Prevents secure processor halting by masking the Cortex-M33's `SPIDEN` and `NSPIDEN` signals.
  - Secure debug can be re-enabled by a Secure register in the OTP block.
  - Re-enable of Secure debug can be disabled by a Secure write-1-only lock register, also in the OTP block.
- **DEBUG\_DISABLE** (reset: **1**): Completely disable the Mem-APs, in addition to disabling everything disabled by the secure

PSM保持系统其余部分处于复位状态，直至OTP PSM完成，以确保在OTP内容确认之前不运行任何软件。

OTP启动序列由本地环形振荡器驱动。该振荡器专用于OTP子系统，与处理器启动时使用的主系统ROSC分开。序列如下：

1. 首先，PSM执行Synopsys启动指令。该过程包括以下步骤：
  - a. 等待电源恢复至“正常”电压值。
  - b. 读取一致性检查位置，直至硬件连续16次读取到正确数值。一致性检查使用存储于与OTP单元模拟特性相似的掩码只读存储器单元中的预定义字。
2. 读取关键标志（非ECC）：每个位在8个OTP行中冗余存储，每个标志采用八选三投票机制。
3. 通过ECC读取接口读取硬件访问密钥。
4. 读取硬件访问密钥的有效位，包括调试密钥（第3.5.9.2节）。
5. 通过原始读取接口从锁定页初始化页锁存寄存器。
6. 向系统上电状态机断言 `st_done`信号。
7. 系统复位序列继续，始于系统ROSC。

RP2350 A3为PSM增加了正确性校验和稳健性。有关这些新增功能的详细信息，请参见RP2350-E16。

## 13.4. 关键标志

关键标志启用硬件安全功能，这是RP2350安全启动实现的基本保障。OTP上电状态机在系统复位序列的早期阶段读取关键标志，先于处理器代码执行。

大多数关键标志位于主启动配置页，页1。这些标志列于OTP数据列表中的CRIT1项下。

例外的是Arm/RISC-V禁用标志，位于芯片信息页，页0。该页面在工厂编程期间被设为只读，用户无法写入CRIT0标志。

关键标志定义0为未编程值，1为已编程值。在空白设备上，所有CRIT1标志均为0。下文指定的复位值是指OTP复位施加与OTP PSM完成之间，分配给内部逻辑网络的值。例如，调试禁用标志的1复位值表示在OTP PSM运行期间调试不可访问，但之后可能可用，具体取决于从OTP存储读取的值。

- **ARM\_DISABLE**（复位：0）：强制将ARCHSEL寄存器设置为RISC-V，其优先级高于RISC-V禁用标志、安全启动启用标志或默认启动架构标志。
- **RISCV\_DISABLE**（复位：0）：强制将ARCHSEL寄存器设置为Arm，其优先级高于默认启动架构标志。
- **SECURE\_BOOT\_ENABLE**（复位：1）：启用bootrom中的启动签名校验，禁用工厂JTAG，并强制将ARCHSEL寄存器设置为Arm，其优先级高于默认启动架构标志。
- **SECURE\_DEBUG\_DISABLE**（复位：1）：禁用工厂JTAG，阻止Mem-APs对安全访问的请求，并阻止对安全处理器的停止请求。
  - 通过屏蔽其`ap_secure_en`信号，防止安全AP访问。
  - 通过屏蔽Cortex-M33的`SPIDEN`和`NSPIDEN`信号，防止安全处理器被停止。
  - 安全调试可通过OTP区块中的安全寄存器重新启用。
  - 安全调试的重新启用可通过OTP区块中的安全写1即锁寄存器禁用。
- **DEBUG\_DISABLE**（复位：1）：完全禁用Mem-APs，此外还禁用所有安全模式下已被禁用的功能。

debug disable flag.

- **BOOT\_ARCH** (reset: 0): set the reset value of the **ARCHSEL** register (0 → Arm, 1 → RISC-V) if it has not been forced by other critical flags.
  - Not critical, but hardware-read.
- **GLITCH\_DETECTOR\_ENABLE** (reset: 0): pass an enable signal to the glitch detectors so that they can be armed before any software runs.
- **GLITCH\_DETECTOR\_SENS**(reset: 0): configure the initial sensitivity of the glitch detector circuits.

Critical flags are encoded with a three-of-eight vote across eight consecutive OTP rows. Each flag is redundantly programmed to the same bit position in eight consecutive rows. Hardware considers the flag to be set if the bit reads as 1 in at least three of these eight rows. The flag is considered clear if no more than two bits are observed to be set.

#### NOTE

As of RP2350 A3 the **ARM\_DISABLE** flag has no effect, removing a potential unlock path for debug on a secured RP2350. Additionally, the combination of **RISCV\_DISABLE=1** and **BOOT\_ARCH=1** is decoded to an invalid state and the chip will not boot.

JTAG disable is ignored only if the customer RMA flag ([Section 13.7](#)) is set.

For further discussion of the effects of the critical flags, see:

- [Section 3.5.9.1](#) for the effects of the debug disable flags
- [Section 3.9](#) for the effects of the Arm/RISC-V architecture select flags
- [Section 10.9](#) for the effects of the glitch detector configuration flags
- [Section 10.1.1](#) for discussion of the bootrom secure boot support enabled by the **SECURE\_BOOT\_ENABLE** flag

## 13.5. Page locks

The OTP protection hardware logically segments OTP into 64 pages (0 through 63), each 128 bytes in size, or equivalently 64 OTP rows.

Each page has a set of lock registers which determine read and write access for that page from Secure and Non-secure code. The lock registers are preloaded from OTP at reset, and can then be advanced (i.e. made less permissive) by software. Lock registers themselves are always world-readable.

Pages 61 through 63 are not so neatly described by a single set of lock registers. These pages store lock initialisation metadata. For more details, see [Section 13.5.4](#). This section describes the more common case of a page protected by a set of page locks.

### 13.5.1. Lock progression

Due to hardware constraints ([Section 13.3.1](#)), read and write restrictions are not orthogonal: it's impossible to disallow reads to an address without also disallowing writes. So, the progression of locking for a given page is:

0. Read/Write
1. Read-only
2. Inaccessible

Lock state *only increases*. This is enforced in two ways:

- Due to the nature of OTP and the choice of encoding, you cannot lower the OTP values preloaded to the lock registers during boot.

调试禁用标志。

- **BOOT\_ARCH** (复位值: 0) : 设置ARCHSEL寄存器的复位值 (0 → Arm, 1 → RISC-V) , 前提是未被其他关键标志强制覆盖。
  - 非关键, 但由硬件读取。
- **GLITCH\_DETECTOR\_ENABLE** (复位值: 0) : 向毛刺检测器传递使能信号, 使其在任何软件运行前即可启动。
- **GLITCH\_DETECTOR\_SENS** (复位值: 0) : 配置毛刺检测电路的初始灵敏度。

关键标志通过三投八表决方式编码, 分布于连续八行OTP中。每个标志均冗余写入连续八行的相同位位置。当该位在

<sup>1</sup> 这八行中至少有三行读取为1时, 硬件即判定该标志已置位。当观察到的置位位数不超过两位时, 视为该标志已清除。

#### **i 注意**

自RP2350 A3版本起, **ARM\_DISABLE**标志不再生效, 从而消除了对已安全锁定RP2350的调试潜在解锁路径。此外, **RISCV\_DISABLE=1**与**BOOT\_ARCH=1**的组合被解码为无效状态, 芯片因此无法启动。

仅当客户RMA标志 (第13.7节) 被设置时, 才会忽略JTAG禁用。

有关关键标志影响的进一步讨论, 请参阅:

- 第3.5.9.1节, 调试禁用标志的影响
- 第3.9节, Arm/RISC-V架构选择标志的影响
- 第10.9节, 故障检测器配置标志的影响
- 第10.1.1节, 关于由**SECURE\_BOOT\_ENABLE**标志启用的BootROM安全启动支持的讨论

## 13.5. 页锁

OTP保护硬件逻辑上将OTP分为64个页 (0至63), 每页128字节, 等同于64个OTP行。

每个页面设有一组锁寄存器, 用于确定安全代码和非安全代码对该页的读写权限。锁寄存器在复位时从OTP预加载, 随后可由软件逐步修改 (即权限收紧) 。锁寄存器本身始终为全局可读。

第61至63页并非由单一组锁寄存器完整描述。这些页面存储锁初始化的元数据。更多详情请参见第13.5.4节, 本节描述由一组页面锁保护页面的较常见情况。

### 13.5.1. 锁定进度

由于硬件限制 (见第13.3.1节), 读写限制并非相互独立: 无法仅禁止对某地址的读取而不禁止写入。因此, 某页面的锁定流程如下:

0. 读写
1. 只读
2. 不可访问

锁定状态只能递增。该规则通过以下两种方式强制实施:

- 鉴于OTP的特性及编码方式, 启动时预加载至锁寄存器的OTP值不可降低。

- The lock registers ignore writes of lower-than-current values.

Secure and Non-secure use separate lock values, which can advance independently of one another. There is no hardware distinction between Non-secure Read/Write and Non-secure Read-only, since Non-secure can not directly write to the OTP anyway. It is still worth encoding, because Secure software performing a write on Non-secure software's behalf can check and enforce the Non-secure write lock.

You can reprogram bits from any state to any higher state. Locks use a 2-bit thermometer code: the initial all-zeroes state is read-write, and locks are advanced by programming first bit 0, then bit 1.

Lock bits in OTP are triple-redundant with a majority vote. They can't be ECC-protected, because they may be mutated bit-by-bit over multiple programming operations.

The OTP-resident lock bits are write-protected by their own Secure lock level. The lock pages are always world-readable.

The Secure lock registers can be advanced by Secure code, and are world-readable.

The Non-secure lock registers can be advanced by Secure or Non-secure code, and are world-readable.

### 13.5.2. OTP access keys

Page 61 contains 128-bit keys. Each key has a **valid bit**: when set, the key becomes completely inaccessible to software. The keys are always read out into hidden registers by hardware during startup so that hardware can perform key comparisons without exposing the keys to software.

Pages can require specific keys for some page permissions. To unlock the page, the user writes their key to a write-only register in the OTP block. The page remains unlocked for as long as the correct key is present in this register. To re-lock the page, erase the active key by writing zeroes to the key register.

The per-page lock config specifies the following:

- a **read key** index 1-7, or 0 if there is no read key
- a **write key** index 1-7 or 0 if there is no write key
- the **no-key state**: either Read-only or Inaccessible, state of the page when no registered key has been entered by software into the key register

The no-key state is encoded as follows:

- 0 for Read-only (lock level 1)
- 1 for Inaccessible (lock level 2).

#### TIP

Key index 7 does not exist in the configuration. If you specify key index 7, it is guaranteed to never match.

The hardware determines the **key lock level** by comparing the entered key to the key config of the current page, as follows:

1. If no keys are registered, the key lock level is 0
2. Else if keys are registered and no matching key is entered, the key lock level is 2 or 1 depending on the "no-key state" config
3. Else if a write key is registered and present, the key lock level is 0
4. Else if a read key is registered and present, the key lock level is 1

Hardware compares the key lock level to the page's lock level for the current security domain (Secure/Non-secure) and takes **whichever is higher**. For example, if a page has been made Non-secure read-only, there is nothing a key can do to make it Non-secure writable.

There are six 128-bit access keys stored in the OTP. Keys 5 and 6 also function as the Secure debug access key and

- 锁寄存器忽略低于当前值的写入操作。

安全区和非安全区使用不同的锁定值，且可独立升级。由于非安全区域无论如何都无法直接写入OTP，因此非安全可读写与非安全只读在硬件上无区别。编码仍然有意义，因为安全软件代表非安全软件执行写入操作时，可以检查并强制执行非安全写锁。

您可以将位从任意状态重新编程至任意更高状态。锁使用2位温度计码：初始全零状态为可读写，锁通过先编程第一个位为0，再编程第二个位为1来升级。

OTP中的锁定位采用三重冗余，并通过多数投票机制确定最终值。这些位不能受到ECC保护，因为它们可能在多次编程操作中逐位发生变化。

驻留在OTP中的锁定位受其自身的安全锁级别写保护。锁页始终对所有用户开放读取权限。

安全锁寄存器可由安全代码升级，且对所有用户开放读取权限。

非安全锁寄存器可由安全或非安全代码升级，且对所有用户开放读取权限。

### 13.5.2. OTP 访问密钥

第61页包含128位密钥。每个密钥具有一个有效位：设置后，密钥对软件完全不可访问。密钥在启动时始终由硬件读取至隐藏寄存器，以便硬件在不向软件暴露密钥的情况下执行密钥比对。

某些页面可能需要特定密钥以授予相应权限。要解锁页面，用户需将其密钥写入OTP模块中的写专用寄存器。只要该寄存器中存在正确密钥，页面即保持解锁状态。若需重新锁定页面，应通过向密钥寄存器写入零值来擦除激活的密钥。

每页锁定配置指定以下内容：

- 一个读取密钥索引，范围1-7，若无读取密钥则为0
- 一个写入密钥索引，范围1-7，若无写入密钥则为0
- 无密钥状态：当软件未在密钥寄存器中输入注册密钥时，页面处于只读或不可访问状态

无密钥状态的编码如下：

- 0 表示只读（锁定级别 1）
- 1 表示不可访问（锁定级别 2）

#### 提示

配置中不存在密钥索引7。若指定密钥索引7，则保证永远不会匹配。

硬件通过比较输入密钥与当前页面的密钥配置，确定密钥锁定级别，具体如下：

1. 如果未注册任何密钥，则密钥锁定级别为0。
2. 若已注册密钥但输入密钥不匹配，则密钥锁定级别为2或1，具体取决于“无密钥状态”配置。
3. 若已注册且存在写密钥，则密钥锁定级别为0。
4. 若已注册且存在读密钥，则密钥锁定级别为1。

硬件将密钥锁定级别与当前安全域（安全/非安全）页面的锁定级别进行比较，取较高者。例如，若某页面被设为非安全只读，则任何密钥均无法将其设为非安全可写。

OTP 中存储了六个 128 位访问密钥。密钥 5 和 6 分别还作为安全调试访问密钥和

Non-secure debug access key, respectively. See [Section 3.5.9.2](#) for information on how the debug keys affect external debug access.

You might use OTP access keys if a bootloader contains OTP configuration that needs to be Secure-writable *only to the board owner*, not to general Secure software on the device.

### 13.5.3. Lock encoding in OTP

Page locks are encoded as a 16-bit value. This value is stored as a pair of triple-redundant bytes, each byte occupying a 24-bit OTP row.

The lock halfword is encoded as follows:

Bits	Purpose
2:0	Write key index, or 0 if no write key
5:3	Read key index, or 0 if no read key
6	No-key state, 0=Read-only 1=Inaccessible
7	Reserved
9:8	Secure lock state (thermometer code 0 → 2)
11:10	Non-secure lock state (thermometer code 0 → 2)
13:12	PicoBoot lock state (thermometer code 0 → 2) or software-defined use if PicoBoot OTP is disabled
15:12	Reserved

### 13.5.4. Special pages

The following pages require special case handling in their lock checks:

- The lock word region itself (pages 62 and 63)
  - Lock words are always world-readable
  - Lock words are writable by Secure code if the lock word itself permits Secure writes
  - Consequently, lock words 62 and 63 are considered "spare", since they do not protect pages 62 and 63; the page 63 lock word is repurposed for the RMA flag
- The hardware access key page (page 61)
  - Contains OTP access keys and debug access keys
  - Each key also has a valid bit (**rbit**)
  - Page 61 (key page) has all of the usual protections from the page 61 lock word
  - If a key's valid bit is set, that key is inaccessible; the converse is not necessarily true

Page 0, known as the **chip info page**, is *not* a special page. Raspberry Pi sets page 0 to read-only during factory test, after writing chip identification and calibration values.

### 13.5.5. Permissions of blank devices

Each RP2350 device has some information programmed during manufacturing test. At this time, a small number of hard page lock bits are also programmed:

非安全调试访问密钥。有关调试密钥如何影响外部调试访问的信息，请参见第 3.5.9.2 节。

如果引导加载程序包含仅限板卡所有者安全写入的 OTP 配置，而非设备上的通用安全软件，则可能会使用 OTP 访问密钥。

### 13.5.3. OTP 中的锁定编码

页面锁定以 16 位值编码。该值以一对三重冗余字节存储，每个字节占据一个 24 位的 OTP 行。

锁定半字编码如下：

位	用途
2:0	写入密钥索引，若无写入密钥则为 0
5:3	读取密钥索引，若无读取密钥则为 0
6	无密钥状态，0=只读，1=不可访问
7	保留
9:8	安全锁状态（温度计代码 0 → 2）
11:10	非安全锁定状态（温度计代码 0 → 2）
13:12	PicoBoot 锁定状态（温度计代码 0 → 2）或在禁用 PicoBoot OTP 时的软件定义用途
15:12	保留

### 13.5.4. 特殊页面

以下页面在锁定检查中需特殊处理：

- 锁定位区域本身（第62和63页）
  - 锁定位始终对全局可读
  - 若锁定位本身允许安全代码写入，则锁定位可由安全代码写入
  - 因此，锁定位62和63被视为“备用”，因其不保护第62和63页；第63页的锁定位被重新用作RMA标志
- 硬件访问密钥页（第61页）
  - 包含OTP访问密钥和调试访问密钥
  - 每个密钥还具有有效位（*rbit*）
  - 第61页（密钥页）受第61页锁定位的所有常规保护
  - 若密钥的有效位被设置，则该密钥不可访问；反命题不一定成立

第0页，称为芯片信息页，非特殊页。Raspberry Pi在工厂测试期间，将第0页设置为只读，此前写入芯片识别和校准数值。

### 13.5.5. 空白设备权限

每个RP2350设备在制造测试阶段均编程写入部分信息。此时，还会编程写入少量硬分页锁定位：

- Page 0, which contains chip information, is read-only for all accesses.
- Pages 1 and 2, which contain boot config and boot key fingerprints, are read-only for Non-secure access, read-write for Secure access, and read-write for bootloader access.
- Page 62, which contains only the page 62 lock word, is read-only for Non-secure access, read-write for Secure access, and read-write for bootloader access (as a partial workaround for [RP2350-E28](#)).
- Page 63, which contains the RMA flag, is read-only for Non-secure and bootloader access, and read-write for Secure access.

This minimal set of default permissions on blank devices avoids certain classes of security model violation, like Non-secure code being able to brick the chip by overwriting the boot key fingerprints with invalid data. In this context, the term *blank device* refers to a device that has gone through manufacturing test programming, but has not had any other OTP bits programmed by the user.

You can add additional soft or hard locks to these default permissions, with the exception of page 0. Page 0 cannot be hard-locked, since the secure read-only permission prevents a user from altering its lock word.

Lock words 2 through 61, covering all pages with user-defined contents, are left unprogrammed. On a blank device, these pages are fully accessible from all domains. Before launching any Non-secure application, you should apply at least a soft read-only lock to all pages that are not explicitly allocated for Non-secure use. To do this, write to `SW_LOCK2` through `SW_LOCK61`. For devices that you don't expect to RMA, such as those that have passed board-level manufacturing tests, you should lock secure writes to the RMA flag.

## 13.6. Error Correction Code (ECC)

ECC-protected rows store data in the following structure, accessible through a raw alias:

- Bits `23:22`: bit repair by polarity (BRP) flag
- Bits `21:16`: modified Hamming ECC code
- Bits `15:0` (the 16 LSBs): data

RP2350 stores the following error correction data in the 8 MSBs of each 24-bit row:

- a 6-bit modified Hamming code ECC, providing single-error-correct and double-error-detect capabilities
- 2 bits of bit repair by polarity (BRP), which supports inverting the entire row at programming time to repair a single set bit that should be clear

Writes first encode ECC, then BRP. Reads first decode BRP, then ECC. When reading through an ECC data alias ([Section 13.1](#)), hardware performs correction transparently. ECC programming operations (writes) automatically generate ECC bits when you use the bootrom `otp_access` API ([Section 5.4.8.21](#)).

ECC is not suitable for data that mutates one bit at a time, since the ECC value is derived from the entire 16-bit data value. When storing data without ECC, use another form of redundancy, such as 3-way majority vote.

### 13.6.1. Bit repair by polarity (BRP)

*Bit repair by polarity* (BRP) compensates for a single bit present at time of programming.

When programming a row, hardware or software first calculates a 24-bit target value consisting of:

- Two zeroes in bits `23:22`
- 6-bit Hamming ECC in bits `21:16`
- 16-bit data value in bits `15:0`

Before programming, an OTP row should contain all zeros. However, sometimes OTP rows contain a single bit that is already set to `1`, either due to manufacturing flaws or previous programming. If a bit is already set (`1`) in an OTP row

- 第0页包含芯片信息，所有访问均为只读。
- 第1页和第2页包含启动配置和启动密钥指纹，非安全访问为只读，安全访问及启动加载程序访问为读写。
- 第62页仅包含页面62锁定位，非安全访问为只读，安全访问及启动加载程序访问为读写（作为RP2350-E28的部分解决方案）。
- 第63页包含RMA标志，非安全访问及启动加载程序访问为只读，安全访问为读写。

此空白设备上的最小默认权限集可防止某些安全模型违规情况，例如非安全代码通过用无效数据覆盖启动密钥指纹而使芯片变砖。在此语境中，术语“空白设备”指经过制造测试编程但未由用户编程任何其他OTP位的设备。

您可以在这些默认权限基础上添加额外的软锁或硬锁，但第0页除外。第0页不可硬锁定，因为安全只读权限阻止用户更改其锁字。

锁字2至61涵盖所有具有用户定义内容的页面，且保持未编程状态。在空白设备上，这些页面对所有域均完全开放访问。在启动任何非安全应用之前，应至少对所有未明确分配给非安全用途的页面施加软只读锁。具体操作为写入[SW\\_LOCK2](#)至[SW\\_LOCK61](#)。对于那些不打算进行退货维修（RMA）的设备，例如已通过板级制造测试的设备，应锁定对[RMA](#)标志的安全写入权限。

## 13.6. 误差纠正码 (ECC)

ECC保护的行以以下结构存储数据，可以通过raw别名访问：

- Bits [23:22](#)：极性位修复（BRP）标志
- Bits [21:16](#)：修正的汉明ECC码
- Bits [15:0](#)（16个最低有效位）：数据

RP2350在每个24位行的8个最高有效位中存储以下纠错数据：

- 6位修正汉明码ECC，提供单错误更正和双错误检测能力
- 2位极性位修复（BRP），支持在编程时对整行取反，以修复应为清零的单个位

写操作先编码ECC，然后编码BRP。读操作先解码BRP，再解码ECC。通过ECC数据别名（第13.1节）读取时，硬件会透明地执行纠错。使用bootrom [otp\\_access](#) API（第5.4.8.21节）进行ECC编程操作（写入）时，会自动生成ECC位。

ECC不适用于逐位突变的数据，因为ECC值来源于整个16位数据值。存储无ECC的数据时，应采用其他形式的冗余机制，如三路多数表决。

### 13.6.1. 极性位修复 (BRP)

极性比特修复(BRP)用于补偿编程时存在的单个位。

编程一行时，硬件或软件首先计算由以下部分组成的24位目标值：

- 位 [23:22](#) 的两个零
- 位 [21:16](#) 的 6 位 Hamming ECC
- 位 [15:0](#) 的 16 位数据值

编程前，OTP行应全部置零。然而，有时OTP行中已存在单个位被设置为1，可能由制造缺陷或之前的编程导致。如果OTP行中的某个位已被设置为(1)

before programming, BRP checks the status of the corresponding bit in the target value. BRP compensates for this single set bit in one of two ways, depending on the corresponding value in the target value:

- If the bit is clear (0), BRP inverts the target row and writes two ones in bits 23:22.
- If the bit is set (1), BRP does not invert the target row, leaving two zeroes in bits 23:22.

When you read an OTP value through an ECC alias ([Section 13.1](#)), BRP checks for two ones in bits 23:22. When both bits 23 and 22 are set, BRP inverts the entire row before passing it to the modified Hamming code stage.

BRP makes it possible to store any 22-bit value in a row that initially has at most one bit set, preserving the correction margin of the modified Hamming code. During manufacturing test, hardware scans the entire OTP array to ensure no rows contain more than one pre-set bit.

### 13.6.2. Modified Hamming ECC

ECC generates six **parity bits** based on the data value stored in bits 15:0 of an OTP row. When programming a row, ECC generates those six parity bits and includes them in the target value as bits 21:16. This code consists of:

- A 5-bit Hamming code that identifies single-bit errors
- An even parity bit which allows two-bit errors to be detected in the Hamming code and the original 16-bit data

When you read an OTP value through an ECC alias ([Section 13.1](#)), ECC recalculates the six parity bits based on the value read from the OTP row. Then, ECC XORs the original six parity bits with the newly-calculated parity bits. This generates 6 new bits:

- the 5 LSBs are the *syndrome*, a unique bit pattern that corresponds to each possible bit flip in the data value
- the MSB distinguishes between odd and even numbers of bit flips

If all 6 bits in this value are zero, ECC did not detect an error. If the MSB is 1, the syndrome should indicate a single-bit error. ECC flips the corresponding data bit to recover from the error. If the MSB is 0, but the syndrome contains a value other than 0, the ECC detected an unrecoverable multi-bit error.

You can calculate 5-bit Hamming codes and parity bits with the following C code (adapted from the RP2350 bootrom source):

```

uint32_t even_parity(uint32_t input) {
 uint32_t rc = 0;
 while (input) {
 rc ^= input & 1;
 input >>= 1;
 }
 return rc;
}

const uint32_t otp_ecc_parity_table[6] = {
 0b0000001010110101011011,
 0b0000000011011001101101,
 0b0000001100011110001110,
 0b000000000011111110000,
 0b0000001111100000000000,
 0b0111111111111111111111
};

uint32_t s_otp_calculate_ecc(uint16_t x) {
 uint32_t p = x;
 for (uint i = 0; i < 6; ++i) {
 p |= even_parity(p & otp_ecc_parity_table[i]) << (16 + i);
 }
 return p;
}

```

编程前，BRP会检查目标值中对应位的状态。BRP根据目标值中对应位的状态，以两种方式之一补偿该单个位：

- 如果该位为清零（0），BRP将翻转目标行，并在位 23:22写入两个1。
- 如果该位为置位（1），BRP不会翻转目标行，保持位 23:22为两个0。

通过ECC别名读取OTP值时（第13.1节），BRP会检查位 23:22中是否为两个1。当位23和位22均为置位时，BRP会在传递至改进汉明码阶段之前翻转整行数据。

BRP允许在最初最多有一位位置的行中存储任意22位值，同时保持改进汉明码的纠错余量。制造测试期间，硬件会扫描整个OTP阵列，确保无任何行包含超过一个预置位。

### 13.6.2. 改进型汉明ECC

ECC基于存储于OTP行位15:0的数据生成六个奇偶校验位。在对行编程时，ECC生成这六个位并将其作为位 21:16包含于目标值中。该码包括：

- 一种能识别单比特错误的5位海明码
- 用于使海明码及原始16位数据检测两位错误的偶校验位

当通过ECC别名读取OTP值时（参见第13.1节），ECC会基于从OTP行读取的值重新计算六个位校验位。随后，ECC将原始六个位校验位与新计算的校验位进行异或操作。由此产生6个新位：

- 最低5位为综合症码，该码为对应数据值中每种可能比特翻转的唯一位模式
- 最高位用于区分奇数和偶数个比特翻转

若此值的所有6位均为零，说明ECC未检测到错误。若最高位为1，综合症码应指示单比特错误。ECC将翻转对应的数据位以纠正该错误。若最高位为0且综合症码非零，说明ECC检测到无法纠正的多比特错误。

您可以使用以下C代码计算5位哈明码及奇偶校验位（改编自RP2350只读存储器源代码）：

```

uint32_t even_parity(uint32_t input) {
 uint32_t rc = 0;
 while (input) {
 rc ^= input & 1;
 input >>= 1;
 }
 return rc;
}

const uint32_t otp_ecc_parity_table[6] = {
 0b0000001010110101011011,
 0b0000000011011001101101,
 0b0000001100011110001110,
 0b000000000011111110000,
 0b0000001111100000000000,
 0b0111111111111111111111
};

uint32_t s_otp_calculate_ecc(uint16_t x) {
 uint32_t p = x;
 for (uint i = 0; i < 6; ++i) {
 p |= even_parity(p & otp_ecc_parity_table[i]) << (16 + i);
 }
 return p;
}

```

}

## 13.7. Device decommissioning (RMA)

Decommissioning refers to destroying a device's sensitive contents and restoring some test or debug functionality when a device reaches the end of its security lifecycle. The OTP hardware can't actually destroy user data without circumventing write protection in some way. Instead, decommissioning is implemented with the **RMA flag**, which modifies devices in the following ways:

- re-enables factory test JTAG which is otherwise disabled by the secure boot critical flag
- makes pages 3 through 61 inaccessible

The RMA flag doesn't change permissions for page 0 (manufacturing data), pages 1 and 2 (boot configuration), page 61 (OTP access keys), or pages 62 and 63 (locks).

The RMA flag is encoded in a spare bit of the page 63 lock word. This lock word would otherwise be unused, since page 63 is one of the lock pages; consequently, it is not protected by a lock word. Instead, each lock word protects itself.

Like all other lock words, the page 63 lock word is protected by its own locks, which means it can be hard- and soft-locked to prevent the RMA flag being set. Locking the RMA flag makes it impossible to re-enable the factory JTAG interface if any of `CRIT1.SECURE_BOOT_ENABLE`, `CRIT1.DEBUG_DISABLE` or `CRIT1.SECURE_DEBUG_DISABLE` is set. This makes it impossible for Raspberry Pi to re-test such devices if they are returned for fault analysis.

### **!** IMPORTANT

Setting the RMA flag does not destroy OTP contents, it merely renders it inaccessible. The design intent is for this to be irreversible, but hardware is never perfect. This is something the user's threat model must account for when programming the RMA flag on devices with sensitive OTP contents – for example, by personalising per-device OTP secrets to avoid class breaks if an attacker is able to retrieve the keys.

## 13.8. Imaging Vulnerability

The RP2350 OTP is intended to store boot key fingerprints and boot decryption keys. The ability to protect encrypted contents in external flash storage depends on the ability to protect the OTP contents from unauthorised or external reads. The OTP uses **antifuse** bit cells, which store data as a charge, similar to a flash bit cell. They do not make use of a physical structural change as used in a traditional fuse cell. This makes them resistant to many imaging techniques, such as optical and scanning electron microscopy. However antifuse cells *can* be imaged using a novel technique called **passive voltage contrast** (PVC), using a focused ion beam (FIB) device.

### PVC Whitepaper

For more information on passive voltage contrast imaging, read the whitepaper by IOActive:

<https://www.ioactive.com/wp-content/uploads/2025/01/IOActive-RP2350HackingChallenge.pdf>

This process involves decapsulating the die. Therefore physical access to the device is a strict requirement, and there is a moderate chance of destroying the die without being able to recover its OTP contents.

### 13.8.1. Best Practices

The following best practices minimise your susceptibility to imaging of OTP contents:

}

## 13.7. 设备退役 (RMA)

退役是指当设备达到其安全生命周期终点时，销毁设备敏感内容并恢复部分测试或调试功能。OTP硬件实际上无法在未规避写保护的情况下销毁用户数据。退役功能通过**RMA**标志实现，该标志对设备进行如下修改：

- 重新启用工厂测试JTAG，该功能通常被安全启动关键标志禁用。
- 使第3页至第61页不可访问。

RMA标志不改变第0页（制造数据）、第1页和第2页（启动配置）、第61页（OTP访问密钥）以及第62页和第63页（锁定）权限。

RMA标志编码于第63页锁字的备用位。该锁字通常未被使用，因为第63页为锁定页之一；因此，该锁字不受保护。锁字分别自我保护。

与所有其他锁定字一样，第63页的锁定字受到其自身锁定的保护，这意味着它可以被硬锁定和软锁定，以防止设置RMA标志。锁定RMA标志会导致在CRIT1.SECURE\_BOOT\_ENABLE、CRIT1.DEBUG\_DISABLE或CRIT1.SECURE\_DEBUG\_DISABLE任一设置时，无法重新启用工厂JTAG接口。

这导致Raspberry Pi无法在设备退回进行故障分析时重新测试该等设备。

### ① 重要

设置RMA标志不会破坏OTP内容，仅使其无法访问。设计意图是该操作不可逆，但硬件从未达到完美。用户在对含有敏感OTP内容的设备设置RMA标志时，必须将此因素纳入其威胁模型——例如通过针对每台设备个性化OTP密钥，以防止攻击者获取密钥后造成整个类别安全破坏。

## 13.8. 镜像漏洞

RP2350 OTP用于存储启动密钥指纹及启动解密密钥。保护外部闪存存储中加密内容的能力，取决于防止只读存储器内容被未经授权或外部读取的能力。只读存储器使用 **antifuse** 位单元，该单元以电荷形式存储数据，类似于闪存位单元。它们不依赖传统熔丝单元中使用的物理结构变化。因此，它们对多种成像技术具备抗性，如光学显微镜和扫描电子显微镜。然而，antifuse 位单元可以利用一种称为**被动电压对比** (PVC) 的新型技术进行成像，该技术使用聚焦离子束 (FIB) 设备。

### PVC 白皮书

有关被动电压对比成像的更多信息，请参阅 IOActive 发布的白皮书：

<https://www.ioactive.com/wp-content/uploads/2025/01/IOActive-RP2350HackingChallenge.pdf>

此过程需进行芯片脱封，故严格要求对设备进行物理访问，且存在在无法恢复只读存储器内容的情况下损坏芯片的中等风险。

### 13.8.1. 最佳实践

以下最佳实践可最大程度降低您暴露只读存储器内容成像的风险：

- Provision unique keys per device, rather than sharing secrets across a fleet of devices.
- Use **chaff** as described in the next section to make imaging more difficult.

### 13.8.2. Chaff

OTP bits come in pairs: two bits are stored in the isolated gates of two transistors, with a common bit line between them. This structure is known as a **bit cell**. In each 64-row OTP page, rows  $i$  and  $32 + i$  share the same bit cells. For example, the ECC halfwords [BOOTKEY0\\_0](#) and [BOOTKEY2\\_0](#) are physically colocated.

The particulars of the PVC technique make it difficult to distinguish which of the two bits in a bit cell is set. If one bit in each pair is known to be zero – for example, a key stored at the bottom of an otherwise blank page – then the data can be trivially read from the PVC image. However the presence of unknown data in both bits frustrates these attempts. This fact can be exploited by storing data redundantly in the top and bottom half of each page. Specifically:

- Store arbitrary data in each row  $i$  from 0 to 31.
- Store the 24-bit bitwise complement of those values in each row  $32 + i$ .

The bitwise operations specified here are on the entire 24-bit raw row contents, including the ECC bit pattern.

An alternative technique is to store a random value in row  $32 + i$  and the XOR of that random value with the desired data value in row  $i$ . This is advantageous from a power side channel perspective because it avoids reading the secret value directly from OTP, and the example RP2350 encrypted bootloader uses a similar technique with a 4-way XOR. However the bitwise complement technique described above is recommended for pairwise chaff. This is the same as the XOR technique with a fixed XOR pattern of [0xffffffff](#).

## 13.9. List of registers

The OTP control registers start at a base address of [0x40120000](#) (defined as [OTP\\_BASE](#) in the SDK).

*Table 1332. List of OTP registers*

Offset	Name	Info
0x000	<a href="#">SW_LOCK0</a>	Software lock register for page 0.
0x004	<a href="#">SW_LOCK1</a>	Software lock register for page 1.
0x008	<a href="#">SW_LOCK2</a>	Software lock register for page 2.
0x00c	<a href="#">SW_LOCK3</a>	Software lock register for page 3.
0x010	<a href="#">SW_LOCK4</a>	Software lock register for page 4.
0x014	<a href="#">SW_LOCK5</a>	Software lock register for page 5.
0x018	<a href="#">SW_LOCK6</a>	Software lock register for page 6.
0x01c	<a href="#">SW_LOCK7</a>	Software lock register for page 7.
0x020	<a href="#">SW_LOCK8</a>	Software lock register for page 8.
0x024	<a href="#">SW_LOCK9</a>	Software lock register for page 9.
0x028	<a href="#">SW_LOCK10</a>	Software lock register for page 10.
0x02c	<a href="#">SW_LOCK11</a>	Software lock register for page 11.
0x030	<a href="#">SW_LOCK12</a>	Software lock register for page 12.
0x034	<a href="#">SW_LOCK13</a>	Software lock register for page 13.
0x038	<a href="#">SW_LOCK14</a>	Software lock register for page 14.
0x03c	<a href="#">SW_LOCK15</a>	Software lock register for page 15.

- 为每台设备分配唯一密钥，避免在大量设备间共享密钥。
- 如下一节所述，使用 **chaff** 以增加成像的难度。

### 13.8.2. 干扰数据

OTP位成对出现：两个比特存储在两个晶体管的隔离栅极中，二者之间有一条公共比特线。该结构被称为比特单元。在每个64行OTP页中，第  $i$  行与第  $32+i$  行共享相同的比特单元。例如，ECC半字BOOTKEY0\_0和BOOTKEY2\_0在物理上共址。

PVC技术的具体细节使得难以区分比特单元中哪一位被设定。如果已知每对中的一个比特为零——例如，密钥存储在其他部分为空白页的底部——则可以轻易地从PVC图像读取数据。然而，当两个比特均包含未知数据时，这些尝试将被挫败。

此事实可用于在每页的上半部和下半部对数据进行冗余存储。具体如下：

- 在每行  $i$  中存储任意数据，范围从 0 至 31。
- 在每行  $32+i$  中存储这些值的24位按位取反。

此处指定的按位操作针对包含ECC位模式的整个24位原始行内容执行。

另一种方法是在行  $32+i$  中存储一个随机值，并在行  $i$  中存储该随机值与所需数据值的XOR。从功耗侧信道角度来看，此方法具有优势，因为它避免了直接从OTP读取秘密值，RP2350加密引导程序示例采用了类似的4路XOR技术。然而，对于成对噪点，推荐使用上述的按位取反技术。这与XOR技术相同，固定XOR模式为 `0xffffffff`。

## 13.9. 寄存器列表

OTP控制寄存器起始地址为 `0x40120000`（在SDK中定义为OTP\_BASE）。

表1332。  
OTP寄存器列表

偏移量	名称	说明

0x144	CRT_KEY_W3	密钥字 3 (位 127..96)，仅写入，读取返回 0x0
0x148	关键	快速检查启动时读取的关键标志值
0x14c	KEY_VALID	启动时有效（已登记）的密钥

Offset	Name	Info
0x150	DEBUGEN	Enable a debug feature that has been disabled. Debug features are disabled if one of the relevant critical boot flags is set in OTP (DEBUG_DISABLE or SECURE_DEBUG_DISABLE), OR if a debug key is marked valid in OTP, and the matching key value has not been supplied over SWD.
0x154	DEBUGEN_LOCK	Write 1s to lock corresponding bits in DEBUGEN. This register is reset by the processor cold reset.
0x158	ARCHSEL	Architecture select (Arm/RISC-V), applied on next processor reset. The default and allowable values of this register are constrained by the critical boot flags.
0x15c	ARCHSEL_STATUS	Get the current architecture select state of each core. Cores sample the current value of the ARCHSEL register when their warm reset is released, at which point the corresponding bit in this register will also update.
0x160	BOOTDIS	Tell the bootrom to ignore scratch register boot vectors (both power manager and watchdog) on the next power up.
0x164	INTR	Raw Interrupts
0x168	INTE	Interrupt Enable
0x16c	INTF	Interrupt Force
0x170	INTS	Interrupt status after masking & forcing

## OTP: SW\_LOCK0, SW\_LOCK1, ..., SW\_LOCK62, SW\_LOCK63 Registers

Offsets: 0x000, 0x004, ..., 0x0f8, 0x0fc

### Description

Software lock register for page  $N$ .

Locks are initialised from the OTP lock pages at reset. This register can be written to further advance the lock state of each page (until next reset), and read to check the current lock state of a page.

Table 1333.  
SW\_LOCK0,  
SW\_LOCK1, ...  
SW\_LOCK62,  
SW\_LOCK63 Registers

Bits	Description	Type	Reset
31:4	Reserved.	-	-
3:2	<b>NSEC:</b> Non-secure lock status. Writes are OR'd with the current value.	RW	-
	Enumerated values:		
	0x0 → READ_WRITE		
	0x1 → READ_ONLY		
	0x3 → INACCESSIBLE		
1:0	<b>SEC:</b> Secure lock status. Writes are OR'd with the current value. This field is read-only to Non-secure code.	RW	-
	Enumerated values:		
	0x0 → READ_WRITE		
	0x1 → READ_ONLY		
	0x3 → INACCESSIBLE		

偏移量	名称	说明
0x150	DEBUGEN	启用已禁用的调试功能若 OTP 中设置了相关关键启动标志（DEBUG_DISABLE 或 SECURE_DEBUG_DISABLE），或 OTP 中标记调试密钥为有效但未通过 SWD 提供匹配密钥，则调试功能被禁用。
0x154	DEBUGEN_LOCK	写入1以锁定DEBUGEN中对应的位。该寄存器在处理器冷复位时重置。
0x158	ARCHSEL	架构选择（Arm/RISC-V），于下一次处理器复位时生效。该寄存器的默认值及其允许值受关键启动标志限制。
0x15c	ARCHSEL_STATUS	获取每个核心当前的架构选择状态。核心在软复位解除时采样ARCHSEL寄存器的当前值，同时该寄存器中相应位也会更新。
0x160	BOOTDIS	指示启动只读存储器在下一次上电时忽略擦写寄存器的启动向量（包括电源管理和看门狗）。
0x164	中断	原始中断
0x168	INTE	中断使能
0x16c	INTF	中断触发
0x170	INTS	掩码与强制后的中断状态

## OTP: SW\_LOCK0、SW\_LOCK1、...、SW\_LOCK62、SW\_LOCK63寄存器

偏移地址：0x000、0x004、...、0x0f8、0x0fc

### 描述

第 N 页的软件锁定寄存器。

复位时，锁定状态由OTP锁定页初始化。该寄存器可写入，以在下一次复位前进一步更新每页的锁定状态，也可读取以检查某页的当前锁定状态。

表1333。  
SW\_LOCK0,  
SW\_LOCK1,...  
SW\_LOCK62,  
SW\_LOCK63寄存器

位	描述	类型	复位
31:4	保留。	-	-
3:2	<b>NSEC</b> ：非安全锁状态。写入操作将与当前值进行按位或运算。	读写	-
	枚举值：		
	0x0 → 读写		
	0x1 → 只读		
	0x3 → 不可访问		
1:0	<b>SEC</b> ：安全锁状态。写入操作将与当前值进行按位或运算。该字段对非安全代码为只读。	读写	-
	枚举值：		
	0x0 → 读写		
	0x1 → 只读		
	0x3 → 不可访问		

## OTP: SBPI\_INSTR Register

**Offset:** 0x100

### Description

Dispatch instructions to the SBPI interface, used for programming the OTP fuses.

Table 1334.  
SBPI\_INSTR Register

Bits	Description	Type	Reset
31	Reserved.	-	-
30	<b>EXEC:</b> Execute instruction	SC	0x0
29	<b>IS_WR:</b> Payload type is write	RW	0x0
28	<b>HAS_PAYLOAD:</b> Instruction has payload (data to be written or to be read)	RW	0x0
27:24	<b>PAYLOAD_SIZE_M1:</b> Instruction payload size in bytes minus 1	RW	0x0
23:16	<b>TARGET:</b> Instruction target, it can be PMC (0x3a) or DAP (0x02)	RW	0x00
15:8	<b>CMD</b>	RW	0x00
7:0	<b>SHORT_WDATA:</b> wdata to be used only when payload_size_m1=0	RW	0x00

Bits	Description	Type	Reset
31:8	Reserved.	-	-
7:0	Which keys were valid (enrolled) at boot time	RO	0x00

## OTP: DEBUGEN Register

**Offset:** 0x150

### Description

Enable a debug feature that has been disabled. Debug features are disabled if one of the relevant critical boot flags is set in OTP (DEBUG\_DISABLE or SECURE\_DEBUG\_DISABLE), OR if a debug key is marked valid in OTP, and the matching key value has not been supplied over SWD.

Specifically:

- The DEBUG\_DISABLE flag disables all debug features. This can be fully overridden by setting all bits of this register.
- The SECURE\_DEBUG\_DISABLE flag disables secure processor debug. This can be fully overridden by setting the PROC0\_SECURE and PROC1\_SECURE bits of this register.
- If a single debug key has been registered, and no matching key value has been supplied over SWD, then all debug features are disabled. This can be fully overridden by setting all bits of this register.
- If both debug keys have been registered, and the Non-secure key's value (key 6) has been supplied over SWD, secure processor debug is disabled. This can be fully overridden by setting the PROC0\_SECURE and PROC1\_SECURE bits of this register.
- If both debug keys have been registered, and the Secure key's value (key 5) has been supplied over SWD, then no debug features are disabled by the key mechanism. However, note that in this case debug features may still be disabled by the critical boot flags.

Table 1353. DEBUGEN Register

Bits	Description	Type	Reset
31:9	Reserved.	-	-
8	<b>MISC:</b> Enable other debug components. Specifically, the CTI, and the APB-AP used to access the RISC-V Debug Module.  These components are disabled by default if either of the debug disable critical flags is set, or if at least one debug key has been enrolled and the least secure of these enrolled key values has not been provided over SWD.	RW	0x0
7:4	Reserved.	-	-
3	<b>PROC1_SECURE:</b> Permit core 1's Mem-AP to generate Secure accesses, assuming it is enabled at all. Also enable secure debug of core 1 (SPIDEN and SPNIDEN).  Secure debug of core 1 is disabled by default if the secure debug disable critical flag is set, or if at least one debug key has been enrolled and the most secure of these enrolled key values not yet provided over SWD.	RW	0x0

7:0	启动时有效（已登记）的密钥	只读	0x00

## OTP: DEBUGEN 寄存器

偏移: 0x150

### 描述

启用已禁用的调试功能若 OTP 中设置了相关关键启动标志（DEBUG\_DISABLE 或 SECURE\_DEBUG\_DISABLE），或 OTP 中标记调试密钥为有效但未通过 SWD 提供匹配密钥，则调试功能被禁用。

具体说明：

- DEBUG\_DISABLE 标志禁用所有调试功能。该标志可通过设置此寄存器的所有位完全覆盖。
- SECURE\_DEBUG\_DISABLE 标志禁用安全处理器调试。该标志可通过设置此寄存器的 PROC0\_SECURE 和 PROC1\_SECURE 位完全覆盖。
- 如果已注册单个调试密钥，且 SWD 未提供匹配的密钥值，则所有调试功能均被禁用。该标志可通过设置此寄存器的所有位完全覆盖。
- 如果已注册两个调试密钥，且通过 SWD 提供了非安全密钥（密钥 6）的值，则安全处理器调试被禁用。该标志可通过设置此寄存器的 PROC0\_SECURE 和 PROC1\_SECURE 位完全覆盖。
- 如果已注册两个调试密钥，且通过 SWD 提供了安全密钥（密钥 5）的值，则密钥机制不禁用任何调试功能。然而，请注意，在此情况下关键启动标志仍可能禁用调试功能。

1	<b>PROC0_SECURE</b> : 写入1以锁定DEBUGEN的PROC0_SECURE位。设置后不可清除。	读写	0x0
0	<b>PROC0</b> : 写入1以锁定DEBUGEN的PROC0位。设置后不可清除。	读写	0x0

## OTP: ARCHSEL 寄存器

偏移: 0x158

### 描述

架构选择（Arm/RISC-V）。该寄存器的默认值及其允许值受关键启动标志限制。

This register is reset by the earliest reset in the switched core power domain (before a processor cold reset).

Cores sample their architecture select signal on a warm reset. The source of the warm reset could be the system power-up state machine, the watchdog timer, Arm SYSRESETREQ or from RISC-V hartresetreq.

Note that when an Arm core is deselected, its cold reset domain is also held in reset, since in particular the SYSRESETREQ bit becomes inaccessible once the core is deselected. Note also the RISC-V cores do not have a cold reset domain, since their corresponding controls are located in the Debug Module.

*Table 1355. ARCHSEL Register*

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>CORE1:</b> Select architecture for core 1.  Enumerated values: 0x0 → ARM: Switch core 1 to Arm (Cortex-M33) 0x1 → RISCV: Switch core 1 to RISC-V (Hazard3)	RW	0x0
0	<b>CORE0:</b> Select architecture for core 0.  Enumerated values: 0x0 → ARM: Switch core 0 to Arm (Cortex-M33) 0x1 → RISCV: Switch core 0 to RISC-V (Hazard3)	RW	0x0

## OTP: ARCHSEL\_STATUS Register

**Offset:** 0x15c

### Description

Get the current architecture select state of each core. Cores sample the current value of the ARCHSEL register when their warm reset is released, at which point the corresponding bit in this register will also update.

*Table 1356. ARCHSEL\_STATUS Register*

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>CORE1:</b> Current architecture for core 0. Updated on processor warm reset.  Enumerated values: 0x0 → ARM: Core 1 is currently Arm (Cortex-M33) 0x1 → RISCV: Core 1 is currently RISC-V (Hazard3)	RO	0x0
0	<b>CORE0:</b> Current architecture for core 0. Updated on processor warm reset.  Enumerated values: 0x0 → ARM: Core 0 is currently Arm (Cortex-M33) 0x1 → RISCV: Core 0 is currently RISC-V (Hazard3)	RO	0x0

## OTP: BOOTDIS Register

**Offset:** 0x160

### Description

Tell the bootrom to ignore scratch register boot vectors (both power manager and watchdog) on the next power up.

If an early boot stage has soft-locked some OTP pages in order to protect their contents from later stages, there is a risk that Secure code running at a later stage can unlock the pages by performing a watchdog reset that resets the OTP.

This register can be used to ensure that the bootloader runs as normal on the next power up, preventing Secure code at

该寄存器由切换核心电源域的最早复位触发复位（发生于处理器冷复位之前）。

核心在热复位时采样架构选择信号。热复位可能由系统电源上电状态机、看门狗定时器、Arm SYSRESETREQ或RISC-V hartresetreq触发。

请注意，当Arm内核被取消选择时，其冷复位域亦将保持复位状态，特别是SYSRESETREQ位在内核取消选择后将无法访问。另请注意，RISC-V内核无冷复位域，因为其对应控制位于调试模块内。

表1355。ARCHSEL  
寄存器

	枚举值：		
	0x0 → ARM：核心1当前为Arm (Cortex-M33)		
	0x1 → RISCV：核心1当前为RISC-V (Hazard3)		
0	<b>CORE0</b> ：核心0的当前架构。处理器热复位时更新。	只读	0x0
	枚举值：		
	0x0 → ARM：核心0当前为Arm (Cortex-M33)		
	0x1 → RISCV：核心0当前为RISC-V (Hazard3)		

## OTP：BOOTDIS寄存器

偏移：0x160

### 描述

指示启动只读存储器在下一次上电时忽略擦写寄存器的启动向量（包括电源管理和看门狗）。

如果早期引导阶段已对某些OTP页面进行软锁定以保护其内容免受后续阶段影响，则存在安全代码在后续阶段通过执行看门狗复位以重置OTP进而解锁这些页面的风险。

此寄存器可用于确保引导加载程序在下次上电时正常运行，防止安全代码在

a later stage from accessing OTP in its unlocked state.

Should be used in conjunction with the power manager BOOTDIS register.

*Table 1357. BOOTDIS Register*

Bits	Description	Type	Reset
31:2	Reserved.	-	-
1	<b>NEXT:</b> This flag always ORs writes into its current contents. It can be set but not cleared by software.  The BOOTDIS_NEXT bit is OR'd into the BOOTDIS_NOW bit when the core is powered down. Simultaneously, the BOOTDIS_NEXT bit is cleared. Setting this bit means that the boot scratch registers will be ignored following the next core power down.  This flag should be set by an early boot stage that has soft-locked OTP pages, to prevent later stages from unlocking it via watchdog reset.	RW	0x0
0	<b>NOW:</b> When the core is powered down, the current value of BOOTDIS_NEXT is OR'd into BOOTDIS_NOW, and BOOTDIS_NEXT is cleared.  The bootrom checks this flag before reading the boot scratch registers. If it is set, the bootrom clears it, and ignores the BOOT registers. This prevents Secure software from diverting the boot path before a bootloader has had the chance to soft lock OTP pages containing sensitive data.	WC	0x0

## OTP: INTR Register

**Offset:** 0x164

### Description

Raw Interrupts

*Table 1358. INTR Register*

Bits	Description	Type	Reset
31:5	Reserved.	-	-
4	<b>APB_RD_NSEC_FAIL</b>	WC	0x0
3	<b>APB_RD_SEC_FAIL</b>	WC	0x0
2	<b>APB_DCTRL_FAIL</b>	WC	0x0
1	<b>SBPI_WR_FAIL</b>	WC	0x0
0	<b>SBPI_FLAG_N</b>	RO	0x0

## OTP: INTEN Register

**Offset:** 0x168

### Description

Interrupt Enable

*Table 1359. INTEN Register*

Bits	Description	Type	Reset
31:5	Reserved.	-	-
4	<b>APB_RD_NSEC_FAIL</b>	RW	0x0
3	<b>APB_RD_SEC_FAIL</b>	RW	0x0
2	<b>APB_DCTRL_FAIL</b>	RW	0x0

在其解锁状态下，后续阶段访问OTP。

应配合电源管理器BOOTDIS寄存器使用。

表1357. BOOTDIS  
寄存器

位	描述	类型	复位
31:2	保留。	-	-
1	<b>NEXT</b> : 该标志写入操作总是与其当前内容做按位或（OR）操作。软件可以设置该位，但不能清除此位。  当核心断电时，BOOTDIS_NEXT位会按位或（OR）进BOOTDIS_NOW位。 同时，BOOTDIS_NEXT位会被清零。设置此位表示下一次核心断电后将忽略启动暂存寄存器。  该标志应由已对OTP页进行软锁定的早期启动阶段设置，以防止后续阶段通过看门狗复位将其解锁。	读写	0x0
0	<b>NOW</b> : 当核心断电时，BOOTDIS_NEXT的当前值会按位或运算合并到BOOTDIS_NOW，随后BOOTDIS_NEXT被清零。  bootrom在读取启动暂存寄存器前会检查该标志。若标志被设置，bootrom将其清除并忽略BOOT寄存器内容。此举防止安全软件在引导加载程序软锁包含敏感数据的OTP页面之前篡改引导路径。	WC	0x0

## 13.10. Predefined OTP data locations

This section lists OTP locations used by either the hardware (particularly the OTP power-on state machine), the bootrom, or both. This listing is for RP2350 silicon revision A2.

OTP locations are listed by row number, not by address. When read through an ECC alias, OTP rows are spaced two bytes apart in the system address space; when read through a raw alias, OTP rows are four bytes apart. Therefore the row numbers given here should be multiplied by two or four appropriately when reading OTP contents directly from software. The OTP APIs provided by the bootrom use OTP row numbers directly, so this row-to-byte-address conversion is not necessary when accessing OTP through these APIs.

For normal (non-guarded) reads, you can access error-corrected content starting at [OTP\\_DATA\\_BASE](#) (0x40130000), and raw content starting at [OTP\\_DATA\\_RAW\\_BASE](#) (0x40134000). The register listings below indicate whether or not a given OTP row contains error-corrected contents. OTP never mixes error-corrected and non-error-corrected content in the same row.

## 13.10. 预定义OTP数据位置

本节列出了由硬件（尤其是OTP电源开启状态机）、bootrom或两者共同使用的OTP位置。本列表适用于RP2350 硅片A2 版本。

OTP位置按行号列出，而非按地址。通过ECC别名读取时，OTP行在系统地址空间中间隔两个字节；通过原始别名读取时，OTP行间隔四个字节。因此，直接从软件读取OTP内容时，应根据情况将此处提供的行号乘以二或四。bootrom提供的OTP API直接使用OTP行号，故通过这些API访问OTP时无须进行行号到字节地址的转换。

对于普通（非保护）读取，可以从[OTP\\_DATA\\_BASE \(0x40130000\)](#)访问经过纠错的数据内容，从[OTP\\_DATA\\_RAW\\_BASE \(0x40134000\)](#)访问原始数据内容。下列寄存器列表指示指定的OTP行是否包含经过纠错的内容。OTP绝不在同一行中混合存储经过纠错和未经纠错的内容。

All predefined data fields have some form of redundancy. Where ECC is not viable, for instance because a location is expected to have individual bits programmed at different times, best-of-three majority vote is used instead. The only exception to this is the critical hardware flags in **CRITO** and **CRIT1**. These flags use a three-of-eight vote encoding for each individual flag: the flag is considered set when at least three bits are set out of the eight redundant bit locations. The description for each row indicates the type of redundancy.

Pages 3 through 60 (rows **0x0c0** through **0xf3f**) are free for arbitrary user content such as OTP-resident bootloaders, and Raspberry Pi will avoid allocating any of these locations for bootrom configuration if possible. This is a total of 7424 bytes of ECC-protected content.

Page 2 (rows **0x080** through **0x0bf**) is also available for user content if secure boot is disabled. It is partially available if secure boot is enabled and fewer than four boot key fingerprints are registered. This is an additional 128 ECC bytes potentially available for user content.

Pages 0, 1, and 61 through 63 are reserved for future use by Raspberry Pi. Software should avoid allocating content in these regions, even if they currently have no defined use in this data listing.

*Table 1362. List of OTP\_DATA registers*

Offset	Name	Info
0x000	<b>CHIPID0</b>	Bits 15:0 of public device ID. (ECC)  The CHIPID0..3 rows contain a 64-bit random identifier for this chip, which can be read from the USB bootloader PICOBLOCK interface or from the <code>get_sys_info</code> ROM API.  The number of random bits makes the occurrence of twins exceedingly unlikely: for example, a fleet of a hundred million devices has a 99.97% probability of no twinned IDs. This is estimated to be lower than the occurrence of process errors in the assignment of sequential random IDs, and for practical purposes CHIPID may be treated as unique.
0x001	<b>CHIPID1</b>	Bits 31:16 of public device ID (ECC)
0x002	<b>CHIPID2</b>	Bits 47:32 of public device ID (ECC)
0x003	<b>CHIPID3</b>	Bits 63:48 of public device ID (ECC)
0x004	<b>RANDID0</b>	Bits 15:0 of private per-device random number (ECC)  The RANDID0..7 rows form a 128-bit random number generated during device test.  This ID is not exposed through the USB PICOBLOCK GET_INFO command or the ROM <code>get_sys_info()</code> API. However note that the USB PICOBLOCK OTP access point can read the entirety of page 0, so this value is not meaningfully private unless the USB PICOBLOCK interface is disabled via the <code>DISABLE_BOOTSEL_USB_PICOBLOCK_IFC</code> flag in <code>BOOT_FLAGS0</code> .
0x005	<b>RANDID1</b>	Bits 31:16 of private per-device random number (ECC)
0x006	<b>RANDID2</b>	Bits 47:32 of private per-device random number (ECC)
0x007	<b>RANDID3</b>	Bits 63:48 of private per-device random number (ECC)
0x008	<b>RANDID4</b>	Bits 79:64 of private per-device random number (ECC)
0x009	<b>RANDID5</b>	Bits 95:80 of private per-device random number (ECC)
0x00a	<b>RANDID6</b>	Bits 111:96 of private per-device random number (ECC)
0x00b	<b>RANDID7</b>	Bits 127:112 of private per-device random number (ECC)

所有预定义的数据字段均采用一定形式的冗余。当ECC不可用时，例如某些位置预期在不同时刻编程单个位，则改用三次投票多数决法。唯一例外是CRIT0和CRIT1中的关键硬件标志。对此类标志采用三选八投票编码：当八个位冗余位置中至少三个位被置位时，即视该标志为已设置。

每行的描述均指明其冗余类型。

第3页至第60页（即行 `0x0c0` 至 `0xf3f`）可供任意用户内容使用，例如驻留OTP的引导加载程序，Raspberry Pi在可能情况下将避免将这些位置分配给bootrom配置。这是总计7424字节的ECC保护内容。

如果禁用安全启动，页面2（行 `0x080` 至 `0x0bf`）亦可用于用户内容。若启用安全启动且注册的启动密钥指纹少于四个，则页面部分可用。这是额外的128字节ECC内容，可能供用户使用。

页面0、1及61至63预留给Raspberry Pi未来使用。软件应避免在这些区域分配内容，即便当前这些区域在本数据列表中尚无明确定义的用途。

表1362。 *OTP\_D*  
ATA寄存器列表

偏移量	名称	说明
0x000	<b>CHIPID0</b>	公共设备ID的第15至0位。（ECC）  CHIPID0至CHIPID3行包含该芯片的64位随机标识符，可通过USB引导加载程序PICOBOOT接口或get_sys_info只读存储器API读取。  随机位数使得出现重复ID的可能性极低：例如，在1亿台设备中，99.97%的概率不存在重复ID。该概率被估计低于顺序随机ID分配过程中的工艺错误概率，实际应用中CHIPID可视为唯一标识。
0x001	<b>CHIPID1</b>	公共设备ID（ECC）的第31至16位
0x002	<b>CHIPID2</b>	公共设备ID（ECC）的第47至32位
0x003	<b>CHIPID3</b>	公共设备ID（ECC）的第63至48位
0x004	<b>RANDID0</b>	私有每设备随机数（ECC）的第15至0位  RANDID0至7行组成了在设备测试期间生成的128位随机数。  该ID不会通过USB PICOBOOT的GET_INFO命令或ROMget_sys_info()API暴露。但请注意，USB PICOBOOT OTP访问点可以读取第0页的全部内容，因此除非  通过BOOT_FLAGS0中的DISABLE_BOOTSEL_USB_PICOBOOT_IFC标志禁用USB PICOBOOT接口，否则该值不具备实质性的隐私性。
0x005	<b>RANDID1</b>	私有每设备随机数（ECC）的第31至16位
0x006	<b>RANDID2</b>	私有每设备随机数的第47至32位（ECC）
0x007	<b>RANDID3</b>	私有每设备随机数的第63至48位（ECC）
0x008	<b>RANDID4</b>	私有每设备随机数的第79至64位（ECC）
0x009	<b>RANDID5</b>	私有每设备随机数的第95至80位（ECC）
0x00a	<b>RANDID6</b>	私有每设备随机数的第111至96位（ECC）
0x00b	<b>RANDID7</b>	私有每设备随机数的第127至112位（ECC）

## OTP\_DATA: CHIPID0 Register

Offset: 0x000

Table 1363. CHIPID0 Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	Bits 15:0 of public device ID. (ECC)  The CHIPID0..3 rows contain a 64-bit random identifier for this chip, which can be read from the USB bootloader PICOBLOCK interface or from the get_sys_info ROM API.  The number of random bits makes the occurrence of twins exceedingly unlikely: for example, a fleet of a hundred million devices has a 99.97% probability of no twinned IDs. This is estimated to be lower than the occurrence of process errors in the assignment of sequential random IDs, and for practical purposes CHIPID may be treated as unique.	RO	-

## OTP\_DATA：CHIPID0寄存器

偏移：0x000

表1363。CHIPID0  
寄存器

位	描述	类型	复位
31:16	保留。	-	-
15:0	公共设备ID的第15至0位。（ECC）  CHIPID0至CHIPID3行包含该芯片的64位随机标识符，可通过USB引导加载程序PICOBLOCK接口或get_sys_info只读存储器API读取。  随机位数使得出现重复ID的可能性极低：例如，在1亿台设备中，99.97%的概率不存在重复ID。该概率被估计低于顺序随机ID分配过程中的工艺错误概率，实际应用中CHIPID可视为唯一标识。	只读	-

Table 1367. RANDID0 Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	Bits 15:0 of private per-device random number (ECC)  The RANDID0..7 rows form a 128-bit random number generated during device test.  This ID is not exposed through the USB PICOBLOCK GET_INFO command or the ROM <code>get_sys_info()</code> API. However note that the USB PICOBLOCK OTP access point can read the entirety of page 0, so this value is not meaningfully private unless the USB PICOBLOCK interface is disabled via the DISABLE_BOOTSEL_USB_PICOBLOCK_IFC flag in BOOT_FLAGS0. ## OTP\_DATA：BOOT\_FLAGS0 寄存器

偏移量: 0x048

### 说明

禁用/启用 RP2350 只读存储器中的启动路径/功能。禁用状态始终优先于启用。当OTP中存在必须有效的其他配置时，提供启用功能。(RBIT-3)

表 1384。BOOT\_FLAGS0 寄存器

位	描述	类型	复位
31:22	保留。	-	-
21	<b>DISABLE_SRAM_WINDOW_BOOT</b>	只读	-
20	<b>DISABLE_XIP_ACCESS_ON_SRAM_ENTRY</b> : 进入 SRAM 二进制文件后禁用所有对 XIP 的访问  请注意，这将导致访问 XIP 的 bootrom API 失败，包括与分区表交互的 API。 。	只读	-
19	<b>DISABLE_BOOTSEL_UART_BOOT</b>	只读	-

Bits	Description	Type	Reset
18	<b>DISABLE_BOOTSEL_USB_PICOBOOT_IFC</b>	RO	-
17	<b>DISABLE_BOOTSEL_USB_MSD_IFC</b>	RO	-
16	<b>DISABLE_WATCHDOG_SCRATCH</b>	RO	-
15	<b>DISABLE_POWER_SCRATCH</b>	RO	-
14	<p><b>ENABLE OTP BOOT</b>: Enable OTP boot. A number of OTP rows specified by OTPBOOT_LEN will be loaded, starting from OTPBOOT_SRC, into the SRAM location specified by OTPBOOT_DST1 and OTPBOOT_DST0.</p> <p>The loaded program image is stored with ECC, 16 bits per row, and must contain a valid IMAGE_DEF. Do not set this bit without first programming an image into OTP and configuring OTPBOOT_LEN, OTPBOOT_SRC, OTPBOOT_DST0 and OTPBOOT_DST1.</p> <p>Note that OTPBOOT_LEN and OTPBOOT_SRC must be even numbers of OTP rows. Equivalently, the image must be a multiple of 32 bits in size, and must start at a 32-bit-aligned address in the ECC read data address window.</p>	RO	-
13	<b>DISABLE OTP BOOT</b> : Takes precedence over ENABLE OTP BOOT.	RO	-
12	<b>DISABLE_FLASH_BOOT</b>	RO	-
11	<b>ROLLBACK_REQUIRED</b> : Require binaries to have a rollback version. Set automatically the first time a binary with a rollback version is booted.	RO	-
10	<b>HASHED_PARTITION_TABLE</b> : Require a partition table to be hashed (if not signed)	RO	-
9	<b>SECURE_PARTITION_TABLE</b> : Require a partition table to be signed	RO	-
8	<b>DISABLE_AUTO_SWITCH_ARCH</b> : Disable auto-switch of CPU architecture on boot when the (only) binary to be booted is for the other Arm/RISC-V architecture and both architectures are enabled	RO	-
7	<b>SINGLE_FLASH_BINARY</b> : Restrict flash boot path to use of a single binary at the start of flash	RO	-
6	<p><b>OVERRIDE_FLASH_PARTITION_SLOT_SIZE</b>: Override the limit for default flash metadata scanning.</p> <p>The value is specified in FLASH_PARTITION_SLOT_SIZE. Make sure FLASH_PARTITION_SLOT_SIZE is valid before setting this bit</p>	RO	-
5	<b>FLASH_DEVINFO_ENABLE</b> : Mark FLASH_DEVINFO as containing valid, ECC'd data which describes external flash devices.	RO	-
4	<b>FAST_SIGCHECK_ROSC_DIV</b> : Enable quartering of ROSC divisor during signature check, to reduce secure boot time	RO	-
3	<p><b>FLASH_IO_VOLTAGE_1V8</b>: If 1, configure the QSPI pads for 1.8 V operation when accessing flash for the first time from the bootrom, using the VOLTAGE_SELECT register for the QSPI pads bank. This slightly improves the input timing of the pads at low voltages, but does not affect their output characteristics.</p> <p>If 0, leave VOLTAGE_SELECT in its reset state (suitable for operation at and above 2.5 V)</p>	RO	-

位	描述	类型	复位
18	<b>DISABLE_BOOTSEL_USB_PICOBOOT_IFC</b>	只读	-
17	<b>DISABLE_BOOTSEL_USB_MSD_IFC</b>	只读	-
16	<b>DISABLE_WATCHDOG_SCRATCH</b>	只读	-
15	<b>DISABLE_POWER_SCRATCH</b>	只读	-
14	<p><b>ENABLE OTP BOOT</b>: 启用 OTP 启动。将从 OTPBOOT_SRC 指定的位置开始，加载由 OTPBOOT_LEN 指定数量的 OTP 行到由 OTPBOOT_DST1 和 OTPBOOT_DST0 指定的 SRAM 位置。</p> <p>加载的程序映像以 ECC 形式存储，每行 16 位，且必须包含有效的 IMAG_E_DEF。未经先行在 OTP 中烧录映像并配置 OTPBOOT_LEN、OTPBOOT_SRC、OTPBOOT_DST0 和 OTPBOOT_DST1，严禁设置此位。</p> <p>请注意，OTPBOOT_LEN 和 OTPBOOT_SRC 必须是偶数行 OTP。等效地，映像大小必须为 32 位的整数倍，且必须从 ECC 读取数据地址窗口中 32 位对齐的地址开始。</p>	只读	-
13	<b>DISABLE OTP BOOT</b> : 优先于 ENABLE OTP BOOT。	只读	-
12	<b>DISABLE_FLASH_BOOT</b>	只读	-
11	<b>ROLLBACK_REQUIRED</b> : 要求二进制文件必须包含回滚版本信息。首次启动具有回滚版本的二进制文件时，自动设置此项。	只读	-
10	<b>HASHED_PARTITION_TABLE</b> : 要求对分区表进行哈希处理（若未签名）。	只读	-
9	<b>SECURE_PARTITION_TABLE</b> : 要求对分区表进行签名。	只读	-
8	<b>DISABLE_AUTO_SWITCH_ARCH</b> : 当启动的（唯一）二进制文件属于另一Arm/RISC-V架构且两种架构均已启用时，禁用CPU架构自动切换。	只读	-
7	<b>SINGLE_FLASH_BINARY</b> : 限制闪存启动路径仅使用闪存起始处的单个二进制文件。	只读	-
6	<p><b>OVERRIDE_FLASH_PARTITION_SLOT_SIZE</b>: 覆盖默认的闪存元数据扫描大小限制。</p> <p>该值由FLASH_PARTITION_SLOT_SIZE指定。设置此位前，请确保FLASH_PARTITION_SLOT_SIZE的有效性。</p>	只读	-
5	<b>FLASH_DEVINFO_ENABLE</b> : 标记FLASH_DEVINFO包含有效且经过ECC校验的描述外部闪存设备的数据。	只读	-
4	<b>FAST_SIGCHECK_ROSC_DIV</b> : 启用签名校验期间ROSC除数的四分之一分频，以缩短安全启动时间。	只读	-
3	<p><b>FLASH_IO_VOLTAGE_1V8</b>: 若设为1，首次通过bootrom访问闪存时，将通过VOLTAGE_SELECT寄存器配置QSPI引脚组为1.8V工作电压。此项设置可稍微改善低电压下引脚的输入时序，但不影响其输出特性。</p> <p>若设置为0，则保持VOLTAGE_SELECT处于复位状态（适用于2.5 V及以上电压下的操作）。</p>	只读	-

Bits	Description	Type	Reset
2	<b>ENABLE_BOOTSEL_NON_DEFAULT_PLL_XOSC_CFG:</b> Enable loading of the non-default XOSC and PLL configuration before entering BOOTSEL mode.  Ensure that BOOTSEL_XOSC_CFG and BOOTSEL_PLL_CFG are correctly programmed before setting this bit.  If this bit is set, user software may use the contents of BOOTSEL_PLL_CFG to calculate the expected XOSC frequency based on the fixed USB boot frequency of 48 MHz.	RO	-
1	<b>ENABLE_BOOTSEL_LED:</b> Enable bootloader activity LED. If set, bootsel_led_cfg is assumed to be valid	RO	-
0	Reserved.	-	-

## OTP\_DATA: BOOT\_FLAGS0\_R1, BOOT\_FLAGS0\_R2 Registers

Bits	Description	Type	Reset
31:24	Reserved.	-	-
23:0	Redundant copy of BOOT_FLAGS0	RO	-

## OTP\_DATA: BOOT\_FLAGS1 Register

Offset: 0x04b

### Description

Disable/Enable boot paths/features in the RP2350 mask ROM. Disables always supersede enables. Enables are provided where there are other configurations in OTP that must be valid. (RBIT-3)

Table 1386.  
BOOT\_FLAGS1  
Register

Bits	Description	Type	Reset
31:20	Reserved.	-	-
19	<b>DOUBLE_TAP:</b> Enable entering BOOTSEL mode via double-tap of the RUN/RSTn pin. Adds a significant delay to boot time, as configured by DOUBLE_TAP_DELAY.  This functions by waiting at startup (i.e. following a reset) to see if a second reset is applied soon afterward. The second reset is detected by the bootrom with help of the POWMAN_CHIP_RESET_DOUBLE_TAP flag, which is not reset by the external reset pin, and the bootrom enters BOOTSEL mode (NSBOOT) to await further instruction over USB or UART.	RO	-
18:16	<b>DOUBLE_TAP_DELAY:</b> Adjust how long to wait for a second reset when double tap BOOTSEL mode is enabled via DOUBLE_TAP. The minimum is 50 milliseconds, and each unit of this field adds an additional 50 milliseconds.  For example, setting this field to its maximum value of 7 will cause the chip to wait for 400 milliseconds at boot to check for a second reset which requests entry to BOOTSEL mode.  200 milliseconds (DOUBLE_TAP_DELAY=3) is a good intermediate value.	RO	-
15:12	Reserved.	-	-

位	描述	类型	复位
2	<b>ENABLE_BOOTSEL_NON_DEFAULT_PLL_XOSC_CFG</b> : 在进入BOOTSEL模式前启用加载非默认XOSC和PLL配置。  设置此位之前, 请确保BOOTSEL_XOSC_CFG和BOOTSEL_PLL_CFG已正确编程。  若设置此位, 用户软件可使用BOOTSEL_PLL_CFG的内容, 根据固定的48 MHz USB启动频率计算预期的XOSC频率。	只读	-
1	<b>ENABLE_BOOTSEL_LED</b> : 启用引导加载器活动指示灯。若设置, 则假定bootsel_led_cfg有效。	只读	-
0	保留。	-	-

## OTP\_DATA: BOOT\_FLAGS1 寄存器

偏移量: 0x04b

### 描述

禁用/启用 RP2350 只读存储器中的启动路径/功能。禁用状态始终优先于启用。当OTP中存在必须有效的其他配置时, 提供启用功能。 (RBIT-3)

表 1386。  
BOOT\_FLAGS1  
寄存器

位	描述	类型	复位
31:20	保留。	-	-
19	<b>DOUBLE_TAP</b> : 通过对 RUN/RSTn 引脚进行双击, 启用进入 BOOTS EL 模式。此功能会根据 DOUBLE_TAP_DELAY 的配置, 显著延长启动时间。  该功能通过在启动时 (即复位后) 等待, 检测是否很快施加了第二次复位来实现。第二次复位由只读存储器借助 POWMAN_CHIP_RESET_DOUBLE_TAP 标志检测, 该标志不会被外部复位引脚复位, 且只读存储器进入 BOOTSEL 模式 (NSBOOT), 以通过 USB 或 UART 等待进一步指令。	只读	-
18:16	<b>DOUBLE_TAP_DELAY</b> : 调整启用 DOUBLE_TAP 双击进入 BOOTSEL 模式时, 等待第二次复位的时间。最小值为 50 毫秒, 该字段的每个单位增加 50 毫秒。  例如, 将此字段设置为最大值 7, 会导致芯片启动时等待 400 毫秒, 以检测请求进入 BOOTSEL 模式的第二次复位。  200 milliseconds (DOUBLE_TAP_DELAY=3) 是一个合适的中间值。	只读	-
15:12	保留。	-	-

Bits	Description	Type	Reset
11:8	<p><b>KEY_INVALID:</b> Mark a boot key as invalid, or prevent it from ever becoming valid. The bootrom will ignore any boot key marked as invalid during secure boot signature checks.</p> <p>Each bit in this field corresponds to one of the four 256-bit boot key hashes that may be stored in page 2 of the OTP.</p> <p>When provisioning boot keys, it's recommended to mark any boot key slots you don't intend to use as KEY_INVALID, so that spurious keys can not be installed at a later time.</p>	RO	-
7:4	Reserved.	-	-
3:0	<p><b>KEY_VALID:</b> Mark each of the possible boot keys as valid. The bootrom will check signatures against all valid boot keys, and ignore invalid boot keys.</p> <p>Each bit in this field corresponds to one of the four 256-bit boot key hashes that may be stored in page 2 of the OTP.</p> <p>A KEY_VALID bit is ignored if the corresponding KEY_INVALID bit is set. Boot keys are considered valid only when KEY_VALID is set and KEY_INVALID is clear.</p> <p>Do not mark a boot key as KEY_VALID if it does not contain a valid SHA-256 hash of your secp256k1 public key. Verify keys after programming, before setting the KEY_VALID bits – a boot key with uncorrectable ECC faults will render your device unbootable if secure boot is enabled.</p> <p>Do not enable secure boot without first installing a valid key. This will render your device unbootable.</p>	RO	-

## OTP\_DATA: BOOTSEL\_PLL\_CFG Register

Offset: 0x057

### Description

Optional PLL configuration for BOOTSEL mode. (ECC)

This should be configured to produce an exact 48 MHz based on the crystal oscillator frequency. User mode software may also use this value to calculate the expected crystal frequency based on an assumed 48 MHz PLL output.

If no configuration is given, the crystal is assumed to be 12 MHz.

The PLL frequency can be calculated as:

$$\text{PLL out} = (\text{XOSC frequency} / (\text{REFDIV}+1)) \times \text{FBDIV} / (\text{POSTDIV1} \times \text{POSTDIV2})$$

Conversely the crystal frequency can be calculated as:

$$\text{XOSC frequency} = 48 \text{ MHz} \times (\text{REFDIV}+1) \times (\text{POSTDIV1} \times \text{POSTDIV2}) / \text{FBDIV}$$

位	描述	类型	复位
5:0	<p><b>CS1_GPIO:</b> 指定用于次级闪存片选 (CS1) 的 GPIO 编号，该片选用于选择映射在系统地址 0x11000000 至 0x11fffff 的外部 QSPI 设备。CS0 无此配置，因为主片选拥有专用引脚。</p> <p>在 RP2350 上，允许的 GPIO 编号为 0、8、19 和 47。</p> <p>如果 CS1_size 为零，则忽略。若 CS1_SIZE 非零，启动只读存储器将在进入闪存启动路径或任何可能使用 QSPI 闪存接口的路径（例如 BOOTS EL 模式 (nsboot)）时，自动将该 GPIO 配置为第二片选信号。</p>	只读	-

5:0	<b>PIN:</b> 用于引导程序活动 LED 的 GPIO 索引。	只读	-

## OTP\_DATA: BOOTSEL\_PLL\_CFG 寄存器

偏移量: 0x057

### 说明

BOOTSEL 模式的可选 PLL 配置。（ECC）

应根据晶体振荡器频率配置此项，以产生精确的 48 MHz。用户模式软件也可使用该数值，基于假定的 48 MHz PLL 输出计算预期的晶体频率。

如果未提供配置，则默认晶体频率为 12 MHz。

PLL 频率可按以下公式计算：

$$\text{PLL out} = (\text{XOSC frequency} / (\text{REFDIV}+1)) \times \text{FBDIV} / (\text{POSTDIV1} \times \text{POSTDIV2})$$

反之，晶体频率可按以下公式计算：

$$\text{XOSC frequency} = 48 \text{ MHz} \times (\text{REFDIV}+1) \times (\text{POSTDIV1} \times \text{POSTDIV2}) / \text{FBDIV}$$

(Note the +1 on REFDIV is because the value stored in this OTP location is the actual divisor value minus one.)

Used if and only if ENABLE\_BOOTSEL\_NON\_DEFAULT\_PLL\_XOSC\_CFG is set in BOOT\_FLAGS0. That bit should be set only after this row and BOOTSEL\_XOSC\_CFG are both correctly programmed.

Table 1395.  
BOOTSEL\_PLL\_CFG  
Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15	<b>REFDIV</b> : PLL reference divisor, minus one.  Programming a value of 0 means a reference divisor of 1. Programming a value of 1 means a reference divisor of 2 (for exceptionally fast XIN inputs)	RO	-

## OTP\_DATA: OTPBOOT\_SRC Register

Offset: 0x05e

Table 1400.  
OTPBOOT\_SRC  
Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	OTP start row for the OTP boot image. (ECC)  If OTP boot is enabled, the bootrom will load from this location into SRAM and then directly enter the loaded image. Note that the image must be signed if SECURE_BOOT_ENABLE is set. The image itself is assumed to be ECC-protected.  This must be an even number. Equivalently, the OTP boot image must start at a word-aligned location in the ECC read data address window.	RO	-

## OTP\_DATA: OTPBOOT\_LEN Register

Offset: 0x05f

Table 1401.  
OTPBOOT\_LEN  
Register

Bits	Description	Type	Reset
31:16	Reserved.	-	-
15:0	Length in rows of the OTP boot image. (ECC)  OTPBOOT_LEN must be even. The total image size must be a multiple of 4 bytes (32 bits).	RO	-

## OTP\_DATA: PAGE0\_LOCK1, PAGE1\_LOCK1, ..., PAGE61\_LOCK1, PAGE62\_LOCK1 Registers

Offsets: 0xf81, 0xf83, ..., 0xffb, 0ffd

### Description

Lock configuration MSBs for page  $N$  (rows  $0x40 * N$  through  $0x40 * N + 0x3f$ ). Locks are stored with 3-way majority vote encoding, so that bits can be set independently.

This OTP location is always readable, and is write-protected by its own permissions.

# Chapter 14. Electrical and mechanical

This section contains physical and electrical details for RP2350.

## 14.1. QFN-60 package

Figure 143. Top down view (left, top) and side view (right, bottom), along with bottom view (right, top) of the RP2350 QFN-60 package

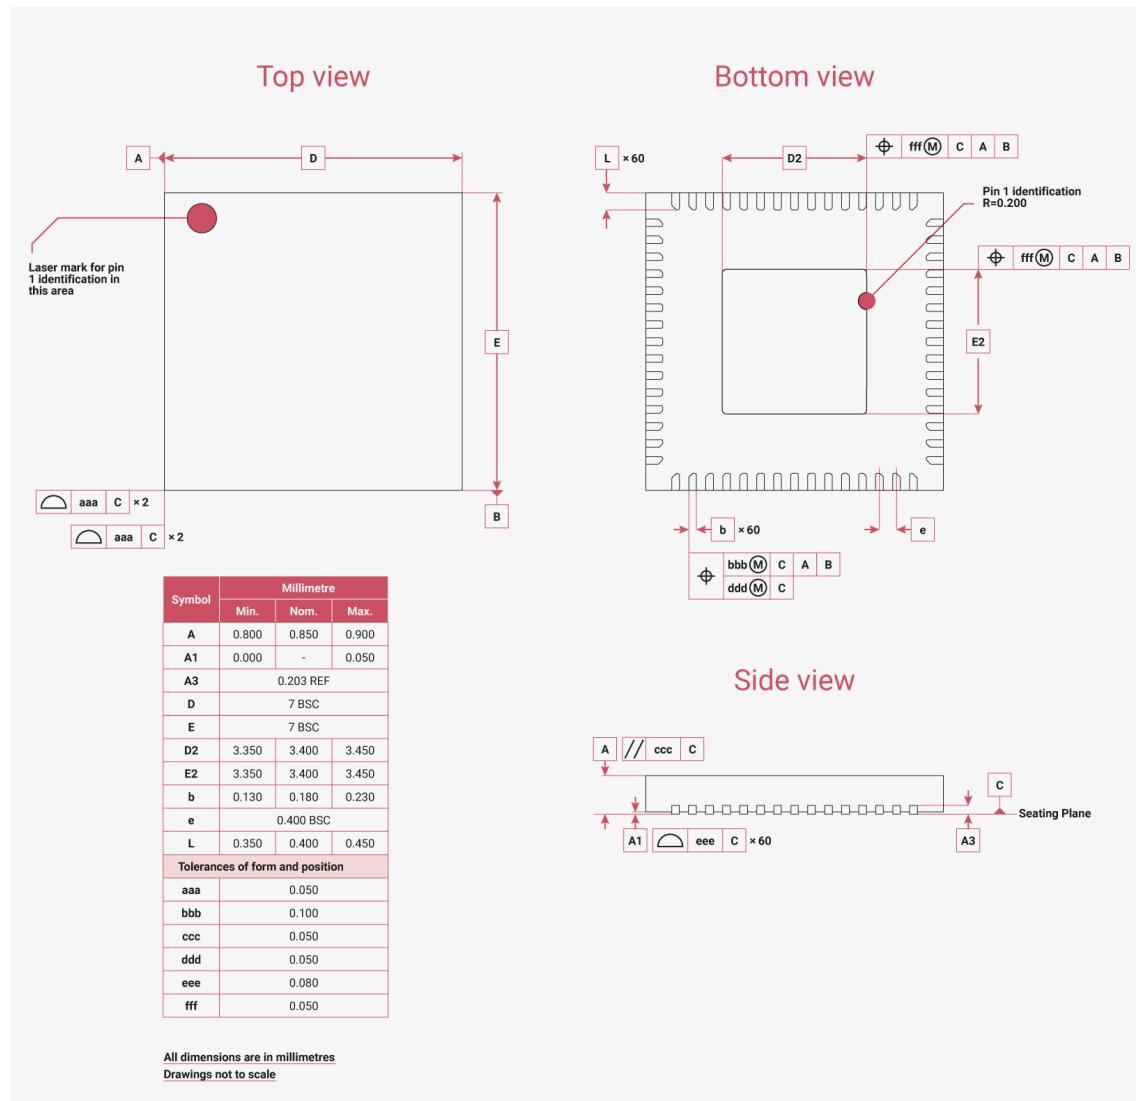

# 第14章。电气与机械

本节包含RP2350的物理及电气详细信息。

## 14.1. QFN-60封装

图 143。RP2350 QFN-60 封装的俯视图（左上）、底视图（右上）及侧视图（右下）

**NOTE**

Leads have a matte Tin (Sn) finish. Annealing is done post-plating, baking at 150°C for 1 hour. Minimum thickness for lead plating is 8 microns, and the intermediate layer material is CuFe2P (roughened Copper (Cu)).

### 14.1.1. Thermal characteristics

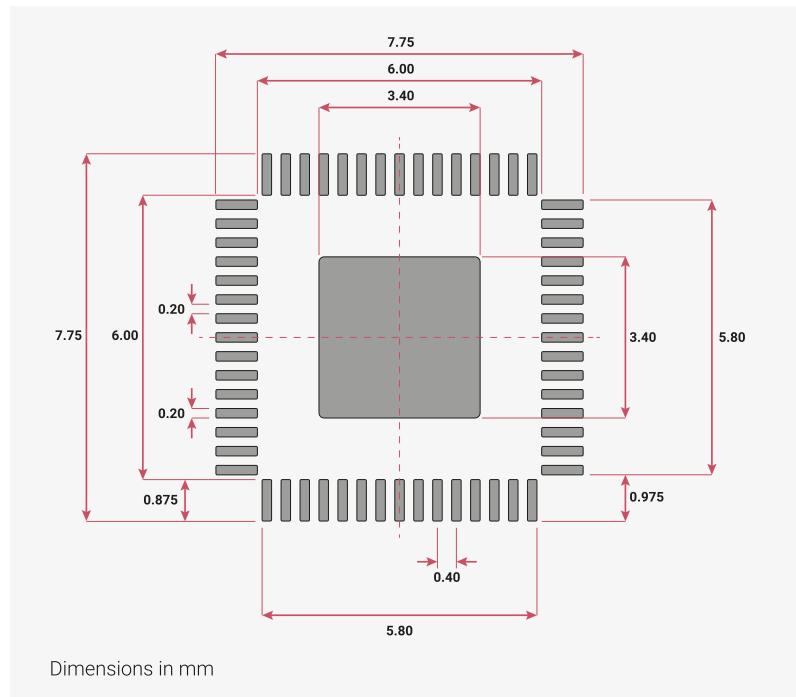

The thermal characteristics of the QFN-60 package are shown in [Table 1423](#).

*Table 1423. Thermal data for the QFN-60 package.*

Device	$\theta_{JA}$ (°C/W) - Still Air	$\theta_{JA}$ (°C/W) - 1m/s Forced Air	$\theta_{JA}$ (°C/W) - 2m/s Forced Air	$\theta_{JB}$ (°C/W)	$\theta_{JC}$ (°C/W)
RP2350A	40.542	31.99	30.264	12.588	14.315
RP2354A	TBD	TBD	TBD	TBD	TBD

### 14.1.2. Recommended PCB footprint

*Figure 144.  
Recommended PCB  
Footprint for the  
RP2350 QFN-60  
package*

## 14.2. QFN-80 package

### ⓘ 注意

引线采用哑光锡（Sn）表面处理。退火在镀层后进行，温度为150°C，时间为1小时。引线镀层的最小厚度为8微米，中间层材料为CuFe2P（粗化铜Cu）。

### 14.1.1. 热特性

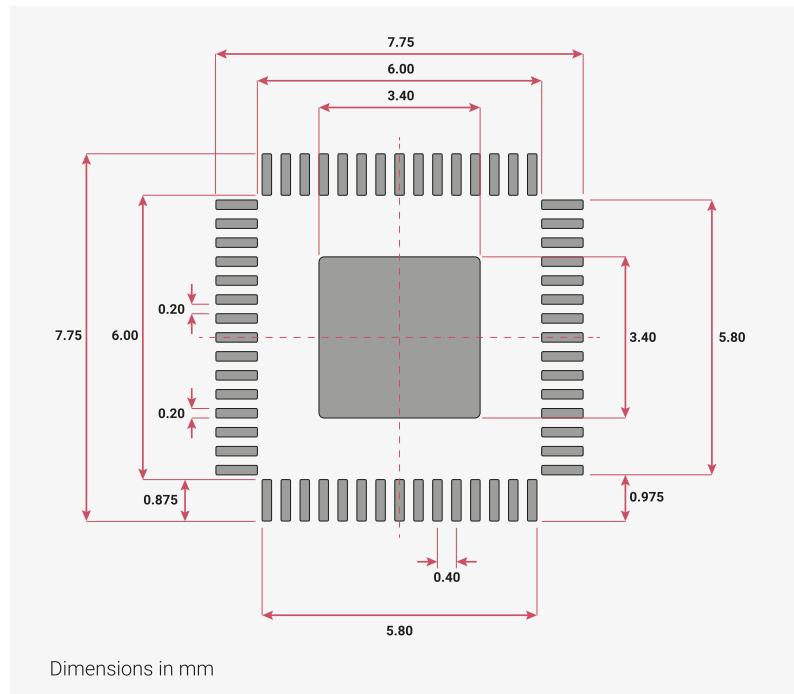

QFN-60封装的热特性见表1423。

表1423。 QFN-60  
封装的热  
性能数据。

器件	$\theta_{JA}$ (°C/W) - 静止 空气	$\theta_{JA}$ (°C/W) - 1m/s 强制空气流	$\theta_{JA}$ (°C/W) - 2m/s 强制空气流	$\theta_{JB}$ (°C/W)	$\theta_{JC}$ (°C/W)
RP2350A	40.542	31.99	30.264	12.588	14.315

### 14.2.2. 推荐PCB封装尺寸

Figure 146.  
Recommended PCB  
Footprint for the  
RP2350 QFN-80  
package

### 14.3. Flash in package

RP2354A and RP2354B feature 2 MB of internal flash. In all other respects, including pinout, they are identical to their flashless counterparts RP2350A and RP2350B. They use the same QFN-60 (RP2354A) and QFN-80 (RP2354B) packages. An RP2354 device contains two stacked silicon die:

- the same RP2350 die as the flashless variants
- a Winbond W25Q16JVWI QSPI NOR flash

#### Winbond W25Q16JVWI datasheet

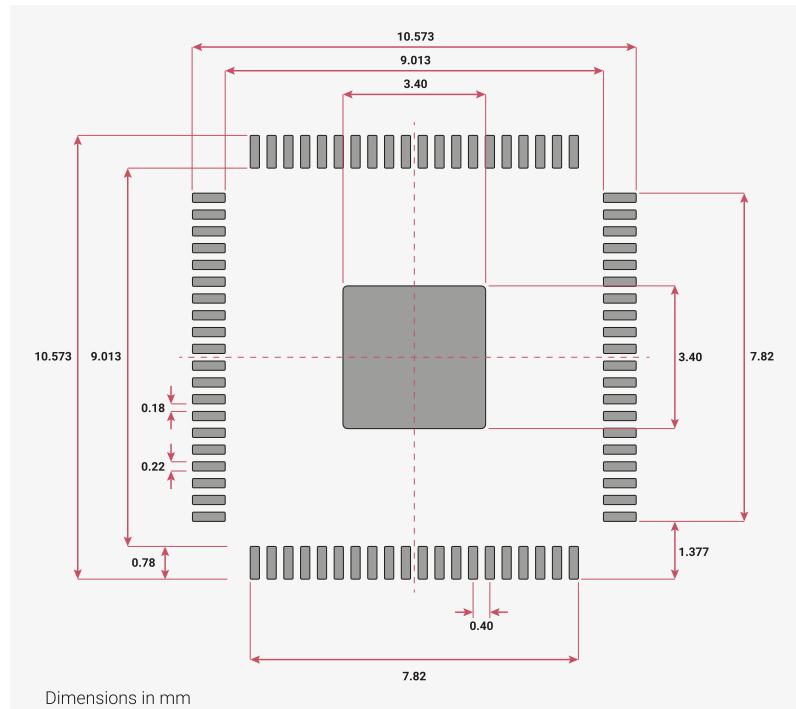

For detailed information on the W25Q16JVWI device used in RP2354 see:

[www.winbond.com/hq/product/code-storage-flash-memory/serial-nor-flash/?\\_\\_locale=en&partNo=W25Q16JV](http://www.winbond.com/hq/product/code-storage-flash-memory/serial-nor-flash/?__locale=en&partNo=W25Q16JV)

The six dedicated QSPI pads on the RP2350 die (`CSn`, `SCK` and `SD0` through `SD3`) connect to both the internal flash die and the external package pins. This makes them behave similarly to flashless RP2350 devices in the following ways:

- The QSPI `CSn` can be driven low at reset or power-up to select BOOTSEL mode
  - This harmlessly selects the internal flash die but does not issue commands to it
- The QSPI `SD1` pin can be driven high when selecting BOOTSEL to choose UART boot
  - UART TX appears on `SD2` and UART RX on `SD3`, as per [Section 5.8](#)
  - Even with the chip select asserted low, the internal flash die maintains a high-impedance state on its `SD0` through `SD3` pins if there are no transitions on `SCK`, so you can keep `CSn` asserted throughout UART boot
- Internal flash can be programmed via UF2 drag-and-drop download using the USB BOOTSEL mode
- A second QSPI device can be attached externally by connecting it to the QSPI pins and a secondary chip select from the Bank 0 GPIOs
  - This may be used for additional flash capacity, or external QSPI RAM

图 146。  
RP2350 QFN-80封  
装推荐PCB封  
装尺寸

### 14.3. 封装内闪存

RP2354A 和 RP2354B 具备 2 MB 内部闪存。在其他所有方面，包括引脚排列，它们与无闪存版本的 RP2350A 和 RP2350B 完全相同。它们采用相同的 QFN-60 (RP2354A) 和 QFN-80 (RP2354B) 封装。RP2354 器件包含两层叠加硅芯片：

- 与无闪存版本相同的 RP2350 硅芯片
- 一颗 Winbond W25Q16JVWI QSPI NOR 闪存

#### Winbond W25Q16JVWI 数据手册

有关 RP2354 中使用的 W25Q16JVWI 器件的详细信息，详见：

[www.winbond.com/hq/product/code-storage-flash-memory/serial-nor-flash/?\\_\\_locale=en&partNo=W25Q16JV](http://www.winbond.com/hq/product/code-storage-flash-memory/serial-nor-flash/?__locale=en&partNo=W25Q16JV)

RP2350 芯片上的六个专用QSPI引脚（**CSn**、**SCK**及 **SD0**至**SD3**）连接至内部闪存芯片及外部封装引脚。这使它们在以下方面表现类似于无闪存的RP2350设备：

- QSPI 的 **CSn** 引脚可在复位或上电时被拉低，以选择BOOTSEL 模式。
  - 此操作仅无害地选择内部闪存芯片，但不会向其发送任何命令。
- 选择BOOTSEL 时，QSPI 的 **SD1** 引脚可被拉高以选用UART 启动。
  - UART 的TX信号通过 **SD2**引脚输出，RX信号通过 **SD3**引脚输入，详见第5.8节。
  - 即使片选信号拉低，且 **SCK**线上无信号变化，内部闪存芯片在 **SD0**至 **SD3**引脚保持高阻抗状态，因此可在UART启动过程中持续保持**CSn**信号为低电平。
- 内部闪存可通过USB BOOTSEL模式下的UF2拖放下载方式进行编程。
- 可以通过将第二个QSPI设备连接到QSPI引脚及来自Bank 0 GPIO的二级片选信号，实现外部附加
  - 该设备可用于扩展闪存容量或外部QSPI RAM

- See [Section 12.14](#) for more details of the RP2350 QSPI memory interface and its capabilities

The internal flash die can also be programmed externally by holding the RP2350 die in reset via the `RUN` pin (active-low reset), and driving QSPI signals *into* the chip from an external programmer.

The internal flash is powered by the `QSPI_IOVDD` supply input. This voltage must be in the range 2.7 to 3.6 V. You should account for the increased high-frequency currents on this supply pin in your decoupling circuit and PCB layout.

The maximum QSPI clock frequency of the W25Q16JVWI is 133 MHz. Consult the [W25Q16JVWI](#) datasheet for detailed timings and AC parameters.

If you do not require access to the RP2350 QSPI bus from the outside, you should minimise the track length connected to the QSPI package pins on your PCB. This avoids unnecessary emissions and capacitive loading of the QSPI bus.

The `PADRESETB` reset input on the W25Q16JVWI is not connected to any external package pins, or to any internal signals on the RP2350 die. This means there is no way to perform a hardware reset of the flash die. When the RP2350 die comes out of reset it initialises the flash die in the same way it would an external flash device by issuing a fixed XIP exit sequence that returns the flash die to a serial command state in preparation for execute-in-place setup.

## 14.4. Package markings

RP2350 comes in 7 × 7 mm QFN-60 and 10 × 10 mm QFN-80 packages, which are marked with the following data:

- Pin 1 dot
- Logo
- Part number
- Date code (Week)
- Silicon lot number
- Date code (Year)

The part number consists of the following:

- Device name "RP2350"
- Package type, "A" for QFN-60 or "B" for QFN-80
- Package revision "0"
- Die stepping "A2", "A3", or "A4"

See [Appendix C](#) for a summary of the differences between die steppings.

## 14.5. Storage conditions

To preserve the shelf and floor life of bare RP2350 devices, follow JEDEC J-STD (020E & 033D).

RP2350 QFN-60 is classified as Moisture Sensitivity Level 1 (MSL1). The MSL of QFN-80 is still being characterised and details will follow in a future datasheet update.

All RP2350 devices should be stored under 30°C and 85% relative humidity.

## 14.6. Solder profile

RP2350 is a Pb-free part, with a  $T_p$  value of 260°C.

All temperatures refer to the centre of the package, measured on the package body surface that faces up during

- 有关RP2350 QSPI存储器接口及其功能的更多详细信息，详见第12.14节

通过将RP2350芯片保持在复位状态（通过RUN引脚，低电平有效复位），并由外部编程器驱动QSPI信号向芯片输入，可对内部闪存芯片进行外部编程

内部闪存由QSPI\_IOVDD电源输入供电该电压必须维持在2.7至3.6伏范围内。设计去耦电路及PCB布局时，应充分考虑此电源引脚上的高频电流增加

W25Q16JVWI的最大QSPI时钟频率为133 MHz。详细时序与交流参数请参阅W25Q16JVWI数据手册

如不需要从外部访问RP2350的QSPI总线，应尽量缩短连接至PCB上QSPI封装引脚的线路长度，以避免不必要的电磁发射及QSPI总线的电容负载。

W25Q16JVWI上的PADRESETB复位输入未连接至任何外部封装引脚或RP2350芯片内部的任何信号，故无法通过硬件方式复位闪存芯片。RP2350芯片退出复位状态时，会通过发出固定的XIP退出序列初始化闪存芯片，恢复其至串行命令状态，为执行就地运行配置做好准备，方式与外部闪存设备一致。

## 14.4. 封装标记

RP2350提供7×7 mm QFN-60封装及10×10 mm QFN-80封装，封装上标注如下信息：

- 引脚1标记点
- 标志
- 部件型号
- 日期代码（周）
- 硅片批号
- 日期代码（年份）

部件编号由以下部分组成：

- 设备名称“RP2350”
- 封装类型，‘A’表示QFN-60，‘B’表示QFN-80
- 封装版本“0”
- 晶圆版本‘A2’、‘A3’或‘A4’

有关晶圆版本之间差异的汇总，请参见附录C。

## 14.5. 存储条件

为保证裸露RP2350器件的存储和使用寿命，请遵守JEDEC J-STD (020E和033D) 标准。

RP2350 QFN-60封装被归类为湿敏等级1 (MSL1)。QFN-80的湿敏等级尚在评估中，相关细节将在未来数据手册更新中公布。

所有RP2350器件应存放于温度低于30°C且相对湿度不超过85%的环境中。

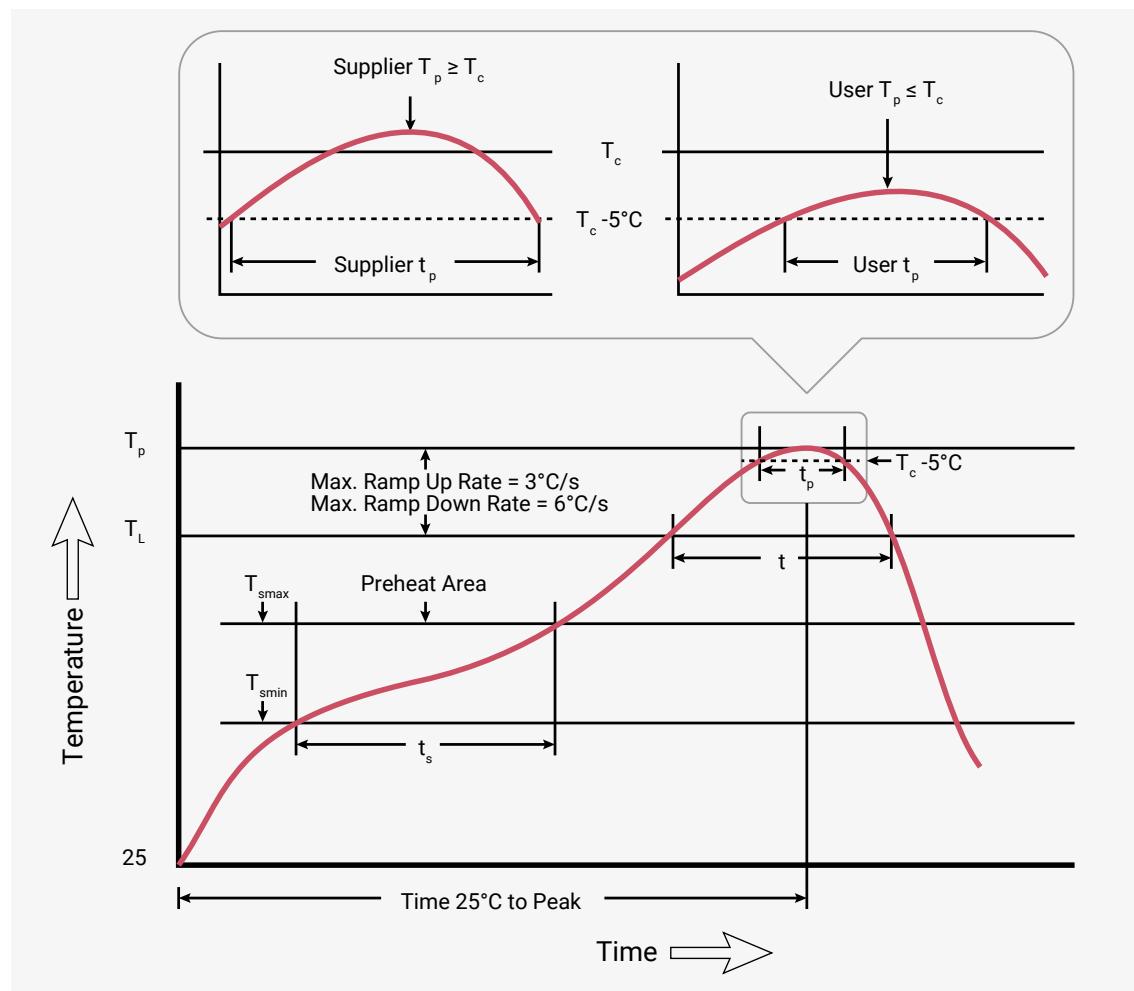

## 14.6. 焊接曲线

RP2350为无铅器件，熔点温度( $T_p$ )为260°C。

所有温度均指封装中心，测量位置为封装正面朝上的封装主体表面。

assembly reflow (live-bug orientation). If parts are reflowed in a different orientation (e.g. dead-bug),  $T_p$  shall be within  $\pm 2^\circ\text{C}$  of the live-bug  $T_p$  and still meet the  $T_c$  requirements; otherwise, you must adjust the profile to achieve the latter.

Figure 147.  
Classification profile  
(not to scale)

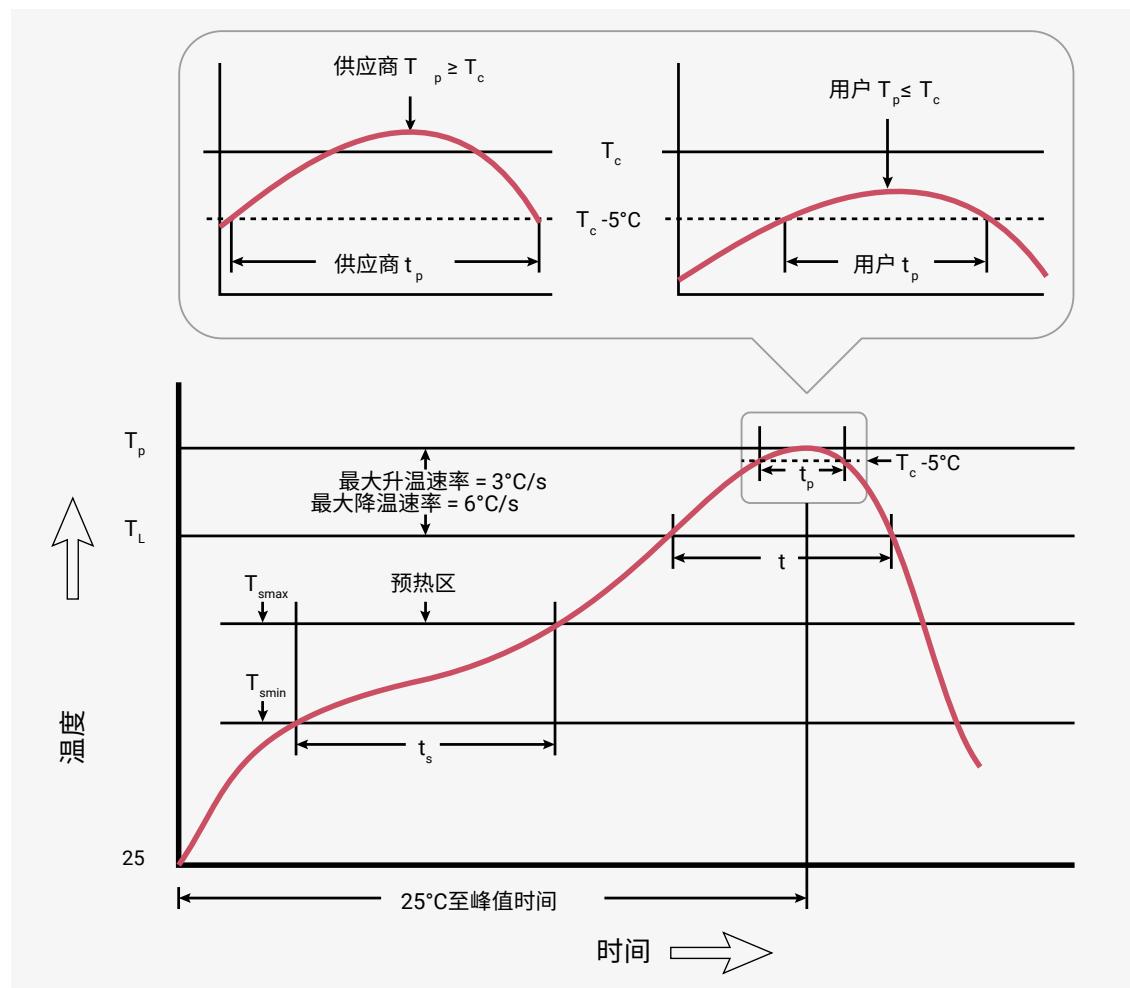

Reflow profiles in this document are for classification/preconditioning, and are not meant to specify board assembly profiles. Actual board assembly profiles should be developed based on specific process needs and board designs, and should not exceed the parameters in [Table 1425](#).

Table 1425. Solder profile values

Profile feature	Value
Temperature min ( $T_{smin}$ )	150°C
Temperature max ( $T_{smax}$ )	200°C
Time ( $t_s$ ) from ( $T_{smin}$ to $T_{smax}$ )	60 - 120 seconds
Ramp-up rate ( $T_L$ to $T_p$ )	3°C/second max.
Liquidous temperature ( $T_L$ )	217°C
Time ( $t_L$ ) maintained above $T_L$	60 to 150 seconds
Peak package body temperature ( $T_p$ )	260°C
Classification temperature ( $T_c$ )	260°C
Time ( $t_p$ ) within $5^\circ\text{C}$ of the specified classification temperature ( $T_c$ )	30 seconds
Ramp-down rate ( $T_p$ to $T_L$ )	6°C/second max.
Time 25°C to peak temperature	8 minutes max.

组装回流（倒置芯片方向）。如果元件以不同方向回流（例如，投死芯片方向）， $T_p$ 应与倒置芯片方向的 $T_p$ 保持 $\pm 2^\circ\text{C}$ 以内，且仍需满足 $T_c$ 的要求；否则，必须调整曲线以满足后者要求。

图 147.  
分类概要  
(非按比例)

本文档中的回流曲线用于分类及预处理，非用于规定板级组装工艺曲线。实际板级组装曲线应依据具体工艺需求及板设计制定，且不得超过表 1425 所列参数。

表 1425. 焊接  
曲线参数

曲线特征	值
最低温度 ( $T_{smin}$ )	150°C
最高温度 ( $T_{smax}$ )	200°C
时间 ( $t_s$ ) 从 ( $T_{smin}$ 至 $T_{smax}$ )	60 - 120 秒
升温速率 ( $T_L$ 至 $T_p$ )	最高 3°C/秒
液相线温度 ( $T_L$ )	217°C
维持温度高于 $T_L$ 的时间 ( $t_L$ )	60 至 150 秒
峰值封装温度 ( $T_p$ )	260°C
分类温度 ( $T_c$ )	260°C
在指定分类温度 ( $T_c$ ) $\pm 5^\circ\text{C}$ 范围内的时间 ( $t_p$ )	30 秒
降温速率 (从 $T_p$ 至 $T_L$ )	最大 6°C/秒
从 25°C 升至峰值温度的时间	最长 8 分钟

## 14.7. Compliance

RP2350 QFN-60 is compliant to Moisture Sensitivity Level 1. The Moisture Sensitivity Level compliance of RP2350 QFN-80 is yet to be fully characterised, and details will follow in a future datasheet update.

RP2350 is compliant to the requirement of REACH Substances of Very High Concern (SVHC), EU ECHA directive.

RP2350 is compliant to the requirement and standard of Controlled Environment-related Substance of RoHS directive (EU) 2011/65/EU and directive (EU) 2015/863.

Raspberry Pi Ltd carried out the following Package Level reliability qualifications on RP2350:

- Temperature Cycling per JESD22-A104
- HAST per JESD22-A110
- HTSL per JESD22-A103
- MSL level per JESD22-A113

The following Silicon Level reliability qualification were also carried out:

- HTOL per JESD22-A108F

### **NOTE**

A tin whiskers test is not performed. RP2350 is a bottom-only termination device in the QFN-60 and QFN-80 packages, therefore JEDEC standard (JESD201A) is not applicable.

## 14.8. Pinout

### 14.8.1. Pin locations

#### 14.8.1.1. QFN-60 (RP2350A)

## 14.7. 合规性

RP2350 QFN-60 符合湿度敏感等级 1 的要求。RP2350 QFN-80 的湿度敏感等级合规性尚未完全确认，相关详情将于未来数据表更新中公布。

RP2350 符合 REACH 高关注度物质（SVHC）欧盟 ECHA 指令的要求。

RP2350 符合 2011/65/EU 欧盟 RoHS 指令及 2015/863 欧盟修订指令关于受控环境相关物质的要求与标准。

Raspberry Pi Ltd 对 RP2350 进行了以下封装级可靠性认证：

- 按 JESD22-A104 进行温度循环测试
- 按 JESD22-A110 进行高加速应力测试（HAST）
- 按 JESD22-A103 进行高温存储寿命测试（HTSL）
- 按 JESD22-A113 进行湿气敏感等级（MSL）测试

同时进行了以下硅片级可靠性认证：

- 按 JESD22-A108F 进行高温运行寿命测试（HTOL）

### ① 注意

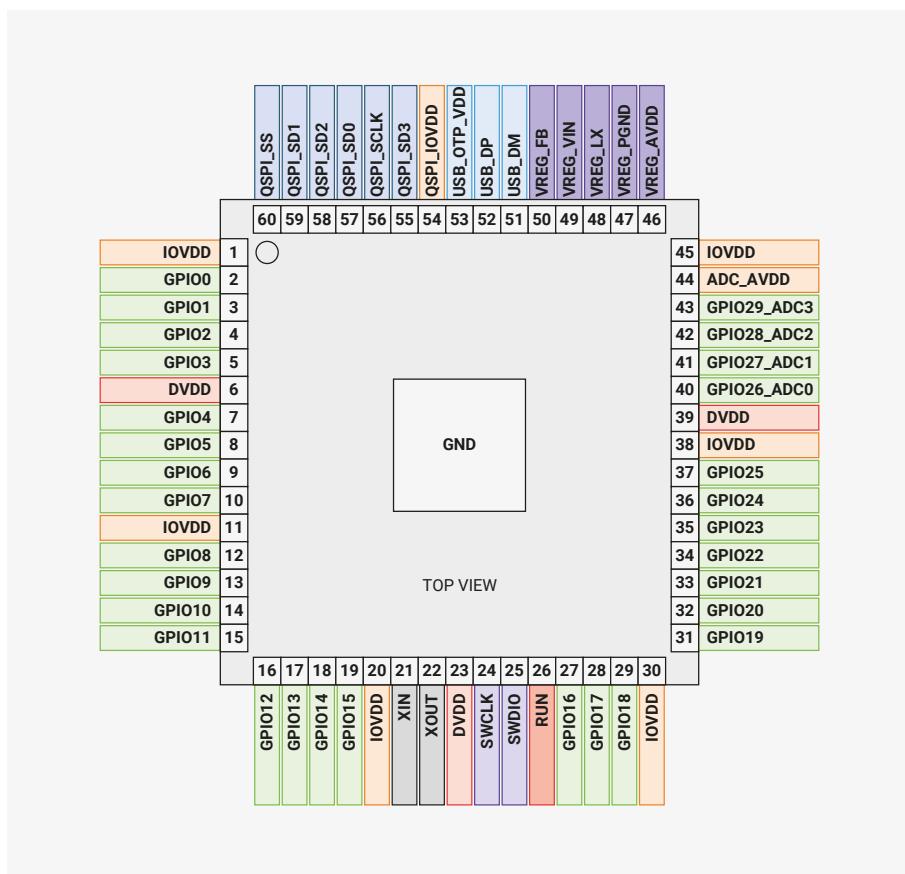

未执行锡须测试。RP2350 在 QFN-60 和 QFN-80 封装中为仅底部端接器件，故不适用 JEDEC 标准（JESD201A）。

## 14.8. 引脚排列

## 14.8.2. Pin definitions

### 14.8.2.1. Pin types

In the following pin tables (Table 1427), the pin types are defined as shown below.

Table 1426. Pin Types

Pin Type	Direction	Description
Digital In	Input only	<b>Standard Digital.</b> Programmable Pull-Up, Pull-Down, Slew Rate, Schmitt Trigger and Drive Strength. Default Drive Strength is 4 mA.
Digital IO	Bi-directional	
Digital In (FT)	Input only	<b>Fault Tolerant Digital.</b> These pins are described as Fault Tolerant, which in this case means that very little current flows into the pin whilst it is below 3.63 V and IOVDD is 0 V. Additionally, they will tolerate voltages up to 5.5 V, provided IOVDD is powered to 3.3 V.
Digital IO (FT)	Bi-directional	These pins have enhanced ESD protection. Programmable Pull-Up, Pull-Down, Slew Rate, Schmitt Trigger and Drive Strength. Default Drive Strength is 4 mA.
Digital IO / Analogue	Bi-directional (digital), Input (Analogue)	<b>Standard Digital and ADC input.</b> Programmable Pull-Up, Pull-Down, Slew Rate, Schmitt Trigger and Drive Strength. Default Drive Strength is 4 mA.
USB IO	Bi-directional	These pins are for USB use, and contain internal pull-up and pull-down resistors, as per the USB specification. USB operation requires external 27Ω series resistors.
Analogue (XOSC)		Oscillator input pins for attaching a 12 MHz crystal. Alternatively, XIN may be driven by a square wave.

### 14.8.2.2. Pin list

Table 1427. GPIO pins

Name	QFN-60 Number	QFN-80 Number	Type	Power Domain	Reset State	Description
GPIO0	2	77	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO1	3	78	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO2	4	79	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO3	5	80	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO4	7	1	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO5	8	2	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO6	9	3	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO7	10	4	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO8	12	6	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO9	13	7	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO10	14	8	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO11	15	9	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO12	16	11	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO13	17	12	Digital IO (FT)	IOVDD	Pull-Down	User IO
GPIO14	18	13	Digital IO (FT)	IOVDD	Pull-Down	User IO

## 14.8.2. 引脚定义

### 14.8.2.1. 引脚类型

在下表（表1427）中，定义了以下引脚类型。

表1426. 引脚类型

引脚类型	方向	描述
数字输入	仅输入	标准数字。可编程上拉、下拉、斜率控制、施密特触发器及驱动强度。默认驱动强度为4 mA。
数字IO	双向	
数字输入（容错）	仅输入	容错数字。这些引脚称为容错型，意指在引脚电压低于3.63 V且I <sub>OVDD</sub> 为0 V时，流入引脚的电流极小。此外，若I <sub>OVDD</sub> 供电为3.3 V，则其可承受高达5.5 V的电压。该引脚具备增强的ESD保护功能。可编程上拉、下拉、斜率控制、施密特触发器及驱动强度。默认驱动强度为4 mA。
数字输入输出（FT）	双向	
数字输入输出 / 模拟	双向（数字），输入（模拟）	标准数字和ADC输入。可编程上拉、下拉、斜率控制、施密特触发器及驱动强度。默认驱动强度为4 mA。
USB 输入输出	双向	这些引脚用于USB，包含符合USB规范的内部上拉电阻和下拉电阻。USB操作需要外部27Ω串联电阻。
模拟（XOSC）		振荡器输入引脚，用于连接12 MHz晶体。或由方波驱动XIN引脚。

### 14.8.2.2. 引脚列表

表1427. GPIO引脚

名称	QFN-60编号	QFN-80编号	类型	电源域	复位状态	描述
GPIO0	2	77	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出
GPIO1	3	78	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出
GPIO2	4	79	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出
GPIO3	5	80	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出
GPIO4	7	1	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出
GPIO5	8	2	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出
GPIO6	9	3	数字输入输出（FT）	I <sub>OVDD</sub>	下拉	用户输入输出

ADC_AVDD	44	59	ADC supply
VREG_AVDD	46	61	Voltage regulator analogue supply
VREG_PGND	47	62	Voltage regulator ground
VREG_LX	48	63	Voltage regulator switching output (connect to inductor)
VREG_VIN	49	64	Voltage regulator input supply
VREG_FB	50	65	Voltage regulator feedback input
GND	-	-	Ground connection via central exposed pad

## 14.9. Electrical specifications

The following electrical specifications are obtained from characterisation over the specified temperature and voltage ranges, as well as process variation, unless the specification is marked as 'Simulated'. In this case, the data is for information purposes only, and is not guaranteed.

### 14.9.1. Absolute maximum ratings

Stresses beyond the absolute maximum ratings listed in the following table can cause permanent damage to the device. These are stress ratings only and do not refer to the functional operation of the device.

Table 1433. Absolute maximum ratings

Parameter	Symbol	Conditions	Minimum	Maximum	Units	Comment
Core Supply (DVDD) Voltage	DVDD		-0.5	1.21	V	
I/O Supply (IOVDD) & QSPI Supply (QSPI_IOVDD) Voltage	IOVDD		-0.5	3.63	V	

名称	QFN-60编号	QFN-80编号	类型	电源域	描述
USB_DM	51	66	USB 输入输出	USB OTP_VDD	USB数据负极。USB操作需27Ω串联电阻

表1432。电源引脚

名称	QFN-60引脚编号	QFN-80引脚编号	描述
DVDD	6, 23, 39	10, 32, 51	核心电源
IOVDD	11, 20, 30, 38, 45, 54	5, 15, 24, 29, 41, 50, 60, 76	IO电源
QSPI_IOVDD	54	69	QSPI IO电源
USB OTP_VDD	53	68	USB与OTP电源
ADC_AVDD	44	59	ADC电源
VREG_AVDD	46	61	电压调节器模拟供电
VREG_PGND	47	62	电压调节器地线
VREG_LX	48	63	电压调节器开关输出（连接至电感）
VREG_VIN	49	64	电压调节器输入供电
VREG_FB	50	65	电压调节器反馈输入
GND	-	-	通过中央裸露焊盘接地

## 14.9. 电气规格

以下电气规格基于指定温度、电压范围及工艺变异的特性测试获得，除非规格标注为“模拟”。在此情况下，数据仅供参考，且不保证准确性。

### 14.9.1. 绝对最大额定值

超过下表所列绝对最大额定值的应力可能导致器件永久损坏。这些仅为应力额定值，不代表器件的功能性操作范围。

表1433。绝对最大额定值

参数	符号	条件	最小值	最大值	单位	备注
核心供电 (DVDD) 电压	DVDD		-0.5	1.21	V	
I/O供电 (IOVDD) 及 QSPI 供电 (QSPI_IOVD) 电压	IOVDD		-0.5	3.63	V	

Parameter	Symbol	Conditions	Minimum	Maximum	Units	Comment
Voltage at IO <i>(Standard)</i>	$V_{PIN}$		-0.5	IOVDD + 0.5	V	
Voltage at IO <i>(FT)</i>	$V_{PIN\_FT}$	IOVDD=3.3V	-0.5	5.5	V	IOVDD must be present
		IOVDD=2.5V	-0.5	4.2	V	
		IOVDD=1.8V	-0.5	3.63	V	
		IOVDD=0V	-0.5	3.63	V	
Junction temperature			-40	125	°C	
Storage temperature				150	°C	

#### 14.9.2. ESD performance

Table 1434. ESD performance for all pins, unless otherwise stated

Parameter	Symbol	Maximum	Units	Comment
Human Body Model	HBM	2	kV	Compliant with JEDEC specification JS-001-2012 (April 2012)
Human Body Model Digital (FT) pins only	HBM	4	kV	Compliant with JEDEC specification JS-001-2012 (April 2012)
Charged Device Model	CDM	500	V	Compliant with JESD22-C101E (December 2009)

#### 14.9.3. Thermal performance

Table 1435. Thermal Performance

Parameter	Symbol	Minimum	Typical	Maximum	Units	Comment
Ambient Temperature	$T_c$	-40		85	°C	

#### 14.9.4. IO electrical characteristics

Table 1436. Digital IO characteristics - Standard and FT unless otherwise stated. In this table IOVDD also refers to QSPI/IOVDD where appropriate

Parameter	Symbol	Conditions	Minimum	Maximum	Units	Comment
Pin Input Leakage Current	$I_{IN}$			1	µA	
Input Voltage High (Standard IO)	$V_{IH}$	IOVDD=1.8V	0.65 * IOVDD	IOVDD + 0.3	V	
		IOVDD=2.5V	1.7	IOVDD + 0.3	V	
		IOVDD=3.3V	2	IOVDD + 0.3	V	

参数	符号	条件	最小值	最大值	单位	备注
IO电压 (标准)	V <sub>引脚</sub>		-0.5	IOVDD + 0.5	V	
IO电压 (FT)	V <sub>引脚_FT</sub>	IOVDD=3.3V	-0.5	5.5	V	IOVDD必须存在
		IOVDD=2.5V	-0.5	4.2	V	
		IOVDD=1.8V	-0.5	3.63	V	
		IOVDD=0V	-0.5	3.63	V	
结温			-40	125	°C	
储存 温度				150	°C	

### 14.9.2. 静电放电性能

表 1434. 除非另有说明，所有引脚的ESD性能

参数	符号	最大值	单位	备注
人体模型	HBM	2	kV	符合JEDEC规范 JS-001-2012 (2012年4月)
人体模型 仅数字 (FT) 引脚	HBM	4	kV	符合JEDEC规范 JS-001-2012 (2012年4月)
带电器件模型	CDM	500	V	符合 JESD22-C101E (2009年12月)

### 14.9.3. 热性能

表 1435. 热性能

参数	符号	最小值	典型值	最大值	单位	备注
环境 温度	T <sub>c</sub>	-40		85	°C	

### 14.9.4. IO电气特性

表 1436. 数字IO特性—标准及FT  
T<sub>c</sub> 除非另有说明。本表中/IOVDD在适当情况下亦指QSP1/IOVDD

参数	符号	条件	最小值	最大值	单位	备注
引脚输入 泄漏 电流	I <sub>IN</sub>			1	μA	
输入电压 高 (标准 IO)	V <sub>IH</sub>	IOVDD=1.8V	0.65 * IOVDD	IOVDD + 0.3	V	
		IOVDD=2.5V	1.7	IOVDD + 0.3	V	
		IOVDD=3.3V	2	IOVDD + 0.3	V	

Parameter	Symbol	Conditions	Minimum	Maximum	Units	Comment
<i>Input Voltage High (FT)</i>	$V_{IH}$	IOVDD=1.8V	0.65 * IOVDD	3.63	V	IOVDD must be powered to tolerate input voltages above 3.63V
		IOVDD=2.5V	1.7	4.2	V	
		IOVDD=3.3V	2	5.5	V	
<i>Input Voltage Low</i>	$V_{IL}$	IOVDD=1.8V	-0.3	0.35 * IOVDD	V	
		IOVDD=2.5V	-0.3	0.7	V	
		IOVDD=3.3V	-0.3	0.8	V	
<i>Input Hysteresis Voltage</i>	$V_{HYS}$	IOVDD=1.8V	0.1 * IOVDD		V	Schmitt Trigger enabled
		IOVDD=2.5V	0.2		V	
		IOVDD=3.3V	0.2		V	
<i>Output Voltage High</i>	$V_{OH}$	IOVDD=1.8V	1.24	IOVDD	V	$I_{OH} = 2, 4, 8 \text{ or } 12\text{mA}$ depending on setting
		IOVDD=2.5V	1.78	IOVDD	V	
		IOVDD=3.3V	2.62	IOVDD	V	
<i>Output Voltage Low</i>	$V_{OL}$	IOVDD=1.8V	0	0.3	V	$I_{OL} = 2, 4, 8 \text{ or } 12\text{mA}$ depending on setting
		IOVDD=2.5V	0	0.4	V	
		IOVDD=3.3V	0	0.5	V	
<i>Pull-Up Resistance</i>	$R_{PU}$	IOVDD=1.8V	32	106	kΩ	
		IOVDD=2.5V	42	123	kΩ	
		IOVDD=3.3V	32	86	kΩ	
<i>Pull-Down Resistance</i>	$R_{PD}$	IOVDD=1.8V	35	189	kΩ	
		IOVDD=2.5V	49	180	kΩ	
		IOVDD=3.3V	36	113	kΩ	
<i>Maximum Total IOVDD current</i>	$I_{IOVDD\_MAX}$			100	mA	Sum of all current being sourced by GPIO pins
<i>Maximum Total QSPI_IOVDD current</i>	$I_{QSPI\_IOVDD\_MAX}$			20	mA	Sum of all current being sourced by QSPI pins
<i>Maximum Total VSS current due to GPIO (IOVSS)</i>	$I_{IOVSS\_MAX}$			100	mA	Sum of all current being sunk into GPIO pins
<i>Maximum Total VSS current due to QSPI (QSPI_IOVSS)</i>	$I_{QSPI\_IOVSS\_MAX}$			20	mA	Sum of all current being sunk into QSPI pins

Table 1437. USB IO characteristics

参数	符号	条件	最小值	最大值	单位	备注
输入电压高 ( <b>FT</b> )	$V_{IH}$	IOVDD=1.8V	0.65 * IOVDD	3.63	V	IOVDD必须供电以承受高于3.63V的输入电压
		IOVDD=2.5V	1.7	4.2	V	
		IOVDD=3.3V	2	5.5	V	
输入电压低	$V_{IL}$	IOVDD=1.8V	-0.3	0.35 * IOVDD	V	
		IOVDD=2.5V	-0.3	0.7	V	
		IOVDD=3.3V	-0.3	0.8	V	
输入迟滞电压	$V_{HYS}$	IOVDD=1.8V	0.1 * IOVDD		V	施密特触发器已启用
		IOVDD=2.5V	0.2		V	
		IOVDD=3.3V	0.2		V	
输出电压高	$V_{OH}$	IOVDD=1.8V	1.24	IOVDD	V	$I_{OH} = 2, 4, 8$ 或 12mA, 取决于设置
		IOVDD=2.5V	1.78	IOVDD	V	
		IOVDD=3.3V	2.62	IOVDD	V	
输出电压低	$V_{OL}$	IOVDD=1.8V	0	0.3	V	$I_{OL} = 2, 4, 8$ 或 12mA 取决于设置
		IOVDD=2.5V	0	0.4	V	
		IOVDD=3.3V	0	0.5	V	
上拉电阻	$R_{PU}$	IOVDD=1.8V	32	106	kΩ	
		IOVDD=2.5V	42	123	kΩ	
		IOVDD=3.3V	32	86	kΩ	
下拉电阻	$R_{PD}$	IOVDD=1.8V	35	189	kΩ	
		IOVDD=2.5V	49	180	kΩ	
		IOVDD=3.3V	36	113	kΩ	
最大总 IOVDD 电流	$I_{IOVDD\_MAX}$			100	mA	所有GPIO引脚输出电流总和
最大总 QSPI_IOVDD 电流	$I_{QSPI\_IOVDD\_MAX}$			20	mA	所有QSPI引脚输出电流总和
最大总 VSS 电流 由GPIO引脚产生的 (IOVSS)	$I_{IOVSS\_MAX}$			100	mA	所有流入GPIO引脚的电流总和
由QSPI引脚产 生的最大总 VSS电流 (QSPI_IOVSS)	$I_{QSPI\_IOVSS\_MAX}$			20	mA	汇入QSPI引脚的总电 流

表1437. USB IO 特性

Parameter	Symbol	Minimum	Maximum	Units	Comment
Pin Input Leakage Current	$I_{IN}$		1	$\mu A$	
Single Ended Input Voltage High	$V_{IHSE}$	2		V	
Single Ended Input Voltage Low	$V_{ILSE}$		0.8	V	
Differential Input Voltage High	$V_{IHDIFF}$	0.2		V	
Differential Input Voltage Low	$V_{ILDIF}$		-0.2	V	
Output Voltage High	$V_{OH}$	2.8	USB_OTG_VDD	V	
Output Voltage Low	$V_{OL}$	0	0.3	V	
Pull-Up Resistance - RPU2	$R_{PU2}$	0.873	1.548	k $\Omega$	
Pull-Up Resistance - RPU1&2	$R_{PU1\&2}$	1.398	3.063	k $\Omega$	
Pull-Down Resistance	$R_{PD}$	14.25	15.75	k $\Omega$

ADC输入 电压范围	$V_{PIN\_ADC}$	0		ADC_AVDD	V	
有效 位数	ENOB	9	9.5		位	
分辨位数				12	位	
ADC输入 阻抗	$R_{IN\_ADC}$	100			kΩ	

表1439。振荡器  
引脚特性

参数	符号	最小值	典型值	最大值	单位	备注
输入 频率	$f_{osc}$	1	12	50	MHz	有关PLL施 加的限 制，请参见 第8.6.3节 。  有关USB和 UART引导 程序施加的 限制，请参见 第5.2.8.1节。

Parameter	Symbol	Minimum	Typical	Maximum	Units	Comment
<i>Input Voltage High</i>	$V_{IH}$	$0.65 \times IOVDD$		$IOVDD + 0.3$	V	Square Wave input. $XIN$ only. $XOUT$ floating
<i>Input Voltage Low</i>	$V_{IL}$	0		$0.35 \times IOVDD$	V	Square Wave input. $XIN$ only. $XOUT$ floating

**NOTE**

By default, USB Bootmode relies on a 12MHz input being present. However OTP can be configured to override the XOSC and PLL settings during USB Bootmode. See [Section 13.10](#) for details.

See [Section 8.2](#) for more details on the Oscillator, and the Minimal Design Example in [Hardware design with RP2350](#) for information on crystal usage.

Table 1440. SWCLK pin characteristics

Parameter	Symbol	Minimum	Typical	Maximum	Units	Comment
SWCLK Input Frequency	$f_{SWCLK}$	0	10	50	MHz	See <a href="#">Table 1430</a> for SWCLK pin definitions.

Host-to-target data on the  $SWDIO$  pin should be transmitted centre-aligned with  $SWCLK$ . Target-to-host data on the  $SWDIO$  pin transitions on rising edges of  $SWCLK$ .

**NOTE**

RP2350 internal SWD logic in the SW-DP operates reliably up to 50 MHz. However, signal integrity of the external SWD signals may be a challenge.

If you observe unreliable SWD operation such as write data parity errors from the SW-DP, reduce the  $SWCLK$  frequency. Always connect ground directly between the SWD probe and RP2350 in addition to  $SWDIO$  and  $SWCLK$ . Minimise the wire length between the probe and RP2350, and avoid multi-drop wiring at higher frequencies.

#### 14.9.4.1. Interpreting GPIO output voltage specifications

The GPIOs on RP2350 have four different output drive strengths, nominally called 2, 4, 8 and 12mA modes. These are not hard limits, nor do they mean that they will always source (or sink) the selected amount of milliamps.

The amount of current a GPIO sources or sinks is dependent on the load attached. It will attempt to drive the output to the  $IOVDD$  level (or 0V in the case of a logic 0), but the amount of current it is able to source is limited and dependent on the selected drive strength.

Therefore the higher the current load is, the lower the voltage will be at the pin. At some point, the GPIO will source so much current and the voltage will drop so low that it won't be recognised as a logic 1 by the input of a connected device. The output specifications in [Table 1436](#) quantify how much lower the voltage can be expected to be when drawing specified amounts of current from the pin.

The Output High Voltage ( $V_{OH}$ ) is defined as the lowest voltage the output pin can be when driven to a logic 1 with a particular selected drive strength; e.g., 4mA sourced by the pin whilst in 4mA drive strength mode. The Output Low Voltage is similar, but with a logic 0 being driven.

In addition to this, the sum of all the IO currents being sourced (i.e. when outputs are being driven high) from the  $IOVDD$  bank (essentially the GPIO and QSPI pins), must not exceed  $I_{IOVDD\_MAX}$ . Similarly, the sum of all the IO currents being sunk (i.e. when the outputs are being driven low) must not exceed  $I_{IOVSS\_MAX}$ .

参数	符号	最小值	典型值	最大值	单位	备注
输入电压 高电平	$V_{IH}$	$0.65*IOVDD$		$IOVDD + 0.3$	V	方波 输入。仅限 $XIN$ 端。 $XOUT$ 悬空
输入电压 低	$V_{IL}$	0		$0.35*IOVDD$	V	方波 输入。仅限 $XIN$ 端。 $XOUT$ 悬空

**注意**

默认情况下，USB引导模式依赖12MHz输入信号。然而，OTP可配置以在USB引导模式期间覆盖XOSC和PLL设置。详情请参见第13.10节。

有关振荡器的详细信息，请参见第8.2节；有关晶体使用，请参见RP2350硬件设计中的最简设计示例。

表1440。SWCLK  
引脚特性

参数	符号	最小值	典型值	最大值	单位	备注
SWCLK 输入 频率	$f_{SWCLK}$	0	10	50	MHz	有关 $SWCLK$ 引脚 定义，请参 见表1430。

主机至目标的数据应通过  $SWDIO$  引脚，且与  $SWCLK$  中心对齐传输。目标至主机的数据在  $SWDIO$  引脚上于  $SWCLK$  上升沿转换。

**注意**

RP2350内部SWD逻辑（位于SW-DP）在最高50 MHz下可稳定运行，但外部SWD信号的信号完整性仍可能存在挑战。

若出现如SW-DP写数据奇偶校验错误等SWD操作不稳定，应降低  $SWCLK$  频率。

除  $SWDIO$  和  $SWCLK$  外，务必直接连接SWD探针与RP2350之间的地线。请尽量缩短探针与RP2350之间的导线长度，并在高频率条件下避免采用多点串联布线。

#### 14.9.4.1. GPIO输出电压规格的解读

RP2350的GPIO具备四种不同的输出驱动强度，标称为2mA、4mA、8mA及12mA模式。这些数值并非严格限制，也不保证GPIO总是输出（或吸收）所设定的电流。

GPIO输出或吸收的电流视所连接负载而定。GPIO会尝试将输出电平驱动至IOVDD电平（逻辑0时为0V），但其可输出的电流有限，且依赖所选驱动强度。

因此，负载电流越大，针脚电压越低。当GPIO输出电流过大时，电压将下降到无法被连接设备识别为逻辑1的水平。

表1436的输出规格量化了在从引脚抽取指定电流时电压预期降低的幅度。

输出高电压 ( $V_{OH}$ ) 定义为在以特定驱动强度驱动输出引脚为逻辑1时的最低输出电压；例如，在4mA驱动强度模式下，针脚输出4mA电流。输出低电压与此类似，但指的是驱动为逻辑0时的电压。

此外，从IOVDD电源组（主要包括GPIO及QSPI引脚）输出（即输出为高电平时）的电流总和不得超过  $I_{IOVDD\_MAX}$ 。同理，所有下拉电流总和（即输出为低电平时）不得超过  $I_{IOVSS\_MAX}$ 。

Figure 150. Typical Current vs Voltage curves of a GPIO output.

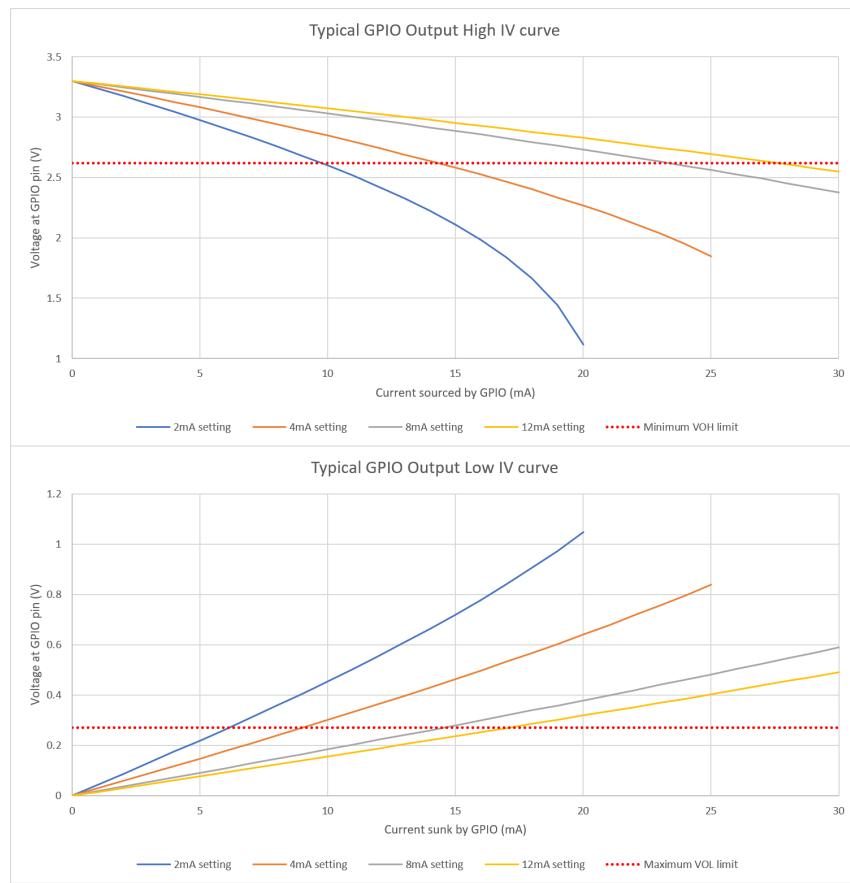

Figure 150 shows the effect on the output voltage as the current load on the pin increases. You can clearly see the effect of the different drive strengths; the higher the drive strength, the closer the output voltage is to IOVDD (or 0V) for a given current. The minimum  $V_{OH}$  and maximum  $V_{OL}$  limits are shown in red.

You can see that at the specified current for each drive strength, the voltage is well within the allowed limits, meaning that this particular device could drive a lot more current and still be within  $V_{OH}/V_{OL}$  specification. This is a typical part at room temperature, but because devices vary, there will be a spread of other devices which will have voltages much closer to this limit.

If your application doesn't need such tightly controlled voltages, you can source or sink more current from the GPIO than the selected drive strength setting. However, experimentation is required to determine if it indeed safe to do so in your application.

#### 14.9.5. Power supplies

Table 1441. Power Supply Specifications

Power Supply	Supplies	Min	Typ	Max	Units
IOVDD <sup>a</sup>	Digital IO	1.62	1.8 / 3.3	3.63	V
QSPI_IOVDD (RP2350 only) <sup>a</sup>	Digital IO	1.62	1.8 / 3.3	3.63	V
QSPI_IOVDD (RP2354 only)	Digital IO	2.97	3.3	3.63	V
DVDD <sup>b</sup>	Digital core	1.05	1.1	1.16	V
VREG_VIN	Voltage regulator	2.7	3.3	5.5	V
VREG_AVDD	Voltage regulator	3.135	3.3	3.63	V

图150。GPIO输出的典型电流-电压曲线。

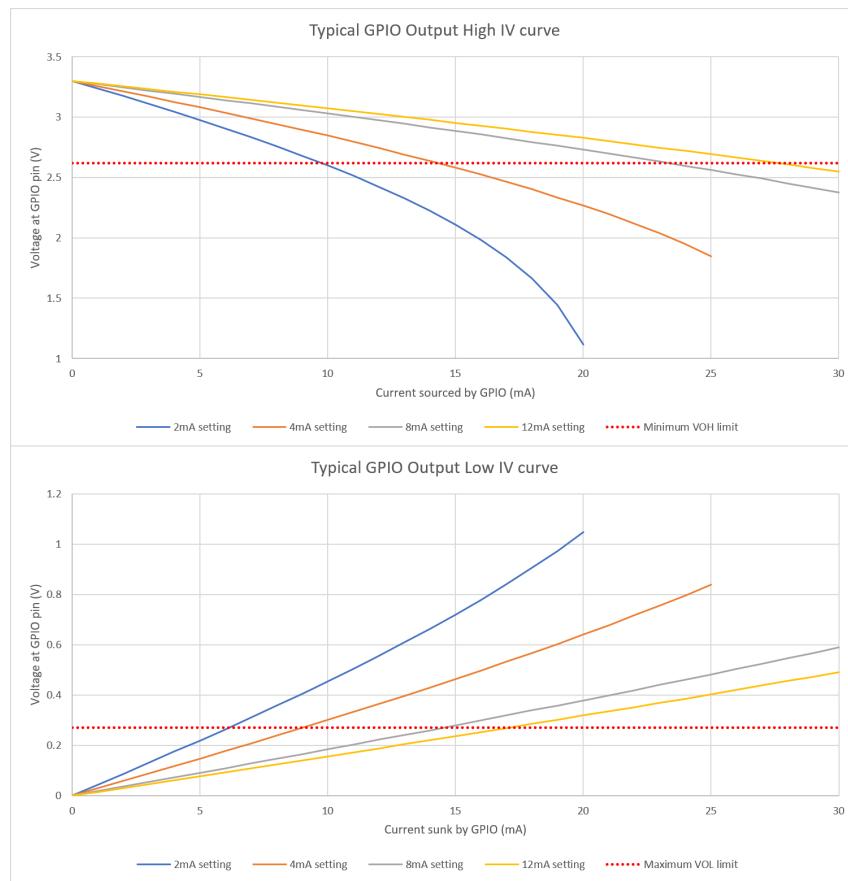

图150显示了随着引脚负载电流增加，输出电压的变化情况。可清晰见到不同驱动强度的影响；在给定电流下，驱动强度越高，输出电压越接近 $\text{IOVDD}$ （或 $0\text{V}$ ）。最小 $V_{\text{OH}}$ 和最大 $V_{\text{OL}}$ 限值以红色标示。

可见每种驱动强度对应的额定电流下，电压均在允许范围内，表明该器件可驱动更大电流且仍满足 $V_{\text{OH}}/V_{\text{OL}}$ 规格。此为室温下的典型器件，但器件存在差异，部分器件电压或将更接近极限值。

若应用不需严格电压控制，可从GPIO源出或吸入超过所选驱动强度设置的电流。但需通过实验验证在具体应用中此操作的安全性。

#### 14.9.5. 电源供应

表 1441. 电源供应规格

电源	供应	最小值	典型值	最大值	单位
<b>IOVDD<sup>a</sup></b>	数字IO	1.62	1.8 / 3.3	3.63	V
<b>QSPI_IOVDD</b> (仅限 RP2350) <sup>a</sup>	数字IO	1.62	1.8 / 3.3	3.63	V
<b>QSPI_IOVDD</b> (仅限 RP2354)	数字IO	2.97	3.3	3.63	V
<b>DVDD<sup>b</sup></b>	数字内核	1.05	1.1	1.16	V
<b>VREG_VIN</b>	电压调节器	2.7	3.3	5.5	V
<b>VREG_AVDD</b>	电压调节器	3.135	3.3	3.63	V

Power Supply	Supplies	Min	Typ	Max	Units
USB_OTP_VDD	USB PHY & OTP	3.135	3.3	3.63	V
ADC_AVDD <sup>c</sup>	ADC	1.62	3.3	3.63	V

<sup>a</sup> If IOVDD <2.5V, GPIO VOLTAGE\_SELECT registers should be adjusted accordingly. See [Section 6.1](#) for details.

<sup>b</sup> Short term transients should be within +/-100mV.

<sup>c</sup> ADC performance will be compromised at voltages below 2.97V

#### **NOTE**

RP2354 contains an internal 3.3V flash device, therefore QSPI\_IOVDD must be 3.3V. Furthermore, if the QSPI pins are to be used to connect to an additional flash or PSRAM device, then IOVDD must be 3.3V, as a GPIO is used as QSPI chip select in this case.

### 14.9.6. Core voltage regulator

Table 1442. Voltage Regulator Specifications

Parameter	Description	Min	Typ	Max	Units
$V_{OUT}$ (normal mode)	regulated output voltage range (normal mode)	0.55	1.1	3.3	V
$V_{OUT}$ (low power mode)	regulated output voltage range (low power mode)	0.55	1.1	1.3	V
$\Delta V_{OUT}$ (normal mode)	voltage deviation from programmed value (normal mode)	-3		+3	% of selected output voltage
$\Delta V_{OUT}$ (low power mode)	voltage deviation from programmed value (low power mode)	-9		+9	% of selected output voltage
$I_{MAX}$ (normal mode)	output current (normal mode)			200	mA
$I_{MAX}$ (low power mode)	output current (low power mode)			1	mA
$I_{LIMIT}$ (normal mode startup)	current limit (normal mode startup)		240	300	mA
$I_{LIMIT}$ (normal mode)	current limit (normal mode)	260	500	800	mA
$I_{LIMIT}$ (low power mode)	current limit (low power mode)	5		25	mA
$V_{OUT\_OK}_{TH,ASSERT}$	$V_{OUT\_OK}$ assertion threshold	87	90	93	% of selected output voltage

电源	供应	最小值	典型值	最大值	单位
USB_OTP_VDD	USB PHY 与 OTP	3.135	3.3	3.63	V
ADC_AVDD <sup>c</sup>	ADC	1.62	3.3	3.63	V

<sup>a</sup> 若 IOVDD < 2.5V，应相应调整 GPIO VOLTAGE\_SELECT 寄存器。详见第 6.1 节。

<sup>b</sup> 短期瞬态应控制在 ±100mV 以内。

<sup>c</sup> 电压低于 2.97V 时，ADC 性能将会受损。

### ● 注意

RP2350 内含 3.3V 内部闪存设备，故 QSPI\_IOVDD 必须为 3.3V。此外，若 QSPI 引脚用于连接额外闪存或 PSRAM 设备，则 IOVDD 必须为 3.3V，因为此情况下 GPIO 用作 QSPI 片选信号。

## 14.9.6. 核心电压调节器

表 1442. 电压  
稳压器  
规格

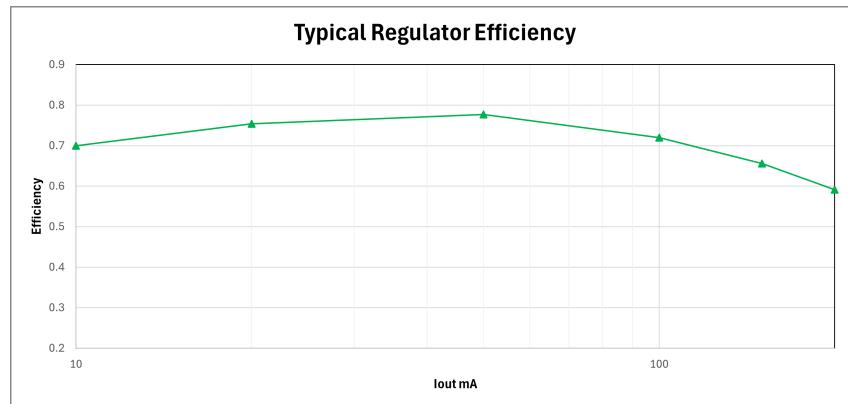

参数	描述	最小值	典型值	最大值	单位
$V_{OUT}$ (正常模式)	调节输出 电压范围 (正常模式)	0.55	1.1	3.3	V
$V_{OUT}$ (低功耗模式)	调节输出电压范 围 (低功耗模式)	0.55	1.1	1.3	V
$\Delta V_{OUT}$ (正常模式)	偏离设定值的电 压 (正常模式)	-3		+3	所选输出电 压的百分比
$\Delta V_{OUT}$ (低功耗模式)	偏离设定值的电 压 (低功耗模式)	-9		+9	所选输出电 压的百分比
$I_{MAX}$ (正常模式)	输出电流 (正常模式)			200	mA
$I_{MAX}$ (低功耗模式)	输出电流 (低功耗模式)			1	mA
$I_{LIMIT}$ (正常模式启动)	电流限制 (正常模式 启动)		240	300	mA
$I_{LIMIT}$ (正常模式)	电流限制 (正常模式)	260	500	800	mA

$V_{OUT\_OK}$ 阈值 · 断言 阈值	$V_{OUT\_OK}$ 断言 阈值	87	90	93	所选输出电 压的百分比

Parameter	Description	Min	Typ	Max	Units
VOUT_OK <sub>TH,DEASSERT</sub>	V <sub>OUT_OK</sub> de-assertion threshold	84	87	90	% of selected output voltage
f <sub>sw</sub>	switching frequency		3		MHz
Efficiency ( $V_{out}=1.1V$ )	I <sub>load</sub> =10mA, VREG_VIN=2.7V		74		%
	I <sub>load</sub> =10mA, VREG_VIN=3.3V		70		%
	I <sub>load</sub> =10mA, VREG_VIN=5.5V		59		%
	I <sub>load</sub> =100mA, VREG_VIN=2.7V		70		%
	I <sub>load</sub> =100mA, VREG_VIN=3.3V		72		%
	I <sub>load</sub> =100mA, VREG_VIN=5.5V		72		%
	I <sub>load</sub> =200mA, VREG_VIN=2.7V		70		%
	I <sub>load</sub> =200mA, VREG_VIN=3.3V		59		%
	I <sub>load</sub> =200mA, VREG_VIN=5.5V		63		%

**WARNING**

$V_{out}$  can exceed the maximum core supply ( $DVDD$ ). While there is a voltage limit to prevent this happening accidentally, the limit can be disabled under software control. For reliable operation  $DVDD$  should not exceed its maximum voltage rating.

Figure 151. Typical Regulator Efficiency,  $V_{out}=1.1V$ , VREG\_VIN=3.3V.

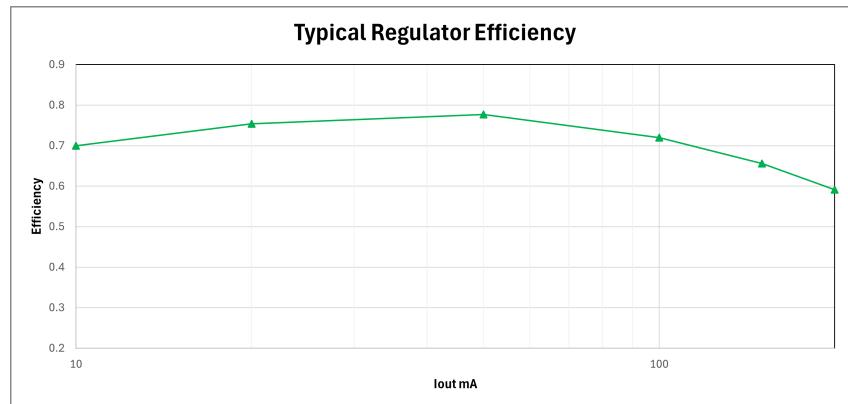

#### 14.9.7. Power consumption

参数	描述	最小值	典型值	最大值	单位
VOUT_OK_阈值·取消断言 阈值	VOUT_OK 取消 断言 阈值	84	87	90	所选输出电 压的百分比
f开关	开关 频率		3		MHz
效率 ( $V_{out}=1.1V$ )	负载=10mA, VR EG_VIN=2.7V		74		%
	负载=10mA, VR EG_VIN=3.3V		70		%
	负载=10mA, VREG_VIN=5.5V		59		%
	负载=100mA, VREG_VIN=2.7V		70		%
	负载=100mA, VREG_VIN=3.3V		72		%
	负载=100mA, VREG_VIN=5.5V		72		%
	负载=200mA, VREG_VIN=2.7V		70		%
	负载=200mA, VREG_VIN=3.3V		59		%
	负载=200mA, VREG_VIN=5.5V		63		%

### ● 警告

$V_{out}$  可以超过最大核心电源 ( $DVDD$ ) 的电压。虽然存在防止意外发生的电压限制，但该限制可通过软件控制予以禁用。  
○ 为确保可靠运行，  $DVDD$  不应超过其最大电压额定值。

图151。典型稳压器效率， $V_{out}=1.1V$ ,  $V_{RE}$   
 $G\_VIN=3.3V$ 。

### 14.9.7. 功耗

#### 14.9.7.1. Peripheral power consumption

Baseline readings are taken with only clock sources and essential peripherals (BUSCTRL, BUSFAB, VREG, Resets, ROM, SRAMs) active in the `WAKE_EN0/WAKE_EN1` registers. Clocks are set to default clock settings.

Each peripheral is activated in turn by enabling all clock sources for the peripheral in the `WAKE_EN0/WAKE_EN1` registers. Current consumption is the increase in current when the peripheral clocks are enabled.

Table 1443. Baseline power consumption

Peripheral	Typical DVDD Current Consumption ( $\mu\text{A}/\text{MHz}$ )
DMA	2.6
I2C0	3
I2C1	3.6
IO + Pads	24.5
PWM	9.9
SIO	2
SHA256	0.1
SPI0	1.7
SPI1	1.4
Timer 0	0.8
Timer 1	0.6
TRNG	0.8
UART0	2.6
UART1	3.6
Watchdog	1.1
XIP	37.6

Because of fixed reference clocks of 48MHz, as well as the variable system clock input, ADC and USBCTRL power consumption does not vary linearly with system clock (as it does for other peripherals which only have system and/or peripheral clock inputs). The following table shows absolute DVDD current consumption of the ADC and USBCTRL blocks at standard clocks settings:

Table 1444. Baseline power consumption for ADC and USBCTRL

Peripheral	Typical DVDD Current Consumption (mA)
ADC	0.14
USBCTRL	1.25

#### 14.9.7.2. Power consumption in Low Power states

Table 1445 shows the typical power consumption in low power states `P1.0 → P1.7`. All voltage supplies are 3.3V (except DVDD which is supplied by the voltage regulator (in low power mode)), with the environment at room temperature.

All GPIOs, `SWDIO` and `SWCLK` are pulled down internally, and not connected externally. QSPI is connected to W25Q16JVSSIQ flash device. USB PHY has been powered down, and the `DP` and `DM` pull-downs were enabled prior to entering the low power state. The USB cable remains connected to a host computer. The table also shows the power consumed when `RUN` is held low. This is not technically a low power state (the voltage regulator is in normal switching mode), but it is included for completeness.

### 14.9.7.1. 外设功耗

基线读数是在仅激活时钟源及必要外设（BUSCTRL、BUSFAB、VREG、复位、只读存储器、SRAM），且相应位于 [WAKE\\_E\\_N0/WAKE\\_EN1](#) 寄存器中的情况下采集。时钟设定为默认值。

通过在 [WAKE\\_EN0/WAKE\\_EN1](#) 寄存器中启用该外设的所有时钟源，依次激活各外设。

电流消耗为启用外设时钟后电流的增量。

表1443。基线功耗

外设	典型DVDD电流消耗 ( $\mu\text{A}/\text{MHz}$ )
DMA	2.6
I2C0	3
I2C1	3.6
IO + 封装引脚	24.5
PWM	9.9
SIO	2
SHA256	0.1
SPI0	1.7
SPI1	1.4
定时器 0	0.8
定时器 1	0.6
TRNG	0.8
UART0	2.6
UART1	3.6
看门狗	1.1
XIP	37.6

由于具有固定的48MHz参考时钟以及可变的系统时钟输入，ADC和USBCTRL的功耗不会随系统时钟线性变化（而其他仅包含系统和/或外设时钟输入的外设功耗则呈线性变化）。下表显示了ADC和USBCTRL模块在标准时钟设置下的绝对DVD D电流消耗：

表1444。ADC和USBCTRL的基线功耗

外设	典型DVDD电流消耗 (mA)
ADC	0.14
USBCTRL	1.25

### 14.9.7.2 低功耗状态下的功耗

表1445显示了低功耗状态 P1.0 → P1.7 的典型功耗。所有电压供应均为3.3V（DVDD除外，其由稳压器供电（在低功耗模式下）），环境温度为室温。

所有GPIO、[SWDIO](#)和[SWCLK](#)均内部下拉，且未外部连接。QSPI连接至W25Q16JVSSIQ闪存设备。USB PHY已断电，并且在进入低功耗状态前启用了[DP](#)和[DM](#)下拉。USB线缆仍连接至主机计算机。表中还显示了当[RUN](#)保持低电平时的功耗。此状态技术上并非低功耗（电压调节器处于正常开关模式），但为完整性而列出。

Table 1445. Low Power States Power Consumption

Low Power State	VREG_VIN (µA)	VREG_AVDD (µA)	IOVDD (µA)	QSPI_IOVDD (µA)	ADC_IOVDD (µA)	USB OTP_VDD (µA)	Total Power (µW)
P1.0	128	0.5	11	22	1	3.5	548
P1.1	77	0.5	11	22	1	3.5	380
P1.2	79	0.5	11	22	1	3.5	380
P1.3	26	0.5	11	22	1	3.5	204
P1.4	120	0.5	11	22	1	3.5	520
P1.5	67	0.5	11	22	1	3.5	345
P1.6	68	0.5	11	22	1	3.5	350
P1.7	19	0.5	11	22	1	3.5	188
RUN=low	40	187	69	22	1	35	1170

#### 14.9.7.3. Power consumption for typical user cases

The following table details the typical power consumption of RP2350 in various example use cases. All measurements were taken using 3.3V voltage supplies (except DVDD, which is supplied by the voltage regulator (set to 1.1V)), with the environment at room temperature.

SWD and SWCLK are not connected externally. GPIO0 and GPIO1 are connected to a Raspberry Pi Debug Probe (UART), but all other GPIOs are not connected (except USB Boot mode, where GPIO0 and GPIO1 are also unconnected). QSPI is connected to W25Q16JVSSIQ flash device, and USB is connected to a host.

hello\_serial, hello\_usb and hello\_adc are basic applications found in pico-examples where characters are constantly transmitted to a serial console.

Table 1446. Power Consumption

Use Case	Condition	VREG_VIN (µA)	VREG_AVDD (µA)	IOVDD (µA)	QSPI_IOVDD (µA)	ADC_IOVDD (µA)	USB OTP_VDD (µA)	Total Power (mW)
USB Boot mode	Bus Idle (average)	6530	220	437	22	1	375	25
	During Boot (peak)						6050	
	During UF2 write (average)						1280	
hello_serial		14690	216	506	22	1	62	51.1
hello_usb		14700	216	453	22	1	570	52.7
hello_adc		14680	216	506	22	142	62	51.6
CoreMark benchmark	Single core @150MHz	11000	212	455	22	1	90	38.7

##### 14.9.7.3.1. Power consumption versus frequency

There is a relationship between the core RP2350 frequency and the current consumed by the DVDD supply. Figure 152 shows the measured results of a typical RP2350 device that continuously runs CoreMark benchmark tests on a single core at various core clock frequencies.

表1445。低功耗状态功耗

低功耗状态	VREG_VIN (μA)	VREG_AVDD (μA)	IOVDD (μA)	QSPI_IOVDD (μA)	ADC_IOVDD (μA)	USB OTP_VDD (μA)	总功率 (μW)
P1.0	128	0.5	11	22	1	3.5	548
P1.1	77	0.5	11	22	1	3.5	380
P1.2	79	0.5	11	22	1	3.5	380
P1.3	26	0.5	11	22	1	3.5	204
P1.4	120	0.5	11	22	1	3.5	520
P1.5	67	0.5	11	22	1	3.5	345
P1.6	68	0.5	11	22	1	3.5	350
P1.7	19	0.5	11	22	1	3.5	188
RUN=低	40	187	69	22	1	35	1170

#### 14.9.7.3 典型用户案例的功耗

下表详细列出了RP2350在各种典型应用场景下的功耗。所有测量均使用3.3V电源供电（DVDD除外，DVDD由电压调节器供电，设定为1.1V），测试环境为室温。

SWD和SWCLK未连接至外部。GPIO0和GPIO1连接至Raspberry Pi调试探针（UART），其余GPIO未连接（USB引导模式下，GPIO0和GPIO1也未连接）。QSPI连接至W25Q16JVSSIQ闪存器件，USB连接至主机。

hello\_serial、hello\_usb和hello\_adc是pico-examples中的基础示例程序，字符持续发送至串口控制台。

表1446。功耗

使用场景	条件	VREG_VIN (μA)	VREG_AVDD (μA)	IOVDD (μA)	QSPI_IOVDD (μA)	ADC_IOVDD (μA)	USB OTP_VDD (μA)	总功率 (mW)
USB引导模式	总线空闲（平均）	6530	220	437	22	1	375	25
	启动期间（峰值）						6050	
	UF2写入期间（平均值）						1280	
hello_serial		14690	216	506	22	1	62	51.1
hello_usb		14700	216	453	22	1	570	52.7
hello_adc		14680	216	506	22	142	62	51.6
CoreMark基准测试	单核@150MHz	11000	212	455	22	1	90	38.7

##### 14.9.7.3.1. 功耗与频率的关系

核心RP2350频率与DVDD电源电流之间存在关联。图152展示了典型RP2350设备在单核不同核心时钟频率下连续运行CoreMark基准测试的测量结果。

Figure 152. DVDD Current vs Core Frequency of a typical RP2350 device, whilst running CoreMark benchmark

心频率关系

# Appendix A: Register field types

## Changes from RP2040

Register field types are unchanged.

## Standard types

### RW:

- Read/Write
- Read operation returns the register value
- Write operation updates the register value

### RO:

- Read-only
- Read operation returns the register value
- Write operations are ignored

### WO:

- Write-only
- Read operation returns 0
- Write operation updates the register value

## Clear types

### SC:

- Self-Clearing
- Writing a 1 to a bit in an SC field will trigger an event, once the event is triggered the bit clears automatically
- Writing a 0 to a bit in an SC field does nothing

### WC:

- Write-Clear
- Writing a 1 to a bit in a WC field will write that bit to 0

# 附录A：寄存器字段类型

## RP2040的变更

寄存器字段类型保持不变。

### 标准类型

#### 读写：

- 读/写
- 读操作返回寄存器值。
- 写操作更新寄存器值。

#### 只读：

- 只读
- 读操作返回寄存器值。
- 写操作被忽略。

#### 只写：

- 仅写
- 读操作返回0。
- 写操作更新寄存器值。

### 清除类型

#### SC:

- 自清除。
- 向SC字段中的某位写入1将触发事件，事件触发后该位自动清零。
- 向SC字段中的某位写入0则无任何动作。

#### WC:

- 写清除。
- 向WC字段中的某位写入1将使该位被写为0

- Writing a 0 to a bit in a WC field does nothing
- Read operation returns the register value

## FIFO types

These fields are used for reading and writing data to and from FIFOs. Accompanying registers provide FIFO control and status. There is no fixed format for the control and status registers, as they are specific to each FIFO interface.

### RWF:

- Read/Write FIFO
- Reading this field returns data from a FIFO
  - When the read is complete, the data value is removed from the FIFO
  - If the FIFO is empty, a default value will be returned; the default value is specific to each FIFO interface
- Data written to this field is pushed to a FIFO, Behaviour when the FIFO is full is specific to each FIFO interface
- Read and write operations may access different FIFOs

### RF:

- Read FIFO
- Functions the same as RWF, but read-only

### WF:

- Write FIFO
- Functions the same as RWF, but write-only

- 向WC字段中的某位写入0不会产生任何效果
- 读操作返回寄存器值。

## FIFO 类型

这些字段用于从FIFO中读取和写入数据。相关寄存器提供FIFO的控制与状态信息。控制和状态寄存器无固定格式，因其针对每个FIFO接口均有所不同。

### RWF:

- 读/写FIFO
- 读取此字段将返回FIFO中的数据
  - 读取完成后，数据值将从FIFO中移除
  - 若FIFO为空，将返回默认值；默认值因具体FIFO接口而异
- 写入此字段的数据会被推入FIFO，FIFO满时的行为取决于具体接口
- 读写操作可能涉及不同的FIFO

### RF:

- 读FIFO
- 功能同读写FIFO，但仅限读取

### WF:

- 写FIFO
- 功能同读写FIFO，但仅限写入

# Appendix B: Units used in this document

This datasheet follows standard practice for use of SI units as recommended by NIST, except in the context of memory and storage capacity. Here it adopts the convention that the prefixes k (*kilo*), M (*mega*) and G (*giga*) always refer to the nearest power of two to their standard decimal value. This aligns the datasheet with common usage for these units.

## Memory and storage capacity

This datasheet expresses memory and storage capacity using the following units:

- b: bit
  - kb: kilobit,  $2^{10}$  b = 1024 b
  - Mb: megabit,  $2^{20}$  b = 1,048,576 b
  - Gb: gigabit,  $2^{30}$  b = 1,073,741,824 b
- B: byte, eight bits, one octet
  - kB: kilobyte,  $2^{10}$  B = 1024 B
  - MB: megabyte,  $2^{20}$  B = 1,048,576 B
  - GB: gigabyte,  $2^{30}$  B = 1,073,741,824 B

The bit is the most basic unit of information. A bit is either true (1) or false (0).

## Transfer Rate

Units for transfer rate are dimensionally the product of one byte or bit with a unit of frequency such as MHz. Therefore the standard SI prefixes apply:

- b/s: bit per second
  - kb/s: kilobit per second, 1000 b/s
  - Mb/s: megabit per second, 1,000,000 b/s
  - Gb/s: gigabit per second, 1,000,000,000 b/s
- B/s: byte per second, 8 b/s
  - kB/s: kilobyte per second, 1000 B/s
  - MB/s: megabyte per second, 1,000,000 B/s
  - GB/s: gigabyte per second, 1,000,000,000 B/s

## Physical Quantities

The following units express physical quantities such as voltage and frequency:

- A: ampere, unit of electrical current, one coulomb per second

# 附录 B：本文件中使用的单位

本数据表遵循NIST推荐的国际单位制（SI）单位使用标准，但内存和存储容量的用法除外。在此，采用前缀k（*kilo*）、M（*mega*）和G（*giga*）始终指代其标准十进制值附近的二进制幂次的惯例。此做法使本数据表与这些单位的惯用表达保持一致。

## 内存与存储容量

本数据表使用以下单位表示内存和存储容量：

- b：比特
  - kb：千比特， $2^{10}$  b = 1024 b
  - Mb：兆比特， $2^{20}$  b = 1,048,576 b
  - Gb：吉比特， $2^{30}$  b = 1,073,741,824 b
- B：字节，八比特，八位字节
  - kB：千字节， $2^{10}$  B = 1024 B
  - MB：兆字节， $2^{20}$  B = 1,048,576 B
  - GB：千兆字节， $2^{30}$  B = 1,073,741,824 B

比特是信息的最基本单位。比特的取值为真（1）或假（0）。

## 传输速率

传输速率的单位在量纲上是字节或比特与频率单位（如MHz）的乘积，因此适用标准国际单位制前缀：

- b/s：比特每秒
  - kb/s：千比特每秒，1000 b/s
  - Mb/s：兆比特每秒，1,000,000 b/s
  - Gb/s：千兆比特每秒，1,000,000,000 b/s
- B/s：字节每秒，8 b/s
  - kB/s：千字节每秒，1000 B/s
  - MB/s：兆字节每秒，1,000,000 B/s
  - GB/s：千兆字节每秒，1,000,000,000 B/s

## 物理量

以下单位表示物理量，如电压和频率：

- A：安培，电流单位，等于每秒一库仑

- mA: milliampere,  $10^{-3}$  A
- $\mu$ A: microampere,  $10^{-6}$  A
- Ω: ohm, unit of electrical impedance or resistance, one volt per ampere
  - MΩ: megohm,  $10^6$  Ω
  - kΩ: kilohm,  $10^3$  Ω
  - mΩ: milliohm,  $10^{-3}$  Ω
- V: volt, unit of electrical potential difference, one joule per coulomb
  - kV: kilovolt,  $10^3$  V
  - mV: millivolt,  $10^{-3}$  V
  - $\mu$ V: microvolt,  $10^{-6}$  V
- Hz: hertz, unit of frequency, one period per second ( $s^{-1}$ )
  - kHz: kilohertz,  $10^3$  Hz
  - MHz: megahertz,  $10^6$  Hz
  - GHz: gigahertz,  $10^9$  Hz
- F: farad, unit of electrical capacitance, one coulomb per volt
  - mF: millifarad,  $10^{-3}$  F
  - $\mu$ F: microfarad,  $10^{-6}$  F
  - nF: nanofarad,  $10^{-9}$  F
  - pF: picofarad,  $10^{-12}$  F
- H: henry, unit of electrical inductance, one volt-second per ampere ( $VsA^{-1}$ )
  - mH: millihenry,  $10^{-3}$  H
  - $\mu$ H: microhenry,  $10^{-6}$  H
  - nH: nanohenry,  $10^{-9}$  H
- s: second, unit of time
  - ms: millisecond,  $10^{-3}$  s
  - $\mu$ s: microsecond,  $10^{-6}$  s
  - ns: nanosecond,  $10^{-9}$  s
  - ps: picosecond,  $10^{-12}$  s
- J: joule, unit of energy or work, one newton-metre
- C: coulomb, unit of electrical charge
  - mC: millicoulomb,  $10^{-3}$  C
  - $\mu$ C: microcoulomb,  $10^{-6}$  C
  - nC: nanocoulomb,  $10^{-9}$  C
- m: metre, unit of length or distance
  - mm: millimetre,  $10^{-3}$  m
- °C: degree celsius, unit of temperature
- W: watt, unit of power, one joule per second ( $J s^{-1}$ ) or one volt-ampere (VA)

- mA：毫安， $10^{-3}$  A
- $\mu$ A：微安， $10^{-6}$  A
- Ω：欧姆，电阻或阻抗单位，等于每安培一伏特
  - MΩ：兆欧， $10^{-6}$  Ω
  - kΩ：千欧， $10^3$  Ω
  - mΩ：毫欧， $10^{-3}$  Ω
- V：伏特，电势差单位，等于每库仑一焦耳
  - kV：千伏， $10^3$  V
  - mV：毫伏， $10^{-3}$  V
  - $\mu$ V：微伏， $10^{-6}$  V
- Hz：赫兹，频率单位，等于每秒一个周期 ( $s^{-1}$ )
  - kHz：千赫兹， $10^3$  Hz
  - MHz：兆赫兹， $10^{-6}$  Hz
  - GHz：千兆赫兹， $10^9$  Hz
- F：法拉，电容量单位，库仑／伏特
  - mF：毫法拉， $10^{-3}$  F
  - $\mu$ F：微法拉， $10^{-6}$  F
  - nF：纳法拉， $10^{-9}$  F
  - pF：皮法拉， $10^{-12}$  F
- H：亨利，电感单位，伏秒／安培 ( $VsA^{-1}$ )
  - mH：毫亨利， $10^{-3}$  H
  - $\mu$ H：微亨利， $10^{-6}$  H
  - nH：纳亨利， $10^{-9}$  H
- s：秒，时间单位
  - ms：毫秒， $10^{-3}$  s
  - $\mu$ s：微秒， $10^{-6}$  s
  - ns：纳秒， $10^{-9}$  s
  - ps：皮秒， $10^{-12}$  s
- J：焦耳，能量或功的单位，等于一牛顿·米
- C：库仑，电荷单位
  - mC：毫库仑， $10^{-3}$  C
  - $\mu$ C：微库仑， $10^{-6}$  C
  - nC：纳库仑， $10^{-9}$  C
- m：米，长度或距离单位
  - mm：毫米， $10^{-3}$  m
- °C：摄氏度，温度单位
- W：瓦特，功率单位，等于一焦耳每秒 ( $J s^{-1}$ ) 或一伏安 (VA)

- mW: milliwatt,  $10^{-3}$  W
- $\mu$ W: microwatt,  $10^{-6}$  W
- nW: nanowatt,  $10^{-9}$  W

## Scale Prefixes

The standard SI prefixes used in the previous sections are:

- G: giga, factor of  $10^9$  (one short billion)
- M: mega, factor of  $10^6$  (one million)
- k: kilo, factor of  $10^3$  (one thousand)
- c: centi, factor of  $10^{-2}$  (one hundredth)
- m: milli, factor of  $10^{-3}$  (one thousandth)
- $\mu$ , micro, factor of  $10^{-6}$  (one millionth)
- n: nano, factor of  $10^{-9}$  (one short billionth)
- p: pico, factor of  $10^{-12}$  (one short trillionth)

The customary binary prefixes used in the memory and storage capacity section are:

- G: giga, factor of  $2^{30}$  (approximately  $10^9$ )
- M: mega, factor of  $2^{20}$  (approximately  $10^6$ )
- k: kilo, factor of  $2^{10}$  (approximately  $10^3$ )

These customary binary prefixes are equivalent to the following prefixes from IEC 60027-2:

- Gi, gibi
- Mi, mebi
- Ki, kibi

## Digit Separators

Numbers written out with many digits may have either commas or spaces inserted for easier reading:

- 1,000,000: one million
- 1 000 000: one million

A comma in a number *never* represents a decimal (radix) point.

- mW：毫瓦特， $10^{-3}$  W
- $\mu$ W：微瓦特， $10^{-6}$  W
- nW：纳瓦特， $10^{-9}$  W

## 单位前缀

前述章节中使用的标准国际单位制前缀如下：

- G：吉，倍数为 $10^9$ （一十亿）
- M：兆，倍数为 $10^6$ （一百万）
- k：千， $10^3$ 次方（千）
- c：厘， $10^{-2}$ 次方（百分之一）
- m：毫， $10^{-3}$ 次方（千分之一）
- $\mu\mu$ ：微， $10^{-6}$ 次方（百万分之一）
- n：纳， $10^{-9}$ 次方（十亿分之一）
- p：皮， $10^{-12}$ 次方（万亿分之一）

内存和存储容量部分采用的常用二进制前缀如下：

- G：吉， $2^{30}$ 次方（约等于 $10^9$ 次方）
- M：兆， $2^{20}$ 次方（约等于 $10^6$ 次方）
- k：千， $2^{10}$ 次方（约等于 $10^3$ 次方）

这些常用二进制前缀对应IEC 60027-2标准中的以下前缀：

- Gi，吉比
- Mi，梅比
- Ki, kibi

## 数字分隔符

书写多位数字时，可能会插入逗号或空格以便于阅读：

- 1,000,000：一百万
- 1 000 000：一百万

数字中的逗号绝不表示小数点（基数点）。

# Appendix C: Hardware revision history

This appendix summarises the differences between RP2350 hardware revisions, referred to as **steppings**. To determine the stepping of an unknown device, check the package markings, as described in [Section 14.4](#). Software running on the device can also read the `CHIP_ID.REVISION` register field, or call the `rp2350_chip_version()` SDK function.

In this appendix:

- The term **fix** refers to an issue that's fully resolved.
- The term **mitigate** refers to an issue that's either partially resolved or believed to be fully resolved but with an unpredictable underlying cause, such as a fault injection vulnerability.
- The term **update** refers to any other difference between steppings.

This appendix offers a high-level overview; for detailed information, refer to individual errata entries in appendix E.

## RP2350 A2

Stepping A2 is identified by a `CHIP_ID.REVISION` value of `0x2`.

A2 is the first generally available version of RP2350, and the earliest stepping documented in this datasheet.

## RP2350 A3

Stepping A3 is identified by a `CHIP_ID.REVISION` value of `0x3`.

### Hardware changes

Stepping A3 introduces the following hardware fixes and mitigations:

- **Fix RP2350-E3:** in QFN-60 package, `GPIO_NSMASK` controls wrong `PADS` registers. Hardware now remaps `GPIO_NSMASK` to the correct `PADS` registers in the QFN60 package.
- **Fix RP2350-E9:** increased leakage current on Bank 0 GPIO when pad input is enabled. The pad circuit is modified to eliminate the erroneous leakage path through the input buffer.
- **Mitigate RP2350-E12:** inadequate synchronisation of USB status signals. Signals used by the bootrom are now valid across the full PVT range in the bootrom's clock configuration. Other software must not rely on these mitigations.
- **Mitigate RP2350-E16:** `USB OTP VDD` disruption can cause corrupt OTP row read data. The following changes apply:
  - Multiple changes to the OTP PSM and OTP read circuits to detect unreliable operation.
  - RISC-V debug is now disabled by `CRIT1.SECURE_DEBUG_DISABLE`, in addition to `CRIT1.DEBUG_DISABLE`. (On A2, only the latter bit was used.)
  - `CRIT0.ARM_DISABLE` no longer disables the Arm processors.
  - Programming both `CRIT0.ARM_DISABLE` and `CRIT0.RISCV_DISABLE` is decoded as an illegal combination, and the device won't boot.

# 附录 C：硬件版本历史

本附录总结了 RP2350 硬件版本之间的差异，称为 **steppings**。要确定未知设备的版本，请检查封装标记，如第14.4节所述。设备上的软件也可以读取 CHIP\_ID.REVISION 寄存器字段，或调用 `rp2350_chip_version()` SDK 函数。

在本附录中：

- “**fix**”一词指已完全解决的问题。
- “**mitigate**”一词指部分解决的问题，或被认为已完全解决但存在不可预测的潜在原因的问题，例如故障注入漏洞。
- “**update**”一词指**steppings**之间的其他任何差异。

本附录提供了高级概述；有关详细信息，请参阅附录E中的各个勘误条目。

## RP2350 A2

版本A2通过 CHIP\_ID.REVISION 值 `0x2`加以识别。

A2是RP2350的首个普遍可用版本，也是本数据手册中记载的最早版本。

## RP2350 A3

版本A3通过 CHIP\_ID.REVISION 值 `0x3`加以识别。

### 硬件变更

版本A3引入了以下硬件修复和缓解措施：

- **修复 RP2350-E3:** 在 QFN-60 封装中，`GPIO_NSmask` 错误控制了 `PADS` 寄存器。硬件现已将 `GPIO_NSmask` 重新映射至 QFN-60 封装中正确的 `PADS` 寄存器。
- **修复 RP2350-E9:** 当引脚输入启用时，Bank 0 GPIO 漏电流增加。电路已修改，以消除通过输入缓冲器的错误漏电通路。
- **缓解 RP2350-E12:** USB 状态信号同步不足的问题。Bootrom 使用的信号现已在 bootrom 的时钟配置中于整个 PVT 范围内有效。其他软件不得依赖这些缓解措施。
- **缓解 RP2350-E16:USB\_OTP\_VDD** 中断可能导致 OTP 行读取数据损坏。下列更改适用：
  - 对 OTP PSM 及 OTP 读取电路进行了多项调整，以检测不可靠的操作。
  - RISC-V 调试现已由 CRIT1.SECURE\_DEBUG\_DISABLE 禁用，除 CRIT1.DEBUG\_DISABLE 之外。（在 A2 版本中，仅使用后者位。）
  - CRIT0.ARM\_DISABLE 不再禁用 Arm 处理器。
  - 同时对 CRIT0.ARM\_DISABLE 和 CRIT0.RISCV\_DISABLE 进行编程时，将被视为非法组合，设备将无法启动。

- **Update** the reset state of the following clock configuration registers:
  - ROSC: [FREQA.DS0\\_RANDOM](#) and [FREQA.DS1\\_RANDOM](#) from [0](#) to [1](#), enabling randomisation of first two drive stages.
  - CLOCKS: [CLK\\_SYS\\_CTRL.SRC](#) from [0](#) to [1](#) (select AUX source).
  - CLOCKS: [CLK\\_SYS\\_CTRL.AUXSRC](#) from [0](#) to [2](#) (select ROSC as AUX source).

## Bootrom changes

The A3 bootrom introduces the following changes:

- **Fix RP2350-E10:** UF2 drag-and-drop doesn't work with partition tables. This previously required a workaround in [picotool](#), but the A3 bootrom no longer requires this workaround. [picotool](#) retains the workaround for compatibility with A2.
- **Fix RP2350-E13:** a binary containing an explicitly invalid [IMAGE\\_DEF](#) followed by a valid [IMAGE\\_DEF](#) (in that order) fails to boot.
- **Fix RP2350-E14:** the bootrom [connect\\_internal\\_flash\(\)](#) function always uses pin 0, ignoring any configured [FLASH\\_DEVINFO](#) CS1 chip select pin.
- **Fix RP2350-E15:** the bootrom [otp\\_access\(\)](#) function applies incorrect access permission to pages 62 and 63.
- **Fix RP2350-E19:** RP2350 reboot halts if certain bits are set in [FRCE\\_OFF](#) when rebooting.
- **Mitigate RP2350-E20:** an attacker with physical access to the chip and the ability to physically glitch the CPU at precise times could cause unsigned code execution on a secured RP2350 by targeting legitimate Non-secure calls to the bootrom [reboot\(\)](#) function.
- **Mitigate RP2350-E21:** an attacker with physical access to the chip and the ability to physically glitch the CPU at precise times, could extract sensitive data from OTP on a RP2350 in BOOTSEL mode.
- **Fix RP2350-E22:** parsing a malformed lollipop [block loop](#) causes the system to halt rather than fail.
- **Fix RP2350-E23:** PICOBEST [GET\\_INFO](#) command always returns zero for [PACKAGE\\_SEL](#)
- **Mitigate RP2350-E26:** RCP random delays can create a side-channel. These delays are disabled in the bootrom.
- **Update** the early boot path to change the [clk\\_ref](#) divider from [1](#) to [5](#), and the ROSC divider from [8](#) to [2](#).
  - Together with the register reset state changes, this increases the boot [clk\\_sys](#) frequency by a factor of 4, to approximately 48 MHz.
  - These changes reduce boot time and fault injection susceptibility.
  - These changes apply for all boot outcomes, including watchdog and POWMAN vector boot.

## RP2350 A4

Stepping A4 is identified by a [CHIP\\_ID.REVISION](#) value of [0x8](#).

## Hardware Changes

This stepping has no hardware changes.

- 更新以下时钟配置寄存器的复位状态：
  - ROSC: FREQA.DS0\_RANDOM 和 FREQA.DS1\_RANDOM 由 0 调整为 1，启用前两驱动级的随机化。
  - CLOCKS: CLK\_SYS\_CTRL.SRC 从 0 变更为 1（选择 AUX 源）。
  - CLOCKS: CLK\_SYS\_CTRL.AUXSRC 从 0 变更为 2（选择 ROSC 作为 AUX 源）。

## Bootrom 变更

A3 只读存储器引导程序引入了以下更改：

- 修复 RP2350-E10：带有分区表的 UF2 拖放功能失效。此前需要在 picotool 中采用变通方法，但 A3 只读存储器引导程序已不再需要该变通方法。picotool 保留了该变通方法，以确保与 A2 的兼容性。
- 修复 RP2350-E13：包含显式无效 IMAGE\_DEF 后紧跟有效 IMAGE\_DEF（按此顺序）的二进制文件无法启动。
- 修复 RP2350-E14：只读存储器引导程序的 connect\_internal\_flash() 函数始终使用引脚 0，忽略任何已配置的 FLASH\_DEVINFO\_CS1 片选引脚。
- 修复 RP2350-E15：只读存储器引导程序的 otp\_access() 函数对第 62 和第 63 页应用了错误的访问权限。
- 修复 RP2350-E19：重启时若 FRCE\_OFF 中设置了特定位，RP2350 重启会停止。
- 缓解 RP2350-E20：攻击者若具备对芯片的物理访问权限且能在精准时机实施物理故障注入，可能通过针对合法非安全调用的 bootrom reboot() 函数，在受保护的 RP2350 上执行未签名代码。
- 缓解 RP2350-E21：攻击者若具备对芯片的物理访问权限且能在精准时机实施物理故障注入，可能从处于 BOOT\_SEL 模式的 RP2350 提取 OTP 中的敏感数据。
- 修复 RP2350-E22：解析格式错误的 lollipop 块循环时，系统应失败而非停止运行。
- 修复 RP2350-E23：PICOBLOCK 的 GET\_INFO 命令始终返回 PACKAGE\_SEL 为零。
- 缓解 RP2350-E26：RCP 随机延迟可能导致侧信道攻击。这些延迟已在 bootrom 中禁用。
- 更新早期引导路径，将 clk\_ref 分频器从 1 更改为 5，ROSC 分频器从 8 更改为 2。
  - 结合寄存器复位状态更改，此举将引导 clk\_sys 频率提高 4 倍，约为 48 MHz。
  - 这些更改缩短了引导时间，降低了故障注入的易感性。
  - 这些更改适用于所有引导结果，包括看门狗和 POWMAN 向量引导。

## RP2350 A4

步进版本 A4 通过 CHIP\_ID.REVISION 值为 0x8 进行识别。

## 硬件变更

该步进版本未涉及硬件更改。

## Bootrom Changes

The A4 bootrom introduces the following changes:

- **Fix RP2350-E18:** the RP2350 forever fails to boot if `FLASH_PARTITION_SLOT_SIZE` contains an invalid ECC bit pattern. This issue is a consequence of [RP2350-E17](#) (a guarded read on a single ECC OTP row causes a fault if the data in the adjacent row isn't also valid ECC data). The underlying hardware issue isn't resolved, but the bootrom avoids the issue in this instance.
- **Mitigate RP2350-E24:** an attacker with physical access to the chip, moderate hardware, and the ability to physically glitch the CPU at precise times, could cause unsigned code execution on a secured RP2350. The A4 bootrom contains additional fault injection mitigations for this vulnerability, and for other potential vulnerabilities with the same underlying mechanism.
- **Fix RP2350-E25:** a `LOAD_MAP` that uses non-word sizes previously didn't cause an error. The bootrom now correctly rejects these structures.

## Bootrom 变更

A4 bootrom引入以下更改：

- 修正**RP2350-E18**：当FLASH\_PARTITION\_SLOT\_SIZE包含无效ECC位模式时，**RP2350**将永远无法引导。该问题源自**RP2350-E17**（对单个ECC OTP行的受保护读取操作若相邻行数据非有效ECC数据，则会引发故障）。基础硬件问题尚未解决，但bootrom在该情况下避免了此问题。
- 缓解**RP2350-E24**：攻击者若具备物理访问芯片的权限、中等硬件资源及能够在精准时机对CPU施加物理故障，可导致加固版RP2350执行未签名代码。A4只读存储器包含针对该漏洞及其它基于相同底层机制潜在漏洞的额外故障注入缓解措施。
- 修复**RP2350-E25**：此前使用非字长尺寸的LOAD\_MAP未触发错误。只读存储器现已正确拒绝这些结构。

# Appendix E: Errata

## ACCESSCTRL

### RP2350-E3

<b>Reference</b>	RP2350-E3
<b>Summary</b>	In QFN-60 package, <a href="#">GPIO_NSmask</a> controls wrong <a href="#">PADS</a> registers
<b>Affects</b>	RP2350 A2, QFN-60 package only
<b>Description</b>	<p>RP2350 remaps IOs, their control registers and their ADC channels so that both package sizes appear to have consecutively numbered GPIOs, even though for physical design reasons the QFN-60 package bonds out a sparse selection of IO pads.</p> <p>The connection between the <a href="#">GPIO_NSmask0</a>/<a href="#">GPIO_NSmask1</a> registers and the <a href="#">PADS</a> registers doesn't take this remapping into account. Consequently, in the QFN-60 package only, the <a href="#">GPIO_NSmask0</a> register bits are applied to registers for the wrong pads. Specifically, <a href="#">PADS_BANK0</a> registers 29 through 0 are controlled by the concatenation of <a href="#">GPIO_NSmask</a> bits 47 through 44, 39 through 33, 30 through 28, 24 through 17 and 15 through 8 (all inclusive ranges).</p> <p>This means that granting Non-secure access to the PADS registers in the QFN-60 package doesn't allow Non-secure software to control the correct pads. It may also allow Non-secure control of pads that aren't granted in <a href="#">GPIO_NSmask0</a>.</p> <p>The QSPI PADS registers (Bank 1) aren't affected because these aren't remapped for different packages.</p>
<b>Workaround</b>	<p>Disable Non-secure access to the <a href="#">PADS</a> registers by clearing <a href="#">PADS_BANK0.NSP</a>, <a href="#">NSU</a>.</p> <p>Implement a Secure Gateway (Arm) or <a href="#">ecall</a> handler (RISC-V) to permit Non-Secure/U-mode code to read/write its assigned <a href="#">PADS_BANK0</a> registers.</p>
<b>Fixed by</b>	RP2350 A3, Documentation, Software

## Bootrom

### RP2350-E10

<b>Reference</b>	RP2350-E10
<b>Summary</b>	UF2 drag-and-drop doesn't work with partition tables
<b>Affects</b>	RP2350 A2
<b>Description</b>	When dragging and dropping a UF2 onto the USB Mass Storage Device, the bootrom on chip revision A2 doesn't set up the flash before checking the partition table. This causes the UF2 download to fail if there is a partition table present.

## 访问控制

### RP2350-E3

参考资料	RP2350-E3
摘要	在 QFN-60 封装中， <b>GPIO_NSmask</b> 控制了错误的 <b>PADS</b> 寄存器。
影响范围	仅限 RP2350 A2，QFN-60 封装
描述	<p>RP2350 对 IO 口、其控制寄存器及 ADC 通道进行了重映射，使两种封装尺寸的 GPIO 编号均连续，尽管因物理设计限制，QFN-60 封装仅引出稀疏选择的 IO 引脚。</p> <p>GPIO_NSmask0/GPIO_NSmask1 寄存器与 <b>PADS</b> 寄存器之间的映射未考虑该重映射。因此，仅在 QFN-60 封装中，<b>GPIO_NSmask0</b> 寄存器位被错误地应用于某些引脚的寄存器。具体而言，<b>PADS_BANK0</b> 寄存器 29 至 0 由 <b>GPIO_NSmask</b> 位 47 至 44、39 至 33、30 至 28、24 至 17 及 15 至 8 的级联组合控制（所有范围均含）。</p> <p>这意味着授予对 QFN-60 封装中 <b>PADS</b> 寄存器的非安全访问权限，不允许非安全软件控制正确的引脚。此外，可能会允许对 <b>GPIO_NSmask0</b> 中未授权引脚的非安全控制。</p> <p>QSPI <b>PADS</b> 寄存器（Bank 1）不受影响，因为它们未针对不同封装进行重映射。</p>
解决方案	<p>通过清除 <b>PADS_BANK0.NSP</b> 和 <b>NSU</b> 位，禁用对 <b>PADS</b> 寄存器的非安全访问。</p> <p>实施安全网关（Arm 架构）或 <b>ecall</b> handler（RISC-V 架构），以允许非安全/U 模式代码访问其分配的 <b>PADS_BANK0</b> 寄存器。</p>

## Bootrom

### RP2350-E10

参考资料	RP2350-E10
摘要	含分区表时 UF2 拖放无法正常工作
影响范围	RP2350 A2
描述	将 UF2 拖入 USB 大容量存储设备时，芯片版本为 A2 的引导只读存储器不会在检查分区表前设置闪存。若存在分区表，UF2 下载将失败。

<b>Workaround</b>	<p>Add a single block at the start of the UF2 with an Absolute family ID, targeting the end of Flash, with block number set to 0 and number of blocks set to 2. This block is written to flash first but doesn't reboot the device, and sets up the flash for the rest of the UF2 to be downloaded correctly.</p> <p>This is handled for you automatically by <code>picotool</code> in the SDK, which adds this block when generating UF2s if the <code>--abs-block</code> flag is specified.</p> <p>This workaround means that the last block of flash is erased when downloading such a UF2, which could overwrite user data.</p> <p>As of <code>picotool</code> version 2.1.0, this additional UF2 block is marked with a Raspberry Pi specific UF2 extension <code>UF2_EXTENSION_RP2_IGNORE_BLOCK (0x9957e304)</code>. The RP2350 A3 and later bootroms, contain a fix for this erratum, and therefore don't need the workaround. The presence of this extension in the UF2 block allows the newer RP2350 to recognize and ignore the workaround block, thus avoiding the risk of overwriting user data.</p>
<b>Fixed by</b>	RP2350 A3 bootrom, Documentation, Software

## RP2350-E13

<b>Reference</b>	RP2350-E13
<b>Summary</b>	A binary containing an <i>explicitly invalid</i> <code>IMAGE_DEF</code> followed by a valid <code>IMAGE_DEF</code> (in that order) fails to boot
<b>Affects</b>	RP2350 A2
<b>Description</b>	<p>When the block loop of a binary contains an <code>IMAGE_DEF</code> that is <i>explicitly invalid</i> before the valid <code>IMAGE_DEF</code> for RP2350, booting from that binary fails.</p> <p>An <code>IMAGE_DEF</code> is <i>explicitly invalid</i> if either:</p> <ul style="list-style-type: none"> <li>• It is for RP2040</li> <li>• It doesn't have a rollback version, and the <code>BOOT_FLAGS0.ROLLBACK_REQUIRED</code> flag is set in OTP</li> </ul>
<b>Workaround</b>	<p>Instead of an <i>explicitly invalid</i> <code>IMAGE_DEF</code>, use an <code>IGNORED</code> item. RP2040 doesn't require an <code>IMAGE_DEF</code> to boot a binary, and when using rollback, the invalid <code>IMAGE_DEF</code> is ignored anyway.</p> <p>SDK uses this workaround for RP2040 binaries. When you set <code>PICO_CRT0_INCLUDE_PICOBIN_BLOCK</code>, the SDK uses an <code>IGNORED</code> item instead of an <code>IMAGE_DEF</code> for RP2040 binaries. You can override this behaviour and use an <code>IMAGE_DEF</code> by setting <code>PICO_CRT0_INCLUDE_PICOBIN_IMAGE_TYPE_ITEM</code>. For an additional example, see the universal binaries in pico-examples.</p> <p><code>picotool</code> uses this workaround for rollback versions. When you use <code>picotool seal</code> to seal a binary and add a rollback version, it converts the first <code>IMAGE_DEF</code> without a rollback version to an <code>IGNORED</code> item.</p>
<b>Fixed by</b>	RP2350 A3 bootrom, Documentation, Software

## RP2350-E14

<b>Reference</b>	RP2350-E14
<b>Summary</b>	The bootrom <code>connect_internal_flash()</code> function always uses pin 0, ignoring any configured <code>FLASH_DEVINFO CS1</code> chip select pin
<b>Affects</b>	RP2350 A2

解决方案	<p>在 UF2 起始处添加一个带有 Absolute 系列 ID 的单独块，目标为闪存末端，块编号为 0，块数为 2。该块首先写入闪存，但不会重启设备，同时为 UF2 后续数据的正确下载配置闪存。</p> <p>SDK 中的 <code>picotool</code> 会自动处理此项，若指定 <code>--abs-block</code> 标志，生成的 UF2 会包含该块。</p> <p>该解决方法意味着下载此类 UF2 时，闪存末尾的块将被擦除，可能覆盖用户数据。</p> <p>截至 <code>picotool</code> 版本 2.1.0，该额外的 UF2 块被标记为 Raspberry Pi 专用 UF2 扩展 <code>UF2_EXTENSION_RP2_IGNORE_BLOCK (0x9957e304)</code>。RP2350 A3 及以后版本的 bootrom 已包含该缺陷的修复，因此无需采用此变通方法。UF2 块中存在该扩展，使较新版本的 RP2350 能识别并忽略该变通块，从而避免覆盖用户数据的风险。</p>
修复者	RP2350 A3 bootrom, 文档, 软件

## RP2350-E13

参考资料	RP2350-E13
摘要	包含一个明确无效的 <code>IMAGE_DEF</code> 且紧跟一个有效的 <code>IMAGE_DEF</code> （二者按此顺序）的二进制文件将无法启动。
影响范围	RP2350 A2
描述	<p>当二进制文件的块循环中包含一个明确无效的 <code>IMAGE_DEF</code>，且该无效的 <code>IMAGE_DEF</code> 位于有效的 <code>IMAGE_DEF</code> 之前时，RP2350 将无法从该二进制文件启动。</p> <p>若满足以下任一条件，<code>IMAGE_DEF</code> 即被视为明确无效：</p> <ul style="list-style-type: none"> <li>该 <code>IMAGE_DEF</code> 用于 RP2040。</li> <li>该版本无回滚版本，并且在 OTP 中已设置 <code>BOOT_FLAGS0.ROLLBACK_REQUIRED</code> 标志</li> </ul>
解决方案	<p>请使用 <code>IGNORED</code> 项替代显式无效的 <code>IMAGE_DEF</code>。RP2040 启动二进制文件时无需 <code>IMAGE_DEF</code>，且在使用回滚机制时，无效的 <code>IMAGE_DEF</code> 将被忽略。</p> <p>SDK 对 RP2040 二进制文件采用此解决方案。设置 <code>PICO_CRT0_INCLUDE_PICOBIN_BLOCK</code> 后，SDK 对 RP2040 二进制文件使用 <code>IGNORED</code> 项替代 <code>IMAGE_DEF</code>。您可通过设置 <code>PICO_CRT0_INCLUDE_PICOBIN_IMAGE_TYPE_ITEM</code> 来覆盖此行为，使用 <code>IMAGE_DEF</code>。更多示例详见 <code>pico-examples</code> 中的通用二进制文件。</p> <p><code>picotool</code> 采用此解决方案处理回滚版本。使用 <code>picotool seal</code> 封装二进制文件并添加回滚版本时，会将首个无回滚版本的 <code>IMAGE_DEF</code> 转换为 <code>IGNORED</code> 项。</p>
修复者	RP2350 A3 bootrom, 文档, 软件

## RP2350-E14

参考资料	RP2350-E14
摘要	bootrom 的 <code>connect_internal_flash()</code> 函数始终使用引脚 0，忽略任何已配置的 <code>FLASH_DE_VINFO</code> 中 <code>CS1</code> 芯片选择引脚
影响范围	RP2350 A2

<b>Description</b>	When using the bootrom function <a href="#">connect_internal_flash()</a> to configure CS1 (for instance, during a flash boot), the bootrom always configures the pad registers for pin 0, ignoring any CS1 pin specified in <a href="#">FLASH_DEVINFO</a> .  As a result, the specified CS1 pin remains isolated (see <a href="#">Section 9.7</a> ). Accesses to the QSPI device connected to the second chip select fails unless CS1 is connected to pin 0.  <a href="#">FLASH_DEVINFO</a> can be configured in OTP or at runtime. For more information, see <a href="#">flash_devinfo16_ptr</a> .
<b>Workaround</b>	Manually configure the CS1 pads registers to remove the isolation after using the bootrom <a href="#">connect_internal_flash()</a> function. Alternatively, connect CS1 to pin 0.
<b>Fixed by</b>	RP2350 A3 bootrom, Documentation, Software

## RP2350-E15

<b>Reference</b>	RP2350-E15
<b>Summary</b>	The bootrom <a href="#">otp_access()</a> function applies incorrect access permission to pages 62 & 63
<b>Affects</b>	RP2350 A2
<b>Description</b>	<p>The bootrom <a href="#">otp_access()</a> function incorrectly applies the access permissions specified in OTP rows <a href="#">PAGE62_LOCK1</a> and <a href="#">PAGE63_LOCK1</a> to the entirety of their respective OTP pages (62 and 63). This is incorrect, as pages 62 and 63 contain lock words for other pages: each lock word is instead protected by the permissions of the corresponding page.</p> <p>The ATE programming then locks down write access from non-Secure software and the bootloader to the page 63 lock word (to prevent non-Secure setting of the RMA flag), and write access from non-Secure software to the page 62 lock word. This prevents non-Secure software from modifying any of the OTP page locks, and the bootloader from modifying the locks for pages 32-63.</p>
<b>Workaround</b>	<p>When running code on the device, don't use the non-Secure <a href="#">otp_access()</a> function to set locks for OTP pages. To set OTP page locks from non-Secure code, implement your own Secure API to do this that can be called from non-Secure code.</p> <p>Page locks for OTP pages 32-63 can be set by <a href="#">picotool</a> using the <a href="#">picotool otp permissions</a> command. This command loads a Secure binary into XIP SRAM on the device to change the permissions before rebooting back into the USB bootloader.</p>
<b>Fixed by</b>	RP2350 A3 bootrom, Documentation, Software

## RP2350-E18

<b>Reference</b>	RP2350-E18
<b>Summary</b>	The RP2350 will forever fail to boot if <a href="#">FLASH_PARTITION_SLOT_SIZE</a> contains an invalid ECC bit pattern
<b>Affects</b>	RP2350 A2, RP2350 A3

描述	<p>在使用 bootrom 函数 <code>connect_internal_flash()</code> 配置 CS1（例如在闪存启动过程中）时，bootrom 始终将引脚寄存器配置为引脚 0，忽略 <code>FLASH_DEVINFO</code> 中指定的任何 CS1 引脚。</p> <p>因此，指定的 CS1 引脚保持隔离状态（详见第 9.7 节）。除非将 CS1 连接至引脚 0，否则无法访问连接至第二芯片选择的 QSPI 设备。</p> <p><code>FLASH_DEVINFO</code> 可在 OTP 中配置，亦可在运行时配置。详情请参阅 <code>flash_devinfo16_ptr</code>。</p>
解决方案	使用 bootrom 函数 <code>connect_internal_flash()</code> 后，需手动配置 CS1 引脚寄存器以解除隔离状态。或者，将 CS1 连接至引脚 0。
修复者	RP2350 A3 bootrom, 文档, 软件

## RP2350-E15

参考资料	RP2350-E15
摘要	bootrom 的 <code>otp_access()</code> 函数对第 62 页和第 63 页应用了错误的访问权限。
影响范围	RP2350 A2
描述	<p>bootrom <code>otp_access()</code> 函数错误地将 OTP 行 PAGE62_LOCK1 和 PAGE63_LOCK1 中指定的访问权限应用于对应的整个 OTP 页（第 62 页和第 63 页）。此说法不正确，因为第 62 页和第 63 页包含针对其他页面的锁定字：每个锁定字实际上受相应页面权限保护。</p> <p>ATE 编程随后锁定非安全软件和引导程序对第 63 页锁定字的写入权限（以防止非安全地设置 RMA 标志），并锁定非安全软件对第 62 页锁定字的写入权限。这防止非安全软件修改任何 OTP 页面锁定，并阻止引导程序修改第 32 至 63 页的锁定。</p>
解决方案	<p>在设备上运行代码时，请勿使用非安全的 <code>otp_access()</code> 函数设置 OTP 页面锁定。若需从非安全代码设置 OTP 页面锁定，请实现您自己的安全 API，允许从非安全代码调用该 API 完成此操作。</p> <p>第 32 至 63 页 OTP 页面的页面锁定可通过 <code>picotool</code> 使用 <code>picotool otp permissions</code> 命令设置。该命令将一个安全二进制文件加载至设备上的 XIP SRAM，以更改权限，然后重新启动进入 USB 引导程序。</p>

## RP2350-E18

参考资料	RP2350-E18
摘要	如果 <code>FLASH_PARTITION_SLOT_SIZE</code> 包含无效的 ECC 位模式，RP2350 将永远无法启动。
影响范围	RP2350 A2, RP2350 A3

<b>Description</b>	<p>If ECC row programming is interrupted, an ECC row may contain a value that fails ECC validation. Because any ECC could potentially contain an invalid, partially written value, the bootrom uses a separate "enable" flag in OTP to indicate whether a particular ECC row is expected to contain a valid value. The user is expected to only set this flag after a particular ECC row is known to have been written correctly.</p> <p>For <code>FLASH_PARTITION_SLOT_SIZE</code>, the "enable" flag is <code>BOOT_FLAGS0.OVERRIDE_FLASH_PARTITION_SLOT_SIZE</code>.</p> <p>In the case of <code>FLASH_PARTITION_SLOT_SIZE</code>, the bootrom reads the row value and asserts the value is valid before checking the enable flag, and thus the boot process will hang if the <code>BOOT_FLAGS0.OVERRIDE_FLASH_PARTITION_SLOT_SIZE</code> row in OTP contains an invalid ECC value.</p>
<b>Workaround</b>	<p>Don't program <code>FLASH_PARTITION_SLOT_SIZE</code> or at least be aware that doing so may brick your device if the programming operation is interrupted or fails.</p>
<b>Fixed by</b>	<p>RP2350 A4 bootrom, Documentation</p>

## RP2350-E19

<b>Reference</b>	RP2350-E19
<b>Summary</b>	RP2350 reboot hangs if certain bits are set in <code>FRCE_OFF</code> when rebooting.
<b>Affects</b>	RP2350 A2
<b>Description</b>	An incorrect assertion in the boot path, assumes the all bits (other than <code>FRCE_OFF.PROC1</code> ) are clear. These bits can only be set during boot if the user had set them and then re-entered the boot path.
<b>Workaround</b>	Don't perform a <code>WATCHDOG</code> or <code>POWMAN</code> boot, or a core0 reset with bits other than <code>FRCE_OFF.PROC1</code> set.
<b>Fixed by</b>	RP2350 A3 bootrom, Documentation

## RP2350-E20

<b>Reference</b>	RP2350-E20
<b>Summary</b>	An attacker with physical access to the chip and the ability to physically "glitch" the CPU at precise times, could cause unsigned code execution on a secured RP2350 by targeting legitimate Non-secure calls to the bootrom <code>reboot()</code> function
<b>Affects</b>	RP2350 A2
<b>Description</b>	<p>The RP2350 bootrom provides a <code>reboot()</code> function to reboot the RP2350. This method is potentially accessible to Non-secure callers via the <code>PICOBOOT</code> interface (e.g. <code>picotool</code>) or, if the corresponding permission is set, to Non-secure code running on the device.</p> <p>A particular reboot type (<code>REBOOT_TYPE_PC_SP</code>) isn't allowed in the bootrom <code>reboot()</code> function when called from Non-secure code as it launches user-provided code in a Secure state post reboot. The <code>reboot()</code> function correctly disallows this reboot type when called from a Non-secure context. However, if a valid reboot type (e.g. <code>REBOOT_TYPE_NORMAL</code>) is passed to the function instead, a late, precisely-timed processor glitch can cause an incorrect code path to be taken, which configures the WATCHDOG scratch registers in a way that allows secure execution of user-provided code post reboot.</p>

描述	<p>如果ECC行编程被中断，ECC行可能包含无法通过ECC验证的值。由于任何ECC行都可能包含无效的、部分写入的值，启动只读存储器（bootrom）使用OTP中的单独“启用”标志来指示特定ECC行是否预期包含有效值。用户应仅在确认特定ECC行已正确写入后设置此标志。</p> <p>对于 <code>FLASH_PARTITION_SLOT_SIZE</code>, 该“启用”标志是 <code>BOOT_FLAGS0.OVERRIDE_FLASH_PARTITION_SLOT_SIZE</code> 来覆盖此值。</p> <p>在 <code>FLASH_PARTITION_SLOT_SIZE</code> 的情况下，启动只读存储器会先读取该行值并断言该值有效，然后再检查启用标志，因此如果OTP中 <code>BOOT_FLAGS0.OVERRIDE_FLASH_PARTITION_SLOT_SIZE</code> 行包含无效的EC值，启动过程将会挂起。</p>
解决方案	请勿编程 <code>FLASH_PARTITION_SLOT_SIZE</code> ，或者至少应明确注意，如果编程操作被中断或失败，可能会导致设备变砖。

## RP2350-E19

参考资料	RP2350-E19
摘要	当重新启动时，如果 <code>FRCE_OFF</code> 中的某些位被设置，RP2350 重启将会卡死。
影响范围	RP2350 A2
描述	<p>启动路径中存在错误断言，假设除了 <code>FRCE_OFF.PROC1</code> 之外的所有位均为清零状态。这些位仅在用户设置后并重新进入启动路径时，才可能在启动期间被设置。</p>
解决方案	请勿在除 <code>FRCE_OFF.PROC1</code> 外的其他位被设置时执行 <code>WATCHDOG</code> 或 <code>POWMAN</code> 启动，或对 <code>core0</code> 进行复位。
修复者	RP2350 A3 只读存储器，文档

## RP2350-E20

参考资料	RP2350-E20
摘要	具有物理访问权限并能在精确时机对 CPU 施加物理“故障注入（glitch）”的攻击者，可能通过针对引导只读存储器中的合法非安全调用 <code>reboot()</code> 函数，使受保护的 RP2350 运行未经签名的代码。
影响范围	RP2350 A2
描述	<p>RP2350 引导只读存储器提供 <code>reboot()</code> 函数用于重新启动 RP2350。该方法可能通过 <code>PICOBOOT</code> 接口（例如 <code>picotool</code>）对非安全调用者开放，或在相应权限被授予时，对设备上的非安全代码开放。</p> <p>在从非安全代码调用 bootrom 的 <code>reboot()</code> 函数时，特定的重启类型（<code>REBOOT_TYPE_PC_SP</code>）不被允许，因为该类型会在重启后以安全状态启动用户提供的代码。<code>reboot()</code> 函数在从非安全上下文调用时，会正确禁止该重启类型。然而，如果传递给函数的是有效的重启类型（例如 <code>REBOOT_TYPE_NORMAL</code>），则一个时序精准的处理器故障可能导致错误的代码路径被执行，从而配置 <code>WATCHDOG</code> 暂存寄存器，允许在重启后安全地执行用户提供的代码。</p>

Workaround	<p>If any <code>WATCHDOG</code> based reboot types other than into the regular boot path aren't required (this includes programmatic reboots into BOOTSEL mode and FLASH_UPDATE boots which are important when using A/B partitions), the OTP flag <code>BOOT_FLAGS0.DISABLE_WATCHDOG_SCRATCH</code> can be set, which causes the WATCHDOG scratch registers to be completely ignored during boot, meaning that the <b>only</b> type of boot available via WATCHDOG reset is regular boot.</p> <p>A more refined approach would be to disable use of the <code>reboot()</code> function from Non-secure code. This is the default case for Non-secure code started by a secure application (see <a href="#">Section 5.4.2</a>). However, the BOOTSEL mode bootloader is itself a Non-secure application that does have access to the function. BOOTSEL mode, however, can be disabled if not needed through <code>BOOT_FLAGS0.DISABLE_BOOTSEL_UART_BOOT</code>, <code>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_PICOBOOT_IFC</code>, and <code>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_MSD_IFC</code>.</p> <p><code>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_PICOBOOT_IFC</code> is the most important because <code>PICOBOOT</code> provides a conduit for a user to pass specific parameters to the bootrom <code>reboot()</code> function. However, any other use of BOOTSEL mode could be vulnerable in conjunction with some other future attack on the Non-secure code.</p>

## RP2350-E21

Reference	RP2350-E21
Summary	An attacker with physical access to the chip, and the ability to physically "glitch" the CPU at precise times, could potentially extract sensitive data from OTP on a RP2350 in BOOTSEL mode.
Affects	RP2350 A2
Description	<p>An attacker with physical access to the chip, could precisely time physical glitch attacks during entry to BOOTSEL mode and cause some OTP page access permissions for BOOTSEL mode not to be applied, leading to possible exposure of sensitive data.</p> <p>The RP2350 BOOTSEL mode exposes an API over PICOBOOT such that a user can read or write OTP rows through <code>picotool</code>. Certain OTP rows (such as encryption keys or other secrets) shouldn't be readable through this method. Equally, certain rows might be protected against writes. This is handled at the page (64 row) level by page locks stored in OTP.</p> <p>On entry to BOOTSEL mode, the OTP should be locked down such that no software (including Secure software) can access anything not marked as accessible to BOOTSEL mode. However, with two precisely timed processor glitches, it's possible to prevent a page being correctly locked.</p>
Workaround	<ol style="list-style-type: none"> <li>Disable the BOOTSEL mode bootloader altogether via <code>BOOT_FLAGS0.DISABLE_BOOTSEL_UART_BOOT</code>, <code>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_PICOBOOT_IFC</code>, and <code>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_MSD_IFC</code>.</li> </ol> <p><code>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_PICOBOOT_IFC</code> is the most important, as PICOBOOT provides the conduit for a user to access the OTP, however any other use of BOOTSEL mode could be vulnerable in conjunction with some other future attack on the non-Secure code.</p> <ol style="list-style-type: none"> <li>Use an OTP access key (<a href="#">Section 13.5.2</a>) to protect OTP data you don't want accessed from BOOTSEL mode, although this only helps if the data isn't needed until your application can provide the key.</li> </ol>
Credit	Thomas Roth

解决方案	<p>如果不需要任何基于 WATCHDOG 的非正常启动类型（包括程序化重启进入 BOOTSEL 模式及用于 A/B 分区的重要 FLASH_UPDATE 启动），则可以设置 OTP 标志 BOOT_FLAGS0.DISABLE_WATCHDOG_SCRATCH，使启动过程中完全忽略 WATCHDOG 暂存寄存器，从而通过 WATCHDOG 复位只能执行常规启动。</p> <p>一种更为细致的方法是禁止非安全代码调用 reboot() 函数。这是由安全应用启动的非安全代码的默认情况（见第 5.4.2 节）。然而，BOOTSEL 模式的引导程序本身是一个非安全应用，能够访问该函数。</p> <p>然而，BOOTSEL 模式可通过 BOOT_FLAGS0.DISABLE_BOOTSEL_UART_BOOT 禁用，若不需要时， BOOT_FLAGS0.DISABLE_BOOTSEL_USB_PICOBOOT_IFC, and BOOT_FLAGS0.DISABLE_BOOTSEL_USB_MSD_IFC。</p> <p>BOOT_FLAGS0.DISABLE_BOOTSEL_USB_PICOBOOT_IFC 是最关键的，因为 PICOBOOT 为用户向引导只读存储器的 reboot() 函数传递特定参数提供了通道。然而，BOOTSEL 模式的任何其他使用在未来针对非安全代码的某些攻击中可能存在安全漏洞。</p>

----------	----------------------------------

## RP2350-E22

Reference	RP2350-E22
Summary	Parsing a malformed "lollipop" <a href="#">block loop</a> will cause a hang rather than a failure
Affects	RP2350 A2
Description	<a href="#">PARTITION_TABLEs</a> and <a href="#">IMAGE_DEFs</a> metadata are stored as part of a block loop. These block loops are parsed during boot and at other times. A "lollipop" block loop is an invalid block loop, which loops back from the last block to a block, which isn't the first. Such an invalid block loop is never generated by the SDK or by <a href="#">picotool</a> ; however, it could potentially be generated by other tooling.
Workaround	Don't use "lollipop" block loops. If you program a "lollipop" block loop into flash such that it's read during the boot process, it will cause a boot hang and also a hang on entry into BOOTSEL mode. Therefore, to re-enable booting, you must clear the flash in some other way, for example, from the debugger over SWD.

## RP2350-E23

Reference	RP2350-E23
Summary	PICOBOOT <a href="#">GET_INFO</a> command always returns zero for <a href="#">PACKAGE_SEL</a>
Affects	RP2350 A2
Description	The PICOBOOT <a href="#">GET_INFO</a> command can be used to get system information in a similar way to the bootrom <a href="#">get_sys_info()</a> function. This information can include the value read from <a href="#">PACKAGE_SEL</a> , which indicates whether the RP2350 package is QFN60 or QFN80.  The <a href="#">SYSINFO</a> block is erroneously left in reset when entering BOOTSEL mode, and thus this register is read as zero when accessed via PICOBOOT.  This problem doesn't affect use of the bootrom <a href="#">get_sys_info()</a> function itself from user code.
Workaround	Determine the package size by reading register_link_macro:[register=OTP_DATA_NUM_GPIOS_ROW] via the PICOBOOT <a href="#">OTP_READ</a> command instead. This workaround is used by <a href="#">picotool</a> .

## RP2350-E24

参考资料	RP2350-E24
摘要	具备物理访问芯片权限、中等硬件设备以及能够在精确时刻对CPU实施物理“干扰”攻击的攻击者, 可能在受保护的RP2350上执行未经签名的代码。
影响范围	RP2350 A2, RP2350 A3

<b>Description</b>	An attacker with physical access to the chip, and the ability to switch the contents of "flash" as read by the RP2350 over QSPI during boot at precise times, could, combined with a precisely-timed physical "glitch" attack of the CPU, trick the bootrom into checking the signature of data other than the program binary as loaded into memory during secure boot.  If this "other" data passes the signature check, then the attacker's binary is executed without itself having passed a signature check, which allows the user to run arbitrary unsigned code on the RP2350.
<b>Credit</b>	Kévin Courdesses (see <a href="https://courk.cc/rp2350-challenge-laser#flash-memory-organization">https://courk.cc/rp2350-challenge-laser#flash-memory-organization</a> )
<b>Workaround</b>	None
<b>Fixed by</b>	RP2350 A4 bootrom

## RP2350-E25

<b>Reference</b>	RP2350-E25
<b>Summary</b>	A <code>LOAD_MAP</code> that uses non-word sizes doesn't cause an error.
<b>Affects</b>	RP2350 A2, RP2350 A3
<b>Description</b>	Non-word sizes in a <code>LOAD_MAP</code> aren't supported and were documented as such. However, they don't currently cause an error. Whilst non-word sizes might currently work in some certain cases, you should never use them because they might not work as you expect in all cases and can be properly treated as an error in the future.  The SDK and <code>picotool</code> don't generate such <code>LOAD_MAP</code> s with non-word sized entries.
<b>Workaround</b>	Don't use non-word (not multiple of 4) sizes in a <code>LOAD_MAP</code> . A best practice is to make sure that linker memory segments are both word-sized and word-aligned.  As of the RP2350 A4 bootrom, non-word sizes are detected when checking the <code>LOAD_MAP</code> and cause the <code>IMAGE_DEF</code> to be considered invalid if present.

## 总线结构

### RP2350-E27

参考资料	RP2350-E27
摘要	APB 和 FASTPERI 仲裁器的总线优先级控制适用于错误的管理者。
影响范围	RP2350 A2、RP2350 A3、RP2350 A4

<b>Description</b>	<p>RP2350 bus fabric consists mainly of an AHB5 crossbar, where 6 upstream ports (managers) are routed to 15 downstream crossbar ports. <a href="#">Figure 5</a> shows the overall structure of the bus fabric, including this crossbar. Because there can be multiple accesses to a given downstream crossbar port on any one cycle, an arbiter circuit selects one transfer to forward to the downstream port, and stalls all other transfers targeting this port.</p> <p>The BUSCTRL <a href="#">BUS_PRIORITY</a> register controls these arbiter circuits. It configures a 1-bit priority level for each of the following four groups of AHB5 managers:</p> <ul style="list-style-type: none"> <li>• DMA write</li> <li>• DMA read</li> <li>• Core 0 instruction fetch and core 0 load/store</li> <li>• Core 1 instruction fetch and core 1 load/store</li> </ul> <p>Accesses from high-priority managers are always routed preferentially over those from low-priority managers. Multiple accesses from managers of the same priority are processed one at a time, taking turns in a repeating cycle (round-robin arbitration).</p> <p>On the FASTPERI and APB arbiters, these signals are mis-wired, such that the wrong managers are prioritised:</p> <ul style="list-style-type: none"> <li>• <a href="#">BUS_PRIORITY.PROC0</a> controls DMA write priority</li> <li>• <a href="#">BUS_PRIORITY.PROC1</a> controls core 0 load/store priority</li> <li>• <a href="#">BUS_PRIORITY.DMA_R</a> controls core 1 load/store priority</li> <li>• <a href="#">BUS_PRIORITY.DMA_W</a> controls DMA read priority</li> </ul> <p>The <a href="#">BUS_PRIORITY</a> controls are applied correctly for all other arbiters: ROM, SRAM, and XIP.</p> <p>For example, if the <a href="#">DMA_R</a> and <a href="#">DMA_W</a> bits were set, this would prioritise DMA over processor access to ROM, SRAM, and XIP. However, peripheral access would prioritise DMA read and core 1 load/store over DMA write and core 0 load/store.</p>
<b>Workaround</b>	<p>There is no complete fix, but the necessary prioritisation can often still be achieved by configuring <a href="#">BUS_PRIORITY</a> for correct priority at the peripherals, and then arranging buffers in SRAM to minimise contention, such as using SRAM8 or SRAM9 as processor-private memories.</p> <p>Also consider the following approaches:</p> <ul style="list-style-type: none"> <li>• Split RAM access across the SRAM0 to SRAM3 and SRAM4 to SRAM7 striped regions to further reduce RAM contention.</li> <li>• Try to reduce overall peripheral bandwidth demand by using wider accesses for peripherals that support it. For example, SPI supports 16-bit data, and HSTX and PIO support 32-bit data.</li> <li>• Avoid processor polling of peripheral status registers. Instead, use interrupts or DMA DREQ signals.</li> <li>• Assess whether the default round-robin arbitration performs better than the reachable asymmetric priority configurations.</li> </ul>
<b>Fixed by</b>	Documentation

## DMA

### RP2350-E5

描述	<p>RP2350总线结构主要由一个AHB5交叉开关组成，其中6个上游端口（管理者）被路由至15个下游交叉开关端口。图5展示了包括该交叉开关在内的总线结构整体架构。由于任一时钟周期内可对给定下游交叉开关端口发起多次访问，仲裁电路选择一个传输转发至该端口，并阻塞所有其他针对该端口的传输。</p> <p>BUSCTRL BUS_PRIORITY寄存器用于控制这些仲裁电路。该寄存器为以下四组AHB5管理者中的每一组配置1位优先级等级：</p> <ul style="list-style-type: none"> <li>• DMA写入</li> <li>• DMA读取</li> <li>• 核心0指令获取及核心0加载/存储</li> <li>• 核心1指令获取及核心1加载/存储</li> </ul> <p>来自高优先级管理器的访问始终优先于来自低优先级管理器的访问。同一优先级管理器的多个访问依次单个处理，按照循环轮询的方式进行仲裁。</p> <p>在FASTPERI和APB仲裁器中，这些信号接线错误，导致优先级判定错误，错误的管理器被优先处理：</p> <ul style="list-style-type: none"> <li>• <a href="#">BUS_PRIORITY.PROC0</a> 控制 DMA 写入的优先级</li> <li>• <a href="#">BUS_PRIORITY.PROC1</a> 控制核心0加载/存储的优先级</li> <li>• <a href="#">BUS_PRIORITY.DMA_R</a> 控制核心1加载/存储的优先级</li> <li>• <a href="#">BUS_PRIORITY.DMA_W</a> 控制 DMA 读取的优先级</li> </ul> <p>BUS_PRIORITY 控制正确应用于所有其他仲裁器：只读存储器、SRAM 和 XIP。</p> <p>例如，如果设置了 <a href="#">DMA_R</a> 和 <a href="#">DMA_W</a> 位，将使 DMA 访问优先于处理器访问只读存储器、SRAM 和 XIP，但外围设备访问时，DMA读取和核心1加载/存储优先于 DMA写入和核心0加载/存储。</p>
解决方案	<p>目前尚无完整的修复方案，但通常仍可通过为外设配置正确优先级的<a href="#">BUS_PRIORITY</a>实现必要的优先级排序，然后在<a href="#">SRAM</a>中安排缓冲区以最小化争用，例如使用<a href="#">SRAM8</a>或<a href="#">SRAM9</a>作为处理器专用内存。</p> <p>还应考虑以下方法：</p> <ul style="list-style-type: none"> <li>• 将RAM访问分散到SRAM0至SRAM3与SRAM4至SRAM7的条带区域，以进一步减少RAM争用。</li> <li>• 尝试通过对支持的外设使用更宽的数据访问，降低总体外设带宽需求。例如，SPI支持16位数据，HSTX和PIO支持32位数据。</li> <li>• 避免处理器轮询外设状态寄存器。应改为使用中断或DMA DREQ信号。</li> <li>• 评估默认的轮询仲裁是否优于可达的非对称优先级配置。</li> </ul>

### RP2350-E5

<b>Reference</b>	RP2350-E5
<b>Summary</b>	Interactions between <b>CHAIN_TO</b> and <b>ABORT</b> of active channels
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>The <b>CHAN_ABORT</b> register commands a DMA channel to stop issuing transfers, and to clear its <b>BUSY</b> flag once in-flight transfers have completed. This was originally intended for recovering channels that are stuck with their DREQ low. An <b>ABORT</b> is initiated by writing a bitmap of aborted channels to <b>CHAN_ABORT</b>. Bits remain set until each channel comes to rest.</p> <p>This erratum is a compound of two behaviours: first, aborting a channel will cause its <b>CHAIN_TO</b> to fire, if and only if the aborted channel is the last channel to have completed a write transfer. Second, a channel undergoing an <b>ABORT</b> is susceptible to be re-triggered on the last cycle before the <b>ABORT</b> register clears, because the channel is both inactive and enabled on this cycle, and the <b>ABORT</b> itself doesn't inhibit triggering. However, since the <b>ABORT</b> is still in effect, the transfer count is held at zero. On the cycle after the <b>ABORT</b> finishes, the channel completes because its transfer counter is zero. This causes the channel's IRQ and <b>CHAIN_TO</b> to fire on the cycle after the <b>ABORT</b> completes.</p> <p>These two behaviours are problematic when aborting multiple channels that chain to one another, since they may cause the channels to immediately restart post-abort.</p>
<b>Workaround</b>	Before aborting an active channel, clear the <b>EN</b> bit ( <b>CH0_CTRL_TRIG.EN</b> ) of both the aborted channel and any channel it chains to. This ensures the channel isn't susceptible to re-triggering.
<b>Fixed by</b>	Documentation

## RP2350-E8

<b>Reference</b>	RP2350-E8
<b>Summary</b>	<b>CHAIN_TO</b> might not fire for zero-length transfers
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>The <b>CTRL.CHAIN_TO</b> field configures a channel to start another channel once it completes its programmed sequence of transfers. The <b>CHAIN_TO</b> takes place on the cycle where the channel's last write completes, and the chainee becomes active on the next cycle.</p> <p>The hardware implementation assumes that <b>CHAIN_TO</b> always happens as a result of a write completion. This isn't the case when a channel is triggered with a transfer count of zero; in this case the channel completes on the cycle immediately after the trigger without performing any bus accesses.</p> <p>A <b>CHAIN_TO</b> from a channel started with a transfer count of zero will fire if and only if that channel is the last channel to have completed a write transfer. This is true only when the channel in question has previously performed a non-zero-length sequence of transfers, and no other channel has completed a write since.</p>
<b>Workaround</b>	Don't use <b>CHAIN_TO</b> in conjunction with zero-length transfers. Avoid zero-length transfers in the middle of control block lists, and replace them with dummy transfers if possible.
<b>Fixed by</b>	Documentation

摘要	活动通道中 <b>CHAIN_TO</b> 与 <b>ABORT</b> 的交互
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>CHAN_ABORT 寄存器指令 DMA 通道停止发起传输，并在当前传输完成后清除其 <b>BUSY</b> 标志。此功能最初用于恢复那些因 DREQ 持续低电平而卡住的通道。通过向 CHAN_ABORT 写入一个中止通道的位图来启动 <b>ABORT</b> 操作。</p> <p>各位保持置位状态，直到对应通道停止工作。</p> <p>该勘误包含两种行为：首先，终止某通道会触发其 <b>CHAIN_TO</b> 信号，前提是被终止的通道为最后一个完成写传输的通道。其次，处于 <b>ABORT</b> 状态的通道可能在 <b>ABORT</b> 寄存器清零的最后一个周期之前被重新触发，因为该通道在该周期既非活动状态且被启用，且 <b>ABORT</b> 本身不阻止触发。但由于 <b>ABORT</b> 仍处于生效状态，传输计数保持为零。在 <b>ABORT</b> 结束的下一个周期，该通道因传输计数器为零而完成操作。这导致该通道的 IRQ 及 <b>CHAIN_IN_TO</b> 信号在 <b>ABORT</b> 完成后的周期被触发。</p> <p>当中止相互链式连接的多个通道时，这两种行为存在问题，因为它们可能导致通道在中止后立即重新启动。</p>
解决方案	在中止一个活动通道之前，请清除被中止通道及其链式连接的所有通道的 <b>EN</b> 位（CH0_CTRL_TRIG.EN）。此操作确保通道不会受到重新触发的影响。

## GPIO

**RP2350-E9**

<b>Reference</b>	RP2350-E9
<b>Summary</b>	Increased leakage current on Bank 0 GPIO when pad input is enabled
<b>Affects</b>	RP2350 A2

## RP2350-E9

参考资料	RP2350-E9
摘要	当 Bank 0 GPIO 使能输入时，漏电流增加。
影响范围	RP2350 A2

<p><b>Description</b></p> <p>For GPIO pads 0 through 47:</p> <p>Increased leakage current when Bank 0 GPIO pads are configured as inputs and the pad is somewhere between <math>V_{IL}</math> and <math>V_{IH}</math> (the undefined logic region).</p> <p>When the pad is set as an input (input enable is enabled and output enable is disabled) and the voltage on the pad is within the undefined logic region, the leakage current exceeds the standard specified <math>I_{IN}</math> leakage level. During this condition the pad can source current (the exact amount is dependent on the chip itself and the exact pad voltage, but typically around 120µA). This leakage will hold the pad at around 2.2 V as that is the effective source voltage of the leakage, and can only be overcome with a suitably low impedance driver / pull.</p> <p>The pad pull-down (if enabled) is significantly weaker than the leakage current in this state and therefore isn't strong enough to pull the pad voltage low.</p> <p>Driving / pulling the pad input low with a low impedance source of 8.2 kΩ or less will overcome the erroneous leakage and drive the voltage below the level where the leakage current occurs, so in this case if the pad is driven / pulled low it will stay low.</p> <p>The erroneous leakage only occurs (and continues to occur) when the pad input enable is enabled; disabling the input enable will reset (remove) the leakage.</p> <p>The pad pull-up still works. If enabled it will pull the pad to <a href="#">IOVDD</a> as it will pull the input voltage out of the problematic range.</p> <p>The voltages and currents above are based on <a href="#">IOVDD</a> at 3.3 V. For <a href="#">IOVDD</a> at 1.8 V the effective source voltage of the leakage becomes 1.8 V and the peak current is around 30µA. This is effectively a pull-up (separate to the standard pad pull-up) when the pad voltage is between 0.6 V and 1.8 V.</p> <p>These graphs show the leakage current versus pad input voltage for a typical chip for <a href="#">IOVDD</a> at 3.3 V <a href="#">Figure 153</a> and 1.8 V <a href="#">Figure 154</a>.</p> <p>In detail, this issue presents under the following conditions, for any GPIO 0 through 47:</p> <ol style="list-style-type: none"> <li>1. The voltage on the pad is in the undefined logic region.</li> <li>2. Input buffer is enabled in <a href="#">GPIO0.IE</a></li> <li>3. Output buffer is disabled (e.g. selecting the <a href="#">NULL</a> GPIO function)</li> <li>4. Isolation is clear in <a href="#">GPIO0.ISO</a>, or the previous were true at the point isolation was set</li> </ol> <p>When all of the above conditions are met, the input leakage of the pad may exceed the specification.</p> <p>This issue may affect a number of common circuits:</p> <ul style="list-style-type: none"> <li>• Relying on floating pins to have a low leakage current</li> <li>• Relying on the internal pull-down resistor</li> </ul> <p>If the internal pull-up is enabled then any floating signal will be pulled high thus removing increased leakage condition as the excess leakage is only sourcing current. This of course can't prevent the increased leakage if the pad is fed via a strong source e.g. strong potential divider.</p> <p>This doesn't affect the pull-down behaviour of the pads immediately following a PoR or RUN reset because the input enable field is initially clear. The pull-down resistor functions normally in this state.</p> <p>This issue doesn't affect the QSPI pads, which use a different pad macro without the faulty circuitry. The USB PHY's pins are also unaffected.</p> <p>This issue does also affect the SWD pads, which use the same fault-tolerant pad macro as the Bank 0 GPIOs. However, both SWD pads are pull-up by default, so there is no ill effect.</p>	
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--

<p><b>描述</b></p> <p>针对 GPIO 引脚 0 至 47：</p> <p>当 Bank 0 GPIO 引脚配置为输入且引脚电压位于 <math>V_{IL}</math> 与 <math>V_{IH}</math> 之间的未定义逻辑区间时，漏电流增加。</p> <p>当引脚设为输入状态（启用输入使能且禁用输出使能）且引脚电压处于未定义逻辑区间内时，漏电流将超过标准规定的 <math>I_{IN}</math> 漏电电平。在该状态下，引脚可能输出电流（具体数值取决于芯片及引脚电压，通常约为 <math>120\mu A</math>）。该漏电流会使引脚电压维持在约 <math>2.2 V</math>，因该电压为漏电流的有效源电压，仅能由适当低阻抗驱动器或上拉电阻克服。</p> <p>如果启用，垫脚下拉电阻在此状态下明显弱于泄漏电流，因此其强度不足以将垫脚电压拉低。</p> <p>使用低阻抗 (<math>8.2 k\Omega</math> 或以下) 电源驱动或拉低垫脚输入，将克服错误泄漏电流，使电压降至泄漏电流发生阈值以下，因此在此情况下，若垫脚被驱动或拉低，将保持低电平。</p> <p>错误泄漏仅在垫脚输入使能开启时发生且持续存在；禁用输入使能将重置（消除）该泄漏。</p> <p>垫脚上拉仍然有效。若启用，它会将垫脚拉至 <math>IOVDD</math> 电位，从而将输入电压拉出问题区间。</p> <p>上述电压和电流均基于 <math>3.3 V</math> <math>IOVDD</math>。对于 <math>1.8 V</math> <math>IOVDD</math>，泄漏的有效源电压为 <math>1.8 V</math>，峰值电流约为 <math>30\mu A</math>。当引脚电压处于 <math>0.6 V</math> 至 <math>1.8 V</math> 之间时，此状态实际上构成一个上拉（与标准引脚上拉独立）。</p> <p>这些图表展示了典型芯片的泄漏电流与引脚输入电压之间的关系，<math>IOVDD</math> 为 <math>3.3 V</math>。  <a href="#">图153及1.8 V 图154</a>。</p> <p>具体而言，该问题在以下条件下发生，适用于任意 GPIO 0 至 47：</p> <ol style="list-style-type: none"> <li>1. 引脚电压处于未定义逻辑区间。</li> <li>2. <math>GPIO0.IE</math> 中启用了输入缓冲。</li> <li>3. 输出缓冲被禁用（例如选择了 <math>NULL</math> GPIO 功能）。</li> <li>4. <math>GPIO0.ISO</math> 中的隔离被解除，或在设置隔离时上述条件成立。</li> </ol> <p>当所有上述条件均满足时，引脚输入泄漏可能超过规格限值。</p> <p>该问题可能影响多种常见电路：</p> <ul style="list-style-type: none"> <li>• 依赖浮动引脚保持低泄漏电流的电路。</li> <li>• 依赖内部下拉电阻的电路。</li> </ul> <p>如果内部上拉被使能，任何悬空信号将被拉高，从而消除因多余漏电仅作为电流源而造成的泄漏增加。当然，如引脚由强源供电，例如强势分压器，则无法防止泄漏增加。</p> <p>由于输入使能位初始为清除状态，此情况不会影响 PoR 或 RUN 复位后紧随其后的引脚下拉行为。在该状态下，下拉电阻功能保持正常。</p> <p>该问题不影响使用不同引脚宏且无故障电路的 QSPI 引脚。USB PHY 的引脚同样不受影响。</p> <p>该问题确实影响采用与 Bank 0 GPIO 相同容错引脚宏的 SWD 引脚，但由于 SWD 引脚默认上拉，因此无不良影响。</p>
------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Workaround</b>	If pad pull-down behaviour is required, clear the pad input enable in <code>GPIO0.IE</code> (for GPIOs 0 through 47) to ensure that the pad pull-down resistor pulls the pad signal low. To read the state of a pad pulled-down GPIO from software, enable the input buffer by setting <code>GPIO0.IE</code> immediately before reading, and then re-disable immediately afterwards. If the pad is already a logic-0, re-enabling the input doesn't disturb the pull-down state.  Alternatively an external pull-down of 8.2 kΩ or less can be used.  PIO programs can't toggle pad controls and therefore external pulls may be required, depending on your application.  As normal, if ADC channels are being used on a pin, clear the relevant GPIO input enable as stated in <a href="#">Section 12.4.3</a> .

## Hazard3

### RP2350-E4

参考资料	RP2350-E4
------	-----------

<b>Summary</b>	System Bus Access stalls indefinitely when core 1 is in clock-gated sleep
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>System Bus Access (SBA) is a RISC-V debug feature that allows the Debug Module direct access to the system bus, independent of the state of harts in the system. RP2350 implements SBA by arbitrating Debug Module bus accesses with the core 1 load/store port.</p> <p>Hazard3 implements custom low-power states controlled by the <a href="#">MSLEEP</a> CSR. When <a href="#">MSLEEP</a>.DEEPSLEEP is set, Hazard3 completely gates its clock, with the exception of the minimal logic required to wake again. Due to a design oversight, this also clock-gates the arbiter between SBA and load/store bus access. (This is addressed in upstream commit <a href="#">c11581e</a>.)</p> <p>Consequently, if you initiate an SBA transfer whilst <a href="#">MSLEEP</a>.DEEPSLEEP is set on core 1, and core 1 is in a WFI-equivalent sleep state, the SBA transfer will make no progress until core 1 wakes from the WFI state. The processor wakes upon an enabled interrupt being asserted, or a debug halt request.</p>
<b>Workaround</b>	<p>Either configure your debug translator to not use SBA, or don't enter clock-gated sleep on core 1. The A2 bootrom mitigates this issue by not setting DEEPSLEEP in the initial core 1 wait-for-launch code.</p> <p>The processors are synthesised with hierarchical clock gating, so the top-level clock gate controlled by the DEEPSLEEP flag brings minimal power savings over a default WFI sleep state.</p>

## RP2350-E6

<b>Reference</b>	RP2350-E6
<b>Summary</b>	PMPCFGx RWX fields are transposed
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>The Physical Memory Protection unit (PMP) defines read, write and execute permissions (RWX) for configurable ranges of physical memory. The RWX permissions for four regions are packed into each 32-bit PMPCFG register, <a href="#">PMPCFG0</a> through <a href="#">PMPCFG3</a>.</p> <p>Per the RISC-V privileged ISA specification, the permission fields are ordered X, W, R from MSB to LSB. Hazard3 implements them in the order R, W, X. This means software using the correct bit order will have its read permissions applied as execute, and vice versa. (See upstream commit <a href="#">7d37029</a>.)</p>
<b>Workaround</b>	When configuring PMP with X != R, use the bit order implemented by this version of Hazard3. In the SDK, the <a href="#">hardware/regs/rvcsr.h</a> register header provides bitfield definitions for the as-implemented order when building for RP2350.
<b>Fixed by</b>	Documentation

## RP2350-E7

<b>Reference</b>	RP2350-E7
<b>Summary</b>	U-mode doesn't ignore <a href="#">mstatus.mie</a>
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4

摘要	当核心1处于时钟门控睡眠状态时，系统总线访问（SBA）会无限期阻塞
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>系统总线访问（SBA）是RISC-V调试功能，允许调试模块在不依赖系统中计算核（hart）状态的情况下，直接访问系统总线。RP2350通过与核心1的加载/存储端口进行仲裁，实现调试模块对总线的访问以支持SBA功能。</p> <p>Hazard3 实现了由 MSLEEP CSR控制的定制低功耗状态。当设置MSLEEP.DEEPSLEEP时，Hazard3完全关闭其时钟，除唤醒所需的最小逻辑外。由于设计疏忽，这也导致SBA与负载/存储总线访问间的仲裁器被时钟门控。（此问题已在上游提交c11581e中修正。）</p> <p>因此，如果在核心1的MSLEEP.DEEPSLEEP被设置时启动SBA传输，且核心1处于等效WFI睡眠状态，则该SBA传输直到核心1从WFI状态唤醒前均不会取得任何进展。当启用的中断被断言或调试停止请求触发时，处理器将被唤醒。</p>
解决方案	<p>请配置调试转换器以避免使用SBA，或避免核心1进入时钟门控睡眠状态。A2启动只读存储器通过在核心1初始等待启动代码中不设置DEEPSLEEP以缓解该问题。</p> <p>处理器采用分层时钟门控综合设计，因此由DEEPSLEEP标志控制的顶层时钟门控相比默认WFI睡眠状态所带来的功耗节省极小。</p>

## RP2350-E7

参考资料	RP2350-E7
摘要	U模式不会忽略mstatus mie
影响范围	RP2350 A2、RP2350 A3、RP2350 A4

Description	The <code>MSTATUS.MIE</code> bit is a global enable for interrupts that target M-mode. Software generally clears this momentarily to ensure short critical sections are atomic with respect to interrupt handlers.  The RISC-V privileged ISA specification requires that the interrupt enable flag for a given privilege mode is treated as <code>1</code> when the hart is in a lower privilege mode. In this case, <code>mstatus.mie</code> should be treated as <code>1</code> when the core is in U-mode.  Hazard3 doesn't implement this rule, so entering U-mode with M-mode interrupts disabled results in no M-mode interrupts being taken. (See upstream commit <a href="#">a84742a</a> .)
Workaround	When returning to U-mode from M-mode via an <code>mret</code> with <code>mstatus.mpp == 0</code> , ensure <code>mstatus.mpie</code> is set, so that IRQs will be enabled by the return.
Fixed by	Documentation

## OTP

### RP2350-E16

Reference	RP2350-E16
Summary	<code>USB OTP VDD</code> disruption can result in corrupt OTP row read data
Affects	RP2350 A2
Description	<p>The OTP array has a read voltage generated from <code>USB OTP VDD</code> using an internal linear regulator. While the regulator has a "power good" signal, it isn't sampled outside of the initial power-on reset startup sequence. External manipulation of <code>USB OTP VDD</code> can result in incorrect data being latched during the array read phase.</p> <p>The erroneous behaviour includes, but isn't limited to:</p> <ul style="list-style-type: none"> <li>• Latching the previous read cycle data from the array</li> <li>• One or many bitlines returning zeroes for programmed bits</li> <li>• Byte-shifted read data</li> </ul> <p>In the case of guarded reads, the first failure mode can result in the guard read check passing and the guard word also ending up as the read data. If the critical data are the <code>CRIT0/CRIT1</code> flags, sampled by the OTP PSM during boot, this can enable Hazard3 debug and disable the Arm cores, which results in a reversion of the effects of the <code>CRIT1.SECURE_BOOT_ENABLE</code> and <code>CRIT1.DEBUG_DISABLE</code> flags.</p> <p>Guarded ECC reads aren't typically vulnerable to corruption of this nature as the guard word is an invalid ECC word, and bit deletion or byte shifting reliably invalidates the ECC check.</p> <p>RP2350 A3 incorporates more safeguards against erroneous OTP behaviour. If any of the following checks fail, the chip is reset back to the start of the OTP PSM stage.</p> <ul style="list-style-type: none"> <li>• The OTP regulator OK signal is continuously checked whenever OTP PSM or user accesses are being performed.</li> <li>• Bit 0 of the row read address selects either the first or second ROM calibration word (<code>0x333333</code> or <code>0xcccccc</code>) for any guarded read, and is validated accordingly.</li> <li>• Reserved-0 bits in the CRIT0/1 rows are checked as reading 0 in the OTP PSM.</li> </ul> <p>These checks are performed regardless of the security state of the chip. The OTP regulator check may be masked with bit 2 of the <code>AUXCTRL</code> register.</p>
Credit	Aedan Cullen (see <a href="https://github.com/aedancullen/hacking-the-rp2350">https://github.com/aedancullen/hacking-the-rp2350</a> )

描述	MSTATUS.MIE位是面向M模式中断的全局使能位。软件通常会暂时清除此位，以确保关键短节在中断处理程序方面保持原子性。  RISC-V特权ISA规范要求，当hart处于较低特权模式时，特定特权模式的中断使能标志应被视为 1。在此情况下，内核处于U模式时，应将mstatus mie视为 1。  Hazard3未实现该规则，因此，在M模式中断被禁用的情况下进入U模式，将不会响应M模式中断。（参见上游提交a84742a。）
解决方案	通过 mret从M模式返回至U模式且mstatus.mpp == 0时，须确保mstatus.mpie被设置，以确保返回时IRQ被启用。

<b>Workaround</b>	None
<b>Fixed by</b>	RP2350 A3

## RP2350-E17

<b>Reference</b>	RP2350-E17
<b>Summary</b>	Performing a guarded read on a single ECC OTP row causes a fault if the data in the adjacent row isn't also valid ECC data.
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>Each "ECC row" in OTP stores 16 bits of user data along with error correction information used to correct and/or detect bit errors. ECC rows are used to store data value, which are written a full 16 bits at a time into OTP.</p> <p>A "guarded" ECC row read is intended to be used by the RP2350 boot path, or other Secure software when it expects to read an ECC row and can't proceed if the row value is invalid. Reading such an invalid ECC value through a "guarded" read halts the chip until it's rebooted.</p> <p>If ECC row programming is interrupted, an ECC row might contain a value that fails ECC validation. Because any ECC could potentially contain an invalid, partially written value, the bootrom uses a separate "enable" flag in OTP to indicate whether a particular ECC row is expected to contain a valid value. The user is expected to only set this flag <i>after</i> a particular ECC row is known to have been written correctly.</p> <p>The RP2350 OTP hardware actually reads a pair of rows (starting on the even row) whenever an ECC read is performed but only returns one row value. When performing a guarded ECC read, it actually checks both rows validity, so the guarded read can cause a halt if either row in the pair isn't a valid ECC value.</p>
<b>Workaround</b>	<ul style="list-style-type: none"> <li>Never store ECC rows and RAW rows in the same pair of rows (a pair of rows starting on an even row number), since the RAW row is unlikely to always contain a valid ECC value. Note however that zero in a RAW row is a valid ECC value.</li> <li>Never store two ECC rows in the same pair of rows if they are protected by different "enable" flags.</li> </ul> <p>This workaround is fine for user use of OTP, however certain pre-existing ECC row pairs used by the bootrom violate workaround 2:</p> <ul style="list-style-type: none"> <li><a href="#">FLASH_DEVINFO</a> and <a href="#">FLASH_PARTITION_SLOT_SIZE</a></li> <li><a href="#">BOOTSEL_LED_CFG</a> and <a href="#">BOOTSEL_PLL_CFG</a></li> </ul> <p>To be absolutely safe, don't update and set the "enable" flag for one half of the pair after you have set the "enable" flag for the other half. If you want to set both ECC values safely, set them both, then set both "enable" flags.</p>

## RP2350-E28

<b>Reference</b>	RP2350-E28
<b>Summary</b>	OTP keys for pages 62/63 are applied to all lock words 0 through 63
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4

解决方案	无
修复者	RP2350 A3

## RP2350-E17

参考资料	RP2350-E17
摘要	对单个 ECC OTP 行执行受保护读取时，若相邻行中的数据非有效 ECC 数据，则会触发故障。
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>OTP 中的每个“ECC 行”存储 16 位用户数据及用于纠正和/或检测位错误的纠错信息。ECC 行用于存储数据值，数据以完整的 16 位一次性写入 OTP。</p> <p>“受保护”的 ECC 行读取设计供 RP2350 启动路径或其他安全软件使用，当其期望读取 ECC 行且该行值无效时无法继续操作。通过“受保护”读取无效 ECC 值会导致芯片停机，直至重新启动。</p> <p>若 ECC 行编程被中断，ECC 行可能包含无法通过 ECC 校验的值。 由于任何 ECC 行都可能包含无效的、部分写入的值，启动只读存储器（bootrom）使用 OTP 中的单独“启用”标志来指示特定 ECC 行是否预期包含有效值。用户应仅在确认特定 ECC 行已正确写入后设置此标志。</p> <p>RP2350 OTP 硬件执行 ECC 读取时，实际上会读取一对行（从偶数行开始），但仅返回一行值。执行受保护 ECC 读取时，硬件会验证该对行的有效性，如任一行无效，受保护读取将导致停机。</p>
解决方案	<ul style="list-style-type: none"> <li>切勿将 ECC 行与 RAW 行存储于同一对行（以偶数行号开始的一对行）中，因 RAW 行通常不含有效的 ECC 值。但须注意，RAW 行中的零值为有效的 ECC 值。</li> <li>若受不同“enable”标志保护，切勿将两条 ECC 行存储于同一对行中。</li> </ul> <p>此解决方法适用于用户使用 OTP，但启动只读存储器（bootrom）预先存在的某些 ECC 行对违反了解决方案 2：</p> <ul style="list-style-type: none"> <li><a href="#">FLASH_DEVINFO</a> 与 <a href="#">FLASH_PARTITION_SLOT_SIZE</a></li> <li><a href="#">BOOTSEL_LED_CFG</a> 与 <a href="#">BOOTSEL_PLL_CFG</a></li> </ul> <p>为绝对安全，设置对中一半的“enable”标志后，不要更新并设置另一半的“enable”标志。若需安全设置两个 ECC 值，应先同时设置这两个值，再同时设置对应的两个“enable”标志。</p>

## RP2350-E28

参考资料	RP2350-E28
摘要	第 62 及 63 页的 OTP 密钥适用于所有锁定字 0 至 63。
影响范围	RP2350 A2、RP2350 A3、RP2350 A4

<b>Description</b>	<p>As described in <a href="#">Section 13.5</a>, the uppermost 64 words (128 rows) of OTP contain protection information for each 128-byte page of OTP. The total ECC data capacity of the OTP is <math>64 \times 128 \text{ B} = 8192 \text{ B}</math>, so there is one such lock word for each page. The permissions in each lock word <math>n</math> cover OTP rows <math>64 * n</math> through <math>64 * n + 63</math> (inclusive), and they also cover the lock word itself.</p> <p>This makes lock words 62 and 63 special because they don't have any associated OTP page. This is because those pages would overlap with the locations where the lock words are stored. Instead, lock words 62 and 63 should only protect themselves. This rule is applied correctly for the effects of <a href="#">LOCK_NS</a> and <a href="#">LOCK_S</a> bits. However, the protection checks for the <a href="#">KEY_R</a>, <a href="#">KEY_W</a>, and <a href="#">NO_KEY_STATE</a> bits don't handle pages 62 and 63 correctly. Instead, they simply divide the row number by 64 to look up the lock word.</p> <p>The effect is that lock words 0 through 31 have a key protection state defined by <a href="#">PAGE62_LOCK0</a>, and lock words 32 through 63 have a key protection state defined by <a href="#">PAGE63_LOCK0</a>.</p> <p>Conversely, the key configuration in lock words 0 through 61 does not affect the accessibility of those lock words. It only affects the accessibility of the actual data pages protected by those lock words.</p>
<b>Workaround</b>	<p>As a partial mitigation, factory programming revokes Non-secure write permission to pages 62 and 63 on all devices. This avoids Non-secure software disabling Secure access to lock words by deliberately installing an invalid key. For the full list of permissions pre-programmed on blank devices, see <a href="#">Section 13.5.5</a>. This mitigation is applied on all versions of RP2350.</p> <p>Software shouldn't rely on OTP access keys for protection of lock words.</p>

## RCP

### RP2350-E26

<b>Reference</b>	RP2350-E26
<b>Summary</b>	RCP random delays can create a side-channel
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>The RCP delay is implemented as a coprocessor stall; this has the effect of completely pausing the associated core. As the core is effectively halted for the duration of the delay, this represents a significant reduction in gate toggle activity across the chip if there are no other bus managers active (e.g. other CPU or DMA). The reduction in toggle activity causes a reduction in DVDD current, and the typical length of the delay means that the reduction is measureable outside of the chip. The reduction in current and subsequent increase may create a fault injection trigger point. Instructions immediately after an RCP delay operation can be more reliably targeted, undoing the cumulative effect of clock randomisation.</p> <p>A second-order effect of the RCP delay probability distribution is that after <math>N</math> RCP instructions for large <math>N</math>, the added latency converges to a normal distribution centred on <math>N * 63</math> cycles. Therefore, instructions after a known number of RCP delays are statistically easier to target.</p> <p>With these two factors in mind, programmers should use RCP delays in Secure code with great care. In particular, avoid using RCP delays:</p> <ul style="list-style-type: none"> <li>• Inside inner loops that may be executed many times.</li> <li>• As part of boilerplate assembly in function prologues/epilogues.</li> <li>• Immediately prior to particularly critical actions, such as modifying <a href="#">ACCESSCTRL</a>.</li> </ul> <p>As a mitigation, as of RP2350 A3, the bootrom uses the non-delay variant for all RCP instructions.</p>
<b>Workaround</b>	Use of the non-delay RCP instruction variant is recommended.

描述	<p>如13.5节所述，OTP最上方64个字（128行）包含每个128字节OTP页的保护信息。OTP的ECC数据总容量为<math>64 \times 128 \text{ B} = 8192 \text{ B}</math>，故每页对应一个锁定字。每个锁定字中的权限 <math>n</math> 覆盖 OTP 行 <math>64 * n</math> 至 <math>64 * n + 63</math>（含），且也涵盖锁定字本身。</p> <p>这使得锁定字62和63具有特殊性，因为它们没有任何关联的OTP页。这是因为这些页会与锁定字存储的位置发生重叠。因此，锁定字62和63应仅保护它们自身。该规则已正确应用于 <code>LOCK_NS</code> 和 <code>LOCK_S</code> 位的影响。然而，针对 <code>KEY_R</code>、<code>KEY_W</code> 和 <code>NO_KEY_STATE</code> 位的保护检查未能正确处理第62和63页。相反，它们仅通过将行号除以64来查找对应的锁定字。</p> <p>其结果是，锁定字0至31的密钥保护状态由 <code>PAGE62_LOCK0</code> 定义，且锁定字32至63的密钥保护状态由 <code>PAGE63_LOCK0</code> 定义。</p> <p>相反，锁字 0 至 61 的密钥配置不会影响这些锁字的可访问性。其仅影响由这些锁字保护的实际数据页的可访问性。</p>
解决方案	<p>作为部分缓解措施，出厂编程会撤销所有设备上第 62 和 63 页的非安全写入权限。此举防止非安全软件通过故意安装无效密钥来禁用对锁字的安全访问。有关空白设备上预先编程权限的完整列表，请参见第 13.5.5 节。该缓解措施适用于所有 RP2350 版本。</p> <p>软件不应依赖 OTP 访问密钥来保护锁字。</p>

### RP2350-E26

参考资料	RP2350-E26
摘要	RCP 随机延迟可能构成侧信道攻击。
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>RCP 延迟通过协处理器暂停实现；这导致相关内核被完全暂停。由于内核在延迟期间被有效停止，若无其他总线管理器（如其他 CPU 或 DMA）活动，将显著减少芯片内门电路的切换活动。切换活动的减少引起 DVDD 电流降低，且延迟的典型持续时间使该降低在芯片外部可被检测。电流的降低及随后增加可能导致故障注入触发点。紧接RCP延迟操作之后的指令更容易被可靠定位，从而抵消时钟随机化的累积效应。</p> <p>RCP延迟概率分布的二阶效应表明，对于较大 <math>N</math>，执行 <math>N</math>条RCP指令后，增加的延迟趋于以 <math>N * 63</math>周期为中心的正态分布。因此，在已知一定数量RCP延迟之后的指令，统计上更容易被定位。</p> <p>基于上述两个因素，程序员应在安全代码中谨慎使用RCP延迟。特别应避免在以下情况下使用RCP延迟：</p> <ul style="list-style-type: none"> <li>• 可能多次执行的内层循环中。</li> <li>• 函数序言或尾声中的模板汇编代码部分。</li> <li>• 特别关键的操作前，例如修改 <code>ACCESSCTRL</code> 寄存器之前。</li> </ul> <p>作为缓解措施，自RP2350 A3版本起，bootrom对所有RCP指令均采用非延迟变体。</p>
解决方案	建议使用非延迟的RCP指令变体。

## SIO

### RP2350-E1

Reference	RP2350-E1
Summary	Interpolator <b>OVERF</b> bits are broken by new right-rotate behaviour
Affects	RP2350 A2, RP2350 A3, RP2350 A4
Description	<p>RP2350 replaces the interpolator right-shift with a right-rotate, so that left shifts can be synthesised. This is useful for scaled indexed addressing in tight address-generating loops.</p> <p>The <b>OVERF</b> flag functions by checking for nonzero bits in the post-shift value that have been masked out by the <b>MSB</b> mask configured by the <b>CTRL_LANE0_MASK_MSB</b> and <b>CTRL_LANE1_MASK_MSB</b> register fields. This is used to discard samples outside of the [0, 1) wrapping domain of UV coordinates represented by <b>ACCUM0</b> and <b>ACCUM1</b>, for example in affine-transformed sprite sampling.</p> <p>The issue occurs because the right-rotate causes nonzero LSBs to be rotated up to the MSBs. These nonzero bits spuriously set the <b>OVERF</b> flag.</p>
Workaround	Either compute <b>OVERF</b> manually by checking the <b>ACCUM0/ACCUM1</b> MSBs, or precompute the bounds in advance to avoid per-sample checks.
Fixed by	Documentation

### RP2350-E2

Reference	RP2350-E2
Summary	SIO SPINLOCK writes are mirrored at +0x80 offset
Affects	RP2350 A2, RP2350 A3, RP2350 A4
Description	<p>The SIO contains spinlock registers, <b>SPINLOCK0</b> through <b>SPINLOCK31</b>. Reading a spinlock register attempts to claim it, returning nonzero if the claim was successful and 0 if unsuccessful. Writing to a spinlock register releases it, so the next claim will be successful. SIO spinlock registers are at register offsets <b>0x100</b> through <b>0x17c</b> within SIO.</p> <p>RP2350 adds new SIO registers at register offsets <b>0x180</b> and above: Doorbells, the PERI_NONSEC register, the RISC-V soft IRQ register, the RISC-V MTIME registers, and the TMDS encoder.</p> <p>The SIO address decoder detects writes to spinlocks by decoding on bit <b>8</b> of the address. This means writes in the range <b>0x180</b> through <b>0x1fc</b> are spuriously detected as writes to the corresponding spinlock address 128 bytes below, in the range <b>0x100</b> through <b>0x17c</b>. Writing to any of these high registers will set the corresponding lock to the unclaimed state.</p> <p>This erratum only affects writes to the spinlock registers. Reads are correctly decoded, so aren't affected by accesses above <b>0x17c</b>.</p>

摘要	Interpolator OVERF 位因新的右旋转行为而损坏
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>RP2350 用右旋转替代了插值器的右移操作，从而能够合成左移操作。这在紧凑的地址生成循环中用于缩放索引寻址非常有用。</p> <p>OVERF 标志通过检查经过由 <code>CTRL_LANE0_MASK_MSB</code> 和 <code>CTRL_LANE1_MASK_MSB</code> 寄存器字段配置的 MSB 掩码屏蔽后仍为非零的后移位值中的位来工作。该标志用于丢弃超出由 <code>ACCU0</code> 和 <code>ACCU1</code> 表示的 [0, 1) UV 坐标环绕域之外的采样点，例如在仿射变换的精灵采样中。</p> <p>该问题产生的原因是右旋转会将非零的最低有效位旋转至最高有效位，这些非零位误触发了 OVERF 标志。</p>
解决方案	可通过检查 ACCU0 / ACCU1 的最高有效位手动计算 OVERF，或预先计算边界以避免对每个采样点进行检查。
修复者	文档

### RP2350-E2

参考资料	RP2350-E2
摘要	SIO SPINLOCK 写操作在 +0x80 偏移处被镜像
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>SIO 包含自旋锁寄存器，编号从 SPINLOCK0 至 SPINLOCK31。读取自旋锁寄存器时尝试获取锁，成功返回非零值，失败返回 0。写入自旋锁寄存器以释放该锁，因此下一次获取必定成功。SIO 自旋锁寄存器位于 SIO 寄存器偏移地址 <code>0x100</code> 至 <code>0x17c</code> 范围内。</p> <p>RP2350 在寄存器偏移地址 <code>0x180</code> 及以上新增了 SIO 寄存器：响铃门控（Doorbells）、PERI_NONSEC 寄存器、RISC-V 软中断寄存器、RISC-V MTIME 寄存器及 TMDS 编码器。</p> <p>SIO 地址解码器通过地址的第 8 位对自旋锁写操作进行检测。这意味着偏移地址范围 <code>0x180</code> 至 <code>0x1fc</code> 的写操作会被错误检测为对应偏移地址低 128 字节范围 <code>0x100</code> 至 <code>0x17c</code> 的自旋锁写操作。对任何这些高地址寄存器的写入将使相应的锁定状态变为未声明状态。</p> <p>此勘误仅影响对自旋锁寄存器的写入操作。读取操作得到正确解码，因此不受高于 <code>0x17c</code> 地址访问的影响。</p>

<b>Workaround</b>	<p>Use processor atomic instructions instead of the SIO spinlocks. The SDK <code>hardware_sync_spin_lock</code> library uses software lock variables by default when building for RP2350, instead of hardware spinlocks.</p> <p>The following SIO spinlocks can be used normally because they don't alias with writable registers: 5, 6, 7, 10, 11, and 18 through 31. Some of the other lock addresses may be used safely depending on which of the high-addressed SIO registers are in use.</p> <p>Locks 18 through 24 alias with some read-only TMDS encoder registers, which is safe as only writes are mis-decoded.</p>
<b>Fixed by</b>	Documentation, Software

## XIP

### RP2350-E11

<b>Reference</b>	RP2350-E11
<b>Summary</b>	XIP cache clean by set/way operation modifies the tag of dirty lines
<b>Affects</b>	RP2350 A2, RP2350 A3, RP2350 A4
<b>Description</b>	<p>The <code>0x1</code> clean by set/way cache maintenance operation performs the following steps:</p> <ol style="list-style-type: none"> <li>1. Selects a cache line: address bits <code>12:3</code> index the cache sets, and bit <code>13</code> selects from the two 8-byte cache lines, which make up the ways of each set.</li> <li>2. Checks if the line contains uncommitted write data (a <b>dirty</b> line).</li> <li>3. If the line is dirty, writes the data downstream and marks the line as <b>clean</b>.</li> </ol> <p>In the third step, in addition to marking the line as clean, the cache controller erroneously sets the cache line's tag to address bits <code>25:13</code> of the maintenance write that initiated the clean operation. The cache uses the tag to recall which of the many possible downstream addresses currently resides in each cache line. Therefore reading the newly tagged address returns cached data from the original address, breaking the memory contract.</p> <p>Consider the following example scenario:</p> <ul style="list-style-type: none"> <li>• QMI window 0 (starting at <code>0x10000000</code>) has a flash device attached</li> <li>• QMI window 1 (starting at <code>0x11000000</code>) has a PSRAM device attached</li> <li>• The cache possesses address <code>0x11000000</code> in the dirty state, and it is allocated in way 0 of the cache</li> </ul> <p>The programmer cleans the cache, starting by writing to address <code>0x18000001</code> to clean set 0, way 0. This cleans the dirty line containing address <code>0x11000000</code>. After cleaning, the cache updates this line's tag to all-zeroes (the offset of the maintenance write). A subsequent read from <code>0x10000000</code> results in a spurious cache hit, returning PSRAM data in place of flash data.</p> <p>See <a href="#">Section 4.4.1.1</a> for more information about cache maintenance operations. See <a href="#">Section 4.4.1.2</a> for more information about cache line states and state transitions.</p> <p>The tag update <i>only</i> affects <code>0x1</code> clean by set/way; is either correct or harmless for the other four cache maintenance operations.</p>

解决方案	<p>请使用处理器原子指令，替代SIO自旋锁。SDK的hardware_sync_spin_lock库在为RP2350构建时，默认使用软件锁变量，取代硬件自旋锁。</p> <p>以下SIO自旋锁可正常使用，因其不与任何可写寄存器地址重叠：5、6、7、10、11及18至31号。根据所使用的高地址SIO寄存器，部分其他锁地址亦可安全使用。</p> <p>18至24号锁与若干只读TMDS编码器寄存器地址重叠，该情况安全，因仅写入操作会被错误解码。</p>

## XIP

### RP2350-E11

参考资料	RP2350-E11
摘要	通过集合/方式操作清理XIP缓存时，会修改脏行的标记。
影响范围	RP2350 A2、RP2350 A3、RP2350 A4
描述	<p>0x1通过 set/way 清除缓存维护操作执行以下步骤：</p> <ol style="list-style-type: none"> <li>选择一个缓存行：地址位 12:3用来索引缓存组，位 13用于从构成每组两条8字节缓存行的组相中选择。</li> <li>检查该行是否包含未提交的写入数据（即 <b>dirty</b> 行）。</li> <li>如果该行为 dirty，则将数据写入下游并将该行标记为 <b>clean</b>。</li> </ol> <p>在第三步中，除了将该行标记为 clean 外，缓存控制器错误地将缓存行的标签设为发起该清理操作的维护写入地址位 25:13。缓存使用标签来识别当前驻留在每条缓存行中的众多可能的下游地址中的哪一个。</p> <p>因此，读取新标记的地址会返回来自原始地址的缓存数据，违反了内存契约。</p> <p>请考虑以下示例场景：</p> <ul style="list-style-type: none"> <li>QMI 窗口 0（起始地址为 <b>0x10000000</b>）连接有闪存设备</li> <li>QMI 窗口 1（起始于 <b>0x11000000</b>）连接有一台 PSRAM 设备。</li> <li>缓存中地址 <b>0x11000000</b>处于脏状态，且位于缓存的方式 0。</li> </ul> <p>程序员通过向地址 <b>0x18000001</b>写入数据开始清理缓存，清理的是集合 0 和方式 0。此操作清理了包含地址 <b>0x11000000</b>的脏缓存行。清理完成后，缓存将该行的标签更新为全零（对应维护写入的偏移地址）。随后，从 <b>0x10000000</b>的读取引发了伪缓存命中，返回了 PSRAM 数据，替代了闪存数据。</p> <p>有关缓存维护操作的详细内容，请参见第 4.4.1.1 节。有关缓存行状态及其转换的详细内容，请参见第 4.4.1.2 节。</p> <p>标签更新仅影响 <b>0x1</b>按集合/方式进行的清理；对于另外四种缓存维护操作，该方法要么正确，要么无害。</p>

Workaround	<p>To avoid spurious cache hits, choose an address that can't alias with cached data from the QMI. This remaps dirty lines outside of the QMI address space after cleaning them, which has the side effect of causing a cache miss on the next access to the dirty address. The SDK <code>xip_cache_clean_all()</code> function implements this workaround.</p> <p>The updated tag is predictable: it is always the address of the maintenance write. For example, use the upper 16 kB of the maintenance space to clean all cache lines:</p> <pre> 1 volatile uint8_t *maintenance_ptr = (volatile uint8_t*)0x1bffc001u; 2 for (int i = 0; i &lt; 0x4000; i += 8) { 3     maintenance_ptr[i] = 0; 4 }</pre> <p>Because the clean operation is a no-op for invalid, clean or pinned lines, this workaround doesn't interfere with lines pinned for cache-as-SRAM use.</p>
Fixed by	Documentation, Software

## USB

### RP2350-E12

Reference	RP2350-E12
Summary	Inadequate synchronisation of USB status signals
Affects	RP2350 A2, RP2350 A3, RP2350 A4 (mitigated on A3)

解决方案	<p>为避免伪造缓存命中，请选择一个不会与来自QMI的缓存数据发生别名冲突的地址。该方法在清理脏行后，将其重新映射到QMI地址空间之外，因而导致下一次访问该脏地址时发生缓存未命中。SDK中的<code>xip_clean_all()</code>函数实现了该规避方案。</p> <p>更新后的标签是可预测的：始终为维护写操作的地址。例如，使用维护空间的高16 kB来清理所有缓存行：</p> <pre> 1 volatile uint8_t *maintenance_ptr = (volatile uint8_t*)0x1bffc001u; 2 for (int i = 0; i &lt; 0x4000; i += 8) { 3     maintenance_ptr[i] = 0; 4 }</pre> <p>由于对于无效、已清理或固定缓存行，清理操作无效，该规避方案不会干扰用于缓存作为SRAM的固定缓存行。</p>

## USB

### RP2350-E12

参考资料	RP2350-E12
摘要	USB状态信号同步不足
影响范围	RP2350 A2, RP2350 A3, RP2350 A4 (A3中已缓解)

<b>Description</b>	<p>Within the USB peripheral, certain Host and Device controller events cross from <code>clk_usb</code> to <code>clk_sys</code>. Many of these signals don't have appropriate synchronisation methods to ensure that they are correctly registered when <code>clk_sys</code> is equal to or slower than <code>clk_usb</code>.</p> <p>The following signals lack appropriate synchronisation methods:</p> <p><b>SIE_STATUS:</b></p> <ul style="list-style-type: none"> <li>• <code>TRANS_COMPLETE</code></li> <li>• <code>SETUP_REC</code></li> <li>• <code>STALL_REC</code></li> <li>• <code>NAK_REC</code></li> <li>• <code>RX_SHORT_PACKET</code></li> <li>• <code>ACK_REQ</code></li> <li>• <code>DATA_SEQ_ERROR</code></li> <li>• <code>RX_OVERFLOW</code></li> </ul> <p><b>INTR:</b></p> <ul style="list-style-type: none"> <li>• <code>HOST_SOF</code></li> <li>• <code>ERROR_CRC</code></li> <li>• <code>ERROR_BIT_STUFF</code></li> <li>• <code>ERROR_RX_OVERFLOW</code></li> <li>• <code>ERROR_RX_TIMEOUT</code></li> <li>• <code>ERROR_DATA_SEQ</code></li> </ul> <p>The bootrom's USB bootloader derives <code>clk_sys</code> from <code>pll_usb</code>. Therefore, the two clock frequencies are identical and have a fixed phase relationship. Under this condition, and at extremes of PVT, lab testing has shown that these events can be lost, which results in unreliable USB bootloader behaviour.</p> <p>RP2350 A3 incorporates hardware fixes that improve timing margins on signals critical to the bootrom, ensuring reliable operation across PVT. However, software must not rely on these fixes, and so they aren't elaborated on.</p>
<b>Workaround</b>	Run <code>clk_sys</code> faster than <code>clk_usb</code> by at least 10% when the peripheral is in use. Signalling of quasi-static bus states such as reset, suspend, and resume aren't affected by this erratum, so <code>clk_sys</code> can be lower in these cases.
<b>Fixed by</b>	Documentation, Software

描述	<p>在USB外设中，某些主机端和设备端控制器事件从 <code>clk_usb</code>跨越至 <code>clk_sys</code>。此类信号多数缺乏适当的同步措施，无法保证在 <code>clk_sys</code>等于或低于 <code>clk_usb</code>时被正确采样。</p> <p>以下信号缺乏适当的同步措施：</p> <p><b>SIE_STATUS:</b></p> <ul style="list-style-type: none"> <li>• <code>TRANS_COMPLETE</code></li> <li>• <code>SETUP_REC</code></li> <li>• <code>STALL_REC</code></li> <li>• <code>NAK_REC</code></li> <li>• <code>RX_SHORT_PACKET</code></li> <li>• <code>ACK_REQ</code></li> <li>• <code>DATA_SEQ_ERROR</code></li> <li>• <code>RX_OVERFLOW</code></li> </ul> <p><b>INTR:</b></p> <ul style="list-style-type: none"> <li>• <code>HOST_SOF</code></li> <li>• <code>ERROR_CRC</code></li> <li>• <code>ERROR_BIT_STUFF</code></li> <li>• <code>ERROR_RX_OVERFLOW</code></li> <li>• <code>ERROR_RX_TIMEOUT</code></li> <li>• <code>ERROR_DATA_SEQ</code></li> </ul> <p>引导只读存储器的USB引导加载程序从 <code>pll_usb</code>生成 <code>clk_sys</code>。因此，两者时钟频率相同，且具有固定相位关系。在该条件及PVT极端情况下，实验室测试显示这些事件可能丢失，导致USB引导加载程序行为不稳定。</p> <p>RP2350 A3包含硬件修复，提升了对引导只读存储器关键时序信号的裕度，确保整个PVT范围内的可靠操作。但软件不得依赖该修复，故未作详细说明。</p>
解决方案	当外设处于使用状态时， <code>clk_sys</code> 的运行速度至少比 <code>clk_usb</code> 快10%。复位、挂起和恢复等准静态总线状态的信号不受该缺陷影响，因此在这些情况下， <code>clk_sys</code> 可以较低。
修复者	文档，软件

# Appendix H: Documentation release history

## 29 July 2025

- Added hardware revision history ([Appendix C](#)), and documented steppings A3 and A4.
- Added new errata.
- Added storage temperature information to [Table 1433](#).
- Corrected minor typos and formatting issues.
- Updated existing errata entries to indicate fix status.
- Updated register reset values of [FREQA.DS0\\_RANDOM](#), [FREQA.DS1\\_RANDOM](#), [CLK\\_SYS\\_CTRL.SRC](#), and [CLK\\_SYS\\_CTRL.AUXSRC](#) to reflect changes in RP2350 A3.

## 20 February 2025

- Added new errata.

## 04 December 2024

- Updated register data.

## 16 October 2024

- Clarified some *and* and *or* logic in [M33 Execution Timings](#).

## 15 October 2024

- Corrected minor typos and formatting issues.
- Added M33 instruction timings section.
- Added link to recommended crystal.
- Documented GPIO bus keeper mode ([Section 9.6.1](#)), which was previously only described in SDK documentation

## 6 September 2024

- Enhanced [RP2350-E9](#) errata description with additional details.
- Improved description of debug and trace components.
- Fixed some minor typos.

# 附录H：文档发布历史

## 2025年7月29日

- 新增硬件版本历史（附录C），并记录了A3和A4步进版本。
- 新增错误修订。
- 在表1433中添加了储存温度信息。
- 修正了少量拼写及格式问题。
- 更新现有错误条目以反映修复状态。
- 更新FREQA.DS0\_RANDOM、FREQA.DS1\_RANDOM、CLK\_SYS\_CTRL.SRC及CLK\_SYS\_CTRL.AUXSRC寄存器的复位值，以反映RP2350 A3的变更。

## 2025年2月20日

- 新增错误修订。

## 2024年12月4日

- 更新寄存器数据。

## 2024年10月16日

- 澄清了M33执行时序中部分 *and*与*and/or*逻辑。

## 2024年10月15日

- 修正了少量拼写及格式问题。
- 新增M33指令时序章节。
- 添加了推荐晶振的链接。
- 记录GPIO总线保持器模式（第9.6.1节），此前仅在SDK文档中描述。

## 2024年9月6日

- 增强版RP2350-E9勘误说明，附加详细信息。
- 改进了调试与追踪组件的描述。
- 修正若干细微拼写错误。

- Implemented some minor readability improvements.
- Fixed word inaccuracy in the Minimum Arm `IMAGE_DEF` description.

## 8 August 2024

- Initial release.

- 实施了若干细微的可读性改进。
- 修正了Minimum Arm **IMAGE\_DEF** 描述中的措辞不准确。

## 2024年8月8日

- 首次发布。
